# Preface

Supply chain management, although practiced in early human civilizations, did not become part of the parlance used by practitioners and academics until the 1980s. Thus, the term and the study of supply chains is a relatively recent, but growing phenomenon. And until more recently, the study and understanding of supply chains was under the purview of specialized academic experts and practitioners. With the recent COVID pandemic, we saw supply chain management as a term and practice enter the popular mindset.

When this handbook – a Palgrave Major Reference Work – was first conceived, it was conceived with this practitioner and academic specialist and student community in mind. Currently, it may be of interest to a much broader community beyond university academics and students and practicing supply chain managers. In fact, journalists, policy makers, and even community leaders may find value in understanding the supply chain field and related phenomena.

In an era characterized by global interconnectedness, rapid technological advancements, sustainability concerns, and an ever-evolving business landscape, the importance of supply chain management has never been more profound. Each of these topics along with COVID have caused an evolution of thought from efficiency and cost management to risk and resilience. As organizations strive to meet the demands of a dynamic marketplace, it is both efficiency and resilience of their supply chains that have become critical factors in achieving success. Agility, lean, green, and integrated are terms that appear throughout the book in various chapters.

This handbook is a comprehensive guide designed to assist professionals, students, and enthusiasts in understanding and mastering the art and science of supply chain management. Understanding supply chains requires an acknowledgment that supply chain management is not just a functional silo within an organization; it fuels the heart of modern commerce. It connects sourcing (upstream), production, distribution (downstream), and logistics into a seamless, coordinated system that strives to optimize operations, reduce costs, and enhance customer satisfaction – and even meeting basic human needs.

It also goes beyond the typical business issues – you have environmental sustainability, closed-loop supply chains, humanitarian, circular economy, and national security that are included in the supply chain discourse. Many of these non-traditional topics are covered in this volume of over 60 chapters.

Supply chain management is a field that encompasses a diverse array of topics, and this book attempts to cover the complex and ever-expanding terrain. The topics and chapters are generally positioned into six major categories – with significant overlap along each. Here is a summary of the parts.

**Strategic Issues** – These chapters cover concerns that have broader and longer-term implications. The issues cut across functional disciplines. The topics range from financial and human resource concerns to broader environmental and social sustainability issues. The topics would be of interest to all in the organization from the boardroom (C-suite) to the individual on the shop floor or consumer. Although these chapters take the perspective of a focal company, they are also likely to imply strategic relationships to outside stakeholders. Under strategic issues, the goal is to consider broader economic and business concerns and then evolve to social and environmental issues in the supply chain.

**Operational Issues** – These chapters focus on internal activities that are shorter term and more concentrated on specific projects and issues. These topics may be the concern of a few or singular functions within the organization. Many are related to traditional operational concerns and focused on operational efficiency and effectiveness of programs and projects. Typically, these topics would be considered under the purview and primary control of a single focal company. Subjects include a variety of continuous improvement projects and programs. Within the operational concerns, the evolution is from programmatic and philosophical operations concerns, such as lean and agility philosophies, to more specific optimization and planning of resource concerns, such as costing, risk, and inventory and human resources management.

**Logistics and Transportation** – In supply chain management, one of the most important ways of managing flows, especially materials flows, within and across boundaries is through logistics and transportation. This categorization is a separate part since the topic has received significant emphasis and sometimes represents core but separate fields within supply chain management. The subjects relate to materials management and materials movement; although each includes strategic and operational contexts, they will be focused on management of these specific functions and processes. These activities and functions occur upstream, downstream, and within organizations. The activities are often outsourced supply chain support activities and have technological linkages. In this part, we begin with general transportation and logistics as chapters, and then get into more specific related topics such as modes of transportation concerns, reverse logistics, and warehousing. We also sought to incorporate some locational analysis and ownership concerns within this context such as outsourcing and insourcing or international location such as off-shoring and on-shoring.

**Upstream Management** – In some fields of thought, the supply chain is meant to focus on the upstream aspects of managing supply. These activities and functions include sourcing, purchasing, procurement, and vendor management activities. These are external linkages between a focal organization and its upstream suppliers. These chapters cover immediate (dyadic) upstream suppliers and multi-tier relationships. Upstream interorganizational collaboration and coordination are also important topics in this context. There will be generic upstream supplier and vendor management topics including selection, development, and auditing. In some cases, specific characteristics and aspects take hold, such as coordination in a specific industry, but generalizations are also made. We also include topics that can fit across multiple stages and categories, such as coordination and collaboration as generic practices which are placed here primarily because much of the research is focused on upstream aspects. These latter topics may easily fit into other parts depending on the perspective taken.

**Downstream Management** – This set of chapters includes post-product or service provisions and is customer facing – relative to the focal organization. The functional characteristics of marketing activities and functions play significant roles in this part. Most of the activities and topics here focus on satisfying external customer needs and requirements. Issues also include end-of-life management or products and after-sales services. The order of these chapters within this part ranges from the most generic topics such as industrial marketing and general marketing and supply chain relationships and do include design and slightly more strategic issues such as customer relationship management and distribution planning. Specific tools and approaches with consideration of after-sales services are included.

**Technology** – The role of technology in the supply chain has its own part because it is a critical resource with significant interest from researchers and practitioners. Information, logistics, product, process, and inter-organizational technologies such as Industry 4.0 are some of the many technologies and technology management topics relating to supply chain management. The management of technology, justification, diffusion, and specific technology roles of emergent and existing technologies are each included. Similar to the previous parts in the book, this part begins with overarching umbrella topics including general technology and innovation management issues within the supply chain. Then more specific aspects such as process and product design with a technological focus introduced including topics such as managing virtual teams in a technological setting. Major portions of contributed chapters likely focus on Industry 4.0 and other emerging technology roles within the supply chain. Some topics include motivation and leadership concerns and others are broader stakeholder and community engagement. These are only example issues covered, with many linking concerns to globalization, the pandemic, resilience, and topics in other parts.

Now that we have spoken about the content. A primary goal of this Major Reference Work is to serve as a valuable resource for those who seek to understand, improve, and excel in supply chain management. Whether you are a seasoned supply chain professional looking to enhance your expertise, a student embarking on your educational journey, or a business owner striving to create a resilient and efficient supply chain, this handbook is the ultimate comprehensive companion.

Key features of this Major Reference Work include:

Comprehensive Coverage: We explore the entire spectrum of supply chain management, from the basics to advanced topics, ensuring that readers gain a well-rounded understanding of the subject.

Real-World Insights: Our content is enriched with real-world case studies and examples to provide a practical perspective on supply chain challenges and solutions.

Expert Perspectives: We have drawn upon the expertise of supply chain professionals and thought leaders to provide valuable insights and cutting-edge strategies. These experts come from a broad range of geographical regions covering every continent. They also include emerging scholars, seasoned scholars, and professionals from industry with years of experience.

Practical Tools: Throughout the Major Reference Work, you will find tools and frameworks that can be applied directly to your supply chain planning and operations.

Global Focus: Supply chain management is a global endeavor, and we explore how to manage supply chains in the context of globalization and international operations.

Sustainability and Innovation: We examine the increasing importance of sustainability and the role of innovation in shaping the future of supply chain management.

As the world continues to evolve so does the field of supply chain management. This Major Reference Work is designed to evolve with it, ensuring that readers are equipped with the latest knowledge and insights. Chapters are structured in a way to provide a brief foundation for the topic of the chapter, some of the current practice and research, and eventually future directions that are expected to occur. Most chapters also include a comprehensive reference set from academic and practitioner literature. There are both managerial and research implications peppered throughout each chapter.

We hope you find this Major Reference Work to be an indispensable resource as you embark on your journey to initially understand and eventually master supply chain management. Whether your goal is to optimize processes, reduce costs, enhance sustainability, manage technology, or simply gain a broader understanding of this critical field, we are confident that the knowledge within these pages will be a valuable asset in your endeavors.

# About the Editor

**Joseph Sarkis** is Professor of Management, former Head of Department of Management, and former Interim Dean within Worcester Polytechnic Institute's (WPI) Business School. His teaching and research interests include topics in supply chain management, business and the natural environment, sustainability, operations, logistics, technology, and information management. He has also taught courses on supply chain management, logistics, operations management, business analytics, management science, sustainability, and business and the natural environment.

He has published over 350 papers in peer-reviewed journals on topics ranging from transportation and supply chains to manufacturing and production technology to service, non-profit, and governmental settings, with the vast majority of publications in SSI/SSCI indexed journals. He has also published over 175 additional papers as chapters in books and in conference proceedings. Twelve of his books have been published. A number of his publications have been recognized with various publishing awards. His work has been cited tens of thousands of times based on Google Scholar citations, with an H-index above 135.

Dr. Sarkis is noted as the world's most productive scholar in the field of supply chain management for the years 1995–2015. He is recognized as one of the most highly cited scholars in the world by the Web of Science (Clarivate) for a number of years starting in 2016 until today; this recognition has been noted by Clarivate as the world's "most influential scientific minds."

Currently, he serves on a number of editorial boards for a broad variety of journals including sustainability, operations and manufacturing, technology management, production, and information systems journals. He has served as editor of *IEEE Engineering Management Review* and *Management Research Review*. Prof. Sarkis's departmental and associate editor duties include and have included the Models and Methodologies department and the Social Issues and Sustainability in Engineering Management department for *IEEE Transactions on Engineering Management*; *Resources, Conservation and Recycling*, *the Journal of Supply Chain Management*, and *Transportation Research Part E*. Dr. Sarkis has served as guest editor of dozens of special issues on Technology, Transportation, Innovation, Sustainability and Business topics in such journals as the *European Journal of Operational Research*, *Decision Sciences*, *Journal of Cleaner Production*, *Business Strategy and the Environment*, *Transportation Research E*, *International Journal of Operations and Production Management*, *International Journal of Production Economic*s, *Greener Management International*, and *Information Systems Frontiers*.

His dozen books include topics on Greening the Supply Chain and Strategic Sustainability. Dr. Sarkis' most recent books include edited volumes entitled *Greening Logistics and Transportation* and *Green Growth: Managing the Transition to a Sustainable Economy*. His most current book is *Green Supply Chain Management*, published with Yijie Dou and the *Handbook of Sustainable Supply Chains*. He is a Springer-Nature book series editor for the Greening of Industry Networks series.

He has served as a visiting scholar at various international locations including Cardiff University's BRASS center and Business School, the University of Oviedo in Spain, Hanken School of Economics in Helsinki, UCSI University in Kuala Lumpur, and a visiting scholar in the EU Erasmus Mondus MESPOM program. He has also been a Sea-Sky Scholar at Dalian University of Technology in China. He is an AT&T Industrial Ecology Fellow. He has given lectures and keynote addresses in a number of countries including Denmark, Egypt, Finland, France, Germany, Hungary, Lebanon, Sweden, Italy, Japan, China, Brazil, the UK, and the Philippines.

He is the holder of the TEC-LOGd Chair d'Excellence for Transport, Circular Economy and Sustainable Supply Chains at the Université Polytechnique Hauts-de-France.

**Abstract**

Strategic management has informed and enhanced the development of supply strategy. Supply strategy is a strategic, collaborative, and policy-oriented field of supply in complex interorganizational networks and systems connecting manufacturing and service, for-profit, and not-for-profit organizations. Originating in production and operations management, supply strategy has grown from its operational roots through building on and incorporating strategic management concepts and theories.

This chapter examines strategic management as content and process of strategies formulated and implemented by firms. ## 1 Introduction

This chapter provides an overview of strategic management and how this topic has informed and developed supply strategy thinking and practice. *Supply strategy* is used in this chapter to represent the various terms and brands of supply chain management, supply chain networks, supply networks, and purchasing and supply management – the terms and the development of the overall field are examined later.

Rather than discuss specifics of the content of business and supply strategies – such as sustainability, innovation, or quality-oriented strategies – this chapter explores how strategic management concepts and theories have gradually been adopted and, to a limited extent, developed by the field of supply strategy. As a result, supply strategy has transformed itself from an operationally focused field encompassing material acquisition, transformation, and flows in purchasing, production, and logistics within manufacturing and distribution, to a more strategic, collaborative, and policy-oriented field of supply in complex interorganizational networks and systems connecting manufacturing and service, for-profit and not-for-profit organizations.

The discussion of strategic management in the chapter is selective, exploring the main concepts and themes that have been imported by supply practitioners and researchers. These concepts and themes are core to strategic management, showing how strategic supply thinking has been closely aligned to the development of strategic management thinking.

Strategic management texts and research publications discuss the burgeoning debates and nuances of their field, including the many different schools of thoughts, their origins, and perspectives on strategy. To date, supply strategy has adopted more normative, rational, design approaches from within these schools of strategic management, rather than more processual, emergent approaches. However, an overview of strategic management approaches is provided in this chapter because the field of supply strategy is currently developing more behavioral, social, and emergent thinking. It is increasingly recognized that *softer* resources such as social capital, knowledge, reputation, and expertise are strategically important to supply decision making, in addition to the harder resources of equipment, information systems, and materials.

The chapter examines strategic management as content and process of strategies formulated and implemented by firms. Strategic management concepts relating to networks of collaborating organizations provide building blocks for developing supply strategy as a multi-organizational, value-adding, strategic endeavor. Supply strategy here is conceptually framed as relating to supply within organizations, buyer–supplier relationships, supply chains, supply networks, and supply systems. Competitive strategy, strategic fit, and strategic alignment are applied and adapted to supply strategy.

*Strategy as content* is interpreted in strategic supply as a set of strategic, structural decisions relative to the boundary of interorganizational thinking and influence. For example, which organizations should be within supply relationships, chains, networks, and systems, and how should this set of organizations be shaped and reconfigured?

*Strategy as process* is interpreted as strategic decisions relating to supply infrastructure, in terms of processes, flows, and activities within supply relationships, chains, networks, and systems.

Stage and maturity models of strategic management have been widely used in supply practice and research and have been further developed, specifically for the field. Structural and infrastructural decisions and implications for supply are considered in this chapter, as organizations, relationships, chains, networks, and systems mature and progress through development stages.

First, a brief history of the development of supply strategy is provided, examining the reasons why and how operations and supply chain management evolved from an internally focused concept to a more strategic, interorganizational, networked perspective. This chronological development path provides the line of trajectory of the field that, in some part, explains why supply strategy takes the perspective of strategy it does.

## 2 Development of Supply Strategy

In their *genealogy of operations management*, Meredith and Amoako-Gyampah (1990) traced the origins of operations management back to *factory management* at the time of the Industrial Revolution. The invention of machinery to replace human labor and the division of labor into organized tasks heralded the development of more scientific approaches to manage factories efficiently, leading to the invention of mass production. In the 1930s *production management* replaced *factory management*, as economic efficiency became the core focus of manufacturing.

During World War II, operations research techniques were introduced to manage manufacturing and support military troops and materials movements, giving birth to a new concept of *logistics*. Modern production and operations management (POM) did not come into its own until the late 1950s to early 1960s. From this time to the late 1980s, POM focused largely on operations inside manufacturing organizations. Core to POM thinking was the transformation of input resources, via a process, to produce outputs – the *input-process-output* model. Most early POM texts concentrated on the tasks performed by the POM manager, and these tasks were internally oriented within the manufacturing firm.

The concept of manufacturing strategy appeared in Wickham Skinner's (1969) ground-breaking identification of manufacturing as being *the missing link* in business strategy. Skinner identified that manufacturing operations, faced by competing demands for productivity, timeliness, quality, and customer service, could not be good at everything and that *trade-offs* had to be made. Wheelwright (1978, 1984) developed these trade-offs, proposing four *competitive priorities* – cost, quality, dependability, and flexibility – and the need for these trade-offs to be consistent with corporate strategy.

In *Restoring our competitive edge: competing through manufacturing* (Hayes & Wheelwright, 1984), patterns of structural and infrastructural decisions represented strategic capability of manufacturing organizations. These decisions were related to capacity, facilities, technology, vertical integration and sourcing, workforce, quality, production planning, materials control, and organization. It is at this time that POM first considered the strategic importance of activities external to the firm, asking questions such as "what boundaries should a firm form around its activities," "how should a firm construct its relationships with suppliers, distributors and customers outside its firm boundaries," and "under what circumstances should a firm change the boundaries of these relationships"?

The term *commercial chain* was used to conceptualize a firm as one link in a larger chain of organizations (Hayes & Wheelwright, 1984). The term *supply chain management* (SCM) predates *commercial chain*, as it was first used by Booz Allen management consultants to signify the internal value chain within a manufacturing organization from inbound to outbound ends of the business (Oliver & Webber, 1982), that is, integration of traditional POM processes. This first use of the term SCM was synonymous to the term *materials management* proposed by Dean Ammer (1962), later discussed more strategically as a profit center in manufacturing organizations (Ammer, 1969). However, the brand *materials management* did not gain traction, but supply chain management did.

Hayes and Wheelwright's (1984) *commercial chain* underpinned the development of operations strategy as an interorganizational strategic endeavor. Wheelwright and Hayes (1985) incorporated consideration of operations external to the firm in their development of the concept of manufacturing strategy.

Interestingly, the whole question of trade-offs that was central to the concept of manufacturing strategy was being challenged, based on learning from Japanese methods of manufacturing. In *Quality is Free*, Philip Crosby (1979) was one of the so-called *quality gurus* who interpreted from learning from Japanese manufacturing that some trade-offs were not necessary. Better quality was shown by the Japanese to be achievable without increased cost. However, these performance variables and their trade-offs remained central to manufacturing strategy thinking.

As manufacturing strategists developed these competitive priorities, or trade-offs, that drove strategic structural and infrastructural decisions, they had not identified how these decisions were integrated into a marketing and business strategy process. Terry Hill (1985) articulated competitive priorities as performance dimensions that won orders – *order-winning criteria* – or allowed the business to compete for orders – *qualifying criteria*. These order-winning and qualifying criteria were:

- Price
- Product quality and reliability
- Delivery speed
- Delivery reliability
- Responsiveness to demand increases
- Technical liaison and support
- Meeting a launch date
- Being an existing supplier
- Product and color range

Hill highlighted that the relative importance of these criteria would differ between companies and possibly between products within the same company and that they were likely to change over time. However, Hill's key contribution to manufacturing strategy was the process that connected corporate strategy with manufacturing strategy. Table 1 below summarizes this process.

Mason-Jones et al. (2000) highlighted how order-winning and qualifying criteria differed across sectors. For example, in the fashion sector, quality, price, and lead time were qualifying criteria, whereas service level was an order-winning criterion. In contrast, quality, lead time, and service level were qualifying criteria for commodities, and price an order-winning criterion.

While Skinner (1974), Hayes and Wheelwright (1984), and Hayes et al. (1988) did identify vertical integration and sourcing as important to manufacturing strategy, relatively little of their texts were devoted to this topic.

From Harvard, David Garvin's text on *Operations Strategy* (Garvin, 1992) did not address upstream and downstream supply issues, focusing on issues internal to

manufacturing. The big leap forward in understanding the importance of upstream and downstream supply issues in manufacturing and operations strategy was made by Hill (1989) where he further developed the strategic concept of positioning, relating this to process positioning. He devoted a chapter to exploring "the width of a firm's internal span of process, the degree and direction of vertical integration alternatives, and its links and relationships with suppliers, distributors and customers." He examined five strategic alternatives to manufacturing in-house:

- Joint ventures where two or more firms co-developed the application of technology and research
- Non-equity-based collaboration involving a longer-term cooperation between firms on a particular project or venture without the formal ownership structure of a joint venture
- Long-term contracts with suppliers to provide added predictability and increased assurance which helped both parties make and achieve long-term plans
- Customer–vendor trust-based relationships over time and over a number of projects
- Just-in-time production requiring coordination between suppliers and manufacturers across various parts of the manufacturing and inventory management process.

Womack et al. (1990) changed manufacturing, operations, and supply strategy thinking by providing two chapters on external aspects of operations strategy, one titled "coordinating the supply chain" and the other "dealing with customers." They moved manufacturing strategy forward by considering:

- Organizational modes other than vertical integration
- The concept of a network of suppliers, suppliers' suppliers, and so on upstream
- The concept of a network of customers, customers' customers, and so on downstream
- The significance of the ultimate consumer (which until then had received almost no attention in operations strategy)
- How relationships with suppliers and customers could be managed
- Performance implications of external relationships
- How this thinking connected with the work in marketing on channel management
- The importance of information technologies in managing external relationships

Womack et al. (1990) coined the term *lean supply*. For the first time, substantial consideration of the management of organizational modes other than vertical integration was provided. Supply-side scholars, notably Richard Lamming (1993) and Toshihiro Nishiguchi (1994) who were both involved in the International Motor Vehicle Program (IMVP) research project on which Womack et al.'s (1990) book was based, developed more fully a strategic approach to forming and managing supplier relationships.

Christopher (1992) took a more strategic, holistic perspective that incorporated downstream distribution channel organizations, leading ultimately to end customers. This upstream and downstream perspective of firms' span of strategic operational concern is embodied in the conceptualization of SCM as a field encompassing traditional internal operations management and connected relationships with suppliers, suppliers' suppliers, customers, and customers' customers, operating at multiple systems levels of internal supply chains, dyadic relationships, external supply chains, and wider supply networks (Harland, 1996).

In parallel, but with little overlap with POM scholars, purchasing and supply management (PSM) focused on how companies should purchase materials and components required for manufacturing, from suppliers (Webster & Wind, 1972; Leenders et al., 1980). The Five Rights – right quality, quantity, delivery, price, and service – were balanced, or traded-off, in operational purchasing decisions to decide with which supplier to place purchase orders. These multiple, parallel strands of thinking of PSM and SCM have been developed and intertwined into today's conceptualization of supply strategy as a far more strategic, interorganizational concept (Ellram et al., 2020), operating at multiple systems levels (Harland, 2021).

## 3 Aligning with Strategic Management

As the field of supply practice and research developed to be more strategic and externally oriented, many of the strategic concepts were drawn from the field of strategic management. The most adopted concepts by the field of supply strategy are summarized below.

To form strategy for an organization, first its strategic environment is examined as this provides the context within which an appropriate strategy is designed.

### 3.1 Strategic Environment

The strategic environment for any organization, or function within it, can be considered at three levels (Narchal et al., 1987).

1. Macro environment is the context within which organizations operate, over which they have little or no individual influence. Traditionally this was characterized as PEST factors – political, economic, societal, and technological factors. There are many different categorizations of macro environment factors, and, more recently, these have included factors such as demography, religion (van Buren et al., 2020), ecology, legal systems, and culture. The macro environment organizations should consider relates to the level of strategy they are forming. For example, the macro environment of a global business might be considered for each region the firm operates in, whereas the macro environment of a small- to medium-sized enterprise might focus on factors within the local economy, government, and society.

2. The sector or industrial environment relates to the specific sector an organization operates in – for example, bioengineering, fashion, or local government. Forces and factors relevant to that sector should be considered when understanding the strategic environment within which the strategy is to be formed. For example, within the food sector, food safety, traceability, and recycling have become important factors driving organizations.
3. The competitive environment is the set of competitors with whom the organization directly competes and their strategies and actions.

Most organizations are not able to influence the macro and sector environments within which they operate, so these become contextual for their strategy formulation and implementation. Typically, only large, powerful organizations can influence governments, industry groups and associations, or changes in legislation and regulation. However, many organizations may be able to influence some factors relating to their competitors.

Michael Porter's (1979) five forces model is commonly used by organizations to understand their competitive environment, but it also considers factors relating to the sector or industry. As an industrial economist, much of the thinking underpinning Porter's concepts and frameworks stem from the industrial organization perspective of Bain (1959) that focuses on economies of scale and scope of organizations within sectors or industries. Porter's approach to *strategic positioning* is about how an organization can position itself to achieve competitive advantage over other organizations in the sector. Organizations seek competitive advantage through an economies-of-scale-based *cost advantage* or through differentiating themselves from the rest of the competitive pack – a *differentiation advantage*.

Rivalry among existing competitors is at the center of Porter's five forces model and considers factors including the number and diversity of competitors, industry concentration, industry growth, brand loyalty, barriers to exit, switching cost, and quality variability of offerings. The other four forces considered are threat of new entrants, threat of substitute products, bargaining power of suppliers, and bargaining power of buyers.

When formulating supply strategy, the bargaining power of suppliers and buyers is highly relevant. Upstream on the supply side, to assess the bargaining power of suppliers, supply chain managers might consider the number and size of suppliers, the uniqueness of each supplier's product, and the ability of the firm to substitute in another component or service from another supplier. Downstream on the customer side, to assess bargaining power of buyers, factors including the number of customers, the size of each customer order, differences between competitors, price sensitivity, buyer ability to substitute, buyer information availability, and switching costs are considered.

It is important to define the boundary of influence when considering the strategic environment, placing those factors that are outside the control of the organization as external influencers on the organization's strategy.

Strategic positioning is also about an organization's position in the *value chain* and *value system*. Strategic management scholars, notably Porter (1980, 1985, 1987), Johnston and Lawrence (1988) and Kogut (1985), identified the strategic significance of managing the chain of value-added for the production and supply of products and services. Porter (1980) described the value system as the sum of value chains of suppliers, manufacturers, distributors, and end customers. Each value chain comprises primary activities from inbound to outbound ends of the business, supported by the firm's infrastructure and support activities, including procurement.

Porter identified that managing beyond the company boundary could improve output performance and cost management, by influencing the configuration of supplier value chains and improving coordination between a firm and its supplier and channel value chains. Kogut (1985) discussed how different firms in the same market choose to own different amounts and parts of the value chain; for example, Dell direct were able to gain competitive advantage of speed and range flexibility through owning downstream sections of their value chain to be closer to end customers.

Upstream, Kogut (1985) also examined *comparative advantage* (originally conceived by the British nineteenth-century economist, David Ricardo) that a firm could gain by having links in its supply chain in particular international locations; for example, dyeing of textiles is often cheaper in Asia than Europe, energy is relatively cheaper in Canada than in many other countries. In strategic management, Johnston and Lawrence (1988) described *value-adding partnerships* as independent companies working closely to manage the flow of goods and services along the entire value chain.

While the most common type of relationship discussed in strategic management historically was vertical integration, or ownership of links in the value chain, intermediate types of relationship between market and hierarchy were identified by Richardson (1972), Blois (1972), and Williamson (1975), based on the original work of Coase (1937). Vertical disintegration was reported as occurring across automotive, machine tools, robots, domestic appliances, and medical equipment manufacturing from the mid-1980s (Thackray, 1986; Porter, 1988).

It can be seen, therefore, that strategic positioning takes an *outside-in* approach to strategy formulation, considering the strategic environment and how an organization tries to achieve competitive advantage over others in the same sector, or industry, to maximize profits. Having considered strategic positioning, the content and process of strategy formulation occurs within this strategic, competitive, environment, to achieve *strategic fit*.

## 3.2 Strategy Content and Process

There are many schools of strategic management including, for example, strategic planning, design, strategic positioning, and cultural schools; for overviews of the various strategic management schools, see Mintzberg (2009) and Pettigrew et al.'s handbook (2006). There have been tensions between two main groups of strategic management schools relating to perceiving strategy as *content* or *process*.

The more normative, planning- and design-oriented strategic approaches that consider strategy as structure and content can be traced back to Chandler's "visible hand" (1977) and Ansoff (1965), while the process-oriented, more emergent perceptions of strategy align with the thinking of Mintzberg (1979). Heated debates on the relative merits of more normative, ordered approaches to strategic management leading to *well-tended gardens* vs. those favoring the more organic development of strategies as in a *weed patch* (Pfeffer, 1993, 1995; van de Ven, 1989; van Maanen, 1995) are now being replaced with greater acceptance of blended strategies.

The boundary between these distinct schools of strategic management thinking have blurred as blended strategies bridge the two main camps (Chakravarthy & White, 2006). Furthermore, the dominance in strategic management of for-profit business strategy has also been questioned as increasing attention is being paid to public sector, not-for-profit and so-called *third sector* organization strategy (Ferlie & Ongaro, 2015).

## 4 Achieving Strategic Fit and Alignment

Functional strategies, such as purchasing and supply chain management and finance strategies, should align their goals with those of the business strategy. This alignment requires consistency between customer priorities that the competitive strategy is trying to satisfy and capabilities of suppliers within the supply strategy.

When there is a greater fit between functional purchasing and supply chain strategies and business strategies, firms achieve higher performance (Baier et al., 2008; González-Benito, 2007). Organization studies and strategic management scholars often promote that *structure follows strategy* and that structural decisions within purchasing and supply chain management strategies should align with the strategy. Misalignment or misfit can impact adversely on purchasing cost and innovation performance (Ates et al., 2018).

Cousins et al. (2008) provided a strategic supply wheel showing five main elements of decision making that should be aligned with corporate and supply strategy, namely, organizational structure, the portfolio of relationships with suppliers, total cost–benefit analysis, skills and competences, and performance measurement. Harland (2002) provided a more detailed picture showing how supply operations, management, strategy, and policy, and their constituent elements, should be aligned, as shown in Fig. 1.

Supply operations, management, strategy, and policy choices should be internally aligned within the supply function, and the strategy and policy choices should *fit* with those of the overall business. To achieve this *corporate coherence*, Rozemeijer et al. (2003) argued that centralized or center-led purchasing is required; decentralized purchasing and organizations with lower purchasing maturity are less likely to make decisions coherent with the business strategy. This *structure follows strategy* argument aligns with strategic management thinking.

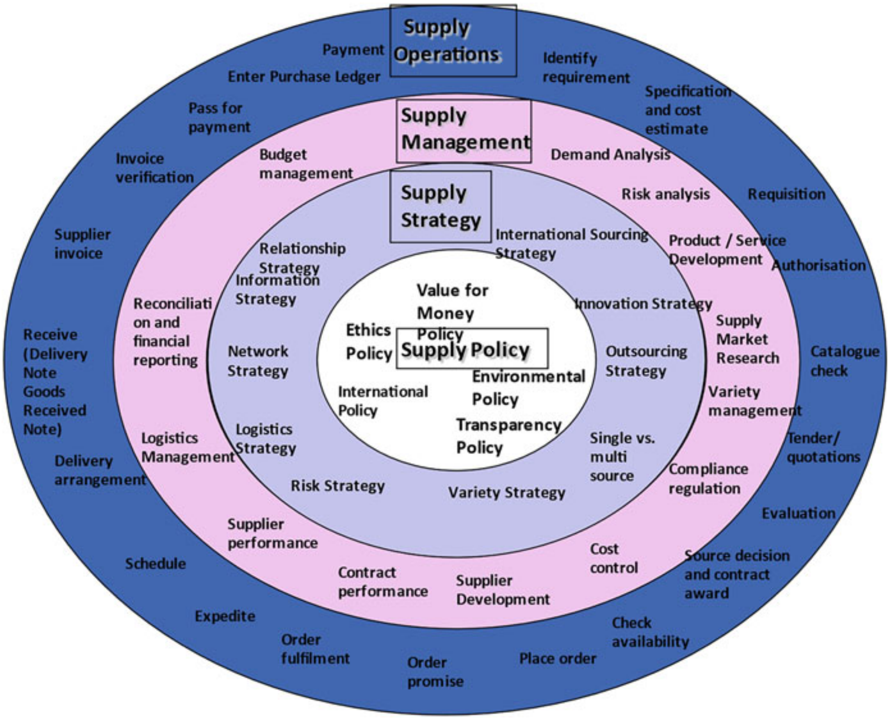

**Fig. 1** Supply operations, management, strategy, and policy

## 5 Supply Structure Decisions

Internal business function organization structure alternatives, including centralized, decentralized, or hybrid organization structures, have been considered in the supply strategy POM and SCM fields. However, there are more strategic structural decisions to be made, beyond internal departmental organization structures. This chapter examines the strategic decisions about choosing which organizations should be in a firm's supply network, how a firm might strategically position itself in a value chain, and the implications of strategic structural decisions.

Supply networks have been conceptualized as comprising a *focal firm*, often depicted in the center of a network of upstream suppliers, suppliers' suppliers, and so on to original source of raw materials and downstream customers, customers' customers, and so on to ultimate *end customers*. Every firm has its own unique supply network; from its individual vantage point, a firm sees a unique upstream and downstream network of organizations.

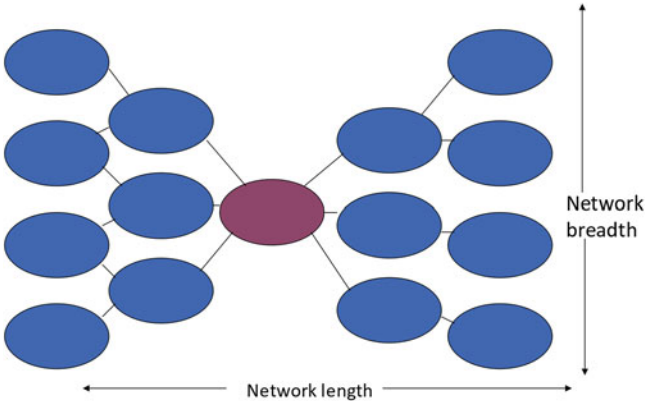

**Fig. 2** Simple supply network structure

Supply networks differ in shapes and sizes according to:

- The breadth of the network – the number of immediate suppliers, suppliers' suppliers, and customers and customers' customers
- The length of the network – the number of echelons or tiers in the network
- The firm's position in the network

Figure 2 shows a simple supply network structure.

## 5.1 Supply Network Breadth

The use of multi-sourcing encouraged price competition among more suppliers, leading to broader networks. However, learning from Japanese manufacturing methods, supply base reduction swept across manufacturing during the 1980s and 1990s, with an increased use of *single sourcing*. For example, Rank Xerox had almost 5000 suppliers in 1981, but reduced this number to around 300 by 1987 (Morgan, 1987).

Lamming (1989) reported that Japanese lean producers involved fewer than 300 suppliers in new product development compared to typical Western manufacturers who used 1000–2500 suppliers. In the service sector, Barnes (1987) discussed "reshaping the supply chain" in healthcare delivery systems, by reducing the number of distributors used to fulfill a service provider's requirements. However, the use of single sourcing was often misunderstood. It was common in Japanese automotive manufacturing to single source a particular component, such as a left taillight, while multi-sourcing the technology and manufacturing capability for all taillights, enabling switching between suppliers. This misunderstanding led to some Western firms exposing themselves to risks of single sourcing capability.

The impact of concentration in supply networks bears various risks. Narrow supply networks can cause individual suppliers to become over-reliant on certain customers. Sabel et al. (1987) discussed how this risk could be hedged through setting limits on the percentage of a supplier's business that a firm should demand. They also identified that dealing with more suppliers, including those dealing with your competitors, can improve access to innovation, learning, and knowledge.

Strategic supply decisions that impact on network breadth and length include modular design of vehicles enabling manufacturers to source modules, rather than components. Economies of scale benefits of modularity include reduced communication and transport costs between firms and their suppliers (Lamming, 1989).

In *Strategic Sourcing*, Nishiguchi (1994) analyzed the supply networks of Japanese automotive manufacturers, and how they had been organized into hierarchies, where first-tier suppliers provide modules to original equipment manufacturers and source components from their suppliers. *Kieretsu* were strategically created complex networks of suppliers involving equity ownership and interlocking directorships (Nishiguchi, 1994). This effectively lengthened supply networks, increasing the distance of a focal firm from its suppliers.

Longer supply networks may suffer more from noise and distortion in the system through the industrial dynamics Forrester or bullwhip effect (Forrester, 1961). Some firms work to get closer to sub-suppliers in their supply networks by reaching around immediate suppliers to form contacts with second- or third-tier suppliers; Patrucco et al. (2022) identified different archetypes of relationships firms have with their suppliers and sub-suppliers in triadic relationships.

There are relative merits of broader and narrower supply networks, as summarized in Table 2 below.

The number of supply connections may differ in the upstream and downstream sections of a supply network. Figure 3 shows how some firms are in supply networks that are highly concentrated upstream but less concentrated downstream. The example shown is the supply network for a precision castings manufacturer that supplies a wide variety of different industries but sources from a limited number of raw material suppliers.

Position in the supply network – whether a firm is located further upstream or downstream – has strategic and operational implications. Most research attention has been paid to relatively centrally positioned, high-volume, low-variety

**Table 2** Relative merits of broader and narrower supply networks

manufacturers, such as many automotive or electronics manufacturers. However, being positioned upstream is very different to being downstream.

Upstream material processors may be quite large-scale, equipment-intensive organizations, such as in oil refining, but there are many other types of upstream businesses, such as food processors or metal processors, as examples. Life in that position in the network is very different. These firms may have a small number of suppliers, but their products may end up in a vast array of sectors. Buyers in these firms could be highly specialized and knowledgeable of their supply markets, but marketing and sales functions would have to deal with a wide range and number of target customer markets. Examples of downstream positioned firms are distributors and retailers.

Competitive advantage can be gained through harnessing the resource potential of the network more effectively than competitors. Supply network dynamics are interesting in networks where there is a powerful, downstream positioned firm, such as Walmart, and a powerful upstream positioned firm, such as Nestle. Each powerful firm may seek to dominate decision making and information systems in the network, possibly causing tensions for smaller firms in the network, caught in the crossfire.

## 6 Types of Supply Relationships

The type of relationship most discussed in the strategic management and industrial organization literature historically was vertical integration or ownership. This was the case until the mid-1980s when the topic of vertical integration started to decline. Stable trading relationships with suppliers were seen as a viable alternative to ownership of the supply chain (Dore, 1983). Buy, rather than make, became the dominant strategy as contracting out, or outsourcing became the new trend (Kumpe & Bolwijn, 1988; Child, 1987). Partnerships, alliances, and cooperative agreements were proliferating rapidly across many industries and countries, representing a global trend (Porter, 1985). However, the trend was nuanced as different variables impacted on the type of relationship being chosen. For example, continuous process operations such as petrochemicals, aluminum, zinc, and paper production still tended to remain vertically integrated (Christopher, 1985; Williamson, 1985, 1986). Growing and maturing firms were less likely to remain vertically integrated (Porter, 1988).

In those industries where information systems were available to control the supply chain, non-owned relationships were more likely (Child, 1987). Focused manufacturers (Skinner, 1974) chose to focus on a manageable set of products and vertically disintegrate their supply chains (Miles & Snow, 1986). Closer, more trust-based relationships were favored over traditional adversarial relationships in organizations seeking to improve product quality (Frazier et al., 1988; Lascelles & Dale, 1990). Risk was also being considered in strategy formulation and firms became concerned about the risk of becoming locked into technologies through ownership in the supply chain (Hayes & Abernathy, 1980). Vertical integration and disintegration decisions swing back and forth like a pendulum; downstream vertical integration becoming more popular again recently (Guan & Rehme, 2012).

An implication of vertically integrated supply chains and networks is the need to balance capacity of each link in the supply chain to match downstream demand. An alternative to this matching is to source in additional capacity requirements of individual firms in the supply chain or supply competitor supply chains with excess capacity.

## 7 Supply Processes and Activities

At an operational level, supply can be conceptualized as an aggregation of all the flows between the various dyadic relationships that make up supply chains and networks. The exchange relationship is core to marketing; Kotler (1991) identified five conditions that must be satisfied for an exchange to take place – there must be at least two parties, each party has something that might be of value to the other party, each party is capable of communication and delivery, each party is free to accept or reject the offer, and each party believes it is appropriate or desirable to deal with the other party.

A transaction takes place if agreement is reached between the parties; transactions are therefore the basic unit of exchange. A transaction could be a single event which, when completed, ends the exchange between the parties. However, continued transactions can lead to the building of an exchange relationship between the parties, which ties them economically, technically, and socially. The original search, negotiation, and agreement formation costs to set up the transaction can be spread over repeated transactions leading to an economies of scale argument in favor of longer-term relationships between the parties.

While much of the focus of attention in the marketing field has been on consumer relationships, business-to-business relationships account for a greater volume and value of business. Industrial buying and marketing differ from consumer buying and marketing in that industrial sellers usually face a more concentrated downstream customer market, industrial buyers have greater resources available to them than consumers have so they are usually able to make more informed, professional decisions, and there is more interaction between industrial buyers and sellers than between consumers and product and service providers. These differences lead to an understanding that industrial buyer–seller supply relationships are more symmetrical and balanced than consumer–seller relationships.

Supply flows in exchange relationships are summarized in Table 3 below.

There is a spectrum of relationship types from short-term exchanges through to vertically integrated organizations. Table 4, provides information on what is exchanged in different types of relationships and examples of each relationship type.

This spectrum of relationship types originates in industrial economics, notably Coase (1937); this was developed later by Williamson (1975, 1985, and 1986) linking relationship type as a form of market structure to market conduct and performance. Ellram (1991) defined supply chain management as an intermediate market form. Others conceptualize supply chain management focused more on operational flows of materials and decisions on inventory positioning.

The shift from short-term, adversarial relationships between buyers and suppliers enabled long-term relationships to be formed, giving rise to institutionalization and adaptation (Hakansson, 1982). The most significant adaptation is moving the relationship to a more strategic sharing of resources and decisions, as shown in Fig. 4.

As Fig. 4 shows, an important activity in forming these relationships is selecting a partner. Establishing and operating the relationship then involve the activities of resource integration, information processing, knowledge capture, social coordination, risk and benefit sharing, shared decision making, conflict resolution, and motivating. Partnerships between buying and selling organizations have become key types of relationships within supply chains, networks, and systems and can operate as "vertical quasi-integration" (Contractor & Lorange, 1988), where

**Table 3** Supply flows in exchange transactions

| Supply flows and exchanges | Description and examples |
|---|---|
| Materials | Raw materials, processed materials, components, finished products, packaging |
| Equipment | Tools, templates to enable the supplier to produce the item |
| Administrative information relating to exchanges from requisition to payments | Enquiries and invitations to tender, purchase orders, delivery schedules, transportation and tracking documents, goods receipts, invoices |

| Relationship type | Exchange elements | Examples |
|---|---|---|
| Integrated hierarchy | People, materials, goods and services, technologies, information, investment, equity | Single product firm, for example, paper or aluminum producer |
| Semi-hierarchy | People, materials, goods and services, technologies, information, money, equity, centralized control, divisional reporting | Multi-divisional firm, holding company, for example, chemicals, food producer |
| Co-contracting | Medium/long-term contract, technologies, people, specifications, materials, goods and services, knowledge | Co-makership, joint venture, for example, automotive |
| Coordinated contracting | Specifications, payment, operations planning and control information, materials | Projects, for example, construction |
| Coordinated revenue links | Contract, performance measures, specification of processes and products/services, brand package, facilities, training | Licensing, franchising, for example, fast food chains |
| Long-term trading commitment | Reservation of future capacity, goods and services, payment, demand information | Single and dual sourcing, blanket orders/framework agreements, for example, electronics |
| Medium-term trading commitment | Partial commitment to future work, reservation of capacity, goods and services, specifications | Preferred supplier, for example, defense equipment |
| Short-term trading commitment | Goods and services, payment, order documentation | Spot orders, for example, stationery purchases |

boundaries between the organizations become blurred, replacing arms-length, or market, relationships with a "quasi-organization" (Lamming, 1993).

A shift in thinking occurred in the 1990s from considering supply chain management as the study of interconnected organizations in dyadic relationships and linear chains of organizations to appreciating the complexity of supply as a networked activity. Christopher (1992) defined the supply chain as "the network of organizations that are involved, through upstream and downstream linkages, in the different processes and activities that produce value in the form of products and services in the hands of the ultimate customer."

Harland (1996) categorized the various definitions and approaches to supply chain management using a systems-level approach, as relating to the internal supply chain within an organization, the dyadic relationship, external supply chains, and supply networks. Extending the systems thinking to consider organizations such as the United Nations that comprise networks of networks, and sector-level supply issues (Harland, 2021), an additional level of the supply system was added, as shown in Fig. 5.

As organizations move from focusing on dyadic buyer–supplier relationships to considering beyond these immediate relationships to other links in supply chains and networks, they may consider who in the network plays strategic roles such as innovation sponsor, advisor, coordinator, information broker, relationship broker, and network structuring agent (Harland & Knight, 2001).

Film and TV productions are highly networked activities, as is evident in the increasing credits of stakeholders shown before movies start. Each of these organizations plays different operational and strategic roles. For example, the director brings with them their own network of actors and creatives that they use for different film projects, and producers tap into their networks of finance and resources. These social networks are residual between projects as they contain and nurture social capital which is "The set of resources, tangible or virtual, that accrue to organizations through social structure, facilitating the attainment of organizational goals" (Leenders & Gabbay, 1999). There are certainly benefits for those within strong social networks, in that they are more likely to be engaged in the next film or TV

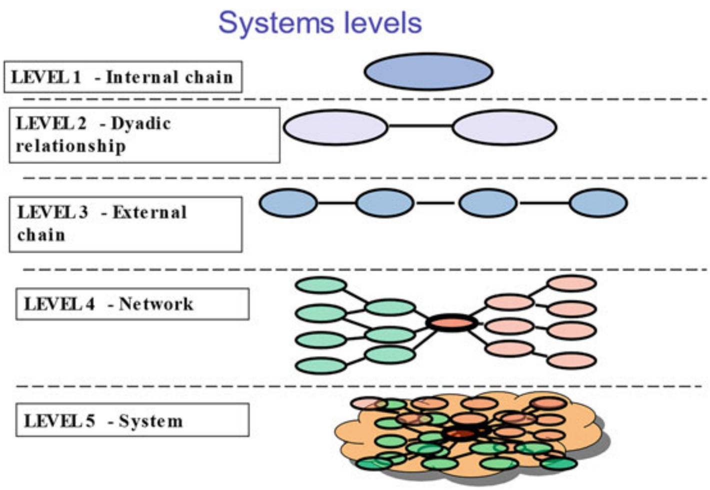

**Fig. 5** Supply systems levels. Source: Developed from Harland (1996)

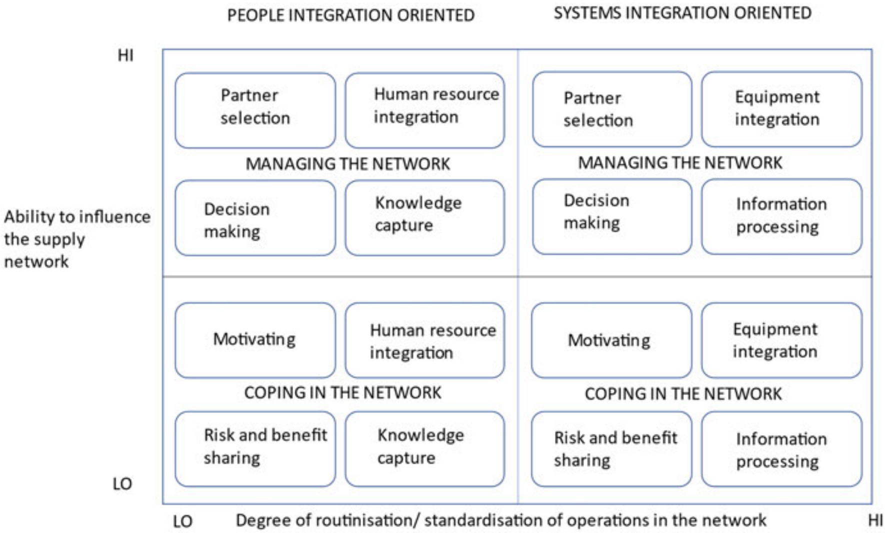

**Fig. 6** A taxonomy of supply networks. Source: Harland et al. (2001)

project and work with colleagues with whom they are familiar, but social capital and strong network connections can raise barriers to entry into these networks (Grugulis & Stoyanova, 2012).

The strategic choice of organizations on the roles and activities they will perform in supply relationships, chains, and networks depends upon their type of supply network. Figure 6 shows a taxonomy of supply networks (Harland et al., 2001).

The empirical research behind this taxonomy found that the two main drivers of difference between types of supply networks were the degree of dynamism or routinization of the network, and the degree of influence the focal firm had in its network. Highly dynamic, innovative networks where the focal firm had little influence over the network (in the top left box) led them to focus on motivating, trying to integrate human resources, share risks and benefits, and capture knowledge; these are all softer, more behavioral activities.

In contrast, dominant firms in quite routinized supply networks, such as automotive networks – in the bottom right box – focus on harder, more tangible activities such as equipment integration and information processing (such as imposing the implementation of enterprise resource planning systems). These firms dominate decision making and can choose their partners.

It is evident that as supply has developed strategically – beyond the boundary of the firm into relationships, chains, networks, and systems of supply – the need for a greater variety of concepts and theories to deal with this complexity has increased. Researchers in the field of supply have turned to strategic management for appropriate concepts and theories.

## 8 Value of Strategic Management Concepts and Theories for Supply Strategy

Researchers in purchasing and supply, supply chain management, and supply strategy have been criticized for insufficient use and development of theory, leading to conclusions that the field of supply cannot yet be recognized as an academic discipline (Harland et al., 2006; Chicksand et al., 2012; Spina et al., 2016). Despite this traditional lack of theory consideration, recently top academic journals have demanded theory contributions, whether they be theory building, combining, elaborating, testing, or application. For a comprehensive guide to theories used in supply, see Tate et al. (2022). In this section, a summary of maturity and stage models is provided, followed by a summary of theories used in strategic management that have been used in the field of supply.

### 8.1 Maturity and Stage Models

As manufacturing, operations, supply chain, and supply strategy concepts have developed, they have been influenced by models from strategic management and marketing strategy, notably maturity and stage models. While often being referred to as *models*, they are frameworks that convey ways of conceptualizing strategy development over time.

Strategic management maturity models are based on the principle that product classes have a *life cycle* akin to biological life cycles from birth through maturity to decline and death. Stage models are based on principles of continuous improvement, proposing that organizations, business functions, or teams can progress from one stage up to the next, aiming to reach the highest stage possible. While not necessarily *theories*, maturity and stage models have featured in manufacturing strategy from the mid-1980s. The conceptual building blocks of these models can be traced back to manufacturing in the Total Quality Management movement and even further back in Taylor's Scientific Management (1911) highlighting an inherent strategic drive for improvement throughout the development path of the field of supply strategy.

The most used maturity model in operations and supply has been the Product Life Cycle (PLC). The Marketing Product Life Cycle – M-PLC – was first proposed in the 1950s and was represented in the form we know today by Levitt (1965), shown below in Fig. 7.

The main principle of the PLC is that classes of products are designed, developed, and introduced to the market, they grow in sales volume until the market for them matures, and eventually demand and sales decline. There are many variations of PLCs and in practice firms try to avoid the decline of sales by relaunching and revamping products.

The principles of PLC stages are used in strategic management and other business functions as they differentiate between appropriate strategies for each stage; in strategic management, Anderson and Zeithaml (1984) examined differences between strategic variables at different stages of the PLC. There have been many

criticisms of the PLC (notably Dhalla & Yuspeh, 1976), highlighting how products within product classes may behave differently, firms do reverse the decline by reinvigorating products, firms are not passive acceptors of PLC but rather their marketing strategies may determine the shape of the PLC, and PLC tends to promote new product introduction as a necessity. However, despite its critics, operations and supply chain strategists have defended its value as a useful tool within the armory (Hayes & Wheelwright, 1979).

In today's networked times, firm-based perspectives of a PLC have been challenged. Cao and Folan (2012) argue that the "extended product" to which value is added by many members of a value chain would not have a single PLC, as different firms in the value chain would have different perspectives relating to their value-adding contribution. Modern circular supply chains involving repair, remanufacture, and recycling also challenge the traditional view of the PLC which was formed at a time of a more *disposable* philosophy for products. Mass customization also challenges the PLC that is more appropriate to mass production and standardization. *Time pacing* is also a more modern introduction, where firms deliberately design and implement timed phases of product introduction, challenging the original, more biological definition of an organic life of a product (Lagnevik et al., 2003).

The PLC was brought into the realm of manufacturing and operations strategy by Hayes and Wheelwright (1979) who created a strategic framework that connected the competitive priorities of a business and marketing strategy with manufacturing strategy, creating differentiated manufacturing and process strategies for stages of a life cycle. Figure 8 provides examples of how competitive priorities may be translated into operations strategy priorities that then can be used to drive process design decisions.

In contrast to maturity models where decline is expected, stage models have been evident in supply strategy since the 1980s. Stage models involve continuous improvement with progression through stages of development. Hayes and Wheelwright (1984) proposed a four-stage model of evolution of manufacturing, shown in Fig. 9.

In this stage model, Hayes and Wheelwright proposed that if the operations function of a business is at stage 1, they are causing problems internally and need to sort themselves out so they no longer have a negative impact on the rest of the business. For example, the firm might have sales orders to satisfy, there might be

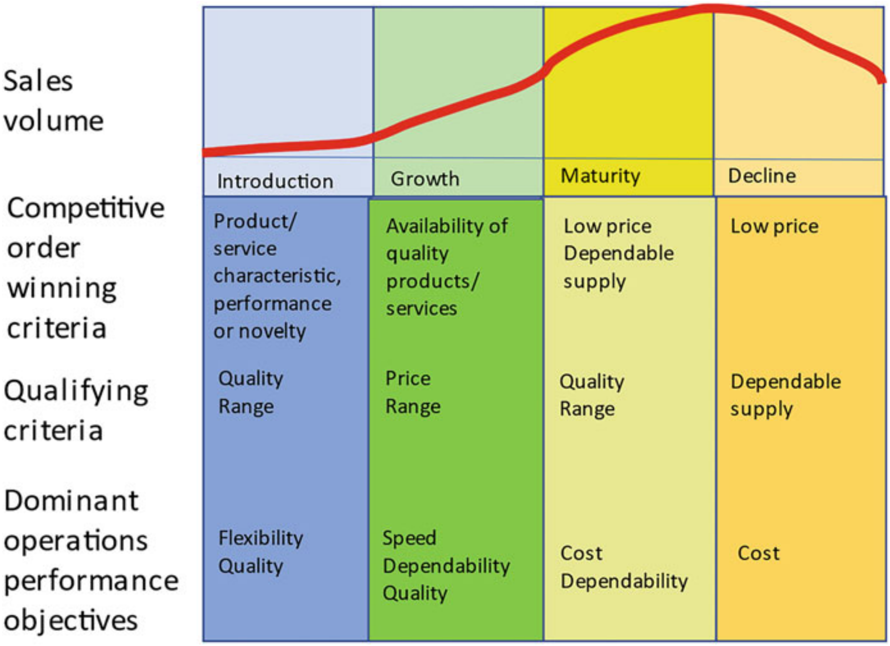

**Fig. 8** Application of PLC to supply

resources available to manufacturing but the operations function just cannot seem to organize themselves to produce on time.

The principles of the framework are that improvement occurs by progressing from one stage to the next, and not to try to jump from stage 1 to stage 4. Followers of the mantras of "world-class manufacturing," "best practice," and "benchmarking" have often failed to understand that aiming to emulate globally leading operations may not be feasible if their own operation is struggling in stage 1 or 2; first they must focus on solving internal problems.

From a purchasing perspective, Reck and Long (1988) also proposed a stage model (although they termed it a maturity model), shown in Fig. 10.

The field of supply chain management has tended to import more organizational and strategic oriented theories than individual or behavioral theories (Harland & Roehrich, 2022). Just as supply has evolved from focusing on flows of materials and associated information inside manufacturing firms to examine other units of analysis of dyadic relationships, chains, and networks of organizations (Harland, 1996), and systems of supply (Harland, 2021), there has been a parallel development in strategic management. Examples of theories used in strategic management and later adopted by supply researchers are provided in Table 5, indicating the system level at which they are appropriate.

The first two theories popularly used in manufacturing and supply chain management were Transaction Cost Economics (TCE) and Resource-Based View (RBV)

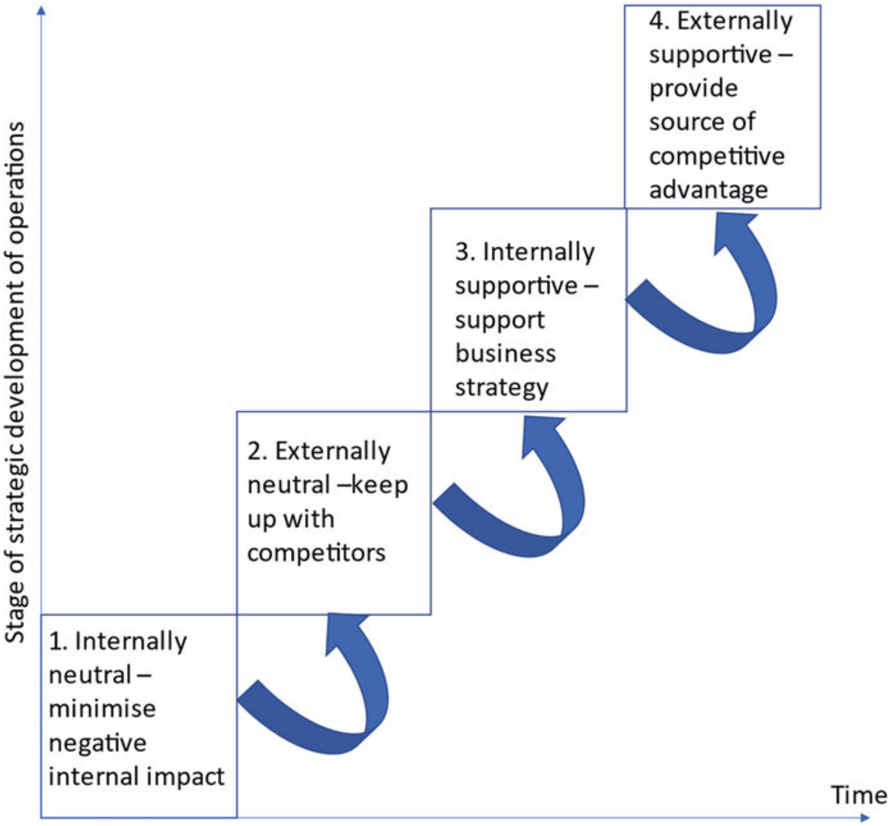

**Fig. 9** Four-stage model of manufacturing/operations strategic development. Adapted from Hayes and Wheelwright (1984)

of the firm. TCE was used to identify, through examining transaction costs, whether firms should make or buy, underpinning the development of theory application to decisions on strategic outsourcing (Williamson, 2008). RBV looked inside firms for the source of competitive advantage residing in valuable, rare, inimitable, and non-substitutable resources (Barney, 1991). RBV spawned a family of related theories including dynamic capabilities (Teece et al., 1997) and resource orchestration theory (ROT) (Sirmon et al., 2011). ROT parallels the strategic management development from firms competing with firms to interorganizational networks competing (Cook, 1977; Thorelli, 1986), appreciated in the burgeoning field of supply chain management (Christopher, 1992).

As strategic management in theory and practice has increasingly understood the competitive power of interorganizational networks of organizations, the field of supply strategy has also developed its thinking and use of theory to understand units of analysis and systems beyond the firm.

## 9 The Future and Conclusion

The chapter has taken an historical, chronological perspective to explain how supply strategy has evolved over time, aligned with parallel development in the field of strategic management. To close, a glimpse into the future of continued complexity and networked businesses, economies, and societies is provided.

Complex problems, such as the COVID-19 pandemic and the unfolding, accelerating climate crisis, have given rise to calls within the field of supply strategy to seek theories outside the field to deal with this complexity (Craighead et al., 2020). More open, networked approaches and more holistic perspectives of management are required to be innovative in the future (Chesbrough, 2020). Appreciation and leverage of "interconnected" networks, rather than simpler connected supply chains of organizations, is required (Harland, 2021).

In addition to greater appreciation and understanding of environmental complexity and interconnectedness, there are also developments within the field of supply that are leading to calls for change. Historically, purchasing and supply research has considered “softer,” behavioral approaches to management, but the dominance of operations management within the supply chain management space has led to more “hard” science approaches being favored; however, calls to increase the relational and “softer” approaches are being made (Caniato et al., 2020; Ellram et al., 2020).

Having originated in detailed operations within factories, the field of supply has passed through metamorphoses of production and operations management, supply chain management, and through to a broader concept of supply strategy and has embraced policy and strategy at different systems levels. Despite the thrust for hard scientific rigor from operations management, purchasing and supply management thinking has also pushed for more behavioral, psychological perspectives. Like strategic management, the field of supply strategy could be characterized as containing several different schools of thought. Senior practitioners of global organizations and academics working in larger systems levels of supply will continue to be influenced by strategic management concepts, theories, and practice.

In conclusion, the field of supply strategy or supply chain management is still evolving. Multiple perspectives are evident, each with their distinct focus on structures or processes, different systems levels, and different competitive drivers, challenging us to define the identity of the field. While not yet passing the tests required to be recognized as an academic discipline, as a field of practice and research, there is no doubt that supply strategy is maturing. Core to the trajectory of development is the more recent focus on supply strategy as a strategic, collaborative, value-adding endeavor, in contrast to the previous inward focus on efficiency and cost reduction. It follows, therefore, that strategic management is of increasing importance to supply strategy and supply chain management thinking and should feature more in supply chain research, teaching, and practice.

# Maturity Tools in the Supply Chain Context: A Framework Proposal

Susana Garrido, Elisabete Correia, Marina Fernandes Aguiar, Daniel Jugend, and Helena Carvalho

## Contents

**Abstract**

The ability to recognize the gradual growth of a given supply chain considering a specific characteristic or factor by understanding its level of maturity is important for progress and benchmarking. These processes allow for a more effective and efficient identification of actions and directions to guide it toward excellence. This chapter aims to explore the theme of maturity tools for supply chain

management by suggesting a framework to guide the construction. Addressing maturity models in an integrated manner, this chapter helps students, researchers, and managers in assessing the current level of performance of their supply chains and making decisions about what can be done toward continuous improvement. In addition, practitioners may go deeper and apply the model presented or even develop a maturity model using the framework proposed as a guideline.

## 1 Introduction

Maturity models provide a description and analysis of a current state of an organization or unit. It provides a structured way to analyze how a company meets certain requirements and which areas require attention to achieve better maturity levels (Aguiar & Jugend, 2022). Maturity models are a well-established practice in the management field, and increased global competition in the context of operations management is a motivating factor for the adoption of these tools (Yatskovskaya et al., 2018). Maturity models enhance the capabilities of firms who take a holistic approach to gaining competitive advantage.

Organizations have recognized the benefits of maturity models (Yatskovskaya et al., 2018). These tools function as a means for addressing organizational or process maturity levels when measuring a certain target (Groschopf et al., 2021). There are various maturity models in the literature covering different application contexts or objectives, such as the sales processes of industrial projects (Voss et al., 2023); processes of organizations that conduct state-commissioned studies (Analysis Capability Maturity Model (ACMM) (Covey & Hixon, 2005); business process management (Business Process Management Maturity – BPMM) (de Bruin & Rosemann 2007; de Bruin et al., 2005b); information technologies (Becker, 2009).

Furthermore, Uhrenholt (2022) states that maturity models enable the identification of the current state of the art in terms of operations and the future developments needed to improve them. According to the authors, this first task – the diagnosis – is of great relevance if maturity models are to sustain competitive advantage.

Researchers and practitioners from different backgrounds have gone to lengths to suggest mechanisms and frameworks to help supply chains improve their effectiveness and performance, through maturity models. Considering the context of supply chain management (SCM), some maturity models focus on assessing supply chain (SC) activities in an effort to achieve better results in an effective and efficient way (Santos et al., 2020; Groschopf et al., 2021). According to Jording and Sucky (2016), the SCM maturity model is formed from four elements that can be used independently or in conjunction, namely: high customer focus, management of the flow of goods, management of information, and inter-corporate coordination and collaboration.

Maturity models are applicable to different domains in the SC context (McCormack et al., 2008). They are variously implemented in the context of digital transformation (Groschopf et al., 2021; Hellweg et al., 2021), Supply Chain 4.0. (Frederico et al., 2020), for product fitting in retail SC (Gustafsson et al., 2019), to assess and improve supply chain operations (Garcia Reyes & Giachetti, 2010; Caiado et al., 2021), and for logistics processes in supply chains (Golinska-Dawson et al., 2023). These maturity models, among other applications, can also identify current situations and their progress toward SC sustainability.

Various frameworks aiming to evaluate sustainability in the supply chain context already exist. However, very few of them provide managers and other stakeholders with a comprehensive understanding of where companies and their supply chains stand in terms of sustainability evolution and what actions are required to continue progressing. Thus, an introduction of the concept of maturity in SC and the development of a maturity model that seeks to assess the current level of SC sustainability and give directions to reach higher levels of maturity could be of great interest. Managerial decision-making can use these tools to provide a structured path for the SC to follow (Reefke et al., 2014). Literature reviews show that maturity models in the context of SC addressing sustainability in a triple bottom line (TBL) approach are still scarce. As Reefke et al. (2014) point out, few models "connect maturity considerations in SCs with sustainability imperatives," so the development of such a model would help bridge this gap.

Several authors (Asah-Kissiedu et al., 2021; Dooley et al., 2001; Bititci et al., 2011; Chen & Fong, 2012) support the notion that properly operationalized maturity models have significant practical application and can enhance performance (Reefke et al., 2014). This relationship, although advocated (Lockamy III & McCormack, 2004; Söderberg & Bengtsson, 2010; McCormack et al., 2008; Aryee et al., 2008), has seen limited empirical evaluation (Söderberg & Bengtsson, 2010).

Thus, this chapter aims to contribute to the theme of maturity models for the supply chain. Initially, the concept of maturity models is presented. Subsequently, specific maturity models for supply chain management are presented and discussed. A framework to guide the construction of supply chain maturity tools is then proposed. Finally, the conclusions of the chapter are presented.

## 2 Maturity Models

The concept of "maturity" is often attributed to the quality movement in the 1930s and to Philip Crosby's Quality Management Maturity Grid (QMMG) (Crosby, 1979). The QMMG represented pioneering work in the development of upcoming maturity models (e.g., Estampe et al., 2013; Introna et al., 2014).

The concept of maturity is more prevalent today. It is associated with concepts such as competency, capability, or even level of sophistication (De Bruin et al., 2005a; Ferradaz et al., 2020). De Bruin et al. (2005a, p. 27) define the maturity of an organization as "a measure to evaluate the capabilities of an organisation regarding a certain discipline."

Several studies have examined the differences between the concepts of maturity and readiness. Pacchini et al. (2019) define readiness as the moment in which a company is ready to execute an activity, while maturity can be understood as the evolutionary level a company has achieved. In this sense, assessing readiness is a process that occurs before assessing maturity (Schumacher et al., 2016). When analyzing the use of technologies, Zoubek et al. (2021) argue that readiness models can be useful before implementing these technologies, by examining if a company is well prepared for its adoption and capable of fulfilling given prerequisites.

Maturity models encompass the description and capture of the *as-is* situation while a process of maturation occurs. Having investigated the factors crucial to industry 4.0 implementation in European countries, Castelo-Branco et al. (2019) state that readiness is how able a company is in developing the infrastructure of industry 4.0 and maturity is the ability to manage the information derived from this infrastructure.

Thus, maturity models are tools used to evaluate the capabilities of an organization in a particular domain (Becker, 2009; Introna et al., 2014). Similarly, for Kohlegger et al. (2009, p. 3), a maturity model "conceptually represents phases of increased quantitative or qualitative capability changes of a maturing element to assess its advances concerning focus areas."

The maturing element may be an individual, an object, or a social system, and the focus areas may be processes, digital resources, people skills (Kohlegger et al., 2009), an organizational function (Klimko, 2001), technology, or a product or a process (Jiankang et al., 2011). Bititci et al. (2014, p. 3065) understand a maturity model as a "matrix of practices that define, for each organisational area, the level of formality, sophistication, and embeddedness of practices, from ad hoc to optimising."

The maturity model adopted is a concept that can represent phases of increased capabilities, phases that reflect the development of an area of interest, or an evolution of the level of sophistication of practices. Either way, maturity models assume a path of development or evolution (Paes, 2011). For Klimko (2001), a maturity model constitutes a given application of the life cycle approach that each entity develops over time. The development path is traced through a sequence of levels, stages, or phases from an initial state to maturity (Becker et al., 2009). Reaching each maturity level allows for incremental and lasting performance improvements (Estampe et al., 2013).

Thus, high levels of maturity lead to high levels of performance. An immature organization, for example, will exhibit reactivity and improvisation (Ferradaz et al., 2020). In these immature situations, decisions aimed at improving processes only come after crises arising from a reactive approach to management. An evolution to a mature stage, involving increased awareness, includes factors such as whether an organization is proactive for learning, seeks to put into practice the lessons learned from mistakes, understands such mistakes as improvement opportunities, and promotes the involvement of the whole team in this process (Ferradaz et al., 2020). The relationship between maturity and performance is well supported by various studies (Dooley et al., 2001; Bititci et al., 2011; Chen & Fong, 2012).

In addition to including the characteristics of each maturity stage, effective maturity models establish a logical relationship between stages (Röglinger et al., 2012). In general, these models have the following characteristics (Klimko, 2001):

(i) The development of an entity is simplified and described as a limited number of maturity levels (usually between four and six);
(ii) The levels are characterized according to specific requirements that the entity must meet at that level; the levels are ordered from an initial stage to a final level;
(iii) The entity successively advances through the levels, none of which can be left out during development.

The ability to recognize the gradual growth of a given organization by understanding its level of maturity allows for a more effective and efficient identification of actions and directions to guide it toward excellence (Introna et al., 2014). But, to do so, it is necessary to determine the current stage of maturity, that is, to capture the perception of the situation in which an organization finds itself. For Maier et al. (2010), this is one of the main merits of a maturity model; and these models are used for several purposes (Pöppelbuß & Röglinger, 2011):

(i) As a descriptive tool to assess strengths and weaknesses (Neuhauser, 2004);
(ii) As a prescriptive tool to develop a roadmap for performance improvement, where the objectives of the next maturity and performance levels are established;
(iii) Companies can focus their resources (McCormack et al., 2008), that is, the models provide a path for improvement by recognizing capabilities, that is, skills or competencies that should be developed in a specific area in an organization (Paulk et al., 1993) to achieve a goal;
(iv) As a comparative instrument, which allows a company and its processes to be assessed and compared with standards and best practices of other organizations (Klimko, 2001; Demir & Kocabas, 2010), thus enabling internal and external benchmarking (Röglinger et al., 2012).

Regarding the last purpose, the study of Maier et al. (2010) points out some divergences between the concepts of a maturity matrix and a maturity model. A matrix is formed by cells encompassing behavioral patterns expected at each level; it can be understood as a grid, or a plateau, which can be applied to organizations in contrasting industrial sectors. A matrix is less complex than a model, which focuses on specific processes, uses structured checklists and questionnaires, and can even guarantee certification after benchmarking (Maier et al., 2010). In this sense, maturity tools can benefit organizations through their use with a process. Steps would include the description of a current state (as-is situation), identifying gaps and highlighting the areas that still require attention if more mature levels are to be reached, and an analysis of actions needed to put improvements into practice (Arekrans et al., 2021). In other words, more than just a diagnosis, these tools can function as a compass, showing the right direction toward improvement initiatives.

There are a number of milestones regarding maturity models. The model for process maturity (Capability Maturity Model – CMM) developed by the Software Engineering Institute (SEI) – at Carnegie Mellon – popularized the concept of maturity. CMM influenced the development of maturity models in different contexts (Dooley et al., 2001; De Bruin et al., 2005a; Bititci et al., 2014). CMM was developed focusing on the function of information systems, covering several processes (People Capability Development, Software Acquisition, System Engineering and Integrated Product Development). CMM allows software organizations to manage their processes through the description of each phase (Garcia Reyes & Giachetti, 2010), based on how they define, implement, measure, control, and improve their software processes (Paulk et al., 1993 in Bititci et al., 2014).

Five maturity levels are defined in CMM: Initial, Managed, Defined, Quantitatively Managed, and Optimizing. In CMM, higher levels of maturity means that companies are managing their processes better and, consequently, the projects they carry out will have fewer risks. More mature companies are more likely to deliver quality products that meet established budgets and schedules (Garcia Reyes & Giachetti, 2010).

The project management area has also developed and proposed maturity models based on the concept of continuous improvement. Among the most disseminated is that proposed by Kerzner (2002), which uses five levels: common language, standard process, singular methodology, benchmarking, and continuous improvement. Using these principles, the Project Management Institute (PMI) proposed the OPM3® maturity model, which is based on the following improvement steps: standardize, measure, control, and continuous improvement. These steps aim to assess and improve project management in companies (Fahrenkrog et al., 2003; Project Management Institute, 2003).

Since their development, maturity models have also been widely adopted and used (Bititci et al., 2014) in various areas of engineering and management (Pigosso et al., 2013; Ferradaz et al., 2020). Used as tools to achieve an informed approach to increase the capability of a specific domain or area within an organization (Paulk et al., 1993), they have been widely applied in information systems (Helgesson et al., 2012) – more than 70 maturity models having been identified in this area (Kohlegger et al., 2009). The application of maturity models is evident in numerous management fields, as can be seen in Table 1.

Beyond these specific management areas, there are also areas associated with sustainability issues, such as eco-design (Pigosso et al., 2013), industrial symbiosis (Golev et al., 2015), corporate sustainability (e.g., Amini & Bienstock, 2014),

circular economy (Sehnem et al., 2019), and circular product design (Aguiar & Jugend, 2022). The next topic of this chapter presents and discusses the concept of maturity applied to supply chain management.

## 3 Maturity Models in the Supply Chain

Companies with unique theoretical and technical knowledge or merely possessing the tools and resources needed for production do not guarantee success (Introna et al., 2014). For success to become a reality, a company must move along specific lines, build strategic alignment, develop adequate technical and organizational skills, provide the method for applying the acquired knowledge, and manage the capacity. By proposing systematized ways of representing the current level of these competencies and the means necessary for improvement, maturity models can help companies improve their performance.

Only a few models are aimed at supply chain management. Most of the maturity models proposed are not developed from an SC perspective (Srai & Gregory, 2005). Such models are function-oriented or dominated by financial measures rather than linked to a company's global strategy and directed to specific sectors of activity. These characteristics are also found in SC-based maturity models (Netland et al., 2007; McCormack et al., 2008), making the comparison even more difficult (Srai & Gregory, 2005).

A number of maturity models have emerged over time (Netland & Alfnes, 2008). For instance, Paes (2011) identified 28 maturity models in the literature, with logistics and SC as application domains, from 1998 to 2009. Based on this study (Paes, 2011), Table 2 presents the frequency with which the following items were investigated: the main focus of the maturity model, research approach, method for data collection, forms of application, presentation of results, and the number of maturity levels.

Table 2 shows the great diversity of the maturity model focus of analysis. Some examples of models applicable to the SC context include models for the maturity of SCM processes (e.g., Garcia Reyes & Giachetti, 2010; Lockamy III & McCormack, 2004; McCormack, 2001), models for the integration of the SC focusing on relationships and systems or technologies (e.g., Aryee et al., 2008), and models for the improvement of relationships in SC (e.g., Meng et al., 2011). However, models that take a broad approach to SC are still limited.

In developing these models, a slight predominance of the quantitative approach is observed. There is some diversity in data collection methods. Surveys directed at a more comprehensive set of respondents and the use of questionnaires represent the most used method. The degree of maturity is also highlighted as the preferred form of application in the maturity models whose results are fundamentally presented through charts. Maturity levels range from three to six, with five levels being the most common number.

Paes (2011) seeks to present a logical conceptual framework to assess and improve SC management in automotive companies. The study identifies 15 areas for maturity levels. These models were evaluated within three SC companies, to assess each maturity level and the degree of the strategic importance of each area. It can be seen from this approach that, even when developed from an SCM perspective, maturity models can evaluate similar and connected companies (e.g., Aryee et al., 2008; Netland et al., 2007): going beyond the observations of Rao and Holt (2005) that most studies on SCM focus on a single member or activity of the SC.

As Table 2 illustrates, there is a diverse range of critical areas or dimensions considered across the different models, even when the focus of analysis is similar. Most models assume the definition and evaluation of practices associated with such dimensions, but the type of practices considered and their number differ from model to model. For example, Foggin et al. (2004) proposed a diagnostic tool that helps identify potential problems and possible improvements in supply chains; and based

on a supply network perspective using the case studies method, Srai and Gregory (2008) suggest a tool for maturity assessment.

Netgland and Alfnes (2008) point out that presenting the practices logically and simply helps categorize them. There is one challenge, the term "practices" used in maturity models can have different meanings. A practice can be a tactic or a method, depending on whether a tactic or method is chosen to perform a particular task or to meet a particular objective (Dooley et al., 2001). Practices can also be defined as an activity, as highlighted by the Project Management Institute (PMI). According to the PMI (2008), practice is defined as a specific type of management activity that helps execute a process by employing one or more techniques and tools (Pigosso et al., 2013).

Similarly, Paes (2011) considers practices as a set of activities performed by an organization to promote the effective management of supply chain processes. Practices can also be understood as processes. According to Netland and Alfnes (2011), a practice is an established organizational process that improves the way a business is run, ranging from teamwork and employee involvement to the use of techniques such as kanban.

These practice definitions are equivalent since a process can be separated into several activities – similar to the definition provided by the IS0 9001 standard. According to this standard, an activity or set of activities using resources and managed to transform inputs into outputs can be considered a process.

The transition from one maturity level to a higher level is usually associated with implementing best practices (Estampe et al., 2013). Best practices describe the state of the art for performing a business (Netland et al., 2007). Dooley (2001) follows the concept of Olsen et al. (1995) who define best practice as a tactic or method from real-life implementation that is successful; cross-functional development teams are a best practice example.

Garcia Reyes and Giachetti (2010) point out that some maturity models (e.g., Stevens, 1989) are theoretical frameworks with little empirical support. A recognized exception is Lockamy III and McCormack (2004), one of the most widely quoted maturity models in the literature (Netland et al., 2007). Lockamy III and McCormack (2004) developed a maturity model for SC processes, based on the SCOR model, and defined five levels of maturity (Ad-hoc, Defined, Linked, Integrated, and Extended). The maturity model for the SC is based on a model oriented to the management of processes (Business Process Orientation – BPO) (Söderberg & Bengtsson, 2010), see Fig. 1.

The SC maturity model (Fig. 2) realizes the characteristics of this BPO model, in which process maturity includes multiple levels. As the process matures, predictability, capacity, control, efficiency, and effectiveness increase (McCormack et al., 2008). Thus, as a SC maturity level increases, the definition and structuring of the SC and its practices increase, the SCM practices for its management are more advanced, and managers introduce a more strategic aspect to the SCM.

Processes progressively assume an inter-organizational nature, extending to the entire SC, also increasing the level of collaboration between SC partners. Although the maturity levels portray groups of practices that are employed at different levels of

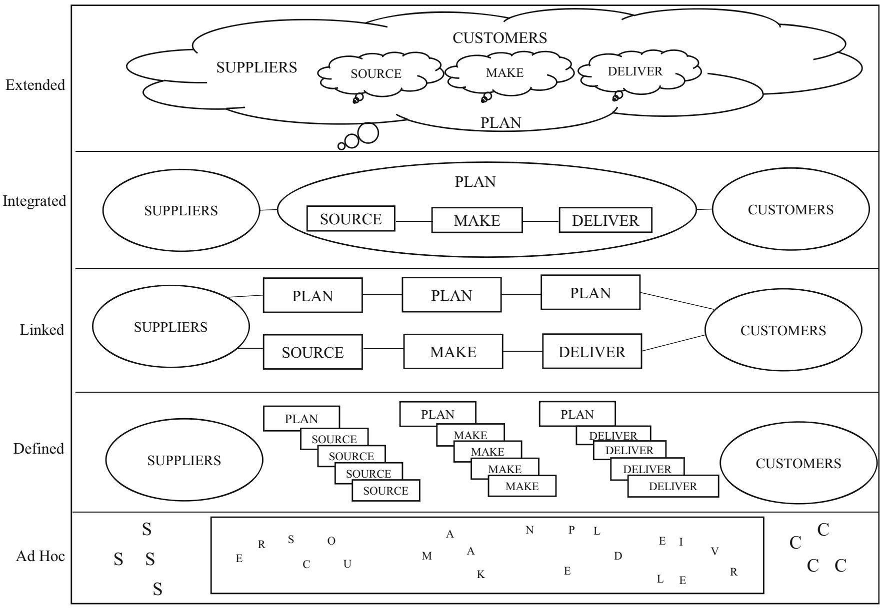

**Fig. 2** SC maturity model. (Source: Lockamy III and McCormack (2004))

process maturity (McCormack et al., 2008), these practices are not indicated in the model proposed by Lockamy III and McCormack (2004).

Progress to higher maturity levels means more predictable process performance, progressive reduction in SCM costs, and increased customer satisfaction. In addition to assessing the maturity of their processes, practices, and activities, many models also seek to establish a relationship between maturity and performance empirically.

In the case of Lockamy III and McCormack (2004), the assessment of the impact of these processes on SC performance was carried out through a survey of 90 companies. The relationship between SC maturity and SC performance was subsequently analyzed using regression analysis. The results indicated degrees of correlation in some of the performance measures (e.g., inventory levels).

The relationship between SC maturity and performance was further tested by McCormack et al. (2008) with 478 Brazilian companies, based on the previous maturity model and using a quantitative methodology. Using a survey and resorting to structural equation modeling, a positive relationship between SC maturity and performance was evidenced, highlighting a higher impact of the distribution process maturity (deliver) on overall performance compared to the impact of the remaining SC processes.

A number of other maturity models incorporate empirical insights and contributions from companies or experts (e.g., Netland et al., 2007; Garcia Reyes & Giachetti, 2010; Oliveira et al., 2011). For example, Garcia Reyes and Giachetti (2010) designed a maturity model describing competencies that a company must master to achieve one or more objectives. A Delphi method is used in their model. Based on this method, 80 experts from various industries contributed to the definition of five proposed maturity levels. Seven areas of competence (views) were defined (supply chain management and logistics; production systems; inventory management; customer relationship management; human resource management; information systems and technology management; performance measurement systems), and the experts define the best practices (including processes, procedures, projects, tasks) which translate into the competences necessary for the SC.

Once these practices have been defined for each maturity level and area, the intention is for managers to evaluate their implementation through an organizational questionnaire. A part of a questionnaire on the first competence area (supply chain management and logistics) is detailed. The model is validated using a pilot study in a Mexican company.

Many times, as is the case with this study, results are presented graphically using a radar plot, which shows the maturity levels and aspects for each area. These radar plots are represented by numbers corresponding to the questions in the questionnaire with the lowest values to be improved. The goal is to design a model that enables companies to assess the maturity of their SCM practices and constitutes a tool to assist in developing plans for the improvement of SCM practices.

Similarly, Aryee et al. (2008) developed a model to assess SC integration and used a survey with twenty-nine UK companies from various activity sectors to test their model. They developed a questionnaire covering several dimensions of analysis: supply chain process integration; manufacturing planning and control (MPC) systems; organizational performance; process and technological knowledge; and collaborative strategies. Several relationships were established between the various levels of collaboration and technological integration and organizational performance for each firm.

Netland et al. (2007) also test the validity of their maturity model in four Norwegian companies. They seek a model that assesses the maturity of SC activities based on the maturity assessment of 50 best practices. These practices are defined based on a literature review for each of the key areas considered in the model: strategy, control, processes, materials, resources, information, and organization. They are assessed considering five maturity levels, defined on a scale from 1 to 5 for each practice.

Another study (Oliveira et al., 2011) uses data from hundreds of companies across different sectors and countries (USA, Canada, United Kingdom, China, and Brazil). The authors identify 13 constructs or factors for maturity modeling including: demand management and forecasting, strategic planning team, strategic behaviors, procurement team, supply network management, production planning and scheduling, distribution network management, order management, process governance, foundation building, responsiveness, collaboratively integrated practices, and customer integration. They develop maturity scores as a continuous variable and a fixed number of 5 clusters in which each one represents a maturity level. They also develop precedence relationships among the 13 constructs, representing groups of SCM process capability indicators.

As mentioned earlier, there is an emphasis on the belief that an increase in maturity will lead to better SC performance, which will translate into an improvement in financial performance (Söderberg & Bengtsson, 2010). Although the existence of a positive relationship between maturity and SC performance is not a consensus (Estampe et al., 2013), it is advocated by several authors (e.g., Lockamy III & McCormack, 2004; Söderberg & Bengtsson, 2010; McCormack et al., 2008; Aryee et al., 2008). But this relationship is empirically proven in a few papers (Söderberg & Bengtsson, 2010).

Some studies (e.g., Aryee et al., 2008) have shown that performance improvement is associated with higher levels of maturity attributed to higher levels of collaboration and technology integration in a supply chain. There is solid evidence of a strong positive relationship between SC maturity and overall SCM performance for small and medium-sized enterprises (Söderberg & Bengtsson, 2010).

Several metrics are used for performance evaluation across different organizational functional areas: Customer service, Cost management, Quality, Productivity, and Asset reform management. Studies have also replicated each other, empirically strengthening these relationships. However, the study of Varoutsa and Scapens (2015) presented a different standpoint, investigating the in-between of the changing phases of a supply chain as it matures.

Recent literature on supply chain maturity has also shed light on emergent fields related to trending demands, such as digital transformation (Groschopf et al., 2021; Hellweg et al., 2023). Considering the term “Supply 4.0,” Frederico et al. (2020) proposed a framework encompassing the maturity level perspective to evaluate Industry 4.0 dispersion across the supply chain. Five constructs were listed as dimensions: managerial and capability supporters, technology levers, process performance requirements, and strategic outcomes. Under this domain, Gustafsson et al. (2019) adopted an innovative point of view, focusing on the challenges that retail supply chains face and exploring the potential outcomes that digitalization brings to the practice of product fitting.

More recent efforts have shifted to multidimensional sustainable supply chain maturity models and matrices (e.g., Chalmeta & Barqueros-Muñoz, 2021). For example, supply chain management can encompass a combination of quantitative and qualitative methods for sustainability assessment. In the qualitative sphere, open-ended interviews and questionnaires can be used. Quantitatively, an analysis of indicators can be used. An example of levels applied would be: Level 0 (no sustainability), Level 1 (partially sustainable in specific areas), Level 2 (sustainable in particular areas), Level 3 (partially sustainable), and Level 4 (totally sustainable).

Montag et al. (2021), based on a theoretical review, proposed a maturity model for the adoption of the circular economy in supply chain management that embraced three dimensions: organization, product, and process, further divided into four levels: linear, minimal developing, defined, and circular.

### 3.1 A Supply Chain Maturity Model Construction Framework

As the development and application of maturity models are critical, a process for doing so is necessary for its adoption by organizations and for future developments. To this end, frameworks for developing maturity tools have been introduced (e.g., De Bruin et al., 2005b; Maier et al., 2010). De Bruin et al. (2005b) developed a generic framework to guide the development of maturity models, taking an evolutionary approach through its six proposed phases: scope, design, populate, test, deploy, and maintain. The first phases are descriptive, starting with a diagnosis, followed by prescriptive and comparative aims. This model can be applied across multiple areas.

From a similar perspective, Maier et al. (2010) proposed a roadmap as a reference and guidance for developing new and evaluating existing maturity grids. The roadmap comprises four phases: planning, development, evaluation, and maintenance, listing decisions that need to be taken to develop such tools.

Exploiting these decisions within the supply chain field by establishing a link between de Bruin's model, Maier's roadmap and Table 2 of this chapter, and using the PDCA Cycle, a framework (Table 3) to guide the construction of supply chain maturity tools is proposed.

The framework proposed in Table 3 can guide users in the construction of a supply chain maturity tool through four stages, each corresponding to the activities that make up part of the PDCA Cycle of continuous improvement: Plan, Do, Check, and Act. In each of these stages, the corresponding phase designed by the authors referenced is identified, a set of suggested activities are to be performed, and the decisions that should be taken are also identified. For each phase, suitable SC contexts are highlighted.

## 4 Conclusion

Although maturity models are a contemporary theme, many companies have difficulty applying them. This chapter aims to help provide a better understanding and diffusion of such tools by presenting a concept of maturity models that can be applied, mainly to supply chain management. In addition, this work also proposes a framework for SC maturity model construction.

Different studies on maturity models in management have been analyzed, especially considering those that can be applied to the supply chain management context. Furthermore, the chapter presented a framework to build maturity models for supply chain management. It is envisioned that the content presented and analyzed here can be added to new theoretical reviews and studies in companies (qualitative or quantitative) on maturity models in supply chain management.

By presenting research on maturity models in an integrated manner, this chapter aims to assist managers assess the current level of performance of their supply chains and making decisions about what can be done toward continuous improvement. In addition, practitioners may go deeper and apply the model presented or even develop a maturity model using that proposed here as a guideline (Table 3). In any business, a higher level of maturity offers many advantages, such as diagnosing weaknesses in current processes; identifying ways, practices, and technologies for improvement; measuring performance; and improving management capability toward better performance levels.

As global demand for products increases and deadlines for orders decrease, companies face greater pressure than ever before and, thus, they need to establish fast, productive, and efficient supply chains. By using technology and information strategically, companies can use supply chain maturity models to benefit from a secure market position.

Despite the contribution of this chapter and the importance of the topic, limitations in terms of business process maturity models cannot be ignored. We could highlight the lack of studies and theoretical base, or the absence of certain crucial elements: human, cultural, and organizational factors among them.

Another limitation could be the confusing way of measuring maturity, a fact that suggests a lack of training and experience. Thus, the maturity model is a way to ensure supply chain security, knowing that the concept of process maturity comes from an understanding that a process has a life cycle/development stage that can be clearly defined and managed throughout.

## 5 Future Directions for Practice and Research

Given what has been presented in this chapter, future research in the area of maturity models should encompass the adoption of methods that in addition to providing an "as-is" diagnosis, could also include a "to be" scenario, such as action research, along with partnerships between academics and companies that are associated with certain supply chains.

The presentation and discussion of the results generated by applying these tools might be relevant to expand knowledge in the field and map opportunities to improve performance in different areas of the focused supply chain. An interesting research and development avenue might be to compare, both theoretically and in practice, the relationship between the concepts of resilience and maturity and how supply chains from different sectors address this issue. Furthermore, it would be desirable to examine the way in which industry 4.0 technologies, including blockchain, Internet of things, and big data, might contribute to supply chains in the search for their maturity. The theoretical development, proposal, and assessment of supply chain maturity models and matrices integrating such technologies might serve to update the current knowledge on the field and support practitioners interested in boosting the performance of supply chains.

# Global Supply Chain Management

Andreas Norrman and Jan Olhager

## Contents

**Abstract**

Global supply chain management concerns the management of sourcing, manufacturing, and distribution that take place in different countries before a product is sold and delivered to the final buyers. From the view of the focal manufacturing firm, a global supply chain consists of three key parts: the upstream supply network, the manufacturing network of plants belonging to the focal firm, and the downstream distribution network. We discuss managerial perspectives on structuring the supply, manufacturing, and distribution networks

as well as the structural aspects of entire global supply chains. In recent years, the number of global and local disturbances has increased, and the number of factors and issues to consider is constantly growing. We discuss considerations concerning restructuring with respect to offshoring and reshoring, tax, national culture, and supply chain risk management and the balance between global and local supply chains.

## 1 Introduction

The globalization of supply chains increased in the 1980s and 1990s. New markets opened up, and companies were looking for global markets as well as new sources of low-cost manufacturing. The outsourcing and offshoring of manufacturing activities changed the global operations landscape, leading to more complex and diverse supply chains. In the beginning of the twenty-first century, manufacturers were beginning to experience problems in the widespread global operations and started to reconsider where production should take place. As a countermovement to offshoring and outsourcing, firms began to reshore and insource to regain control of the supply chain and improve resilience (Johansson & Olhager, 2018a). In the post-COVID-19 pandemic era, global trade has been undergoing a reduction caused by, for example, Brexit, the US–China Trade War, the replacing of the North American Free Trade Agreement (NAFTA) with the United States–Mexico–Canada Agreement (USMCA), and the Trans-Pacific Partnership (TPP). Many countries, such as China, India, France, the UK, and the USA, have moved from globalization to nationalism for public health, national security, and economic reasons (Tompkins, 2021). Manufacturing firms operating globally must pay careful attention to macro-level changes since such changes may have profound effects on global supply chains.

A global supply chain can be defined as a transnational network of suppliers, manufacturers, and distributors to produce and distribute a specific product to the final buyer. Global supply chain management is then concerned with the management of sourcing, manufacturing, and distribution that take place in different countries before a product is sold and delivered to the final buyers. All three key parts of the global supply chain – sourcing, manufacturing, and distribution – need to be managed and potentially restructured when global events occur. The configuration of the supply, manufacturing, and distribution networks is related to location, that is, geographical dispersion, and ownership. While the manufacturing network is owned by the focal firm, the supply and distribution networks are often dominated by external partners (suppliers and third-party logistics service providers, respectively) even though joint ventures are possible.

## 2 Global Sourcing, Manufacturing, and Distribution

The first step in becoming a global firm has traditionally been to set up a sales office or subsidiary in a new market at the time of entry. The purpose is to develop the foreign market, with the sales office acting as the extended arm of the headquarters. The second step is to establish manufacturing facilities in select markets to take advantage of local low-cost labor, to provide local responsiveness to product design customization needs, and to avoid high trade tariffs and export restrictions. Some markets employ local content requirements, which forces firms to have manufacturing operations in the market to be able to sell to that particular market. The next step can be to internationalize most or all types of resources by adding, for example, local responsibility for supply chain management and product and process development. The final step is to consider the global operations system as one capability network. The ways in which companies source, manufacture, and distribute to satisfy global demand differ. The globalization aspect concerns all three parts: sourcing, manufacturing, and distribution.

A manufacturing firm's perspective on global supply chains focuses on its own network of manufacturing plants, that is, those plants that are owned by the firm. Many firms produce a variety of products and potentially use many different technologies. Consequently, two plants of the same firm may have completely different products as well as different technologies – with very little in common. In this situation an analysis of the entire manufacturing network of the firm would not be able to provide detailed insights. Instead, to be able to understand the logic of the manufacturing network and its plants, it is advisable to look – not at the entire set of plants – but at a sub-network level or specifically at the product group level (Feldmann et al., 2013; Ferdows et al., 2016; Feldmann & Olhager, 2019).

The subset of plants involved in the manufacturing of a particular product group are connected via product design and development – since it is the same product group – and often via material flows between plants. Later, we will discuss when a firm divides an internal manufacturing network for a product group into two or more self-sufficient geographical regions; where the material flow connection may be minimal, while the product design unites the regions.

Many firms have a clear distinction between two types of plants – *component plants*, which are concerned with parts manufacturing and supply semi-finished goods; and *assembly plants* which finalize products before distribution to customers.

Figure 1 captures the distinction between the plant types for manufacturing of a particular product group and the other plants belonging to the same firm. Figure 1 illustrates that there are two component plants serving two assembly plants. Figure 1 also includes the upstream supply network and the downstream distribution network for the focal product group. Since the set of suppliers and distribution channels may differ between product groups, it is necessary to focus on the supply and distribution networks for the particular product group. Figure 1 emphasizes that the supply, manufacturing, and distribution networks for a particular product group are connected via the material flows.

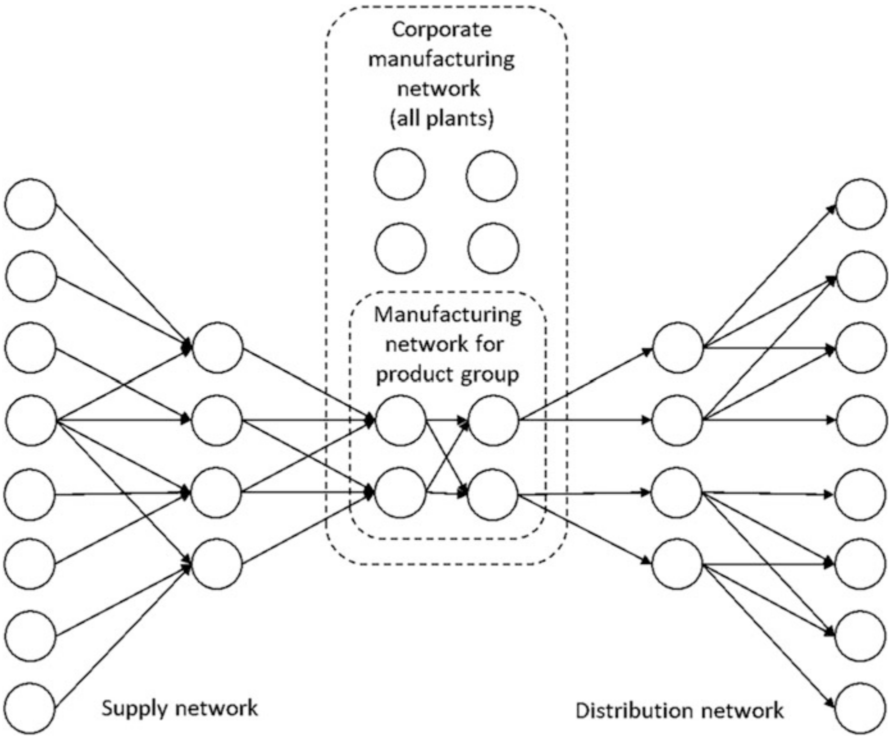

**Fig. 1** Supply, manufacturing, and distribution networks for a particular product group of the focal firm

## 2.1 Supply Network Issues

The supply network is concerned with the upstream suppliers and how they are connected (Fig. 1). For example, the number of suppliers per item, global or local suppliers, and what kind of partners to involve have to be determined. A key aspect in the supply network is the number of suppliers per item: single or multiple sourcing. During 1980–2000, supply base rationalization was commonly practiced by reducing the supplier base and selecting one supplier per item, which is single sourcing. The purpose was often to reduce the total transaction costs and distribute the total purchase value to fewer suppliers to enable volume increases and deeper relationships with the suppliers that remained. Since the millennium shift, risk management has often led to multiple sourcing – the use of two or more suppliers per item.

Recently, another alternative has become increasingly attractive to many firms – *make some and buy some*. An interesting example is IKEA and its internal manufacturer of wooden furniture, IKEA Industry. IKEA Industry accounts for approximately half of the wooden furniture supply to IKEA, which makes it the world's largest manufacturer of furniture. The *make some and buy some* strategy implies that IKEA first turns to external suppliers for new assignments for purchasing flexibility.

IKEA Industry is used for three reasons (Ferdows & Olhager, 2020): (i) to maintain knowledge about production processes to help its research and development [R&D], product design, exploit its scale to innovate, develop new concepts, and invest in new wood manufacturing technologies; (ii) to have updated information about production costs, which is useful in price discussions with external suppliers in the wood industry; and (iii) for contingency purposes if suitable external suppliers cannot be found. With its size, IKEA Industry becomes an excellent reference in the wood industry segment for both buying and manufacturing.

Global sourcing implies that the supply base is spread among many regions throughout the world. With increasing globalization, it has become easier and more relevant for firms to look for suppliers further away from their own facilities since world-class suppliers are probably not in the immediate vicinity. Some suppliers may be active in many regions – potentially in all regions where the focal manufacturing firm is operating – or only in one or a few regions. The geographical dispersion of supplier plants may influence the decision to buy from a particular supplier. For example, if the product is considered a global product – a product that is identical in all parts of the world – it is preferable to have the same set of suppliers close to all manufacturing plants in order to maintain a certain level of consistency in terms of product quality and performance.

The major advantage of a global supplier is generally considered to be low-cost manufacturing due to economies of scale. This aspect has led many firms to source from low-cost countries. However, a lower purchasing price must be weighed against longer transportation lead times, distances, and costs. If quick response is required, a local supplier in the geographical vicinity is more likely selected.

A complementary strategic sourcing aspect is whether the supplier should contribute with low-cost production or with flexibility. Fisher (1997) suggests that low-cost suppliers are required in physically efficient supply chains designed for products with stable demand, whereas flexible suppliers are needed in market-responsive supply chains for innovative products with volatile demand over potentially short product life cycles.

Typically, only the first tier is visible from the focal firm or plant, which implies that problems further upstream in the supply chains are hidden until a major issue occurs (Choi et al., 2021). Finding the constraints in terms of critical raw materials or suppliers has become increasingly important for managing global supply chains. The concept of a nexus supplier refers to a supplier in a multi-tiered supply network that potentially exerts a profound impact on a buyer's performance due to its network position (Yan et al., 2015). A nexus supplier may well be several tiers upstream in the supply network and hence very difficult to identify. Nevertheless, it is becoming increasingly important to identify these types of suppliers irrespective of where they may be positioned in the supply network.

## 2.2 Manufacturing Network Issues

As competition becomes global, and the complexity of the environment in which companies operate is increasing, managing an integrated international network has become an increasingly important task for managers (Ferdows, 1997, 2018). Global manufacturing implies that the manufacturing firm has plants in various regions across the globe. Important considerations for the structure of the global manufacturing network include location factors, plant roles in networks, and network–plant relationships.

## Location Factors

Location factors are related to the geographical dispersion of plants. There is a multitude of factors that can be relevant in specific situations and influence the decision on where to locate a plant; see, for example, MacCarthy and Atthirawong (2003) and Bhatnagar and Sohal (2005). Table 1 lists a few common factors. Some factors can be quantified in terms of costs, while others are assessed as qualitative factors.

There is a difference between component plants and assembly plants concerning the relative importance of certain factors. Proximity to transportation hubs may be important for both plant types, but component plants are more likely to search for proximity to raw materials and strategic suppliers, while assembly plants are typically located closer to customers and markets. The fewer and larger the plants, the more strategic is the location decision.

Ferdows (1997) found that three location factors dominate in terms of strategic importance, namely, access to low-cost production, access to skills and knowledge, and proximity to market. Johansson and Olhager (2018b) tested these location factors in the context of offshoring and backshoring and found that access to low-cost operations was the dominating location factor for offshoring, while development competences (including access to skills and knowledge, technology, and R&D) was the dominating factor for backshoring. Market proximity was not a strong driver of manufacturing relocation in any direction, suggesting that this factor per se did not motivate a change in manufacturing location.

### Plant Roles in Networks

All plants in a manufacturing network do not have to be identical, perform similar tasks, or have the same set of equipment and competences. Instead, plants can take on different roles in a network. Ferdows (1997) identified six different roles with respect to the strategic reason for site location and the level of site competence. The ultimate plant type was called the "lead" plant – the global hub for product and process knowledge.

Feldmann and Olhager (2013) tested the framework in Ferdows (1997) with data from more than 100 Swedish manufacturing plants and found that the various site competences could be grouped logically into three bundles related to (i) production, (ii) supply chain, and (iii) development. Feldmann and Olhager (2013) further identified three plant types with different types and levels of the three competence bundles: one type having only production competences; another type having production and supply chain competences; and a third type possessing production and supply chain as well as development competences. The three plant types and their competence bundles are illustrated in Fig. 2.

The level of production competence increases with higher plant types, that is, when more competences are added to the site. This result suggests that supply chain competences require a solid base of production competences and that development competences require even more solid competences in production as well as supply chain competences. Plant type 3 exhibits the highest plant performance on cost efficiency, quality, and the rate of new product introduction, and significantly higher than plant type 1. This finding supports the idea of co-locating production and

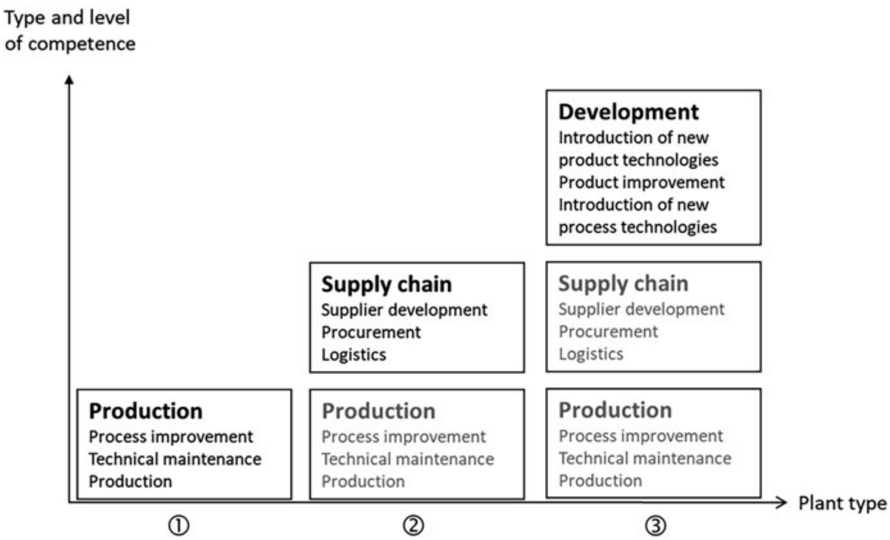

**Fig. 2** Three plant types with respect to type and level of site competence bundles (Based on Feldmann & Olhager, 2013)

product development to support the efficient industrialization of new products (Feldmann & Olhager, 2013).

## Network–Plant Relationships

Manufacturing networks can be looked at from two perspective: the headquarters view, concerning the entire network, and the plant view, focusing on the individual plant (Shi & Gregory, 1998; Cheng et al., 2011, 2015). A central aspect in manufacturing networks is that of the division of decision making between headquarters (the network level) and the individual plants (the plant level). The benefits and problems of using a centralized or decentralized approach for manufacturing strategy decision making include (Hayes et al., 2005): (i) centralized decisions can lead to the standardization of policies, procedures, and systems as well as common business practices that may improve communication and coordination across the network, while (ii) decentralized decisions can lead to greater responsiveness to customer needs and improved adaptability to local operating conditions. Companies can also operate "somewhere in between the two extremes" but finding the appropriate middle ground can be a source of intense disagreement between facility managers (who tend to prefer local autonomy) and corporate directors of manufacturing (who usually prefer a centralized approach) (Hayes et al., 2005).

The distribution of manufacturing decision making along the spectrum from complete centralization with no local influence to full plant decentralization, where all strategic manufacturing decisions taken at the plant, was evaluated by Olhager and Feldmann (2018) who identified three different approaches to the distribution of decision-making authority: centralized, decentralized, and integrated. The third approach means that decisions are taken jointly between headquarters and the plant concerning the strategic direction of the manufacturing operations at the plant. These three approaches align well with the discussion in Hayes et al. (2005) and are illustrated in Fig. 3.

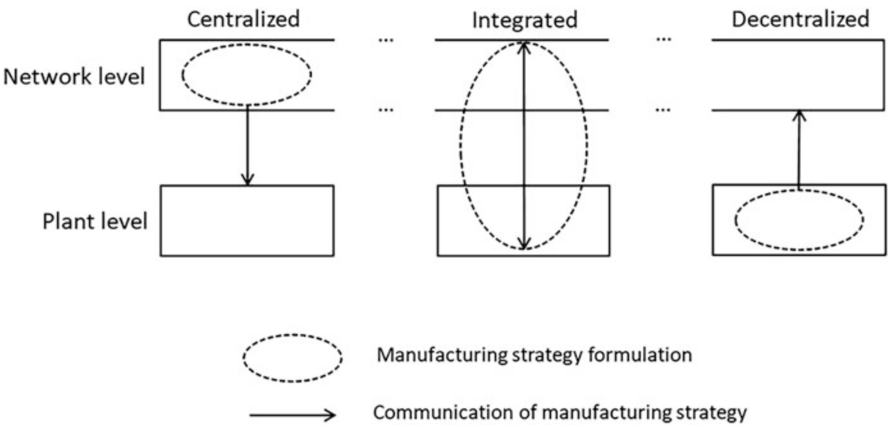

**Fig. 3** Three manufacturing strategy decision-making structures. (Source: Olhager & Feldmann, 2018)

Lohmer et al. (2021) conducted a complementary multiple-case study investigating the network perspective of four German-based multi-plant manufacturing firms. Lohmer et al. (2021) found that the centralized decision-making structures dominated, while integrated and decentralized structures were limited to certain decision categories such as short-term production planning and capacity decisions. The relationship between plant roles and decision-making structures can be grouped into two categories (Olhager & Feldmann, 2021): plants with only production competences have very little decision autonomy (i.e., decisions are located centrally at the headquarters), and plants with production, supply chain, and development competence are likely to have full local autonomy (i.e., a decentralized approach).

## 2.3 Distribution Network Issues

The distribution network implies decisions on how many tiers to use and the kind of actors who reach out to immediate customers and to end customers. In terms of ownership, a global firm can sell through its local sales subsidiaries or through independent distributors, wholesalers, and retailers. The number of actors tends to increase for consumer goods in contrast to industrial goods. An increased number in terms of ownership transfers leads to more independent decision makers, who often want to manage inventory by themselves and have their own warehouses. Other driving forces for more tiers in the distribution network are lead time requirements and the ability to leverage economies of transportation, both of which are characteristics of global supply chains.

However, since the 1990s, a trend toward the centralization of distribution networks has been observed, especially in the B2B context, where many local stock points were consolidated into larger distribution centers (Abrahamsson et al., 1998). This has led to leveraging economies of scale and specialization and improving information systems and transportation planning. This evolution has contributed to improvements including: inventory reductions by pooling inventories for demand from multiple regions; lead-time reductions by better order-to-delivery processes; and transportation cost remaining stable through consolidated and leveled demand.

Instead of having many local warehouses geographically positioned close to customers, one or two distribution centers could supply European demand in one to two days, for example. But for industries with much shorter lead-time requirements, more stock points are needed so they can be closer to customers. The current trend among consumers to require very short lead times (counted in hours), such as in omni-channel retailing (Kembro & Norrman, 2020), are strongly influencing a return evolution toward more stock points again and an increased decentralization of distribution structures. An important factor is whether new decision-making tiers will be introduced. That is, will decentralized decision making return which could increase the demand dynamics and lead to new bullwhip effects, or whether this could be mitigated by increased information sharing and coordinated decisions (e.g., through vendor-managed inventory).

The postponement boundary problem is also dependent on the manufacturing network design (Lee, 2010). The postponement boundary problem also concerns when and where certain value-adding and product differentiating activities (such as assembly and packaging) should be performed. If these activities could be postponed such that they take place at a distribution center, demand could be pooled to this location, potentially leading to a good balance between manufacturing, inventory, and transportation costs.

Increased direct distribution also includes concepts such as drop shipment and merge-in-transit. Drop shipment means direct deliveries from the supplier (or plant) direct to the customer without passing intermediate stocks. This concept is often practiced among on-line retailers today. Merge-in-transit is a more advanced setup, where multiple drop shipment flows from different suppliers are coordinated and merged during transportation to the final customer without passing through the warehouse of the selling firm. An important decision concerns who should operationally manage the required transportation and warehousing activities. Today, most transportation and many warehousing activities are outsourced to logistics service providers, which could be either large global players or smaller local firms. For a global distributions network, both distribution time and cost can be considerable for a product – favoring the use of specialized logistics service providers.

Distribution network may include multiple tiers, it is important to look beyond the immediate customer to identify and understand the industries the downstream customers belong to and the specific industry criticality. For example, are there customers in the early, middle, or late stages of a business cycle? A well-informed understanding of such positions can provide vital guidance in an early warning system for detecting how and when changes in the business cycle will affect the demand for the products produced by the focal firm.

## 3 Global Supply Chain Structures

There are different approaches for serving global demand in terms of how sourcing, manufacturing, and distribution in various parts of the world are constructed and interact. Figure 4 illustrates four basic supply chain structures – linear, divergent, convergent, and mixed – building on the manufacturing network structures in Feldmann and Olhager (2019). The geographical regions include – the Americas, EMEA (Europe, the Middle East, and Africa), and Asia (including Oceania). Taking the supply chain and geographical perspectives, the four structures show that the linkages between successive supply chain stages can be very simple or very complex.

The structures include suppliers, component and assembly plants, and retailers and customers. For simplicity, we include only the first-tier strategic suppliers and how they are connected to the internal manufacturing plant network. The letters A, B, and C in the box for the strategic suppliers refer to a category of components or to a specific component that is critical. Such critical components tend to be sourced from a single supplier, who may be the sole component supplier that can meet quality standards or other product properties.

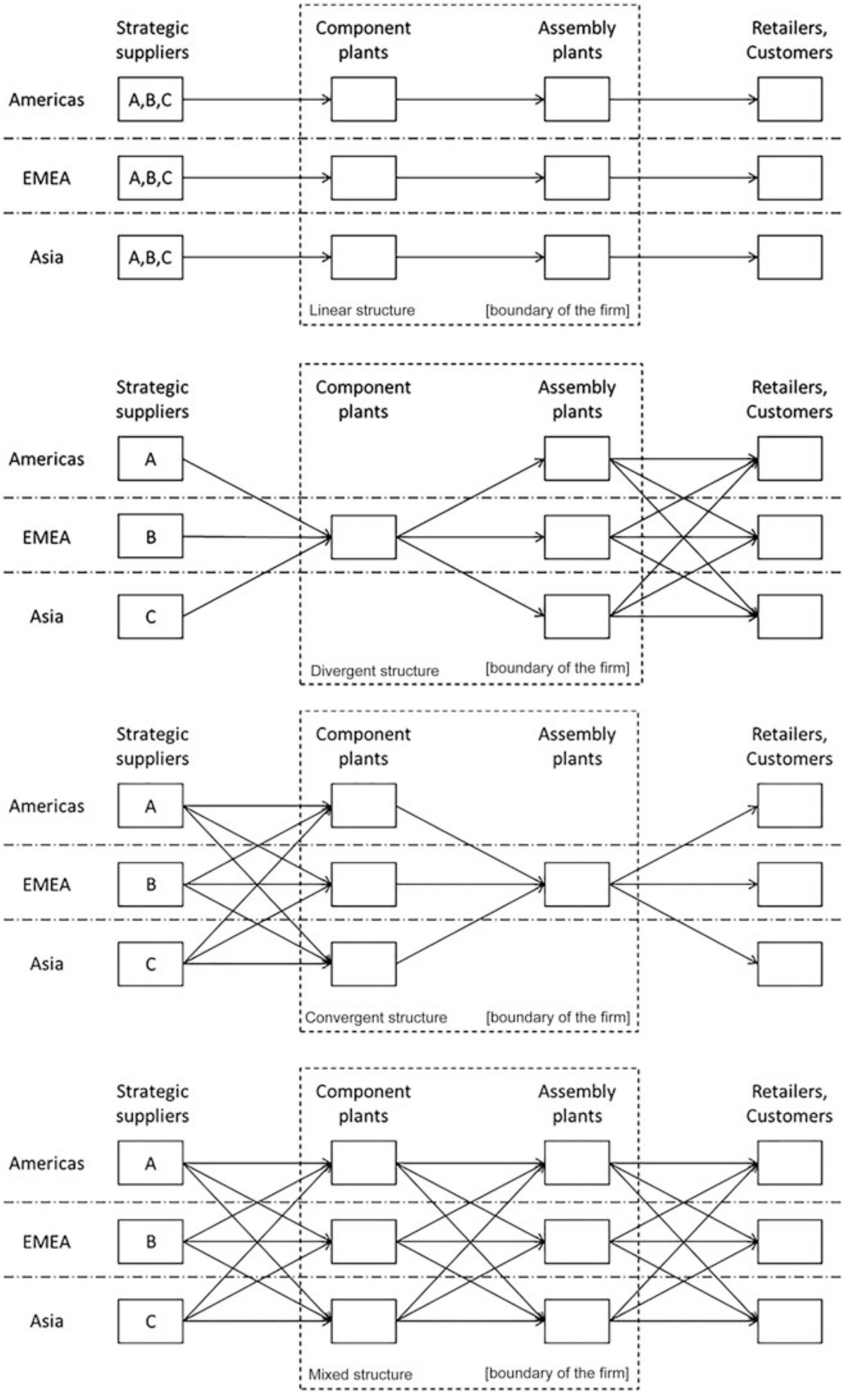

**Fig. 4** Four basic global supply chain structures, focusing on the manufacturing network; from top: linear, divergent, convergent, and mixed (based on Feldmann & Olhager, 2019)

The overall impression of Fig. 4 is that the four structures are distinctly different in how they connect to suppliers and customers as well as the internal relationships among plants. The number of internal plants is four to six for all four structures, which is rather typical for internal manufacturing networks for a particular product group (Feldmann & Olhager, 2019, pp. 167–168).

### 3.1 Linear Supply Chain Structures

The implementation of a linear supply chain structure is typically related to a division of the world into three regions: the Americas, EMEA (Europe, the Middle East, and Africa), and Asia (including Oceania). Figure 5 illustrates this approach. Some firms may even divide the supply chain for Asia into two parts: one for China and one for the rest of Asia. Each region has a complete supply chain, with regional sourcing, manufacturing, and distribution serving the demand in the same market region. The three supply chains work in parallel.

The product is typically of simple design with little intellectual property content and can therefore be produced locally at many locations near the relevant market areas. Typically, the product development responsibilities rest with one "lead" plant, while the other local assembly plants can be assigned responsibility for local product customization and potentially for local product designs (Feldmann & Olhager, 2019). With the

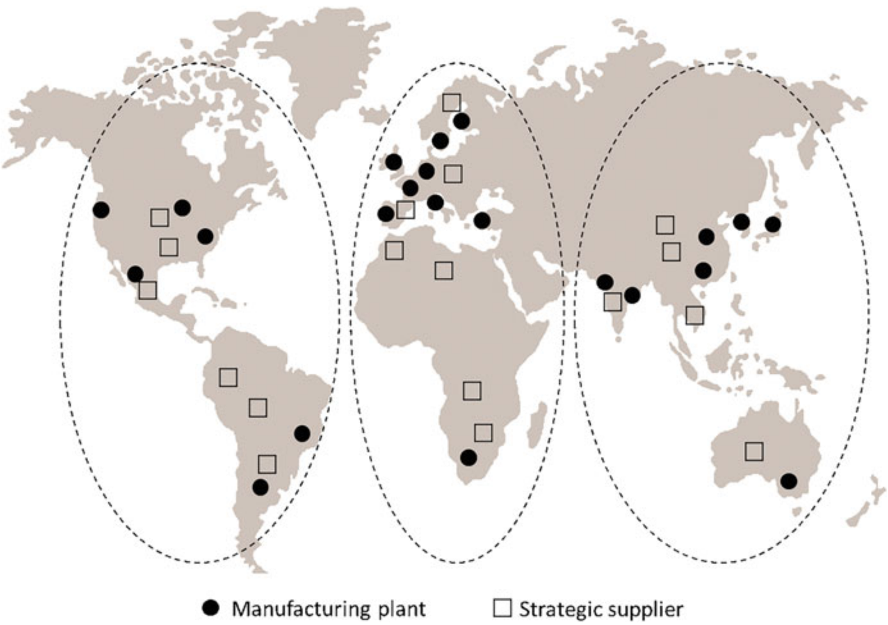

**Fig. 5** Dividing the globe into three regions with self-sufficient supply chains, regional sourcing, manufacturing, and distribution for regional markets

responsibility to serve a local region follows an economies of scope approach for each assembly plant, that is, offering a broad product range to the designated market area.

The advantages with linear supply chain structures include simplicity (few relationships), easy communication (same time zone), market responsiveness (short lead times), and low environmental impact (short transportation distances). With respect to running two or more supply chains in parallel, the following aspects can be added: resiliency (redundancy) and clear structures for sharing best practices (matching counterparts in parallel supply chains). However, there are a few disadvantages: limited supplier selection, restricted to regional suppliers, which are not necessarily world-class; and lower levels of economy of scale and specialization, since an assembly plant focus needs to be on economies of scope. A key managerial challenge is related to how R&D responsibilities should be distributed among the parallel linear supply chains, including this issue of coordination of product standardization vs. local customization across the parallel supply chains.

### 3.2 Divergent Supply Chain Structures

The divergent supply chain structure is connected globally through a core component plant, which typically is the "lead" plant of the entire network and co-located with an assembly plant. Such a "lead" plant has full responsibility for global product and process development, including the introduction of new technologies (Feldmann & Olhager, 2019). The component plant feeds a number of assembly plants that are located globally in reasonable proximity to each respective market. This situation implies that the overall material flow structure is divergent.

The key drivers are economies of scale at the component plant and the protection of intellectual property rights (IPR). If IPR issues concerning product designs or manufacturing processes are of paramount importance, it becomes necessary to keep them under tight control at the "lead" plant for that particular product group. Overall, divergent supply chain structures combine economies of scale at the component plant for critical components with market proximity at the assembly plants for quick response and low logistics cost for reaching customers.

The key managerial concern is how to serve the global demand from a set of assembly plants. If demand in a certain region increases, or if the firm decides to enter a new market, the question arises of where to locate a new assembly plant. The assembly plants may be responsible for sourcing complementary and less complex material in addition to performing the final assembly operations and delivering to the local customers.

### 3.3 Convergent Supply Chain Structures

The convergent supply chain is fundamentally a reverse copy of the divergent one. The core plant is the single assembly plant, which becomes the "lead" plant in the internal manufacturing network and is often co-located with a component plant. A predominant characteristic of the convergent supply chain is that the products and many components are highly specialized, with substantial R&D investments and high levels of skills and knowledge at both component and assembly plants (Feldmann & Olhager, 2019). The product is often a high-end one with high-quality performance. Hence, the control and testing of the finished product are important enough to centralize the function to one plant globally before the global distribution of the end product.

Economies of scale drive this structure at the assembly plant with related control of the finishing operations. There are two key managerial challenges – one strategic and one tactical. Since some R&D responsibilities are distributed to some or all component plants, it is important to maintain the central control and coordination of the product designs. In addition, operational excellence at the assembly plant depends on timely deliveries from component plants located elsewhere, wherefore the tactical synchronization of material flows is important.

## 3.4 Mixed Supply Chain Structures

The mixed supply chain structure exhibits the highest levels of complexity in terms of number of manufacturing plants and long cross-regional transportation. A greater number of plants involved in the manufacturing of a particular product group, means greater likelihood that the supply chain structure will be mixed. The material flow can connect all plants, at least connect all component plants with all assembly plants, which can include many trans-regional shipments on a regular basis.

This supply chain structure is typically related to the extensive division of production tasks among plants, often related to modular product designs (Feldmann & Olhager, 2019). Different product modules are manufactured at different sites (typically focusing on one module) and transported to various regional assembly plants. Even though modular product designs are considered to be highly favorable from a manufacturing and customer perspective – by producing a limited number of modules that can be combined into multiple end-product configurations – the global supply transportation consequences can be quite unfavorable. Therefore, modular product designs must be evaluated from a global operations network perspective (Pashaei & Olhager, 2015, 2017, 2019).

Configuration and coordination managerial challenges in this environment can be quite significant. The network is complex, with additional complex relationships among the plants, including many cross-border flows. A market change in one part of the world may affect the balance of the network, which in turn could require adaptation to the new situation. Hence, there is eventually a need to rebalance networks through expansion, consolidation, and relocation, which forms the essence of the managerial challenges associated with a mixed supply chain structure.

## 4 Current Concerns

Current concerns include interesting global supply chain management issues related to supply chain restructuring, tax considerations, national culture, and risk management.

### 4.1 Restructuring the Global Supply Chain

Restructuring the global supply chain can imply changes concerning who should be doing what and where in the world. The "who" question concerns ownership, the "what" question relates to the manufacturing tasks that are subject for redistribution, and the "where" question is a location issue. These three dimensions are not independent. The manufacturing that is to be relocated (i.e., what) is moved from a host plant (i.e., where) to another plant – either domestically or abroad, either internal or external to the firm. The following four concepts are of particular interest in this context:

- "Outsourcing" is the act of obtaining semi-finished products, finished products, or services from an outside company if these activities had been traditionally performed internally (Dolgui & Proth, 2013).
- "Insourcing" is the decision to reincorporate an outsourced activity within a company that had formerly been transferred to an external supplier (Cabral et al., 2014), in other words, outsourcing in reverse.
- "Offshoring" is concerned with relocating value-adding activities across the national borders of the firm (Roza et al., 2011).
- "Backshoring" refers to a relocation back to the domestic location of the firm (Kinkel, 2014), in other words, offshoring in reverse.

There are some related concepts to the previous four mentioned. A joint venture with co-ownership between the focal firm and a partner in (typically) another country is a mixed form of internal and external ownership. *Nearshoring* denotes repatriating value creation tasks from the foreign host country to a location closer to, but not within, the borders of the home country (Fratocchi et al., 2014). From a Western European perspective, nearshoring could refer to a move from a far-away location to a country in Eastern Europe. Similarly, from the US perspective, Mexico would be a nearshoring opportunity. The concept of reshoring is more general and refers to relocation from one location to another and not necessarily back to the original location or to a nearshore destination but to a third country in general. An example of further reshoring is when a European firm first offshores production to China and later moves this production to Vietnam.

Offshoring and backshoring are first and foremost a location aspect. A change of location can involve a change in governance. Hence, it is often important to include the perspectives of outsourcing and insourcing when considering offshoring and backshoring. Thus, relocation refers to a move of (some or all) operations for the

| | | Governance of host plant | |
|---|---|---|---|
| | | Internal | External |
| Relocation direction | Offshoring | Captive offshoring | Outsource offshoring |
| | Backshoring | Captive backshoring | Insource backshoring |

**Fig. 6** Shoring and sourcing alternatives: relocation direction and governance modes of the host plant

focal plant or firm to another location across the country's national borders, either internally (within the company's own production network) or to an external party (supplier or contract manufacturer). Backshoring refers to the reverse decision, that is, a relocation of production activities back to the company's domestic facility either from an external supplier or from another unit within its own network.

Figure 6 combines the perspectives of location and ownership and shows the main change options. These refer to the four basic shoring and sourcing alternatives that relate to off- and backshoring as well as out- and insourcing.

Offshoring has increased over the years and is expected to continue to grow in the near future, although there is no consensus regarding the absolute extent of the activity (Mihalache & Mihalache, 2016). As a counter-movement to offshoring, backshoring is lagging in time by definition (Stentoft et al., 2016). In addition, Johansson and Olhager (2018a) found that the amount of offshoring exceeded that of backshoring during the period of 2010–2015 in Sweden; the number of backshoring projects during the period was only 56% of the corresponding number of offshoring projects. The net effect is successive reduction of manufacturing activity in Sweden, as in many other European countries.

Research on reshoring in general has focused on drivers, contexts, effects, and creating conceptual frameworks (Stentoft et al., 2016; Boffelli & Johansson, 2020). Over time, a consensus view has been established on the main drivers for both offshoring and backshoring activities (Johansson & Olhager, 2018a, b; Johansson et al., 2019; Boffelli & Johansson, 2020); see Table 2.

The message from Table 2 is clear: The key drivers for offshoring are few and focus on cost and imitation (i.e., do what the competitors do), while the drivers for backshoring are many and diverse – where cost and imitation dimensions are absent. Even though the drivers in individual cases may be few and specific, the list in Table 2 includes drivers that have been cited in case and survey research, which encompass both offshoring and backshoring (based on Johansson & Olhager, 2018a, b; Boffelli & Johansson, 2020). It should be noted that most research on off- and backshoring concerns cases where the home plants are located in developed countries, predominantly in Europe.

The other dimension in Fig. 6, the aspect of governance was captured by Feldmann and Olhager (2008), who investigated the choice between internal vs. external sources. The dominating criterion for choosing internal

**Table 2** Typical offshoring and backshoring drivers

| Category | Offshoring drivers | Backshoring drivers |
|---|---|---|
| Competitive priorities | Labor costs<br>Price competitiveness (related to labor costs) | Quality (product quality)<br>Lead time<br>Flexibility |
| Development competences | – | Access to skills and knowledge<br>Access to technology<br>Proximity to R&D |

suppliers was "corporate decision," followed by quality and competence. Quality, cost, and delivery dependability factors dominated for external suppliers. Interestingly, "corporate decision" was the only criterion that was rated significantly higher for internal suppliers than for external suppliers, while many of the other factors exhibited significant differences in the other direction.

The following nine criteria were rated as significantly more important when choosing external suppliers: quality, cost, delivery dependability, volume flexibility, delivery speed, size of company, logistical solution, design flexibility, and geographical coverage. These results suggest that the choice of an internal supplier is largely based on the availability of an internal source – since the criteria for choosing an internal source is significantly lower for multiple aspects. Thus, if the firm has the possibility to source in-house, meaning within their own manufacturing network, they tend to do it. In addition, the results strongly suggest that a wide range of competences are requested from an external supplier (as opposed to an internal supplier) in order to be selected (Feldmann & Olhager, 2008).

Research on the interaction between location and ownership is still largely absent but would be a welcome addition to the understanding of offshoring and backshoring. Initial insights suggest that internal sourcing is preferable over external sourcing since the manufacturing activities and competence stay within the same firm, which is associated with more degrees of freedom. The two dimensions of location and ownership concern the shoring and sourcing decisions, with the ultimate goal being "rightshoring" and "rightsourcing." However, these decisions are complex and have many dimensions, which ultimately forces decision makers to weigh benefits against risks.

## 4.2 Tax Considerations

Supply chain globalization and the explosion of world trade means that raw materials, components, and finished products cross country borders many times. Changes in trading blocs (EU, USMCA, ASEAN, etc.), the World Trade Organization, geopolitical tensions, and differences in government regulations and customs tariffs make the location of value-adding operations a crucial factor in global supply chain network design. State and local governments also compete to attract companies to locate in certain areas by offering different "packages" of tax incentives.

Thus, for supply chain structures involving multiple jurisdictions, tax-related implications are increasingly relevant for practitioners (Cohen & Lee, 2020). How and where nodes are established and value-adding activities performed (manufacturing, assembly, packaging, etc.) influence customs duties as well as direct and indirect taxes. Practitioners from the legal, fiscal, and logistics domains design global product flows, including where and how products are sourced, value-added, and distributed (Norrman & Henkow, 2014).

Global product flows along with organizational and legal structures and financial flows determine the tax implications. Whether the tax structure or global supply chain is optimized first does not matter; changing either one will reciprocally impact the other. This interaction requires deeper analysis, but logisticians normally locate according to production and logistics costs, neglecting the role of taxation (Shunko et al., 2017), whereas fiscal experts seem to simply consider tax savings without addressing logistics complications from the cross-country setting (Adams, 2008).

Pre-tax operating savings from a pure logistics analysis may not necessarily transform into an actual cost reduction after taxes, while supply chains based on tax optimizing principles may become very strange from a logistics perspective (Balaji & Viswanadham, 2008). Cross-border transports may be introduced that are efficient for profit after tax but unnecessary from a logistics and environmental point of view, where local drop-shipment or merge-in-transit might be favorable (Henkow & Norrman, 2011).

The huge variety of tax structures, introduced by different jurisdictions, poses great boundary-crossing challenges for global firms (Cohen & Lee, 2020), where country specifics have clear implications for tax rates and import duties. Key tradeoffs between tax-related costs (e.g., duties, corporate income taxes, and value-added taxes [VAT]) and traditional logistics costs must be considered with careful evaluation of cross-border flows (Norrman & Henkow, 2014; Prataviera et al., 2020). Frictions may arise because the supply chain, legal, and fiscal domain analyses are often based on different principles.

Customs duties and compliance rules are applied to cross-border movement and value-adding activities, direct taxes are levied on the income, and indirect taxes are applied to the transfer of goods (Hsu & Zhu, 2011; Dong & Kouvelis, 2020). These fiscal elements are briefly described below, and then elements useful for the joint supply chain mapping and development of an operating model that could bridge the gap between the domains are suggested.

### Customs Duties and Compliance

Customs duties, trade tariffs, and customs requirements are important aspects of global supply chains and are generally meant to protect national competitiveness from foreign competition. These trade barriers are usually classified into tariff and non-tariff barriers (Adams, 2008).

Tariff barriers refer to paying taxes on the import and export of goods. Customs duties are taxes levied on the importation of certain goods into a customs jurisdiction (Cohen & Lee, 2020) and often computed as a percentage of the product value that crosses the border but may also be levied based on weight or volume. Duties depend on the origin of the imported goods and the associated goods classification (i.e., the tariff code). The jurisdiction of primary manufacturing activities is important. However, origin is sometimes determined by the location of the last substantial transformation. Transformation can include any operation that changes the product's tax code such as when a product gets a "new name, character, or use" that differs from the one that it possessed prior to processing.

The concept of substantial transformation is ambiguous, creating unclear legal boundaries. The product's complete bill-of-material should be examined and implications for component vs. product compared in relation to different trade agreements (Lee, 2010). The current servitization of products and software's increased role in defining a product's capability and capacity also increase the complexity in classification for tax codes and customs duties (Henkow & Norrman, 2011) especially as jurisdictions classify differently. As software upload and testing in many cases are easier to move than manufacturing, the postponement of such activities could change product class and with commensurate tax implications.

Non-tariff barriers include local content requirements, technical standards, quota restrictions, and complexity in the required documentation (Lee, 2010). Trade agreements may also entail lower customs duties or special treatment if specific requirements are met. Indeed, given changing trade agreements and customs duties, changes both in goods classification and in customs duties must be observed (Henkow & Norrman, 2011). Cross-border flows must be compliant with various administrative requirements and restrictions, such as formalities for export and import that could extend lead times. In certain cases, goods may be placed in specially designated areas where they are considered not to be imported, such as a free-trade zone, a bonded or customs warehouse, to avoid import duties in the country where the storage facility is located (Hsu & Zhu, 2011). However, these solutions may involve additional costs and nontrivial complexity due to special monitoring and auditing required by customs.

### Direct Taxes, Corporate Income Tax, and Principal Structure

Direct taxes are levied on the income. In cross-border situations, differences in tax legislation and tax rates between countries create several opportunities for global firms. Low tax rates become attractive for profitable products when tax savings are not offset by supply chain costs (Webber, 2011). For corporate income taxation (CIT), the legal basis of establishing tax consequences is the "principal approach" related to the fact that global firms often divide themselves into different legal units.

One way to reduce overall tax liabilities is to centralize high-value operations (and risks) into a "principal structure" (Bhutta et al., 2003) and then locate the principal in a low-tax jurisdiction (Shunko et al., 2017). This approach can consolidate profits but also increase tax and other fiscal considerations (Adams, 2008; Prataviera et al., 2020). Transfer prices between sub-units in a global firm can influence how profits are divided and how software versus content hardware is valued.

A jurisdiction's incentives could also require that physical operations be located in low-tax jurisdictions to justify the profits planned to be reported there (Hsu & Zhu, 2011; Joseph et al., 2017). Sometimes the relocation of operations seems to be more "on paper" than substantive. Thus, governments are asserting the "substance over form" principle to challenge structural changes perceived as merely tentative to reduce taxable income and shift profits to low-tax jurisdictions (Petriccione, 2007). Tax authorities require that any restructuring of existing operations should produce substantial operational changes and can introduce penalties when the "substance over form" principle is not respected (Adams, 2008). For global supply chain design, different jurisdiction assessment of activities considered for economic substance must be understood.

### Indirect Taxes, Value Added Tax and Sales Taxes, and Permanent Establishment

Indirect taxes – such as sales tax and VAT – are consumption taxes applied to the transfer of goods aimed at being neutral for companies and are indirectly levied on supplies of goods. While sales tax is levied at one stage – often at the retail stage in the USA – VAT is a multiple-stage consumption tax system in the EU.

A cornerstone of international taxation is the term "permanent establishment" (PE), which means a fixed place of business that typically gives rise to income or VAT liability in a particular jurisdiction (Petriccione, 2007; Norrman & Henkow, 2014). The PE mandates that the business be wholly or partly carried out through that fixed place. PE should reduce taxpayer uncertainty for cross-border activities and lead to a fair sharing of taxing rights among jurisdictions. While a subsidiary company does not necessarily constitute a PE of the parent company, it can trigger a PE – and the related CIT or VAT – through employee activity, business activity, or revenue creation in a fixed place of business. In some cases, even outsourced activities could trigger a PE.

Different approaches to combine hardware and software, and different country-specific regulations (e.g., in terms of PE creation), have different tax implications related to – for example – the postponement of value-adding activities. These approaches influence where and how much tax should be paid (Henkow & Norrman, 2011; Joseph et al., 2017). This situation is related back to economic substance, referring to whether its activity or role is for real or established only for fiscal reasons (Prataviera et al., 2020).

Therefore, to claim to pursue substantive activities and not only formal tax planning, some global firms move their warehouses to where their principals are located (Balaji & Viswanadham, 2008; Webber, 2011). If the principal is just a post box not aligned with the creation of a PE in the country, the "substance over form" principle is not respected, causing alarms and public scrutiny.

### Tax-Aligned Supply Chain Mapping and Operating Model

To facilitate communication and decision making between domains, a common iconographic platform could be useful (Henkow & Norrman, 2011). Traditionally, supply chain maps describe material and information flows by using icons such as arrows, triangles, and circles, which can be attributed with volumes, time, capital, costs, frequencies, uncertainties, and locations to illustrate the supply chain and identify improvement areas.

Within the legal and fiscal domain, this kind of mapping is not as entrenched. However, to make proper decisions, fiscal experts need to understand certain attributes of structure, processes, risks, and the management of material and financial flows. The different customs areas – direct taxes and indirect taxes – have different aims; see Table 3.

By adding icons (see Fig. 7) for other types of products (e.g., services); different kinds of territorial borders connected to custom procedures; and more abstract icons for payment flows, change of risk (ownership); and finally different kinds of legal persons (such as PE), a joint mapping could be facilitated, giving answers to the most relevant questions.

To further harmonize global procedures and provide guiding principles, some global firms define operating models (Henkow & Norrman, 2011), clarifying roles and responsibilities and tying together the supply chain structure with the legal and financial structure. An operating model combines definitions, principles, and maps illustrating different flow set ups – product, information, and financial flows – for different jurisdictions or trade blocs. An operating model can mitigate the many risks faced globally and help pursue overall tax optimization (Petriccione, 2007). Consequently, the operating model plans for and influences the creation of a company's PEs in different countries, the classification of goods (which can vary by country),

## 4.3 National Culture

An interesting question is whether managers in different parts of the world would, based on their heritage, make different supply chain decisions when faced with the same decision factors or whether there is a "globally correct" answer for supply chain problems. Managing an established global supply chain, or transforming and restructuring one, naturally involves global partners and colleagues that must be aligned. But people's origin and heritage have implications for how problems are understood, solved, and communicated and how decision making works.

People understand things differently – whether within a global firm or between different companies in a supply chain – which can create misunderstandings and tensions, decreasing the effectiveness of supply chain management. Griffith and Myers (2005) showed that firms were successful when using different strategies for information sharing with supply chain partners from different countries or cultures: for example, US firms performed better when they had low levels of information exchange with other US firms but high levels of information exchange with Japanese firms.

National culture could significantly explain international operations management behaviors (Pagell et al., 2005). Many managers have probably experienced the same – what works well in one's homeland might be less appropriate elsewhere. It can be frustrating to not understand why suppliers, remote plants, and customers are not responding as expected. To manage such situations in global supply chains, the first step is to identify and understand the factors to consider and then assess whether systematic differences could have implications for supply chain management.

A relevant lens to use is that of Hofstede (1980), who defines national culture as the collective mental programming of the people in a national context. He uses a quantitative classification scheme for measuring differences and similarities between national cultures (see https://geerthofstede.com). National cultures differ in their set of values, beliefs, ideas, attitudes, and morals, which guide the behaviors of individuals. The difference in national culture spans to the organizational culture, influencing the management and operations of daily processes performed and managed by local people. Studying regions (such as North America, Europe, Asia, Asia Pacific, and Africa) is not enough (Hofstede, 1980; Pagell et al., 2005) as different behaviors between national cultures can be observed. But not all countries differ notably, and many countries and their workers share common factors such as language, religion, customs, borders, beliefs, rules, and ethnic heritage. However, Hofstede (1980) points out the following various cultural dimensions as important to understand; see Table 4 for an explanation and examples.

- "*Power distance,*" which relates to authority.
- "*Individualism–Collectivism,*" which addresses the degree of interdependence between society and its members. The overall self-perception of one being an individual or being part of a group, referring to whether "I" or "we" dominates.
- "*Masculinity–Femininity*" describes what motivates people.
- "*Uncertainty avoidance*" is about the reaction to ambiguous events.
- "*Long-term vs. short-term orientation,*" which refers to orientation in life. It cultivates the adaptation of firms in aligning their objectives and plans to meet the needs of partner firms, with an aim to develop a long-term relationship being likely to nurture a collaborative relationship and deter the opportunistic behavior of partner firms (Wong et al., 2017).

Relating back to the previous example (Griffith & Myers, 2005), Hofstede's lens would tell us that the characteristics of the USA are to be individualistic, short-term oriented with small power distances. Japan's national characteristics are the opposite – collectivistic, long-term, and having high power distance. In the USA, information could be seen as power, and sharing could threaten one's position. In Japan, information sharing fits with aspects such as harmony, long-term collectivistic thinking, and where power follows authority.

Successfully managing and transforming global supply chains takes more than understanding that supply chain decisions might vary in different countries or regions. It is important to understand what issues make global supply management different and challenging, such as understanding how and what dimensions of national culture could influence supply chain decisions. Many of the aspects discussed would probably help explain how (well) cross-national supply chain work together by establishing integrated relationships. But culture is a multi-

**Table 4** Hofstede's cultural dimension (for more country examples, see https://geerthofstede.com)

| Cultural dimensions | Explanation | Example countries |

| Uncertainty avoidance | "*Low uncertainty avoidance*" means that people embrace unpredictability and have less adherence to rules, procedures, and hierarchies. People are more relaxed risk takers, and more informal actions such as ad hoc negotiation for the settlement of disputes will be accepted<br>"*High uncertainty avoidance*" indicates that people are threatened by the unknown and thus need more stable and predictable workplaces. In general, risk taking is avoided, and there is a reliance on rules | *Low uncertainty avoidance*:<br>Singapore, Denmark, UK<br>*High uncertainty avoidance*: Greece, Portugal, Belgium, Japan, Spain, Russia |
| Long-term vs. short-term orientation | "*Long-term orientation*" is the fostering of virtues oriented toward future rewards, perseverance, and thrift. dimensional construct, and countries may differ on one element but not on all. It is important to first understand one's own characteristics. Managers should, independent of their own origin and heritage, analyze both themselves and their supply chain partners to understand if and how national cultural differences influence the design, coordination, integration, and transformation of their global supply chain.

## 4.4 Risk Management

Supply chain risk management (SCRM) has been defined as "collaborating with partners in a supply chain to apply risk management process tools to deal with risks caused by, or impacting, logistics related activities or resources" (Norrman & Jansson, 2004, p. 436). SCRM has offered many useful tools for *identifying, assessing, managing*, and *monitoring* risks. The SCRM practice has developed over time, by increasing its scope (in terms of risk types focused on and supply chain length analyzed), developing capabilities (such as information systems and their integration), increasing cross-functional and inter-organizational work, balancing proactive and reactive work, and getting a risk culture in place (Norrman & Wieland, 2020). Compared to a more local supply chain, a global network means both more potential risk sources to identify and assess but, alternatively, more potential mitigation strategies to use. Finally, the fact that national cultures differ – such as uncertainty avoidance and long-term orientation – influences how easy it will be to get a joint global risk culture in place.

*Risk identification* means discovering all relevant risks and uncertainties (Fan & Stevenson, 2018). Given that organizational resources are normally limited, it is necessary to have a structured risk identification approach (Kern et al., 2012). This will surely mean more work the more global the supply chain. Companies with global supply chains must have a global scope when identifying risks, consider various supply chain partners, and how the environment in their countries might differ from the focal firm's environment (Manuj & Mentzer, 2008).

In a general, a cross-functional supply chain mapping over many tiers should be the starting point. This mapping can help understand how finished goods, products, and customers are connected to different components and raw material and where bottlenecks (e.g., single sources upstream; cf. Fig. 1) and critical locations (e.g., due to natural hazards, geopolitical developments, transportation problems) exist.

First looking into larger risk areas and then going deeper into different risk types and associated factors would support a systematic review of traditional supply chain risk sources (see Table 5). Such a "list of potential risks" would complement the supply chain mapping and other tools for risk identification such as the Kraljic matrix, cause-effect diagrams, fault tree analysis, event tree analysis, SWOT analysis, brainstorming, and supplier audits and scorecards (Norrman & Jansson, 2004; Jüttner, 2005; Norrman & Wieland, 2020). Contemporary tools for information intelligence can increase a company's reactive capability to spot risks from such things as natural hazards – earthquakes, storms, and flooding – early on.

**Table 5** Examples of risk sources that can support risk identification

| Risk area | Risk types | Risk factors |
|---|---|---|
| Macro risks | Economic | Exchange rate fluctuations, changes in interest rate, changes in the overall economic situation |
| | Environmental | Natural disasters, man-made disasters, weather, pandemics, security, sabotage, terrorism |
| | Infrastructural | Poor infrastructure, port congestion, customs delays, security check delays, changes in transportation network, infrastructure security |
| | Legal | Uncertainty in external legal environment, (potential) new regulations |
| | Political | Changes in government policies, changes in export or import regulations, tariff changes, administrative and bureaucratic issues, political instability, sanctions, wars |
| | Social | Changing social demands, labor strikes, boycotts, social riots |
| Networks risks | Network behavior | Chaos in system, opportunistic behavior, lack of ownership, supply chain inertia |
| | Supply market | Production/capacity constraints on supplier market, limited available suppliers, market failures, commodity price fluctuations, geographic concentration of suppliers |
| Supply risks, internal risks (in/between plants) | Commercial | Supplier-specific price escalations |
| | Corporate fit | Cultural differences, poor communication, reluctance to share information, poor alignment and coordination, relationship issues |
| | Financial | Supplier's financial health, credit risk, tax evasion |
| | Legal | Contracts and agreements regarding liability, bribery, false claims, patent infringements, antitrust claims, price fixing accusations |
| | Logistical | Delivery reliability issues, problem with unloading facilities |
| | Operational | Breakdown in equipment(s), improper product handling and storage, internal accidents, skills of workforce, poor forecasting, planning and inventory management, supplier stock-outs |
| | Quality | Product quality does not conform to specifications, lack of quality control |
| | Security | Security breaches |
| | Sustainability | Poor product material, design, and safety, contamination and degradation of resources, unhealthy, unsafe, and unhygienic working environment, excessive labor worktime, unfair wages, child labor, discrimination, exploitive hiring policies, unethical treatment of animals, biological risks |

(continued)

**Table 5** (continued)

| Risk area | Risk types | Risk factors |
|---|---|---|
| | Technology | Incompatible IS/IT systems for information sharing, unreliable IT systems, unfinished transformation initiatives, inability to follow rapid technological development |
| Demand risks | Demand | Demand variation, sudden large demand fluctuations, bullwhip effects, systematic forecasting errors |
| | Market and competition | Market changes, competition changes, new product introductions |
| | Customers | Risks affecting customers, branding issues |

In global supply chains, transportation and lead time normally increase, which in general increases uncertainty and risks. Currency fluctuations become more important to handle as does exposition for geopolitical issues such as trade wars and tax-related changes. Cultural differences could increase uncertainty, and supply chains become harder to monitor and control. But while globalization makes some supply risks more important to consider (such as macro and network supply risks), many supply risks' importance remain, in general, the same, but the *variation* of supplier performance levels normally increase. More global supply chains imply increased work and complexity to obtain the information needed for risk identification.

The main purpose of the *risk assessment* step is to determine the criticality of the identified risks and prioritize risks that require additional attention (Manuj & Mentzer, 2008). Usually, one tries to understand the probability and the impact of different risk sources. This logic is not changed by globalization, and similar tools and methods can be used, such as the frequently used risk matrixes, Delphi techniques, or failure modes and effects analysis.

When risks are assessed and evaluated, relevant *risk mitigation strategies* should be applied. Risk mitigation strategies are created with the purpose of reducing the probability of losses associated with risk events to an acceptable level or to reduce the impact of the risk source. Effective risk mitigation requires close collaboration between the supply chain actors and support from top management. Many different supply chain risk mitigation strategies have been proposed over time and structured differently (Norrman & Jansson, 2004; Jüttner, 2005; Manuj & Mentzer, 2008; Fan & Stevenson, 2018). In general risk management strategies revolve around accepting risks, buffering against uncertainty, collaborating with partners, using contracting to transfer or share risks, decreasing risks through supply network design, improving planning, securing different flows, and standardizing elements of the supply chain (see Table 6).

For global supply chains, strategies related to network design are important. Factors such as the number of plants and suppliers and their locations, insourcing vs. outsourcing, offshoring vs. backshoring, and transportation each can contribute to risk. However, the implications of other strategies, such as how to buffer, with whom to collaborate, and understanding how to improve secure flows – which could imply leaving certain risky geographical locations – need to be analyzed and understood.

**Table 6** Examples of risk mitigation strategies

| Risk mitigation strategy | Example | Explanation |
|---|---|---|
| Accepting | Accept risk | "Do nothing strategy" to passively accept the risk with no mitigation strategy |
| Buffering | Excess inventory | Add extra inventory (e.g., by increasing safety stock levels) to reduce stock-out risks |
| | Excess capacity | Add excess capacity in production, storage, handling, and/or transport to make the company more flexible for unplanned changes |
| Collaboration | Information sharing | Share key information with supply chain partners to increase visibility and enable more effective and efficient decision making |
| | Supplier development | Invest in supplier development for critical suppliers/ components to gain performance improvements |
| | Early supplier involvement | Include suppliers earlier in the product development process to avoid problems at later stages |
| | Supplier scorecard/ audits | Use supplier audits and scorecards to gauge and monitor the development of supplier performance |
| | Supply chain partner education | Educate supply chain partners to make them aware of how their decisions have an impact on the overall supply chain |
| | Supply chain coordination | Coordinate decisions and actions across company borders in the supply chain to improve overall supply chain performance |
| | Jointly developed mitigation strategies | Develop mitigation strategies jointly with supply chain partners to ensure alignment |
| Contracting | Insurances | Use insurance contracts to transfer part of the risk to insurance companies |
| | Inventory liabilities | Use contracts to transfer inventory liability to supply chain partners |
| | Delivery agreements | Change delivery agreements to transfer part of the risk to supply chain partners |
| | Dynamic contracts | Make contracts dynamic to the external environment and behavior of the involved parties to share risk with the supply chain partners |
| | Financial hedging | Use financial contracts to mitigate currency fluctuation risk |
| | Contract enforcement | Enforce contracts to reduce transaction costs and supplier opportunism |
| | Negotiate long-term contracts | Use long-term contracts to mitigate price increases from suppliers |
| Network design | Multiple sourcing | Use multiple sourcing to hedge against risks from individual supplier performance |
| | Geographically diversified sourcing | Use a geographically diversified sourcing network to hedge against location-specific risks |
| | Local sourcing | Use local sourcing to, e.g., minimize lead time risks |
| | Source from responsive suppliers | Source from responsive suppliers to maintain flexibility |

(continued)

**Table 6** (continued)

| Risk mitigation strategy | Example | Explanation |
|---|---|---|
| | Source from creditworthy suppliers | Source from creditworthy suppliers to ensure the financial performance of suppliers |
| | Outsourcing | Outsource non-critical activities to transfer the risk to supply chain partners |
| | Insourcing/vertical integration | Take control over critical suppliers/activities to control the risk |
| | Choose strategic stocking locations | Locate the inventories wisely to minimize costs and increase service level |
| | Flexible transportation | Have a flexible transportation network using multiple modes, carriers, and routes to avoid mode/carrier/ route specific risks |
| Planning | Postponing | Delay actual commitment of resources and costs to maintain flexibility |
| | Speculating | Take decisions based on anticipated customer demand to be better prepared |
| | Pricing and promotion planning | Incentivize customers to act in ways using pricing and promotions to limit supply risks of certain components and products |
| | Assortment planning | Make assortment decisions with supply situation in mind to limit supply risks of certain components and products |
| | Silent product rollover | Avoid informing customers about new product launches to avoid specific product demand |
| | Supply-demand synchronization | Make supply and demand decisions jointly to avoid supply-demand mismatch |
| | Improved forecasting | Improve forecasting techniques to allow for better decision making |
| | Develop contingency/ security plans | Develop contingency/security plans to be better prepared and facilitate the recovery |
| Securing | Improve data security | Improve data security to protect against data and information losses from external threats, e.g., cyber risks |
| | Improve inspection routines of goods | Improve inspection routines to easier identify security threats |
| | Avoid risky locations | Avoid risky locations when choosing locations of suppliers, warehouses, offices, using information to avoid location-specific risks |
| Standardization | Standardize processes | Standardize processes to remove complexity and allow more flexibility in operations |
| | Standardize products and components | Standardize products and components to remove complexity and allow more flexibility in operations |

## 5 Emergent Concerns and Future Directions

Globalization and global supply chains are being reconsidered with respect to new emerging types of global disturbances and more frequently occurring traditional disturbances. Some researchers expect that the combined effect of the increased global risks and decoupling of economies (through heightened nationalism and protectionism) will lead to a decline in or retreat of globalization (Ajami, 2022; Belke & Gros, 2021). Others argue that the new risks are only marginally higher and can be managed by global firms through alternate cross-border strategies and emerging technologies (Contractor, 2022). Ciravegna and Michailova (2022) proposed that although increasing globalization is needed in the post-COVID-19 era, the reconfiguration of global value chains will nevertheless result in a less globalized and more regionally fragmented world economy.

The alternative to a global supply chain is a local supply chain that is self-sufficient within a predetermined geographical area. If the ambition is to capture and satisfy global demand, a number of such local supply chains are needed; see Fig. 5. The drivers for creating global vs. local supply chains differ. Depending upon the situation, some aspects may dominate over others and influence the firm to move in a particular direction. Table 7 summarizes some key drivers for deciding on global versus local supply chains.

A global supply chain is characterized by aiming for the best options for every aspect of "who should be doing what and where" along the supply chain. This options analysis means trying to find the best suppliers globally for each component, locating its own production in locations that are well suited for the particular manufacturing processes, supplying the global markets through efficient distribution channels, and connecting these parts via good infrastructures. There are several arguments for having global supply chains, and include:

- Economies of scale in that each individual plant can serve the entire global demand

**Table 7** Drivers for global versus local supply chains

| Global supply chains | Local supply chains |
|---|---|
| Efficiency<br>  Economies of scale<br>  Relative advantages of countries<br>  Inventory pooling between markets | Market proximity<br>  Follow market changes<br>  Local responsiveness<br>  Short lead times and quick response |
| Suppliers<br>  World-class suppliers<br>  Global suppliers active in many regions | Environmental impact<br>  Shorter transportation distances |
| | Risk management<br>  Control<br>  Communication<br>  Cultural similarities<br>  Resilience regarding trade wars |

- Competent suppliers, searching for the best suppliers for all individual components
- Utilization of the comparative advantages of countries with respect to low-cost manufacturing, cheap labor, manufacturing clusters, and innovative product and process development
- More degrees of freedom in designing the global system for suppliers, production, distribution and markets as more options are available

A local or regional supply chain is characterized by having suppliers, manufacturing, and distribution in the same region and serving a geographically concentrated market. These considerations are a valid alternative even when the markets are global. In that case, a number of regional supply chains are needed that are self-sufficient in each region. Overall, it can be seen as having a number of parallel systems with suppliers, production, and markets. Arguments for such an approach include the following:

- Better adaptation to local needs as the facilities are adapted to produce the local market's complete product range.
- Less capital tied up through increasingly shorter lead times.
- Less environmental impact through shorter transports and no transcontinental transports.
- Lower risks in the supply chains in that the supply chains are independent and self-sufficient. Earthquakes, tsunamis, hurricanes, storms, volcanic eruptions and forest fires often affect a limited area, leaving other local supply chains unaffected.
- Less risk of "bullwhip" effects through greater transparency and flexibility as all actors are in the same region.
- Minor cultural differences between the various actors in the chain through concentrated geographical coverage.
- Barriers to trade and requirements for local processing (production and suppliers) may constrain the options.

The negative aspects of global and local supply chains are fundamentally the absence of the drivers for the other supply chain types. Besides the risk aspects discussed above for global supply chains, poor communication due to cultural dissimilarities and long lead times resulting in higher total inventory investments are often cited as problems. There are also some difficulties in creating efficient local supply chains, which have to do with operating in a limited geographical area, as follows:

- Limited supplier competence. It can be difficult to find sufficient suppliers for all component types within the region. This may require an adaptation of product designs or active supplier development.
- Difficult to create a balance between supply and demand, especially in a dynamic market. If demand increases, it can be difficult to get all suppliers to adjust supply volumes to align with demand volumes or, alternatively, find new suppliers.

- Cost inefficiencies through higher labor costs in certain regions, which possibly can be compensated by higher levels of automation, robotization, and digitization.

The total investment in setting up a number of local supply chains is probably higher but must be weighed against the potential savings in distribution, transportation, and inventory costs. However, it is not clear which setup will have the overall lowest cost for running the system, wherefore the balancing decision between global and local supply chains is far from trivial.

How can the supply chain take advantage of economies of scale with global operations and a global supplier base and simultaneously maintain an ability to adapt product designs to local conditions and needs? Girod et al. (2010) advocated that the most important activities and capabilities should be identified and assessed before determining the global and local challenges associated with them, implying a granular approach. In essence, the choice of position in the spectrum between global and local supply chains is to strike the optimal balance between global efficiency and local responsiveness.

However, changing the global operations footprint takes time. While individual manufacturing tasks and processes can be transferred to other facilities in the short term, entire manufacturing facilities are not easily moved due to great inherent inertia. Since changes in the marketplace tend to be much quicker than any manufacturing system can adapt to, decisions on how to supply specific markets and find new suppliers are necessary to adjust to such market changes.

## 6 Summary and Conclusion

The core perspective of managing global supply chains is to decide on "who should be doing what and where" along the global supply chain. Two additional perspectives can be added in terms of "how" (first and foremost related to the type and level of technology) and "with how much capacity" (i.e., "rightsizing" with respect to the balance between cost efficiency and flexibility). Every manager of global supply chains or global operations aims for a well-balanced or optimal global network but acknowledges that the number of factors and issues to consider is constantly growing.

The recent events of the COVID-19 pandemic and the war in Ukraine have exposed the limitations (or inability) of the global supply chains to be proactive. For example, the risks with lean supply chains have been exposed, and many firms have drawn the conclusion that more inventory is needed along the supply chain. Inventories are generally considered to be a "necessary evil," but the question for the future is whether the emphasis will be on "necessary" – as a motivation to maintain high inventory levels – or on "evil" – as a motivation to reduce and minimize inventories along the supply chain.

With respect to the inherent dynamism in the global environment, pendulum movements are likely to continue in the future between free trade and protectionism as well as between global and local supply chains. The risk dimension of decision making on global supply chains is likely to grow in importance for decisions on the location and number of facilities and inventory investments in the supply, manufacturing, and distribution networks, while potential costs advantages, access to rare materials, and market opportunities will drive further globalization.

**Abstract**

The vast majority of 55 nations on the African continent are considered emerging economies. In conjunction with this classification, supply chain management (SCM) and logistics in Africa are prone to particularities such as the different levels of infrastructural development and political instability. Yet, there is an underrepresentation of Africa in SCM literature. This chapter adds to the scarce research on SCM in the African context by presenting both the perspectives of emerging and developed economies in empirical studies. A Delphi study conducted during different stages of the pandemic gives insight into risks and

vulnerabilities of supply chains (SCs) in Africa and presents restoration and resilience building measures named by the expert panel. The second study on the expected impacts, risks, and opportunities of the German Act on Corporate Due Diligence in Supply Chains elaborates on German firms with SC ties to Africa. The use of secondary data from global non-profit sources and research papers allows a comprehensive assessment of how SCM is carried out in the African context. Disruptions of the fragile supply chains such as the ongoing COVID-19 pandemic continue to challenge the economic stability and growth while acting as potential incubators for developments such as digitization and reshoring. In depicting frame conditions of supply chains in Africa such as macroeconomic factors, infrastructure, and material flows to identify SC risks and measures to build SC resilience, this chapter aims to provide results that might also be applicable for emerging economies in different regional contexts. Readers find insight into challenges and opportunities of SCM with regard to African operations and gain valuable understanding for related decision-making. Practitioners my gain new perspectives and helpful guidelines for doing business in Africa.

## 1 Introduction

For several decades, managing supply networks has become a key success factor for industries and economies worldwide (Ohmayer & Kilimann, 2008) and an increasingly relevant topic of scientific research (Min et al., 2019). Researchers have studied supply chain management (SCM) mainly from the perspective of industrialized regions while neglecting the view from emerging economies (EE) and developing countries (Svensson et al., 2008; El Baz et al., 2018). Only very recently have SCM scholars started broadening the geographical scope of their analyses to (sub-Saharan) Africa (Nnamdi & Owusu, 2014; El Baz et al., 2018) or studying operations and logistics at the base-of-the-pyramid (Gold et al., 2013; Khalid et al., 2015; Seuring et al., 2019).

Given the large economic growth potential of Africa and the particularities of logistics and SCM in this continental region, it is surprising that related SCM research still is in its infancy. Characteristics of the economic and cultural environment need to be considered when studying SCM in Africa (Georgise et al., 2014). Specific factors include a lack of hard currencies, qualified personnel, cultural aspects in logistics, and efficiency impacts of personal relationships between supply chain (SC) actors (El Baz et al., 2018). Scientific analyses mainly evaluate product-specific SCs and (third-party) logistics operations, risk and performance management, or sourcing (El Baz et al., 2018). Studies often focus on a particular industry, e.g., textile and apparel (Brandenburg et al., 2022) or agriculture and food (Aworh, 2021), or they analyze information technology (IT) as enabler of SCM (Schilling & Seuring, 2021).

Studying topics as green logistics, sustainable operations, SC ethics, and social responsibility in African supply networks with a focused lens from a single perspective necessarily limit the scope of analysis. Instead, interdisciplinary and intercultural investigations are recommended. These types of investigations are needed to leverage the full research potential, reveal new insights, and deliver strong research contributions. However, only 15 percent of all studies on logistics operations and SCM in Africa reflect theories related to micro- and macroeconomics (El Baz et al., 2018). The management research perspective on African supply networks could and need to be complemented by the view on global value chains in Africa from an economics and governance perspective (see, e.g., (Whitfield et al., 2020).

In 2003 Hamel and Välikangas noted that the world is changing more turbulently than companies are becoming resilient and that success has never been so fragile. Technological advances, fast-paced globalization processes, regulatory upheavals, geopolitical shocks, industry deverticalization and disintermediation, as well as sudden changes in consumer wishes underline the importance for risk reduction mechanisms (Hamel & Valikangas, 2003). In addition, many companies have taken SC adjustment measures, like Just-in-Time or lean manufacturing, to increase sales or reduce costs in a stable business environment. This research stream may also be promising for studying SCM in Africa.

The focus of this chapter is set on the African continent. The study takes a closer look at the different phases of resilience and identifies areas that are crucial for overcoming disruption in a particular phase. Two empirical studies elaborate two very different perspectives on SCM in Africa. First, a Delphi study presents the views of African experts on SC risk and resilience concerning the continent during the COVID-19 pandemic. Second, German businesses with SC ties to Africa are the basis of a study on the expected impacts, risks, and opportunities of the German Act on Corporate Due Diligence in Supply Chains.

The next section will give an overview of frame conditions of supply chains in Africa and outline definitions respectively used in this chapter. This will provide a base for the further study and helps to delimit the input of this chapter. Based on this background, existing concepts of SC risk and SC resilience in research and practice are outlined. The third section consists of two empirical studies giving insight into (1) SC risk and resilience during the COVID-19 pandemic and (2) the impact and perceived risks and opportunities of government regulation toward sustainability. The managerial implications section provide a strengths, weaknesses, opportunities, and threats (SWOT) analysis summarizing the internal and external environment of SCM in Africa. The conclusion and an outlook outlining ideas for future research are provided in the final section.

# 2 Background

## 2.1 Frame Conditions of Supply Chains in Africa

### Emerging Economies in Africa

The World Bank clusters EEs as all economies ranked with low income (< 1035 USD) and lower middle income (1036–4045 USD), defined by the thresholds developed for the per capita gross domestic income (GDI) (The World Bank, 2020a). By using only one key performance indicator (KPI) determined by the Atlas method, to classify economies, the World Bank provides a simple framework while knowing that the per capita gross national income (GNI) cannot summarize the complex levels of development and welfare. Still, according to the World Bank, the indicator can evidently be correlated with “other, nonmonetary measures of the quality of life, such as life expectancy at birth, mortality rates of children, and enrolment rates in school” (The World Bank, 2020a). African countries make 58 percent of the total EEs, and 46 African countries are defined as EEs (Fig. 1). For simplicity reasons, this study includes the remaining nine countries into the previous definition for the cause of this study.

In order to prepare for unforeseen events, it is necessary to be aware of possible weaknesses and their consequences. Especially in EEs with “limited health-care capacity, deeply integrated global value chains, heavy dependence on foreign financing and extensive reliance on international trade” are likely to experience significant decrease in commodity exports and tourism (Martin, 2020). According to the thresholds for EEs defined by the World Bank, African countries make 79 percent of the world’s lower-income countries and 46 percent of lower middle-income countries (The World Bank, 2020b).

## 2.2 Macroeconomic Factors, Infrastructure and Material Flows

In their annual report released in 2021, the African Development Bank projects the average African gross domestic product (GDP) to grow by 3.4 percent after a 2.1

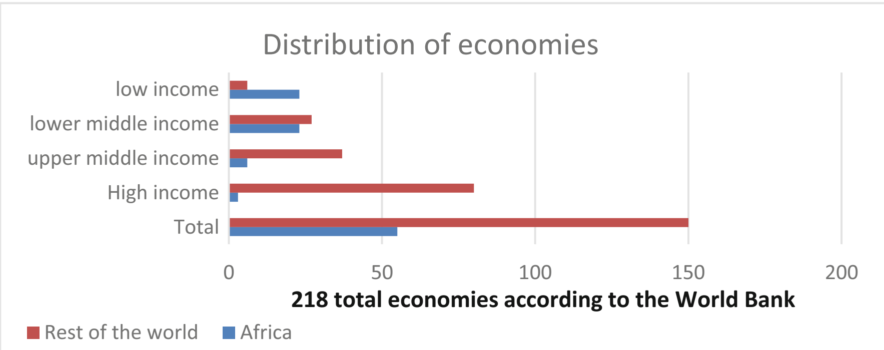

**Fig. 1** Own Illustration based on the distribution of global income groups (World Bank, 2020a, b)

percent decline in 2020. In line with developments globally, the current macroeconomic environment, performance, and prospect of the African continent is strongly influenced by the effects of the ongoing COVID-19 pandemic. While the number of COVID-19-related deaths in 2020 is lower compared to other continents, the negative development of the GDP growth rate was in line with the rest of the world (African Development Bank, 2021).

The impact of the pandemic was and still is as individual as the 55 economies of the continent. Exemplary for these differences is the pandemic-related GDP decline of 11.5 percent in tourism-dependent economies compared to a comparably low decline of 1.5 percent in Africa's oil-exporting economies. The report concludes that due to the pandemic, increased fiscal deficits, higher debt burdens, fluctuations in exchange rates, and disrupted financial inflows weakened the macroeconomic fundamentals of the continent (African Development Bank, 2021).

Infrastructure development facilitates economic growth and strengthens equity and thus reduces poverty. Of all EEs, countries in sub-Saharan Africa rank at the bottom of all dimensions of infrastructure performance – transportation, energy, and digital (Calderón, 2021). In their framework, El Baz et al. (2018) consider infrastructure to be one of the six challenges influencing African-based SCM practices and logistics, the other five being (1) geography/natural disasters, (2) technology shortage, (3) political risks, (4) inefficient networks, and (5) regulations and institutional aspects. A means to meet this need for infrastructure development is funding through foreign direct investments, which increased by 11 percent right before the pandemic (UN, 2019).

The limited access of rural areas to roads and geographical disadvantages as remoteness of most of the region's economies from global market centers increase transportation costs. The cost of moving imported goods to customers inland is 50 percent higher than in other regions and obstructs accessibility to consumers and interregional trade (El Baz et al., 2018; Calderón, 2021). There are geographical disadvantages of landlocked countries in the region – for example, Ethiopian textile and apparel producers that need to wait up to 21 days for goods to arrive through the port of Djibouti. Adding to this geographical disadvantage are political conflicts, which is the reason goods have to be moved through the port of Djibouti despite Eritrean ports being closer to some industrial sites (Warasthe et al., 2020; El Baz et al., 2018).

## 2.3 Risk and Resilience of Supply Chains

Every company decision and activity is accompanied with uncertainty, since wrong decisions might result in unforeseen impacts. In order to avoid these consequences, potential risks must be constantly factored in and controlled (Heckmann et al., 2015). Due to increasing complexity in intertwined modern supply networks and increased concerns about the rise of SC risks, the significance of risk management has increased (Hohenstein et al., 2015). Whole SCs are put in jeopardy if not managed accordingly. Therefore, after the establishment of SCM as an academic field, SC risks and their management received great consideration through a change in business practices starting at the beginning of the twenty-first century (Zsidisin & Henke, 2019).

Increased SC complexity makes them more prone to disruptions (Fiksel, 2015). External factors such as natural disasters, global outsourcing (Bakshi & Kleindorfer, 2009), and shorter product life cycles (Sodhi et al., 2012) further increases SC risk. A global pandemic such as COVID-19, which is still a global disruption, leads to unpredictable changes. COVID-19 exposes entire SCs to major social, economic, and ecological risks, influencing the development of the whole economic market (Alicke et al., 2020).

In April 2020, the department "Statistics South Africa" released its report on "Behavioral and health impacts of the COVID-19 pandemic in South Africa." Being one of the economically strongest countries in Africa, the participants of the survey rank economic collapse, the health of vulnerable persons and the overload of the health system as the most critical impacts resulting from the COVID-19 pandemic (Statistics South Africa, 2020). SC resilience needs to be strengthened to decrease the probability of disruption as well as impact of damages resulting from disruptive events (Seuring & Freise, 2011). Research combining a global pandemic, SC risk management, and SC resilience in EEs is scarce and requires investigation.

Current literature defines SC risk in a rather generalized, ambiguous, and unquantifiable manner. The understanding of SC risk and the attendant views on the design of risk management vary widely since researchers have tackled the topic from different perspectives (Sodhi et al., 2012). Therefore, their definitions often focus on specific functions of the SC and do not consider the whole chain (Ho et al., 2015). Heckmann et al. (2015) define SC risk as follows: "Supply chain risk is the potential loss for a supply chain in terms of its target values of efficiency and effectiveness evoked by uncertain developments of supply chain characteristics whose changes were caused by the occurrence of triggering-events" (Heckmann et al., 2015, p. 130).

SC risk management occurs at the interface of risk management and SCM (Fig. 2). As part of the planning and controlling of SC processes, it follows a collaborative and structured approach in order to minimize risks that jeopardize the company's target achievement (Tang, 2006).

In a more comprehensive approach, Ho et al. (2015) define SC risk management as "an inter-organizational collaborative endeavour utilizing quantitative and qualitative risk management methodologies to identify, evaluate, mitigate, and monitor unexpected macro and micro level events or conditions, which might adversely impact any part of a supply chain" (Ho et al., 2015, p. 5036). According to the literature review of Pournader et al. (2020), literature on SC risk management can be summarized into two main categories. One part aims to develop a framework to identify, categorize, evaluate, and handle SC risk, while the other part focuses on a specific type of risk, such as climate change (Ghadge et al., 2020) or the COVID-19 pandemic.

While SC risk management focuses on the identification of risks SCs can be confronted with and the management of such risks, SC resilience deals with developing frameworks and tools to prepare for such unforeseen events in order to recover

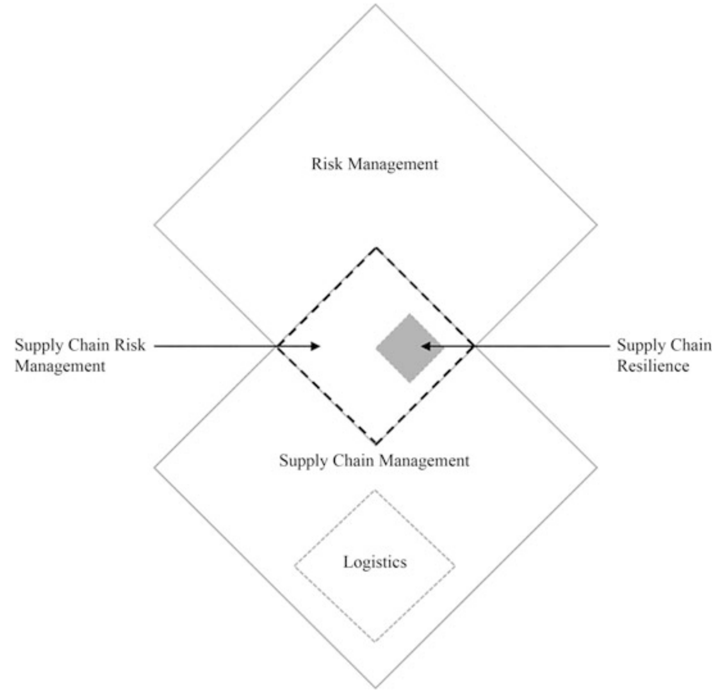

**Fig. 2** Schematic representation of the classification of SCM, SC risk, SC risk management, and SC Resilience (Biederman, 2018)

from them swiftly. The continuous adaptation and development of these capabilities needed in order to make SCs more resilient can create a sustainable competitive advantage (Hamel & Valikangas, 2003).

SC resilience has become increasingly visible in literature, yet the term and concept for creating SC resilience are still vague and still under development. There is no generally accepted definition for resilience (Hohenstein et al., 2015). In economic terms, resilience means "the capacity for an enterprise to survive, adapt and grow in the face of turbulent change" (Fiksel, 2006). But the term can also be found in areas unrelated to business. For instance, ecological science standardized resilience as "the ability for an ecosystem to rebound from a disturbance while maintaining diversity, integrity, and ecological processes" (Folke et al., 2004). This definition is also applicable to SCs, as they can be understood as a network of "living" systems. Christopher and Peck (2004) therefore also linked their definition of SCs with the definition from ecology: "The ability of the system to return to its original state or move to a new more desirable state after being disturbed." For the cause of this chapter the latter is used.

Studies distinguish different approaches to build resilience. According to Pettit et al. (2010), SC resilience can be developed by focusing on company's SC vulnerabilities and SC capabilities. SC resilience increases with increasing capabilities and decreasing vulnerabilities. Pettit et al. (2010) define capabilities as "attributes that enable an enterprise to anticipate and overcome disruptions" and vulnerabilities as "fundamental factors that make an enterprise susceptible to disruptions."

As Kochan and Nowicki (2018) point out in their literature review, the terms vulnerability, vulnerability drivers and factors, resiliency reducers, risks, risk sources and factors, and risk drivers are used interchangeably. In this chapter the terms risk and vulnerability will be used interchangeably. A similar variety of terms exists for capabilities. The term "elements" by Christopher and Peck (2004) or "antecedents" by Ponomarov and Holcomb (2009) as well as the terms "resilient enhancers," "attributes," and "competencies" are used in the literature (Hohenstein et al., 2015).

An organization with high vulnerability that does not have sufficient capabilities is at risk. In response, it should improve the necessary capability. Conversely, an organization that faces fewer vulnerabilities but has strong resilience capabilities might unnecessarily undermine its profits. Therefore, it is beneficial for firms to try to balance both sides. Within this "balanced zone of SC resilience" profits are neither undermined nor excessive risks are taken. To enhance its performance and achieve a sustainable competitive advantage, companies need to analyze their SC vulnerabilities and build up appropriate and matching SC capabilities (Pettit et al., 2019).

Hohenstein et al. (2015) identified in their literature analysis 36 different capabilities of SC resilience necessary to build a resilient SC. The major capabilities detected are flexibility, collaboration, visibility, agility, and multiple sourcing. This is broadly in line with the results of Jüttner and Maklan (2011) and Sá et al. (2020). These capabilities should be established prior to a disruption in order to build resilience (pre-disruption). In addition, other researchers focus on resilience capabilities that are necessary after a disruption (post disruption). These are capabilities such as recovery time, cost, and response effort (Sheffi & Rice, 2005). Some support the consideration of three phases of resilience, including (1) a required level of readiness during the pre-disruption phase, as well as (2) response and (3) recovery in the post-disruption phase (Chowdhury & Quaddus, 2016; Hohenstein et al., 2015). Chowdhury and Quaddus (2016) also point out the interdependency of the phases, since, e.g., higher readiness enables quicker response and recovery from the disruption.

Readiness describes a SC's ability for dynamic control and adaptive management in the time of disruptive events. It includes having the ability "to recognize, anticipate and defend the SC against risks before consequences occur" (Chowdhury & Quaddus, 2016, p. 712) as well as to "forecast, identify risk, asses risk and monitor deviation to prepare for mitigating disruptions" (Chowdhury & Quaddus, 2016, p. 712). By having these capabilities, precautions against disruptions can be taken. Therefore, readiness includes processes to proactively scan the environment, but also includes improved preparing processes linked to previous disruptive events. Besides readiness, current academic research focuses on response and recovery capability to build SC resilience. The ability to react and recover effectively from and quickly toward challenging situations is an important determinant for SC resilience, because a late response can be costly (Chowdhury & Quaddus, 2016). Therefore, it can be argued that those two post disruptive phases are necessary to build resilience.

Risk management and SC resilience are especially important for African countries, which represent the majority of EEs and therefore face specific vulnerabilities. The starting point of facing internal challenges such as weak infrastructure, geographical disadvantages, and dependencies from foreign investment exacerbates the effects of unforeseen external disruptions like the COVID-19 pandemic.

## 3 Emergent Supply Chain Risk and Regulatory Issues in the Africa Context

The following research studies on risk and resilience of SCs in Africa and the German Act on Corporate Due Diligence in Supply Chains have been published in conferences and summarized for this section.

### 3.1 Risk and Resilience of Supply Chains in Africa: Insights from a Delphi Study

We provide insights in risk and resilience of African SC from a three-round qualitative Delphi study. The study determined the risks and vulnerabilities caused by COVID19 in Africa as well as the measures to restore operations and build resilience. The majority of African countries were at the beginning of the pandemic; hence long-term consequences were not yet sufficiently apparent given the early study period (mid-2020), but general insights are still valuable from this time period.

*Vulnerabilities* within the COVID-19 pandemic are considered to be mainly caused by financial and logistical challenges, SC disruptions, and SC disturbances. Africa's dependence on China is an additional factor though seldomly mentioned by the respondents. Due to China's significance as a center of global economic activity, the outbreak in China led to international spill overs, particularly in international trade, mobility, finance, and commodity markets (Ni & Betti, 2020).

Countries with challenging political structures and health infrastructures as well as already existing vulnerabilities in the financial sector are particularly exposed to movements in the global markets (Utz et al., 2020). Due to the characteristics of EEs, among others, institutional constraints within the welfare system, labor market, and political leverage contribute to being exposed to global risks (Keen & Wu, 2011). Ernst and Young discuss a changed customer behavior and brand protection as an additional vulnerability (Dekker et al., 2020). They warn of non-reversible changes in values, habits, and consumption patterns. Consumer loyalty is inter alia built by communication, loyalty programs, and customer segmentation. Approaches to build long-term value range from "building trust in capital markets, having a positive social and environmental impact, or creating an inclusive culture of personal development and purpose" (Dekker et al., 2020).

Within the *response* phase, the reaction to the vulnerabilities is an improvement in financing and in addition the strengthening of the supply network, the digitalization of processes, and increasing SC agility. The identified problems of logistics can be solved by a high degree of agility within the response phase. Chowdhury and Quaddus (2016) combine several studies and support the study's findings. Without the ability to respond to and quickly recover from a changing environment, potential costs of several hundreds of million dollars may occur for companies and SC partners.

It is interesting to note that a strong supply network and the digitalization of the SC are essential in all phases for overcoming the disruption, as well as for building SC resilience. This importance is confirmed, for example, by Alicke et al. (2020), which draws a connection between close corporation among the supplier ecosystem and the resulting increase of SC resilience. COVID-19 has laid bare the negative aspects of globalized SCs to firms, and voices calling for localization are raised. Ivanov and Das (2020) identified in interviews with SC managers that localism is a key concern when redesigning SCs. The Boston Consulting Group also supports diversification and localization of manufacturing and supply networks as a method to mitigate risk (Aylor et al., 2020). As the experts have already pointed out, the supply network has undergone localization and will probably continue to do so to a greater extent in the future.

While the digitalization of SCs is also met with challenges such as the lack of spatially comprehensive digital infrastructure in some African countries, it should have a strong impact on the supply network. A digitalized SC strengthens the ability to anticipate risks, generate transparency and coordination between actors, and manage problems together, thereby reducing the risk for each individual (Alicke et al., 2020) and improving the response quality to disruptions (Queiroz et al., 2020). The resulting data is in turn of importance for the SC risk management, as it enables predictions of potential disturbances and reactions to disturbances to be derived (Ivanov & Dolgui, 2021). Yet, some scholars emphasize the complexity of forecasting and detecting disturbances (Ambulkar et al., 2015; Pettit et al., 2010).

The Delphi study shows that contingency planning is particularly important in the phase of recovery as well as for the construction of resilience, during the phase of readiness. Such plans are nevertheless mostly not implemented for reasons of cost and inertia (Ivanov & Das, 2020). In the context of malaria – a major disease affecting the African continent – Parvin et al. (2018) have shown that effective transport planning might contribute to a significant reduction of costs and shortages. However, the implementation is determined, independent of the disruption, by challenges such as lack of communication, weak governmental commitment, and poor logistical infrastructure (Parvin et al., 2018). In the readiness phase, contingency planning receives little acknowledgment in our study. According to Dekker et al., increasing the communication and assessing support programs is essential for businesses to understand the public policy landscape and to shorten the response time.

During the recovery and readiness phase, the importance of the supply network, digitalization, and contingency planning remains and is supported by a strong human resources management. Deloitte (2020) emphasizes and thus supports the findings that educating employees to prevent COVID-19 and introducing control mechanisms and promoting flexible working arrangements are means to handle the crisis.

In general, the recovery phase is one of the key phases within SC resilience. However, there is little research on this subject (Ivanov & Rozhkov, 2020).

However, the following limitations need to be noticed. As mentioned, the time frame in which the study is carried out has a decisive influence on the result. In the early stages of the epidemic, it was difficult to predict how the situation will further develop, which other long-term consequences will occur and how companies will react to survive the disruption and build resilient SCs. The generalization of received answers is limited by the demographic information provided by the experts in conjunction with the number of contacted countries. Kenya, Ghana, Namibia, and South Africa are the only confirmed countries participating in the study. Nevertheless, the results provide profound insights and in-depth information, as well as prospects are provided by the expert panel.

### 3.2 Impacts of the German Act on Corporate Due Diligence in Supply Chains: An African Perspective

It can be difficult to allocate products and resources to specific production sites which do not comply with human rights. Therefore, transparency along the global supply chain is considered an important mean to assure that human rights are mandatory for all participants of a supply chain. This can be achieved by governmental legislation or by self-regulation of companies (New, 2020). The lack of control in several countries, especially in developing and emerging countries in the global south, amplifies the need for home state regulation to enforce human rights along supply chains (LeBaron & Rühmkorf, 2017).

To meet its perceived universal responsibility of promoting human rights, the German government proclaimed in July 2021 the German Act on Corporate Due Diligence in Supply Chains ("Lieferkettensorgfaltspflichtengesetz") which aims to improve social and to a limited extent also environmental sustainability along the global supply chains of Germany-based enterprises (Bundesregierung, 2021). Effective by 2023 the act will commit Germany-based firms with a headcount of minimum 3.000 full-time equivalent employees (1.000 effective 2024) to fulfill certain due diligence obligations regarding a responsible management of their supply chains.

The act adopts a risk-based approach, as proposed by the UN Guiding Principles on Business and Human Rights (UN, 2011), obliging firms to implement a risk management system with measures to detect, prevent, end, or minimize the violation of social sustainability or environmental obligations caused by the firm, within its supply chain or to which the firm contributed. Most obligations are limited to direct (Tier-1) suppliers. Documentation and reporting duties enable the responsible federal office for economy and export control to examine the fulfillment of the obligations by companies. It is also able to impose fines on non-compliant companies.

Shortly before the German parliament has passed the Act on Corporate Due Diligence in Supply Chains in July 2021, research to study the resulting implications of this act for German firms with SC ties to Africa was conducted. In particular, the

perception of risks and opportunities, measures to put the requirements into practice, and the expected impacts on sustainability performance were analyzed using empirical-qualitative case study research. Between Q2/2021 and Q3/2021, nine semi-structured interviews were conducted with managers of German firms with a head count higher than 1000 from different industry sectors with SC ties to Africa. Managers were chosen as interview partners based on their specialized knowledge and occupation of key positions concerning sustainability issues in the considered firms. The interviewees are employed at a cross-sectional variety of companies that are amenable to the due diligence act (Table 1).

### 3.3 Perceived Risks and Opportunities of the Act on Due Diligence

The data shows that the perceived risks outweigh the perceived opportunities of the act since interviewees discuss risk during the interviews three times more often than opportunities. Among the perceived risks of the act, uncertainty due to the broad scope of interpretation for the requirements was mentioned most frequently. Interviewees feel that the burden of defining and interpreting the relatively unspecified due diligence obligations is left to the affected firms since the act causes a high degree of insecurity. To firms it seems still unclear which measures will be considered appropriate under the law. This could also lead to the implementation at the lowest, least strict and least costly level. While one interviewee considered this to be a poor legal construct, another judged this as the inevitable downside of necessary flexibility.

Excessive bureaucracy is another frequently mentioned risk. It is based in the expectation that the implementation of the act's obligations regarding documentation and reporting will result in an immense administrative effort that could distract efforts for true sustainability improvements by setting a wrong focus on detailed administrative tasks. Consequential to the increased administrative effort, firms are worried about additional costs which will also affect them indirectly through their suppliers. Three interviewees see the withdrawal of their firms from markets associated with higher risks for human rights violations as one extreme potential consequence of a competitive disadvantage against international competitors, especially such from Asian countries who are not underlying a legal standard like the German Act on Due Diligence. If in turn these competitors increase their market share in African economies, it might lead to a subsidence of the overall sustainability level in global supply chains and also profit loss of German firms as a result of their withdrawal. The act is perceived as a potential barrier for German companies to operate in those markets.

Two firms believe that some German firms might individually be unable to accomplish the act's objective to safeguard human rights in international supply chains. They see possible conflicts with local regulations and consider the German government or the European Commission responsible for bilaterally negotiating better working conditions. Further risks mentioned are the market exclusion from public procurement due to mistakes made by the firm in high-risk markets and competitive disadvantages for medium-sized companies due to their limited bargaining power. It can be concluded that financial risks regarding the cost of complying to the law are of higher concern than such regarding overall instability or political environment of the supplier or buyer markets.

Despite not being discussed as often as risks in the interviews, the perceived opportunities of the act point to an increased awareness of the interviewees concerning social sustainability. With the exception of one interviewee, every firm mentioned at least one opportunity concerning the implementation of the act though remaining rather vague. Some of the opportunities are interlinked or can be considered a consequence of another.

The most frequently mentioned opportunity is a potentially improved standing of sustainability by putting the act's specifications into action. Thus, the significance of sustainability considerations increases in a firm's decision-making and business practices as stated by several interviewees. Interviewees are in favor of an expected formation of a level playing field which implies that the law creates equal requirements and conditions at least for German firms as all are required to comply with the act. Hence, keeping up with competition is considered less of an obstacle to sustainable business practices. The act can be considered as a form of quality assurance if a firm's supply chain complies with the act which can be attained by, e.g., improved sustainability monitoring safeguards.

### 3.4 Measures to Put the Requirements into Practice

Regarding the expected adjustments required to comply with the law, the responses are balanced as to whether firms will require measures or none at all. One adjustment mentioned is the need to define policies, i.e., implementing new policies or remodeling existing policies to oblige with the law. This might affect internal policies or policies concerning supplier relationships like a (supplier) code of conduct. Another adjustment considered is the mere fact of writing an additional report as the firms consider themselves prepared regarding the risk and sustainability management measures but expect an additional bureaucratic burden by reporting annually. The respondents that consider their respective firms prepared and with no need of adjustments have implemented more comprehensive sustainability measures in the past. There are also responses that imply an uncertainty about the need to adjust, particularly since the interviews were conducted before the final draft of the act was passed.

### 3.5 Expected Impacts on Sustainability Performance

Every interviewee without exception qualified the act on due diligence's impact on their own company's sustainability performance as neutral. Hence, this can be considered as the clear prevailing perception within the context of the study. Five of the nine firms argue that their current sustainable supply chain measures already comply with the act's regulations to a large extent and therefore perceive no need for major adjustments. Others doubt the act's capability to contribute to real improvements. At the same time, three respondents expect of a positive impact that the act might have by giving increased value and focus to sustainability and human rights in supply chains. Negative impact due to practical difficulties is mentioned as well and thus considering the act as an undesirable development.

To sum up, it can be said that SC due diligence acts represent important frame conditions and constraints for SCM in Africa which practitioners must adhere to in daily business. From a research perspective, the efficacy and impacts of such laws need to be explored and evaluated.

## 4 Sustainability of Supply Chains in Africa: Prerequisites, Practices, and Sustainable Development Goals

In addition to risk and resilience and to the due diligence act, sustainability issues are important concerns of SCM in Africa. These perspectives are briefly outlined in this section.

Prevailing working conditions especially in developing and emerging economies that produce for global markets are prone to most basic human rights violations. An example showing the dimension and significance of this challenge is the so-called Marikana massacre which took place in South Africa in 2012. During this incident, miners were shot by police after protesting for better working conditions and higher wages (Marinovich, 2016). While this case of human rights oppression is a widely known example, it is to assume that a many other violations remain unnoticed. According to the United Nations (UN) Guiding Principles on Business and Human Rights, businesses are responsible for respecting human rights and required to avoid contributions to adverse human right impacts and to mitigate those impacts that are directly linked to their operations (UN, 2011, pp. 13–26).

In sustainable SCM, the traditional focus of SCM is extended from economic criteria to socio-ecologic factors (Brandenburg et al., 2014). Growth in studies on green and social SCM has accompanied this development (Fahimnia et al., 2015). Although the African continent is most vulnerable to social and environmental sustainability and most strongly limited in capacity to manage these issues, fewer than 10 percent of all studies on logistics and SCM in Africa include aspects of sustainability (El Baz et al., 2018). Thus, the limited general SCM research in Africa is even scarcer for SSCM.

This large research gap shows the strong need for research on topics such as green logistics, sustainable operations, SC ethics, and social responsibility in African supply networks. Further research perspectives include cultural aspects and their importance for and influence on SCM (El Baz et al., 2018) analyses of developing country suppliers.

Societal effects of green and SSCM, namely, food security and environmental impacts, are topics of recent studies also in context of the COVID-19 pandemic. The resulting impact on vulnerable African societies and their food production and consumption varies depending on the proximity to rather rural or urban areas. Short food supply chains and urban gardening increase resilience and sustainability, while the reliance on global imports for food security proved to be particularly challenging the food security during the pandemic (Nchanji & Lutomia, 2021). Small- and medium-scale enterprises (SMEs) play a significant role in African agri-food chains. SMEs start to transform their practices toward social sustainability by implementing social compliance measures or collaborations, yet are aware of the challenges of their efforts. Customers' sustainability requirements such as food safety, labor condition, and traceability prove to be strong drivers also in the agri-food context (Agyemang et al., 2022).

The emphasis on the role of digitalization as enabler of sustainable practices in SCs is increasing globally across all industries. While SCs with ties to African countries are part of this development, they are met with challenges such as inter alia the local digital infrastructure and connectivity. The need for transparency along supply chains is driving the implementation of block chain technologies, yet the application along with artificial intelligence, Big Data, and Internet of Things in African countries is still scarce (Abban & Abebe, 2022; Bai et al., 2022).

## 5 A SWOT Analysis and Managerial Implications

In order to summarize and categorize the particularities of SCM in Africa derived from secondary data, research papers as well as own empirical research a SWOT analysis is conducted (see Fig. 3). It allows the exploration of internal and external environments based on strengths, weaknesses, opportunities, and threats (Ghazinoory et al., 2011).

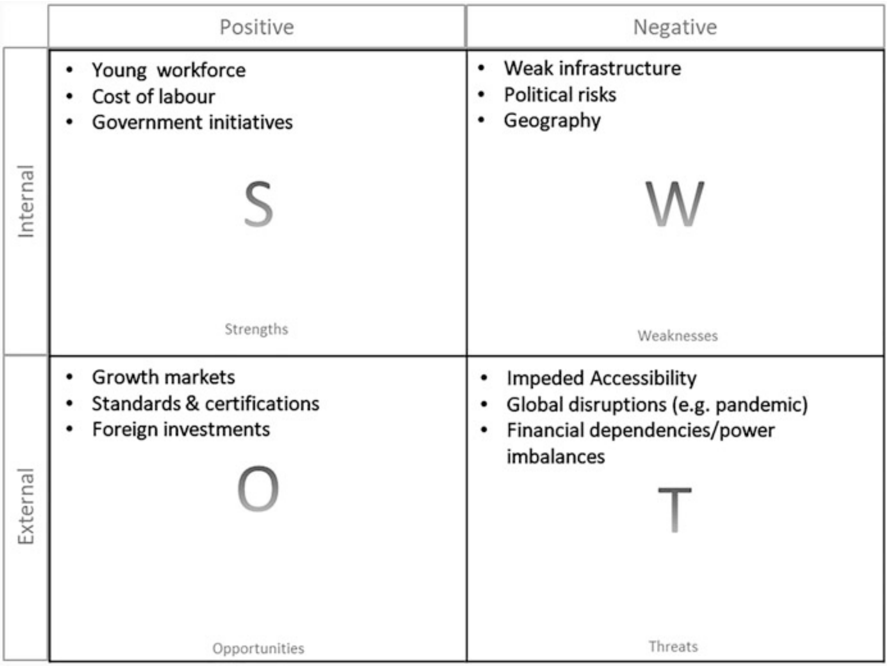

**Fig. 3** Supply chain management in Africa – a SWOT analysis

One of the strengths of African economies is the young workforce combined with the low cost of labor. The development away from agricultural to industrialized economies is enabled by this potential. This can be observed in Ethiopia, where the government launched initiatives to push industrialization through initiatives attractive for foreign investors, e.g., tax exemptions (Warasthe et al., 2020; Adikorley et al., 2017). Another strength is the multitude of government initiatives to tackle the weaknesses in African supply chains. Several African countries launched infrastructure projects expecting to improve the quality of their SCM practices and thus reduce freight costs and time delays (El Baz et al., 2018; African Development Bank, 2021).

The African continent's infrastructure can generally be considered one of its weaknesses. As described in previous paragraphs, countries in sub-Saharan Africa rank at the bottom of all dimensions of infrastructure performance (Calderón, 2021), and infrastructure is considered to be one of the core challenges influencing African-based SCM practices and logistics (El Baz et al., 2018). The limited access of rural areas to roads obstructs accessibility to consumers and hinders trade. The results from the empirical study on the German Act on Corporate Due Diligence in Supply Chains show that political instability and corruption are perceived risks when operating and sourcing from African countries. This further validates the findings of El Baz et al. (2018), who find political risks to be an obstacle to SCM. The geographical disadvantage of landlocked countries is more severe due to the lack of direct access to ports in order to import and export goods at low cost.

The opportunity of being considered one of the last growth markets and frontiers in trade encourages foreign investors to look at potential business ventures in African countries. While the COVID pandemic curbs the growth expectations, several African economies, such as those focusing on tourism and mineral oil, are expected to bounce back swiftly (African Development Bank, 2021). The presence of foreign firms is considered as a potential to positively influence SCM practices by attracting other businesses to supply to, manufacture in, and or source from African countries (El Baz et al., 2018). In order to ensure quality standards but also socially and environmentally sustainable operations, foreign investors rely on standards and certificates. A supplier with globally approved certifications and quality standards is considered trustworthy and a preferred business partner (Warasthe et al., 2020).

The impeded access of African businesses to foreign markets poses a threat to their economies. The remoteness of most of Africa's economies from global market centers leads to 50 percent higher cost of moving imported goods to customers inland and thus hampers accessibility to consumers and interregional trade (El Baz et al., 2018; Calderón, 2021). The Delphi study shows that global disruptions, such as the ongoing COVID-19 pandemic, invert the evolved competitiveness and economic growth of the pre-pandemic years. The financial dependencies of African economies lead to power imbalances, often with regard to China (Deloitte, 2020; Ni & Betti, 2020). Countries suffering from existing vulnerabilities in the financial sector are particularly exposed to and threatened by movements in the global markets.

## 6 Summary and Conclusion

While still underrepresented in research, SCM in the African context is defined by its vulnerabilities. This chapter has shown that intensifying structural transformation through government initiatives and foreign investments may lead to resilience. This chapter has also illustrated that Africa's transformation to a more resilient and sustainable post-pandemic recovery is still at the beginning and is dependent on foreign investment. (German) firms with SC ties to Africa will have to consider regulations to tighten further and their own responsibilities to maintain and further sustainability practices in those chains. Researchers may understand the two different empirically studied perspectives on SCM in Africa as opportunities to conduct broader empirical research.

The pandemic laid bare and acted as an incubator for vulnerabilities of supply chains in African countries, but also for response measures, restoring operations, and resilience building. As individual as the 55 African countries are, so are the effects of COVID-19 on these countries and how they deal with them. This chapter may be helpful to get a broad insight into the challenges and opportunities of SCM in African countries. It may increase the understanding of the particularities and future developments of the African countries tied to global markets.

## Contents

**Abstract**

This chapter aims to present issues on supply chain management in Latin America. To do so, we evaluate the body of literature and we identified 34 studies from which we collected information about: country in which the research was carried out, cooperation (Universities and authors), methodology used, and sector in which the research was performed. Finally, the main focus, results, challenges, and concerns about SCM are presented, along with a suggestion of future research, so that the theme supply chain management in Latin America can develop.

## 1 Introduction

Since the 1980s, globalization and the demands of stakeholders allied to various environmental and social challenges have expanded the scope of logistics operations from companies. These challenges caused a shift of the competitive focus of organizations evolving to considering competition among networks of companies. This new design's – supply chain management (SCM) – main purpose is to improve the costs of operations and deliver to customers a better service (Zhu et al., 2008).

SCM has served to describe the networking management relationships within a company among organizations and business units. These units encompass material suppliers, purchasing, production facilities, logistics, and marketing functions. SCM is also focused on upstream and downstream flow systems that include reverse logistics, materials, services, finance, and information from the original producer to the final customer. The ultimate purpose is to add value to customers while maximizing profitability through efficiency gains (Stock & Boyer, 2009).

The SCM focus can be characterized in four ways (Ahi & Searcy, 2013): (i) focus on the flow of materials, services, and information throughout the supply chain; (ii) focus on coordination consisting of the coordination activities within and among organizations, especially regarding the product life cycle or activities in all channels in the supply chain; (iii) focus on stakeholders by making explicit reference to stakeholders in the chain's business as customers, consumers, and suppliers; and (iv) focus on the relationship between the organizations and their business processes.

SCM philosophy is based on the tenet that organizations, in isolation, cannot meet all the demands of the market, so they need to partner to create competitive advantages through a close and lasting relationship. This partnering requires SCM supply chain management to be strategically important to organizations (Andersen & Skjoett-Larsen, 2009) contributing to organizational competitive advantages (Tarofder et al., 2017).

Despite SCM's importance in Latin America, there are institutional conditions which do not seem to favor the participation of its researchers in a global dialogue on SCM. Few studies address SCM with a particular emphasis on Latin America. A similar situation has already been detected in the research by Teixeira et al. (2020) on the state of the art of Green Supply Chain Management in Latin America – a major subtopic in SCM.

This chapter aims to integrate and systematize the current knowledge about SCM in Latin America demonstrating the main research, challenges, and concerns. The chapter also proposes a future research agenda to guide and encourage the development of SCM research and understanding in Latin America.

## 2 Supply Chain Management: An Overview

Numerous SCM definitions exist. The Council of Supply Chain Management Professionals (CSCMP 2023) defined the SCM as [. . .] "encompasses the planning and management of all activities involved in sourcing and procurement, conversion, and all Logistics Management activities. Importantly, it also includes coordination and collaboration with channel partners, which can be suppliers, intermediaries, third-party service providers, and customers. In essence, Supply Chain Management integrates supply and demand management within and across companies." SCM has also been defined as "the coordination of activities, within and between vertically linked firms, for the purpose of serving end customers at a profit" (Larson & Rogers, 1998, p. 2).

A third definition of SCM is "the management of a network of relationships within a firm and between interdependent organizations and business units consisting of material suppliers, purchasing, production facilities, logistics, marketing, and related to systems that facilitate the forward and reverse flow of materials, services, finances and information from the original producer to final customer with the benefits of adding value, maximizing profitability through efficiencies, and achieving customer satisfaction" (Stock & Boyer, 2009).

SCM'S overall purpose is to create customer value. Customers demand improvements in products and services with low prices (Min et al., 2019). This multiplicity of goals has caused organizations to invest in older and emergent technologies such as the Internet of Things (IoT), Big Data, Artificial Intelligence (AI), and blockchain so that they can improve the management of their supply chains.

The Covid-19 disruption of global supply chains has caused greater investigation into crises such as natural disasters, wars, and how they can affect supply chain resilience and viability (El Baz & Ruel, 2021; Ruel & El Baz, 2021; Ivanov, 2021). Companies looking for establishing lean supply chains (using single sources and suppliers, for example) are rethinking SC design. SCM continues evolving from needs and changes in markets and technological changes.

Supply chains need to be efficient, responsive, agile, resilient, responsible, innovative, and adaptable, and that digital transformation will require integrated supply chains through new technologies and digital platforms (Min et al., 2019). Meeting these goals is not easy and will only be possible from partnerships and collaboration between supply chain members.

As supply chains constantly change and evolve because of technological advances, customers and markets require major organizational evolution as well. Personnel working across supply chain functions will need to acquire new and improved skills, as their assignments and challenges in managing supply chains change and grow. Despite the robust and diverse body of research, and knowledge about SCM competencies, they are still fragmented and inconclusive, as research and definitions on the subject vary in scope and meaning (Derwik & Hellström, 2017).

Shifting the focus, we recognize that supply chains in emerging markets are more vulnerable and prone to problems. They lack advanced technology, financial stability, adequate strategies, transport infrastructure problems, and poorer efficiency of rail and port services – see Global Competitiveness Report 2019 – (World Economic Forum, 2022) – to name a few pernicious difficulties they face. Understanding the current state of the literature of SCM in Latin America can help understand the issues and propose future directions or developments for Latin American practice and research in SCM.

## 3 Supply Chain Management in Latin America

To analyze the state of the art of SCM practice and research in Latin America, we turn to the research literature. Specifically, we looked into the broad-based Scopus database using the keywords of "supply chain management" and "Latin America," "supply chain management" and "South America," and "supply chain management" and Latin American Country Name (the country names were keywords – see Table 1).

We found 34 published studies. Their contents were evaluated, and we now report some of the findings.

### 3.1 Description of Latin America Supply Chain Management Studies

We first overview the various countries of the Latin American SCM studies, cooperation (Universities and authors), methodologies used, and the industrial sectors of the studies (see Sect. 3.1). Mainly, study results and challenges of these studies are then analyzed (see Sect. 3.2).

## Country

This category identifies the Latin American countries in which the SCM studies have been conducted. According to Fig. 1, 70.59% of the surveys were conducted in Brazil (24), 8.82% in Mexico (3), and 25.88% in Colombia, and other country studies with one study each includes the following: Ecuador, Cuba, Haiti, and Argentina (2.94%). Clearly, Brazil dominates and this makes sense since it is the largest country in Latin America (Fig. 1).

## Cooperation

We now consider author and university participation and cooperation. Only eight (25%) studies had international partnerships. Brazil was again the most represented cooperating country. São Paulo State University (Brazil) is the university investigating this area the most with six (18.75%) publications. Professor Ana Beatriz Lopes de Sousa Jabbour is the author or coauthor of the articles, therefore the most prominent author in Latin America.

## Research Type

The articles were also classified according to the research type (Fig. 2). The intention was to identify which methods are being used the most in Latin America: quantitative, qualitative, quantitative, qualitative (mixed), or others. It was found that

**Fig. 1** Latin American countries in which the SCM studies have been conducted

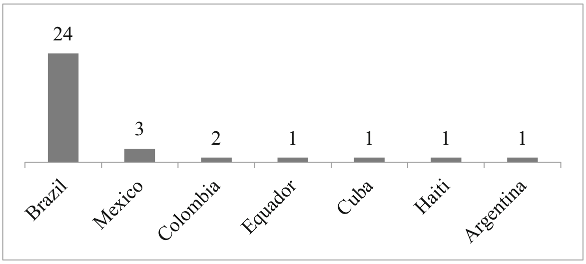

**Fig. 2** Research type

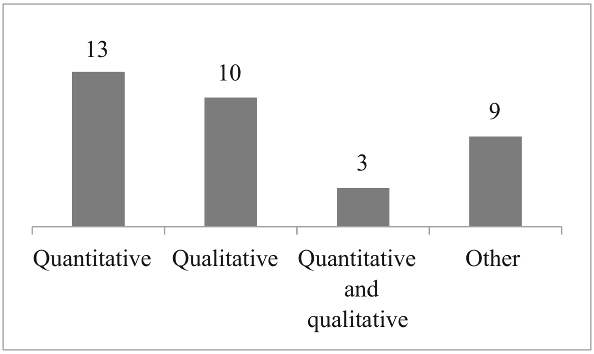
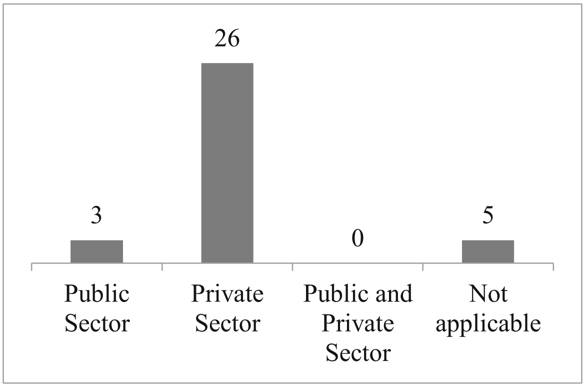


38.23% of these studies used quantitative research, 29.41% employed qualitative research, and only 8.82% used mixed methodologies (quantitative and qualitative).

**Sector**

The 34 articles can be separated into public, private, public, and private (altogether) sectors. They were not applicable when the study was not conducted in a specific sector, e.g., a literature review is also a category. The results indicated that more than half of the studies, 76.47%, were conducted in the private sector, 8.82% public sector, and 14.70% not applicable.



## 3.2 Focus and Main Results of Research

Based on the research methodology adopted, the first article involving SCM in Latin America was published in 1997 by the authors Chiappe and Herrero (1997), and addressed SCM in Argentina's food industry. The main objective of the article was to analyze the drives and trends emerging at the time.

The second study, published in 2011, appeared 14 years later and highlights and reaffirms the importance of supply chain management in the public sector to control current spending. The authors Tridapolli, Fernandes, and Machado (2011) develop a theoretical operational model of supply chain management for the government with an emphasis on government procurement using information technology techniques, process management, and e-commerce and affirm that the management of public spending in Brazil should be addressed to all stages of the supply chain of goods and services, from the survey of needs to the final use. Also in 2011, Machline (2011) developed a conceptual article demonstrating the evolution of concepts from the era of transportation to the era of supply networks, through the era of business logistics and the era of the supply chain.

de Sousa Jabbour et al. (2012) analyzes the level of adoption of SCM practices in the electronics sector in Brazil and identifies the management and information technology actions that have been implemented to support the adoption of these practices. The authors conclude that Enterprise Resources Planning (ERP), workshop with customers, Electronic Data Interchange (EDI), workshop with customers, and the use of electronic kanban are practices commonly used to support SCM practices.

The article is entitled Factors affecting the adoption of green supply chain management practices in Brazil: Empirical evidence by the authors de Sousa Jabbour et al. (2013) identifies and analyzes the factors that affect the adoption of green supply chain management (GSCM) practices in the Brazilian electronics sector. Among their findings, the authors mentioned that the size of the company, its previous experience with environmental management systems, and the use of dangerous inputs are correlated with the adoption of GSCM practices. In addition to this chapter, the article by Jabbour et al. (2013) entitled green supply chain management in local and multinational high-tech companies located in Brazil sought to analyze how GSCM practices are being adopted by high-tech companies in Brazil and identified that the most adopted practices are internal environmental management, investment recovery, and reverse logistics. Additionally, they report that Brazilian environmental legislation and international policies are driving the adoption of GSCM practices.

Studies involving the theme GSCM were further developed in seven more works:

- Da Rosa et al. (2017) conduct a theoretical survey on GSCM in the manufacturing and agriculture sector and affirm that there is a timid advance in the adoption of GSCM practices in the SCM of Brazilian companies.
- Lopes and Pires (2020), based on the most adopted practices of GSCM around the world, conduct a Delphi study and quantitative research with researchers and professionals from the automotive industry in Brazil to evaluate how these practices are understood. In addition, they identify and evaluate which practices are most adopted (e.g., internal environmental management) and least adopted (collaboration, green purchasing, and life cycle analysis), which most influence the environmental performance of companies (collaboration with suppliers).
- Teixeira et al. (2020) conducted a systematic review of the literature on GSCM in Latin America identifying gaps and suggesting future research agenda.
- Govindan et al. (2013) sought to identify the dependency relationship between GSCM practices in the electronics industry sector from Brazil. The findings conclude that the practice of cooperation with customers for the practice of eco-design is driving other GSCM practices in the sector; in addition, they found that the commitment as GSCM of senior managers and cooperation with customers for cleaner production occupy the highest level.
- Jabbour et al. (2014) conducted a study to verify the relationship between the maturity levels of environmental management (EM) and the adoption of GSCM practices in companies in the electronics sector in Brazil. They report that, in fact, the level of maturity of EM influences the adoption of GSCM practices and that there is coevolution between these variables, that is, the further the EM is

developed in the companies, much more complex are the GSCM practices adopted.

- Stefanelli, Jabbour, and Sousa Jabbour (2014) tested the research hypothesis: "can the adoption of GSCM practices improve the environmental performance of companies (micro, small and medium-sized Brazilian companies supplying inputs for the production of sugarcane and ethanol)"? Its results confirm that the proposed relationship is relevant in the companies studied and that GSCM practices are also being adopted to improve operational issues and the security of operations.
- Finally, de Sousa Jabbour and Souza's article (2015) presented the main barriers to the adoption of GSCM practices in companies in the automotive batteries sector installed in Brazil and discussed how these companies are dealing with these barriers. Its main results indicate that internal barriers "organizational values and factors," "human resources," external barriers, and "suppliers and consumers" are the main barriers to the adoption of GSCM.

Sanches and Lima Jr (2014) conducted a study to investigate the hockey stick phenomenon at the end of the sales period at Brazilian branch of a large multinational in the nondurable consumer goods sector. The results showed that the phenomenon impacted negatively to the long-term financial performance, and that there are policies capable to improving financial performance and proposed ideas to carry out the process of change.

Tesfay, Sakita, and Mawrides (2014) use simulated data (lead time, accidents, number of products shipped, and number of defective products after shipment) of a paint company in Brazil in order to discuss the various ways in which it can approach new markets for its products from the point of view of the supply chain, pointing out criteria and factors that should be considered to select a certain type of carrier, discuss key performance indicators (KPIs) when deciding to hire a logistics provider, and point out criteria to be prioritized in the screening of potential suppliers and critical success factors for the company's paint market in Brazil. For this, some dimensions are taken into account: actual size and market potential, growth and profitability of the market. In addition, the authors use indicators of the Panama Channel expansion, growth of the shipbuilding industry, logistics services, and infrastructure.

The next three articles deal with the theme sustainable supply chain management (SSCM). Van Hoof and Thiell (2014) studied 14 focal companies and 177 small- and medium-sized enterprises belonging to the Mexican Sustainable Supply Program (MSSP) with the objective to highlighting the collaboration capacity as a multidimensional organizational construction in cleaner production (CP) initiatives and propose a framework for the operationalization of this collaboration capacity in SSCM. Thus, the study identified that different levels of supplier collaboration capacity are explained by the organizational characteristics and profiles of their managers, that the collaboration capacity contributes to the implementation of cleaner production, and that few suppliers demonstrate coordination routines to involve external stakeholders.

Silva, Fritz, and Nunes' article (2015) brings a literature review on publications of the theme SSCM in Brazil and also applied a questionnaire to experts into the subject. The main objective of the article was to analyze how publications in Brazil are considering the relationship between sustainability and supply chain management. The results indicated that publications have been increasing, that social issues are not the focus of most articles, that the environmental dimension is leading the research on SSCM, and that the focus of publications in Brazil is economic.

The last article published on the theme SSCM deals with solid waste management in the largest Brazilian slum "Rocinha." The authors Azevedo, Scavarda, and Caiado (2019) proposed a framework for solid waste management on the perspective of SSCM in slum areas demonstrating actions supported by SSCM enablers in a real-world, complex, and chaotic scenario.

To develop a simple electronic system capable of managing a pharmacy's supply chain in a hospital in Haiti, Holm, Rudis, and Wilson (2015) propose a collaborative project to build a computerized software system to track the acquisition, storage, distribution, and use of medicines in order to optimize the availability of medicines and reduce their shortage.

Based on the research criteria adopted, Pires (2015) presents the first article that deals with the state of the art of the SCM theme in Brazil. The goal was to present to the public a broad overview of the situation of the SCM disseminating knowledge about fundamental aspects that characterize and influence it. Briefly, the article points out several positive aspects that Brazil has for the success of the SCM, while citing negative aspects that should receive attention that most often are the responsibility of the Brazilian government.

Ruiz-Torres, Mahmoodi, and Ayala-Cruz (2012) present a literature review on SCM in Latin America. Among their main findings, they show that the supply chains of many companies in Latin America have numerous internal vulnerabilities that can make it difficult for them to participate in global markets. Among the main factors, scholars point to economic integration, political risks, social concerns, geographic obstacles, inadequate infrastructure, inefficient logistics networks, and poor relations with suppliers as the region's main challenges.

López-Milán and Pià-Aragonés' academic work (2015) discussed the problem of planning the harvest, transport, and delivery for the management of the sugarcane supply chain in Cuba and proposed a model for optimization incorporated into a decision support system. The idea is to minimize transport costs and ensure the supply of sugarcane.

De Mattos and Laurindo (2016) conducted a study (literature review and cluster analysis) with companies in Brazil to analyze the application of collaborative tools in the supply chain and verify whether managers identified performance improvements in the group of companies that apply them. In fact, the authors conclude that managers of companies with more significant collaborative profile have different perceptions about performance and demonstrate the impact of collaboration technologies on the integration of SCM, and the importance of working on internal and external integration based on information and electronic connectivity for better coordination of processes and activities within and between organizations.

Colin et al. (2016) conducted a survey with managers of 288 Manufacturing SMEs in Mexico to analyze the relationship between information technologies (ITC), strategies, and SCM. The results of this research indicate the following: (i) Strategies and ITCs have an impact on the performance of SCM; (ii) more than one-third of companies (36%) have defensive strategies; (iii) the ITCs impact on the quality control of supplier products and services and on the quality of customer service; and (iv) companies that focus on the development of strategies have important intentions in favor of new developments of opportunities and know how to face important challenges to stay in the market.

Viana and Sousa-Filho (2017) investigated, through multiple case studies in the textile, footwear, and food industries in Brazil, the SCM role in relational competitive advantage. Among the contributions of the article, the authors highlight the application of RBT theory to understand how relationships and CMS may contribute to the relational competitive advantage, and the need to develop relational resources and capacities that are aligned to the competitive positioning of companies and allow the exploration of competitive advantages.

Tanco et al. (2018) carry out a bibliometric analysis with the aim of discussing the contribution of Latin American researchers in the area of SCM. Furthermore, the authors raise, together with Latin American researchers and consultants, what would be the main difficulties that cause the greatest negative impacts in the field of SCM in Latin America. They conclude that there are five main areas that should be the subject of further investigation: SCM for small firms, use of data-driven and emerging technologies to reduce bureaucracy and customs paperwork, establishment of priorities for investment in logistics infrastructure, implementation of innovative solutions for urban logistics and last mile operations, and finally strengthening human capital and needed skills over SC in Latin America.

Roque Júnior, Frederic, and Costa (2019) developed a case study in a Brazilian biotechnology company (molecular biology) with the main purpose of showing the level of maturity and complexity of the SCM and the relationship between them. In addition to establishing the dimensions of the company's SCM maturity, they conclude that there is a clear relationship between the maturity levels of the SCM and its complexity.

Aldana-Bernal and Bernal-Torres' academic work (2019) involved a study from 232 companies of the several sizes, and economic sectors in Colombia with the objective of analyzing the relationship between social capital (SC) and the integration of supply chain management (SCI) processes. The results indicate a significant relationship between CS and SCI, which indicates that soft elements (behavioral factors), and specifically those of social capital, are key factors for the development of organizational functions and for the strengthening of interorganizational integration.

The article by Campos et al. (2019) aims to analyze the competencies of professionals in SCM in the medium supermarket sector in Brazil with the idea of broadening the understanding about the importance and use of skills in business development. For so much, the authors collected data from 60 managers and 34 supermarkets and identified that the ethical and moral posture followed, respectively, by leadership, relationship management, creative problem solving, communication, budget and cost control, and information technology which are considered the most important. In addition, they point out that there is a low use of specific SCM competencies in the sample studied and these companies do not focus on external relations, internally. However, these companies do not put logistics as a business strategy. The authors also suggest that a focus on external relations would require a stronger approach to developing competencies related to ECR (Engineering Change Request), and skills to maintain relationships with suppliers aiming at good demand, inventory, and purchasing management in order to put customer needs ahead of operational concerns.

Peña, Livisaca, and Siguenza-Gusman (2020) lead a systematic review of blockchain literature on food supply chain management in Ecuador demonstrating its main contributions and potential benefits. In their results, they point out that only two works on blockchain were developed in Ecuador, and there is no study (in Ecuador) on the joint use of IoT (Internet of Things) and blockchain technologies, which can harm SCM.

Reis, Minerbo, and Miguel (2021) developed a survey with 239 logistics/SCM professionals to raise the skills required for SCM professionals in Brazil. The authors found eight main competencies in this order: logistics and distribution skills, knowledge in negotiations and purchases, technical and specific expertise, analytical skills, behavioral skills, awareness of business dynamics, expertise in systems and processes, and knowledge about other areas.

Lejarza, Pistikopoulos, and Baldea (2021), in their academic work, based on information on storage and transportation conditions, presented a decision-making framework that mitigates losses in the food chain-balancing stock deterioration, and the energy use to refrigerate all the food which come out from Mexico and are transported to the United States.

Patrucco et al. (2022) analyze how the skills and competencies of SC employees, their external network of relationships, their job satisfaction, and the company's investments in training are related to the results of SC growth. The results indicate that a broad professional network of relationships contributes to increasing the skills and competencies of SC professionals, which, in turn, impact job satisfaction and SC performance, reinforcing the importance of investing in employee training to obtain better competitiveness in SC.

Finally, the last study analyzed, Ferreira and Marques (2022), demonstrates that cultural and infrastructure peculiarities in Brazil create barriers to the collaboration and integration of supply chains, which may be hindering the country's insertion in global supply chains, and require attention of the researchers.

## 4 Discussions About the State of Art Concerning the SCM Subject in Latin America and Recommendations for Further Future Research

Overall, it is clear that few studies exist on SCM in Latin America. This is surprising given that Latin America is composed of 20 countries. Even much more concerning is that from the 34 studies, 24 studies (70.58%) were developed in a single country, Brazil, demonstrating that, in fact, Latin America is outside the global discussion on SCM. Few researchers in Latin America have been interested in the subject which is very harmful to the region – especially given globalization of the supply chain is more critical now.

A large number of publications have occurred between Brazilian authors and universities, including with regard to international partnerships. However, there are still few international partnerships involving authors from Latin American countries and even fewer partnerships when considering authors from Latin America and other parts of the world.

Most studies addressed either quantitative (38.23%) or qualitative (29.41%) research, separately. Few studies have used mixed methodologies, e.g., qualitative and quantitative at the same time. Research using mixed methodologies are important because they can be complementary and important to filling gaps about SCM in Latin America.

Another very interesting point of the research on SCM in Latin America is that only 8.82% of the research was developed in the public sector, that is, the vast majority of studies were developed in the private sector (76.47%). In this context, we recommend more studies are needed in the public sector. Given that only 34 papers on SCM in Latin America were found in one of the most reputable databases worldwide, researchers from Latin America need to devote themselves much more to developing cutting-edge research on SCM (e.g., through partnerships). Some of this can include special issues in flagship supply chain journals on the topic SCM. Special issues/call for papers contemplating SCM in Latin America can greatly increase the number of articles, but understanding the need for these types of studies is critical.

Therefore, according to our results, the research on SCM in Latin America lacks studies, especially with regard to its dissemination in journals indexed to important international databases. This further damages the development of the subject, therefore a great challenge for researchers in the area to change these statistics.

Continuing, Table 2 summarizes the 34 studies (see Sect. 3.2) found in the literature and presents the main challenges highlighted by the authors. In Table 1, we tried to create group studies that had similar subjects to facilitate reading and understanding.

From Table 2, it is observed that there is much to advance. First, almost 40% of the studies deal with the themes GSCM (nine papers) and SSCM (three papers) and only 22 studies address some subject related to SCM. Considering the several decades of development of the SCM theme around the world, it is clear that Latin America is out of the world discussion, and even on more recent topics related to the supply chain (e.g., GSCM and SSCM mentioned above) there is still little research

and most of them have been developed in organizations located in Brazil. We have not found any work that addresses to circular supply chains.

Regarding the challenges for SCM in Latin America, there is a large avenue with numerous intersections to be explored (see some tips in the last column to the right of Table 1), and taking into account the current issues already discussed in the first sections of this chapter, research that explores the following topics in the context of Latin America is mainly suggested:

- Social and environmental demands and their implications for SCM
- Technological changes (e.g., Internet of Things (IoT), Big Data, Artificial Intelligence (AI), and blockchain) and its implications for SCM
- Infrastructure issues and fiscal complexity
- Bureaucracy
- Viability and resilience of SC
- Provide SC professionals with competencies and skills that follow the social, environmental, and technological changes mentioned above
- And, not at least, studies on behavioral skills needed aiming at good relationships to enable better planning, integration, and coordination of SC

## 5 Final Considerations

The main objective of this chapter was to integrate and systematize the literature on SCM in the Latin American context presenting the main research, challenges, and concerns. Furthermore, we propose a future research agenda to guide and encourage cutting-edge research on SCM in Latin America. Studies of this nature categorize what has already been published on the subject and suggest future research agendas capable of guiding academics and professionals interested in work in this field of research (Teixeira et al., 2020). Therefore, the main role of this chapter is to demonstrate the existing research gaps on SCM in Latin America and the main challenges faced for its development, while directing academics, professionals, organizations, and governments to develop work/actions that can prioritize and lap Latin America in the global discussion on SCM.

We hope that this chapter will be able to empower readers with important information about the research gaps in Latin America and the need for further studies on infrastructure issues, market changes, technological changes, and the new skills of SC professionals in the search for better control, integration, planning, and coordination of SCs in order to provide greater value to customers, and competitive advantages for organizations and their supply chains.

# Entrepreneurship in Supply Chain Management

Yiming Zhuang

## Contents

**Abstract**

Research at the interface of supply chain management and entrepreneurship is relatively new and scattered in its focus. However, researchers and practitioners have increasingly been directing their attention to this area. With the aim of capturing these emerging developments, this book chapter focuses on the articles exploring the interface of supply chain management and entrepreneurship. We first present an overview of the current developments in this stream of research to offer a better understanding of the field. Based on the review, we consider multiple directions for future development.

## 1 Introduction

Supply chain management (SCM), as defined by Mentzer et al. (2001), involves multiple functions of a firm. Due to the cross-functional nature of SCM, studies on the interface of SCM and other fields have been quite common in the literature (Ketchen & Giunipero, 2004). For instance, marketing is a domain that is frequently linked to SCM, and the term "demand chain management" has been proposed based on the integration of marketing and SCM (Jüttner et al., 2007). The interface of supply chain issues and finance has recently been studied under the umbrella of supply chain finance (Gelsomino et al., 2016). Firms also commonly adopt information systems to better support their supply chain activities. For example, Jayaram et al. (2000), studies have been conducted on the effects of information system infrastructure on supply chain time performance. The intersection of strategic management and SCM has been explored in the extant literature through the application of strategic management theories, such as the resource-based view, knowledge-based view, and institutional theory (Ketchen & Giunipero, 2004). Consistent with the previous efforts conducted in other fields, we in this chapter take a look at the interface between SCM and entrepreneurship.

Entrepreneurship, in general, is defined as "the process whereby an individual or a group of individuals use organized efforts and means to pursue opportunities to create value and grow by fulfilling wants and needs through innovation and uniqueness, no matter what resources are currently controlled" (Coulter, 2001). The extensive benefits of entrepreneurship create problems that are of interest to researchers from various academic disciplines and fields. Like SCM, the cross-disciplinary nature of entrepreneurship also offers great opportunities to study entrepreneurial phenomena through different lenses. For instance, strategic entrepreneurship brings together unique perspectives from strategic management and entrepreneurship (Ketchen & Craighead, 2020). In addition, the integration of marketing and entrepreneurship has been widely explored in the extant literature (Edwards et al., 2020). Phan and Chambers (2013) have even called for theoretical advancement in entrepreneurship research from the perspective of operations management. Therefore, reviewing the efforts to examine the interface of SCM and entrepreneurship benefits not only the SCM field but also other entrepreneurship fields. Both SCM and entrepreneurship problems are cross-disciplinary in nature and need to be taken into consideration simultaneously in decision-making.

This chapter looks at the interface of entrepreneurship and SCM research in the literature. Scholars have outlined a number of research opportunities at the interface of SCM and entrepreneurship (Ketchen & Craighead, 2020). Specifically, Cortes et al. (2021) recently conducted a review of the usage of entrepreneurial orientation in SCM. Our chapter extends their review by covering additional aspects of entrepreneurship, instead of only focusing on entrepreneurial orientation. In another review on entrepreneurship research, Ireland and Webb (2007) conducted a review including accounting, anthropology, economics, finance, management, marketing, operations management, political science, psychology, and sociology in relation to SCM. This chapter offers a more recent overview of the research on the interface between SCM and entrepreneurship.

After synthesizing the existing research on entrepreneurship in SCM, we propose multiple directions for future research. We believe integrating entrepreneurship-related concepts into SCM can bring novel perspectives to both scholars and practitioners. Both entrepreneurship and SCM are essential components of the economy and have a huge effect on society. This chapter also identifies some managerial implications for managers and policymakers.

Accordingly, the rest of this chapter is structured as follows. We begin with a brief description of SCM and entrepreneurship, followed by a presentation of various areas of SCM related to entrepreneurship. We conclude the paper with a discussion and suggestions for future research.

## 2 Areas of SCM Related to Entrepreneurship

The studies with interface of SCM and entrepreneurship cover the various topics from the upstream to the downstream of the supply chain. To better organize these topics, we cluster reviewed papers into five categories depending on the main focus: strategic issues, upstream management, operational issues, and logistics and transportation. Note that the scope of our chapter considers SCM activities in small and medium enterprises (SMEs) for multiple reasons. First, as stated by Olusegun (2012, p. 487), they argue that "entrepreneurship is a process leading to the creation of SMEs." SMEs are commonly entrepreneurial in nature. Second, this review especially followed the protocol of the study by Olanrewaju et al. (2020), who conducted an extensive review of studies on the interface of social media and entrepreneurship. SME-related terms are included in their review. Third, a substantive proportion of SMEs is start-up companies, which are founded by entrepreneurs to grow into scalable businesses (Katila et al., 2012). Fourth, the research regarding the intersection of entrepreneurship and SCM is at a very early stage. Including SME can expand the scope of this review and cover more relevant studies.

### 2.1 Strategic Issues

This stream of research includes strategic issues regarding the intersection between SCM and entrepreneurship. Strategic issues focus on the supply-chain-related decisions that are strategically important to firms. Multiple strategic issues are discussed below.

## Sustainability in Supply Chains

As suggested by Elkington (1998), organizational sustainability includes three elements: the natural environment, society, and economic performance. Due to the importance of sustainability, it has become a strategic issue in many firms. There are multiple studies included in this stream of research. Studies cover either only one element of sustainability or all three elements. There are studies that focus on environmental sustainability by examining the antecedents of environmental practices (Centobelli et al., 2021) or supply chain ecosystem in startups (Wagner, 2021). In addition, a study has examined the influence of entrepreneurial orientation on firms' adoption of social sustainability supply chain practices (Marshall et al., 2015). Studies further address sustainability as a unified construct. Topics vary from voluntary sustainability initiatives (Peters et al., 2011) to sustainable performance and development (Ndubisi et al., 2021). Relevant studies are summarized in Table 1.

## Supply Chain Finance

Supply chain finance refers to "an approach for two or more organisations in a supply chain, including external service providers, to jointly create value through means of planning, steering, and controlling the flow of financial resources on an inter-organisational level" (Hofmann, 2005, p. 3). Adopting financing options such as supply chain finance becomes a strategic issue to firms (Li et al., 2020). Multiple studies fall into this category by studying the implementations of supply chain finance practices such as reverse factoring (Lekkakos & Serrano, 2016) and buyer-backed purchase order financing (Huang et al., 2018). Work has also been extended to explore the role of financial service providers and banks in helping Chinese SMEs to access finance (Song et al., 2018). Relevant studies are summarized in Table 2.

## Supply Chain Capabilities

Supply chain capabilities are defined as "the ability of an organization to use internal and external resources to facilitate supply chain performance" (Rajaguru & Matanda, 2019, p. 304). Various supply chain capabilities, which are strategically important to firms, are also a topic at the nexus of entrepreneurship and SCM discussed in the reviewed papers. Supply chain capabilities can be intra-organizational and inter-organizational. Multiple studies focus on intra-organizational capabilities such as new product development capability (Bolumole et al., 2015) and SCM implantation (Schulze-Ehlers et al., 2014).

Multiple studies examine inter-organizational capabilities. For instance, Hsu et al. (2011) proposed a new concept of entrepreneurial SCM competence, which refers to an SCM capability of discovering entrepreneurial opportunities to promote firm growth. Entrepreneurial SCM competence encompasses multiple dimensions such as Innovation orientation and relational capital skill. Coopetition and knowledge acquisition have been studied to develop capabilities with distributor firms with entrepreneurial orientation in supply chains (Li et al., 2011). In addition, a new concept of supply chain entrepreneurial embeddedness is proposed, which refers to

large firms' decisions to integrate entrepreneurial business capabilities into supply chains (Ketchen & Craighead, 2021). Relevant studies have been summarized in Table 3.

## Performance Measurement and Management

Multiple studies focus on various types of performance in the supply chain and its measurement. Performance measurement systems play a crucial role in business

operations by providing information to make business decisions (Gunasekaran & Kobu, 2007). Performance measurement systems have been linked to different aspects of entrepreneurship such as in various international contexts (Dung et al., 2020; Pešalj et al., 2018). Terjesen et al. (2016) explored the supply chain actions to increase the new ventures' survival chances in Portugal. Relevant studies have been summarized in Table 4.

#### Partnership Development

Building partnerships is an important and strategic component of SCM. Carnovale and Yeniyurt (2014), Carnovale et al. (2016), and Carnovale et al. (2017) explore the role of various types of network structures in the formation of joint ventures in the supply chain. Relevant studies have been summarized in Table 5.

## 2.2 Upstream Management

There is a stream of studies that focus on firm upstream activities in supply chain management. Multiple topics are included in this category. Three studies focus on the upstream supply chain performance and quality. For instance, Ren et al. (2010) investigated the factors in determining the quality of outsourcing partnerships in China. The antecedent of supplier performance in India is investigated by Mani et al. (2020). Essuman et al. (2021) examined the influence of purchasing recognition on purchasing quality performance. Studies under this category focus on public procurement. Specifically, Loader (2015) analyzed the challenges faced by SME suppliers in public procurement in the UK. Glas and Eßig (2018) examined the determinants of SME supplier success in public procurement in Germany. There are studies that evaluate knowledge acquisition and innovation in upstream of the supply chain. Specifically, studies have focused on the SMEs' collaborative

innovation with suppliers (Benitez et al., 2021). In addition, a study found that external supply knowledge acquisition promotes SME's supply performance in Finland (Kilpi et al., 2018). Additionally, studies have focused on outsourcing in the supply chain. Ren et al. (2011) studied software outsourcing in Chinese SMEs. Bjørgum et al. (2021) examined the sourcing decisions in new ventures in Norway. There are studies that are focused on the new venture suppliers. Zaremba et al. (2016) studied the determinants of new venture suppliers selection. Zaremba et al. (2017) looked at the new venture partnering capability with suppliers in Europe.

## 2.3 Operational Issues

Studies also had a major focus on organizational operational issues. Multiple topics are included in this stream of research. These multiple operational issues include:

### Operational Performance

The topics regarding various types of operational performance have been discussed in the extant literature. For instance, Martínez-Caro and Cegarra-Navarro (2010) and Brazhkin (2018) have studies productivity-based performance. Martínez-Caro and Cegarra-Navarro (2010) found postive impact of e-business on SME's capital productivity in the UK. Brazhkin (2018) assessed the labor productivity in a small warehouse. Other studies examine the various antecedents of operational performance such as operational supply chain risk (Chowdhury et al., 2019), innovation quality (Guo et al., 2020), and entrepreneurship orientation (Dubey et al., 2020). All relevant studies are summarized in Table 7.

### Operational Capabilities

Meanwhile, the literature also focuses on the different types of operational capabilities, which refer to "firm-specific sets of skills, processes, and routines, developed within the operations management system, that are regularly used in solving its problems through configuring its operational resources" (Wu et al., 2010).

**Table 7** Relevant studies on operational performance and linkage to entrepreneurship

| Dubey et al. (2020) | Big data analytics and artificial intelligence pathway to operational performance under the effects of entrepreneurial orientation and environmental dynamism: A study of manufacturing organisations | Dynamic capabilities view; contingency theory | 256 firms in India | Survey | Operational performance |

Specifically, studies investigate the various antecedents and consequences of different operational capabilities. Studies have a focus on the driving factors such as corporate entrepreneurship (Hsu et al., 2014), entrepreneurial orientation (Sahi et al., 2019), and in promoting different operational capabilities, including operations core competency, operational responsiveness, and operational ambidexterity respectively. Other studies explored the performance-related outcomes of different operational capabilities such as manufacturing agility (Ismail et al., 2011), operational responsiveness (Shin et al., 2015), and manufacturing capability (Linder, 2019). In addition, Goodale et al. (2011) explored the moderating effect of operational control in the relationship between corporate entrepreneurial activity and innovation performance. Mittal et al. (2020) proposed a framework for smart manufacturing in SMEs. All relevant studies are summarized in Table 8.

#### Quality Management

Quality management is an important operations topic. Quality management includes practices such as total quality management, Six Sigma, lean production, and ISO 9001. Studies under this category have examined the various practices, antecedents, and consequences of quality management.

The implementation of quality management practices and frameworks has been investigated or proposed in various contexts (Knol et al., 2018, 2019). Studies have also linked quality management to various performances such as firm performance (Kitchot et al., 2021), financial performance (Shashi et al., 2019), and strategic alignment (McAdam et al., 2019).

Meanwhile, three studies take a look at the factors that determine quality management. Agarwal et al. (2013) explored the factors in determining the quality management practices in SMEs in New Zealand. The relationship between ERP systems and lean production has been studied by Powell et al. (2013). All relevant studies are summarized in Table 9.

#### Miscellaneous Topics

Finally, there are two studies focusing on miscellaneous topics related to operational issues. Phan and Chambers (2013) discussed how operations management could advance theory in entrepreneurship. Similarly, Shepherd and Patzelt (2013) proposed a concept of operational entrepreneurship, which aims to advance entrepreneurship from the perspective of operations management. Darby et al. (2021) have focused on production planning and decisions in family business. All relevant studies are summarized in Table 10.

### 2.4 Logistics and Transportation

This stream of research focuses on the downstream supply chain issues related to logistics and transportation. This stream also includes the relevant issues regarding customer relationship management. As compared to another stream of research, there are fewer studies under this category.

Studies have focused on the customer management in downstream of the supply chains in SMEs (Kitchot et al., 2021). Mitręga and Choi (2021) explored how SME transportation firms in Poland manage asymmetric customer relationships when facing the COVID-19 pandemic. Customer involvement, as a type of SCM practice, has been studied for its influence on firm performance among SMEs in Thailand (Kitchot et al., 2021).

Logistics-related partnerships are another topic that has been studied in the literature. It includes different forms of partnership in logistics activities such as joint routing and truck deployment (Zhen et al., 2020) and horizontal logistics alliances (Gao et al., 2017). Multiple types of logistics capability and performance have been addressed, including distribution capabilities (Eng, 2016), logistic responsiveness (Belvedere et al., 2010), and logistics performance (Tuan, 2017). All relevant studies have been summarized in Table 11.

A diagram to summarize the results is presented (Fig. 1).

## 3 Future Directions and Managerial Implications

In the following sections, we outline a few suggestions for future research regarding the interface of SCM and entrepreneurship. These suggestions are based on the above review results and include theoretical and methodological issues. Meanwhile, implications for managers have been discussed.

### 3.1 Relying on and Developing Theories

Based on the review results, it is clear that most studies consistently lack a theory. Theory is used to systematically describe the knowledge in a particular area and to explain the mechanism by which it works. A good theory is able to offer a coherent

explanation for findings derived from empirical analysis while excluding the seemingly plausible relationships that are derived from the data (Flynn et al., 2020). Thus, we encourage scholars to incorporate more theories into their SCM and entrepreneurship interface research.

In addition, both SCM and entrepreneurship have called for the development of domain-specific theories (Flynn et al., 2020; Wiklund et al., 2011). Scholars from these two areas borrow theories from other fields, and this borrowing is supported by the review results. The lack of domain-specific theory could be attributed to the fact that both SCM and entrepreneurship have only recently obtained their legitimacy as disciplines. While borrowing theories from other fields has several advantages, a number of problems may arise since they are not developed for the specific domain context (Flynn et al., 2020). These problems include both theoretical formulations and methodology-related issues. Consequently, future research could consider developing and testing theories tailored to the interface research between SCM and entrepreneurship.

## 3.2 Multilevel Modeling Studies

While most research in the areas of SCM and entrepreneurship use a firm as the unit of analysis, some studies from these two areas also employ an inter-organizational and individual level of analysis. In SCM research, scholars look at the dyadic relationship between buyers and suppliers (Clottey & Benton Jr., 2020) or explore issues such as supply chain integrations across the whole supply chain. Network analysis has been used in SCM research analysis for some time. Entrepreneurship research uses individual entrepreneurs or teams as its unit of analysis. For instance, entrepreneurial passion literature looks at “an entrepreneur’s intense affective state accompanied by cognitive and behavioral manifestations of high personal value" (Chen et al., 2009, p. 199).

Among our reviewed papers, there are multiple studies that introduced the concept of entrepreneurial orientation into SCM research. These studies mostly used the firm-level of entrepreneurial orientation. However, entrepreneurship literature also includes individual- and team-level entrepreneurial orientation (Covin et al., 2020). Research concerning the interface between SCM and entrepreneurship involves phenomena that are multilevel in nature. For example, its founders' entrepreneurial passion could influence a firm's overall supply chain and operational performance. Using a multilevel modeling approach could better explain the mechanism regarding the interactions between SCM and entrepreneurship.

From a manager's perspective, it is essential to look at the relationship between entrepreneurship and SCM at different levels (i.e., strategic, tactical, and operational levels). At the strategic level, managers can look at the role of firms' strategic mission and vision in the interactions between entrepreneurship and SCM. At the tactical level, managers can focus on how each business unit within the firm impacts entrepreneurship and SCM. At the operational level, managers can spotlight the role of individuals such as an employee in affecting entrepreneurship and SCM.

## 3.3 Novel Data Sources and Analysis Methods

Based on the review results, the survey method predominates in the extant literature. This could be due to several reasons. First, since most samples are SMEs, it isn't easy to find archival databases that include relevant information. Second, many constructs in SCM and entrepreneurship – such as SCM performance and entrepreneurial orientation – are more easily captured using surveys. However, survey studies have multiple limitations. For instance, the self-administered survey is subject to a low response rate, which makes it more difficult for the results to be generalized (Coughlan et al., 2009).

Appropriate sample selection could be another issue that needs to be seriously addressed. In addition, while single respondent bias and social desirability bias could be reduced using specific methods, they could not be eliminated entirely. Also, survey measures are based on the respondents' subjective perceptions, thus increasing the likelihood of bias. For instance, most studies reviewed in our sample used respondent survey answers to measure SCM performance, operational performance, and firm performance. This method may not reflect the actual performance of the firms.

Alternatively, future research could look for archival data sources related to entrepreneurship and SCM. For instance, immigrant entrepreneurship has gained more attention over the past decades (Dheer, 2018). Relating to SCM research, future studies could explore whether immigrant entrepreneurs are more likely to choose international sourcing. Similarly, because they are more aware of uncertainties in the global supply chain and have more international experience, firms with immigrant entrepreneurs are less likely to be subject to supply chain disruptions.

Researchers could obtain data from platforms like crunchbase.com concerning the backgrounds of entrepreneurs in start-up and young firms. In addition, future studies could use data crawling and scraping methods to retrieve unique data. Massimino (2016) discussed the techniques of web-crawling and information-scraping in SCM research, while Hain and Jurowetzki (2020) considered data crawling in entrepreneurship research. However, scholars should pay attention to the ethical and confidential issues involved in data crawling and scraping. Some journals require that a letter of data authorization be included with manuscript submissions.

Since most studies in the extant literature rely on surveys to collect data, the methods used for data analysis are limited to structural equation modeling and regression analysis. Multiple novel analysis methods are featured among the reviewed papers. For instance, Sabahi and Parast (2020) used multiple machine learning algorithms (i.e., lasso, ridge, support vector machines, neural networks, and random forest) to investigate the relationship between an individual's entrepreneurial orientation and project performance. These novel methods offer unique perspectives that have not been observed using conventional methods. Accordingly, there are several methods that could potentially be used in the interface research between SCM and entrepreneurship. For instance, future research could use facial recognition techniques (Choudhury et al., 2019) to analyze the CEO personality in SMEs, which in turn affects firm SCM activities.

## 3.4 The Impact of the Pandemic

The COVID-19 pandemic has created unprecedented effects on businesses (Sarkar & Clegg, 2021). Supply chain crises have demonstrated firms' lack of resiliency in their supply chains (Ivanov & Dolgui, 2020). The impact of the pandemic has caused even more difficulties for SMEs. For instance, based on the large-scale survey collected by the National Defense Industry Association, Melnyk et al. (2021) found that the weakest suppliers in the early stages of the pandemic were the very small SMEs. Moreover, the authors found that most government measures and initiatives are not effective in helping these suppliers. Future research could investigate how firms responded to the outbreak of the pandemic regarding their supply chain functions.

An interesting industry to explore is the farm industry, which is an important economic sector the world over (Timmer, 1992). Among the reviewed papers, a few address the SCM issues in the SEMs and family businesses of the farm industry (Darby et al., 2021). Most firms in the farm industry are either SEMs or family businesses. Due to limited resources and technology, these farms are struggling to survive, a situation worsened by the COVID-19 pandemic. Future research should focus more on identifying SCM solutions for these farms during the pandemic.

From the perspective of managers, firms have faced unprecedented challenges during the pandemic. The disruption of the supply chain due to the pandemic led to a huge impact on firms' operations. Therefore, managers need to proactively approach to designing a robust supply chain network to mitigate the risk of unexpected events like the pandemic. In addition, managers need to also pay attention to the effects of post-pandemic challenges. Some firms have re-design the supply chain network due to the pandemic, and therefore it is important to closely monitor the influence due to these changes.

### 3.5 Cross-Disciplinary Perspectives

While the interface research between SCM and entrepreneurship is cross-disciplinary in nature, scholars could take an even broader view by also looking at the problems that interact with other disciplines. For instance, future studies could explore the influence of the characteristics and personalities of CEOs and top management on SCM-related outcomes in SMEs. Although CEO characteristics and personalities are common topics of studies in the field of strategic management, SCM areas have been neglected. The roles of CEOs and top management are even more important in SMEs than in larger firms because they have more power and control over the firms.

The research connecting marketing concepts to SCM and entrepreneurship is well-established in the extant literature. However, few studies integrate the concepts from these three fields simultaneously. In small firms, SCM and the marketing department always work closely. In some cases, the marketing department takes charge of SCM activities. Thus, it is particularly important to determine how to achieve a cohesive relationship between SCM and the marketing function.

In the area of information systems, researchers could look at the role of social media (e.g., Facebook, Instagram, Twitter, and TikTok) in the interface between SCM and entrepreneurship. Some studies have looked at the interface between social media and SCM (Huang et al., 2020). Some exemplary topics demand forecasting and new product development based on social media mining, supplier management with the help social media, and customer communication in product return and recall on social media (Huang et al., 2020). Similarly, there are studies examining the interaction between social media and entrepreneurship (Olanrewaju et al., 2020). The openness and connectivity of social media overcome entrepreneurs' incompetence or difficulty in identifying and seeking expert opinions and guidance (Kuhn et al., 2016). For example, young firms could advertise their products and brands on social media platforms at a lower cost (Brink, 2017). However, research concerning the interface of entrepreneurship, SCM, and social media is rare in the literature. Future studies could take a look at how SMEs or young firms can use social media to better manage their supply chain activities.

From a practical point of view, managing social media in order to build a positive firm image is crucial for firms. Firms share information regarding how they take the responsibility of protecting the environment by reducing carbon emissions in supply chains on social media platforms such as Twitter. For instance, Walmart has regularly addressed its solutions to climate change on its Twitter account.

### 3.6 Interface of Global SCM and International Entrepreneurship

A firm's supply chain commonly involves international activities, such as global sourcing and purchasing, and the customers of the firm may be dispersed all over the world. A firm's manufacturing plants could be built overseas to leverage local resources. Tesla is a typical example. Tesla has suppliers and customers from different countries and has manufacturing plants all over the world, in places such as Germany and Shanghai. A firm's SCM, in the global context, faces a greater variety of uncertainties. Similarly, international entrepreneurship, defined as "the discovery, enactment, evaluation, and exploitation of opportunities—across national borders—to create future goods and services" (Oviatt & McDougall, 2005, p. 540), also positions entrepreneurship in a global context. Both global SCM and international entrepreneurship focus on the firm's activities in the global context. Future research could focus on the problems that are related to the interface. For instance, scholars could explore how young firms build their local supply chain networks when they penetrate into new foreign markets. NIO, a young Chinese automobile manufacturer, entered its first overseas auto market – Norway – in 2021 and plans to deliver 20 battery swap stations by the end of 2022. Future research could investigate how these young firms manage their supply chains when entering new overseas markets.

From a practical point of view, globalization in the past few decades has created numerous opportunities for supply chain practitioners and entrepreneurs. Firms rely on global sourcing to reduce costs and search for components and materials of the best quality. It increases the demand for people who have international backgrounds. Entrepreneurs in the start-ups can also seize the opportunities to expand their international business. Platforms such as AliExpress help these start-ups reach out to the international markets and provide support for logistics activities.

### 3.7 Government, Policy, and Regulation

The government plays an important role in both SCM and entrepreneurship by implementing policies and enforcing regulations due to their important position in the economy. However, studies that have examined the role of government are fragmented when it comes to addressing both SCM and entrepreneurship research. Government forms the institutional environment in which business is conducted. Both a firm's supply chain and entrepreneurship activities are profoundly influenced by the institutional environment, as well as policies and regulations. SCM scholars have called for research at the intersection of SCM and government regulation and public policy (Fugate et al., 2019). Consequently, future studies could explore how SCM and entrepreneurship have been influenced by the government. For instance, President Biden's bipartisan infrastructure law, with its focus on investment in the nation's infrastructure and competitiveness, has had a huge impact on logistics and entrepreneurship. Future studies could specifically examine government influence in the long run.

## 4 Summary and Conclusion

Our review synthesizes existing research on entrepreneurship in SCM based on selected papers. Specifically, we summarized the topics into four categories: strategic issues, upstream management, operational issues, and logistics and transportation. This review serves as a foundation for researchers and practitioners to explore more opportunities in the study of the role of entrepreneurship in SCM research. We argue that there exist various research and practical opportunities for integrating entrepreneurship concepts into SCM. We have also outlined various directions for future researchers to explore and multiple implications for practitioners.

# Gender Diversity for Supply Chain Sustainability

## Challenges and Opportunities

## Contents

**Abstract**

The study of gender diversity in supply chain management (SCM) has been overlooked in the literature and still remains a marginal subject for most companies even though it is part of the Sustainable Development Goals from the United Nations. Nevertheless, this chapter provides an overview of the scientific literature on the subject within three frames: from the careers of women in SCM, analyzing the expected benefits of true diversity management in SCM, and to the issue of women and transgender "victims" approach linked to supply chain

activities. This overview leads us to ratify the importance of debating gender diversity as a vital issue towards sustainability. Examples of companies' initiatives and other representative organizations are presented as illustrations of these frames. All the elements presented allow us to draw up managerial implications on the benefits companies could gain from an increased gender diversity and how to get there. Finally, avenues for future research are presented to foster the subject.

## 1 Introduction

In 2015, the United Nations created the 2030 Agenda for Sustainable Development, represented by the 17 Sustainable Development Goals (SDG). The fifth SDG refers to achieving gender equality and empowering all women and girls. According to the World Health Organization,[1] *"The word gender is used to describe the characteristics, roles and responsibilities of women and men, boys and girls, which are socially constructed. Gender is related to how we are perceived and expected to think and act as women and men because of the way society is organized, not because of our biological differences."* Thus, this chapter aims at showing how gender diversity has been discussed and practiced in supply chain management (SCM).

Gender diversity is about the fair representation of different genders within a particular context and is often measured through ratios of men and women, for instance, within a company. However, gender diversity includes many other nuances that need to start being recognized in the SCM field (Ozar, 2006). For example, Paiva et al. (2020) highlight the inclusion of self-identified transgender people as a relevant group often marginalized in society, which is addressed in this chapter. In this chapter, we refer only to women and men expressions since they cover both cisgenders and transgenders; however, we understand the existence of nonbinary people who are not part of our current debate due to its exploratory phase. Therefore, we acknowledge that greater woman representation in a male-dominated context such as supply chains (Zinn et al., 2018) alone cannot impact gendered organizational practices (Grosser & Moon, 2019). Further factors are to be taken into account such as institutions, culture, and socioeconomic context for sustainability, which we will touch upon through specific examples of gender diversity in supply chains.

This chapter is structured in four main parts: (1) a background of research on gender diversity and supply chain management. We present here general information on what has been published on the subject; (2) the current concerns such as the victimization approach (Jeffrey, 2005) related to gender diversity. By presenting both the deliberated and the taken-for-granted perspective of victimization, we argue

how challenging it is to stop thinking as solving current problems and instead to start looking for new solutions; (3) the emergent concerns as how to analyze women as change-makers overcoming the victimization approach; and (4) we explore conclusions by providing a research agenda for future research on the topic and implications for managers. More than focusing on what has been done, this chapter goes a step forward to demonstrate that supply chain sustainability is only possible when gender challenges are addressed and opportunities taken as part of SCM and procurement departments' daily operations.

## 2 Background

Historically, SCM is a function where men as professionals are in a majority, since the logistics professions – transport and storage – are male-dominated. Although the trend for more women working in the field is increasing (from 37% women employees in 2018 to 41% in 2021), few women have top management positions (between 11% and 17%) (Gartner, 2021). So, it is important to understand the *ins* and *outs* of this situation to help companies solve this imbalanced situation.

However, the literature on gender in supply chains is scarce. Some research on different academic databases (i.e., Ebsco, Emerald, and Science direct) with the string "gender" AND "supply chain" returns very few relevant articles. The first studies were published in transport-oriented journals, then in management-oriented or business ethics-oriented journals. Recently, Zinn et al. (2018) confirm and call for research in this area as they notice that the topic is under-researched, while Yawar and Seuring (2017) show that gender is one of the main social issues in supply chains. Figure 1 provides a snapshot of research trends over the years (1995–nowadays).

**1995–2001** – The first studies date from the 1990s. They focused on transportation and career. André (1995) compared career status among genders. She found that women within the SCM function are younger than men and that women held less top management positions than men. Lynagh et al. (1996) and Knemeyer et al. (1999) concluded identically and added that their average salary is lower. Lynagh et al. (1999) offered an explanation for this result. They explained that women have reservations about careers in SCM and that education is one of the keys to make a difference.

**2002–2008** – Ten years later, researchers focused on the practices in the purchasing and transportation sectors to better understand these phenomena. Prieto Carron (2008) highlighted that no gender discrimination means equal pay and fair treatment. So it is crucial to identify what are the contributors to equity.

1. Larson and Morris (2008) confirmed the previous research on the impact of education. Education is the first lever for equity. In the supply chain, women are often at the lowest position. To access higher positions, women need to access higher education. At the same time, managers with a C.P.P earn over 13 k$ more

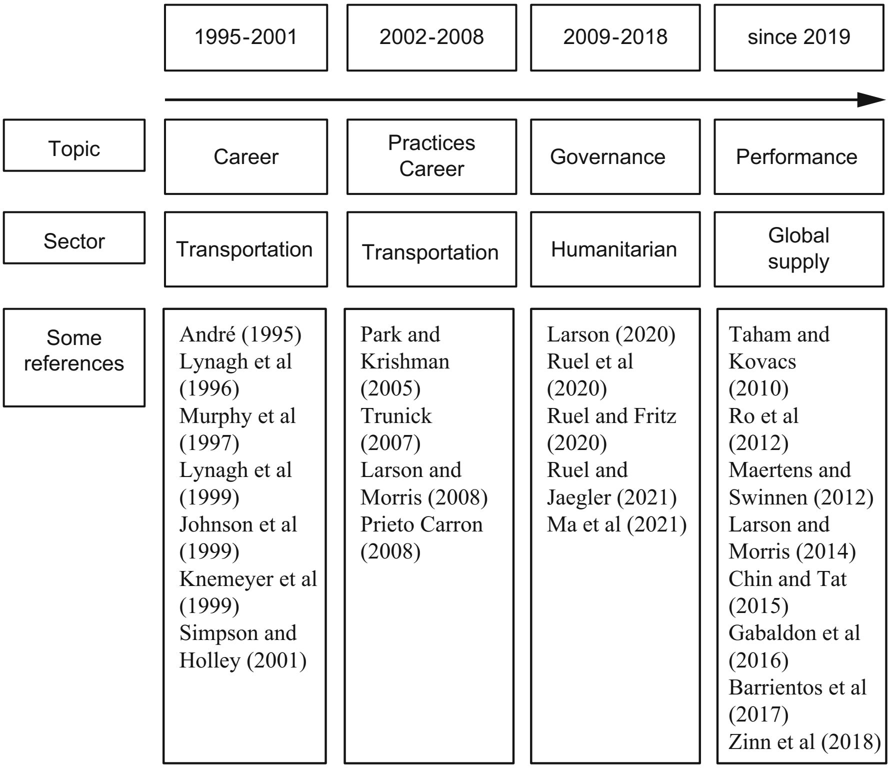

**Fig. 1** Research trends on gender in SCM. (Source: the authors)

than managers without. Educated women will gain twice: higher positions and higher salaries.

2. A second lever is to consider the division of labor at home as Trunick (2007) explained the gender differences by the work-family conflicts. Women are *de facto* out of the network, because they are more often in charge of the family and therefore do not have time for after work drinks. Moreover, for the same reason, they often travel less, and refuse or are refused jobs that require them to travel.
3. A third one is the image of the profession (Trunick, 2007). SCM is seen as a difficult function, with long working hours, travel, and high pressure, which women identify as incompatible with their personal life and feel that it is not a good fit for them. A glaring example is in the textile supply chains. In this sector, Burchielli et al. (2009) indicated that homeworkers are mainly women. Homeworkers are in precarious situations with weaker social protections. Thus, when women work in the supply chain, they not only do not reach top management but they are also the most numerous in precarious positions.

To increase equity, these contributors have to be activated as numerous research studies show the positive impact of women at different levels. Women can be part of the SCM and procurement departments and thus take part in the decisions. Nevertheless, some of them are already "at the helm" of international supply chains, and the share of women managers/directors is gradually (though slowly) increasing. Yet, the impacts of gender diversity on boards of directors can be spotted in the literature: on climate change (Galbreath, 2010; Ben-Amar et al., 2017) and on moral duties of boards (Flynn & Adams, 2004). Moreover, with regards to supplier selection, it appears that there are significant differences in the way women and men select suppliers and evaluate them afterwards. Park and Krishnan (2005) show that women supply chain managers have a greater focus on the long-term future of their suppliers and on workplace safety issues at suppliers, while men supply chain managers are more likely to look primarily at the economic performance of suppliers.

This research is indicative of a more sustainable, time-based view of women as decision makers in the supply chain. While this result may seem surprising at first, it is easily explained by women's ability to collect and process information while using their emotional intelligence to interpret it (Thayer & Johnsen, 2000). Second, these findings confirm the preliminary results from Park and Krishnan (2005) about supplier selection practices by pointing out that women will better look at and include social aspects in the selection process. Overall, this research retains the determining impact of gender diversity in the SCM function on the social pillar of sustainability that is usually understudied (Seuring & Müller, 2008; Ruel & Fritz, 2021). Thus, the presence of women acts on sustainability: they are change-makers.

**2009–2018** – Tallontire et al. (2005) confirmed the previous research and that most marginalized supply chain workers are women. Taham and Kovacs (2010) showed that the humanitarian logistic exacerbates these phenomena. The research also highlighted the fact that women face a glass ceiling – it is more difficult for them to access managerial and executive positions (Lawrence et al., 2018).

However, research goes even further by looking at governance, performance, and compliance in more diverse sectors than before. In the field of corporate governance, the research of Dawar and Singh (2016) has pointed out that when women are part of the board of directors, they influence decision-making for sustainability as it appears that gender diversity at the supply chain managerial level would bring more empathy and listening skills which are necessary to improve the social sustainability in the supply chain, which has long been undermined (Yawar & Seuring, 2017; Ashby et al., 2012; Benoît et al., 2010). More women on board has a positive impact on the environmental and sustainability management of the company (Post et al., 2011; Bernardi & Treadgill, 2011; Harjoto et al., 2015). In the same line, a gender diverse board composition is positively influencing the sustainability ratings of the company (Bear et al., 2010). Other positive impacts of board gender diversity can be spotted in the literature: on climate change (Galbreath, 2010; Ben-Amar et al., 2017), on the quality of sustainability reporting (Al-Shaer & Zaman, 2016), or on environmental sustainability (Kassinis et al., 2016) and workplace, social, and economic sustainability (Zahid et al., 2020).

Focusing on specific sectors, some research highlights other positive impacts. With regards to violations reporting in the supply chain, Short et al. (2016) highlight that in the field of supply chain auditing, having more women is crucial. Indeed, the audit team's gender composition impacts the capacity of the team to detect and report violations. They show that the most efficient teams are the ones based only on women or which are mixed-gendered.

Gender bias in the buyer-supplier relationship has also been found to exist (Ro et al., 2012), which argues for diversity as women are more collaborative in both ways – as suppliers or buyers. Finally, research has shown that women are more likely to adhere to and follow rules than men (Portillo & DeHart-Davis, 2009). Additionally, in line with Short et al. (2016), women in the supply chain pay more attention to rules, especially quality, health, safety, and environment (QHSE) rules, which is an essential aspect of supply chain sustainability (Ruel & Fritz, 2021).

In entrepreneurship, women-owned family businesses show both more innovation and sustainability (Gundry et al., 2014). One should note that the contribution of gender diversity to supply chain sustainability is indeed not limited to multinational company actions but also to micro, small, and medium enterprises (MSMEs). The UN (2020) report shows multiple ways of contribution from MSMEs to the SDG number 5 – gender equality – which is aligned with the change-maker perspective. For example, this report mentions that a significant proportion of MSMEs are owned by women and that MSMEs employ many women. With this finding in mind, it is understood that a gender balance is possible within supply chains when thinking of the power to promote sustainability (UN, 2020). Women employees and leaders are key to reaching supply chain sustainability.

**2019–2021** – Some recent research reinforces previous works or introduces new perspectives. One study shows fewer women are in SCM master degree programs (Ruel & Jaegler, 2021) and with women still experiencing slower career progression, which is problematic since gender inequality generates lower performance (see Larson, 2020; Ma et al., 2021).

In SCM, as shown, the issue is therefore very recent and totally emerging. Since research about the impact of women on sustainable decision-making in supply chains is in its infancy (Ruel et al., 2020; Ruel & Fritz, 2021), it seems necessary to look in other areas at how they appear to contribute to sustainability. In R&D, including more women, also leads to more innovations that are effective in the fight against global warming (Le Loarne-Lemaire et al., 2021). In the end, if in other functions of the company a better gender distribution leads to an improvement in decision-making in favor of sustainability, it seems relevant to question whether such an analogy is possible in SCM.

Very little work in SCM exists indicating how more gender diversity improves decision-making for sustainability, or even sustainable performance (Ruel et al., 2020; Ruel & Fritz, 2021). Ruel and Fritz (2021) further highlight such conclusions based on qualitative research with supply chain consultants and managers. They show that women in the supply chain bring soft skills that support more social sustainability in management (empathy) and operations (responsible supplier selection, procurement practices). Ruel and Fritz (2021) also show that women in SCM are more rules-compliant which makes it possible to advance on sustainability issues at the workplace, especially for the most operational tasks within the warehouses.

In the supplier selection process, women pay more attention to social considerations, e.g., well-being at work, equal treatment of employees, workplace atmosphere. Thus, gender diversity supports higher sustainability performance in terms of health and safety, the respect of rules and social relations (Amorelli & García-Sánchez, 2021). Ma et al. (2021) find that both men and women are more collaborative when paired with women and that the supply chain is more efficient when there are female buyer-supplier pairings.

The research over the past couple decades has seen a number of concerns and issues related to gender specific supply chain management concerns. Yet, much of this research and these findings cannot fill the many gaps that remain. Some of these current gaps and requirements are now identified.

## 3 Current Concerns

Despite the previously presented growth, the literature on gender diversity in SCM is more focused on reporting a few existing initiatives than developing insights on how to move forward. For instance, why are women, in most research studies, considered victims? In this section, it is argued that this situation occurs because of deliberated or taken-for-granted reasons.

First, there is a movement to deliberately put genders that are not cisgender-male as victims (HRC, 2021; UN, 2021). This happens because of the existence of a male hierarchy or homophily, especially in SCM. Second, there are local cultural elements that take-for-granted such victimization. This is related to a historical sequence of events in which the society already accepts that only purely male genders are stronger and powerful enough to develop some actions and take decisions in many areas, including in SCM. We explore these elements along this section.

## 4 Deliberate Victimization

One of the main issues related to social sustainability addresses the need for social justice and equal treatment in society with changes in behaviors (Vallance et al., 2011). However, there are multiple contrary actions to reach this perspective, which directly covers gender diversity. For example, Paiva et al. (2020) highlight the existence of gender inequality in SCM based on three main issues: (1) low participation of women-owned business in supply; (2) wage inequality along the supply chain; and (3) gender-related modern slavery or forced labor throughout multiple tiers. These issues seem to demonstrate that in one way or another gender diversity is deliberately avoided based on few beliefs and decisions. In this context, there is a trend to understand women as victims of the system, which needs to be challenged (Ruel et al. 2020). Based on this reflection, studies need to increase interest on gender diversity in SCM; however, at the same time, they also need to question and overcome this victim approach. More than studying and defining gender diversity through victimization, it is necessary to understand the existing potential within diversity.

The deliberate approach assumes that gender diversity should be something not expected or necessary since the industry is centrally dominated by males (Zinn et al., 2018), which makes it difficult to overcome the victim approach. For example, Lawrence et al. (2018) claimed that women procurement professionals suffer with underrepresentation because of the existence of homophily, which is the tendency to have a bias against those that do not belong to your group when recruiting and promoting (Smith et al., 2012). Homophily also refers to the tendency to engage more with those who share a mindset, which is easier inside the male-dominated perspective (Smith et al., 2012).

Homophily in SCM exists at a significant level. For example, Johnson et al. (1999) expressed the necessity for many companies to insist that existing managers (mainly men) recruit more women; otherwise, they did not pay attention to recruiting women. Despite this recognition, often it is through the recognition of victim conditions that bring new reflections on the subject. It is not an easy task to overcome this approach because there are some embedded issues that make no male identification being affected by behavioral and cultural issues.

## 5 Taken-for-Granted Victimization

The existing victimization approach refers to a constant identification and reporting of issues and examples that make gender diversity more related to a challenge than an opportunity in supporting SCM and supply chain sustainability. Most studies assume that gender diversity should be analyzed with the same lens for different countries and industries, which is not possible. For example, when focusing on corporate governance (Ruel et al., 2020), many studies have shown that the number of women in the board of directors is positive in Europe or in the USA; however, the opposite occurs when it refers to Latin American countries (Husted & Sousa-Filho, 2019). Two main reasons exist for this difference: (1) because the small number of women (i.e., maximum three per company), a lack of critical mass exists since they usually are unable to join deliberations effectively and (2) the cultural setting of Latin America does not work in favor of supporting women as part of a board of directors (Husted & Sousa-Filho, 2019).

These issues represent the taken-for-granted victimization since they are institutionalized and are usually accepted without further questions. This is an example of the need to understand gender diversity based on singular characteristics of each SCM context, whether it is industry based, product based, or regionally based contingencies.

When considering specific industrial sectors, a victim-approach is also taken in some specific areas such as the informal mining sector, as studied by Fritz (2017). In this research, it is highlighted that informal mining is taking place for a variety of minerals in developing countries, mainly on the African, Latin American, or Asian continents. It is taking place in countries where other activities do not allow to earn such a good living as with mining, often referred to as the "vicious circle of poverty" (Fritz, 2017). Informal mining, contrary to large-scale mining, consists of activities led by small groups of miners and their community, often including women and children. Women often work in mining to support the schooling of their children (when possible) and provide their families with basic needs (Fritz, 2017). They participate mostly in cleaning and crushing minerals extracted by men, or in cooking and selling food on mining sites, and in some cases, they also prostitute themselves. Women thus appear as victims of men-led activities. But, it is not so simple. Culture plays an important role and women as miners are sometimes not accepted due to cultural beliefs (Fritz, 2017).

Nongovernmental organizational (NGO) programs used to exclude women from training on mining because of the taken-for-granted victimization, thus perpetuating this exclusion of women from the more lucrative mining activity. This situation is one example among many others that reinforces the need to consider country, culture, and sector specificities when addressing gender diversity in SCM.

Amidst the existent examples globally, we found two very representative company initiatives – L'Oreal and Schneider Electric – demonstrating the uniqueness of a region, even though it is still based on a taken-for-granted victims approach. As previously mentioned, we are still experiencing the need to rise above this issue in research and understanding, thus the more examples highlighted, the more we advance to see gender diversity as an opportunity for supply chain sustainability.

First, consider the sourcing program of L'Oreal – a multinational cosmetics company – which is interested in contributing to social inclusion worldwide. Among their multiple projects, various regions can address a different marginalized group. An important and key project exists in Mexico to ensure gender diversity to overcome their victim situation. The program consists in stimulating suppliers in Mexico to hire single mothers, who are marginalized in this marketplace. Second is the example of Schneider Electric, a multinational electric company, which develops engaging actions toward gender diversity in Brazil. They developed a program to ensure equal opportunities to include transgender individuals as employees, but also with some partners locally. This issue is key, because Brazil is the country with the largest number of deaths of transgender people in the world because of prejudice. Both examples support gender diversity, while seeking to reduce this victimization approach. It is necessary that further actions are taken beyond the need to solve a problem, such as considering these people as change-makers in SCM, that deserve further attention and opportunities.

## 6 Emergent Concerns, Outstanding Research, and Future Directions

The research and current knowledge in this area offers an initial stepping-stone to avenues for improving diversity within the supply chain. Gender diversity in SCM has often been observed in research under the prism of victims. This perspective is especially true in emerging countries, where large companies exploiting – sometimes in a very inequitable way – both natural and human resources. Research needs to move away from a victimization emphasis to reinforce the potential of diversity as an agent of change.

In previous subsections, we have seen facts, figures, and hints that highlight that more gender diversity in SCM could make supply chains more sustainable. Increasing such opportunities can take two forms: either gender diversity in supply chains is supported by some external stakeholders and organizations through initiatives that can be considered as positive discrimination, or gender diversity is put in place by women themselves which we refer to as "change-makers" with a proactive approach.

## 7 Positive Discrimination and Representative Organizations

As shown several years ago, one of the key factors to increase sustainability in supply chains is the legal framework (Seuring & Müller, 2008). By acting on laws, governments can force companies to increase gender diversity with a binding quota on women. So far, such laws have not focused on SCM, but on boards of directors in general. Several countries have opted for this solution to increase gender diversity among top management (e.g., France, Italy, Germany) but limited research has investigated the impact of such quotas on the short and long term, except in Norway (Smith, 2018). Studies on the Norwegian case are not very conclusive so far as there is a need for "diffusion" of gender diversity impacts in companies, which takes time (Smith, 2018).

It is believed that quotas set by politicians may not be the most effective way to increase gender diversity: *"politicians might have to change the focus from quotas at the top of the organization to the much broader task of getting a more equal gender division of careers within the family. This might be achieved through gender-neutral family policies and quotas for fathers in parental leave schemes"* (Smith, 2018, p.9).

Indeed, bringing more gender diversity through binding quotas accompanied by sanctions or fines in case of noncompliance allows reaching a higher number of women in top positions. But, these changes should not be only a question of numbers, instead impacts on firm and supply chain performance should be assessed and the wider socioeconomic environment should be studied. Voluntary and bottom-up initiatives have also been successful in some cases (ILO, 2021). However, what is highlighted in the "quota debate" is the essential need for managers and politicians to engage in a dialogue in order to ensure a sufficient number of women are trained and qualified to access top management positions, according to company needs (ILO, 2021). Furthermore, companies need to create the right conditions to attract more women in the workplace in sectors and firms where they are underrepresented compared to their male counterparts (ILO, 2021). Again, in such sources, it is a question of men versus women, which would benefit from being extended to other genders as well.

Other approaches exist to increase gender diversity such as women training and empowerment. For instance, in the mining sector, a male-dominated sector, the International Women in Mining organization works on the topic and highlights that more women in the sector will *"improve diversity, governance and sustainability"* (WIM, 2021). Through their work, they underline four key lessons as put by Gillian Davidson, Chair of the Board of Directors of International Women in Mining

(IWiM) and leading sustainability, corporate social responsibility, and responsible supply chains specialist.

First, "*Women in Mining (WIM) organisations have an important role to play. Women get support through the WIM organisation to have their voices heard at a national or regional level to obtain the support they need.*" Second, *"The gender agenda needs global alliances,"* which WIM works on by representing women in mining and developing partnerships at a global level to enhance gender equality. Third, *"Data is a challenge."* There is a lack of experience-sharing among women and a lack of data from companies, governments, and associations to better understand the challenges around gender diversity in the sector and to develop better practices. Such data is necessary to reinforce WIM activities and develop more factual arguments in favor of gender diversity.

Fourth, *"We all have a role to play,"* which enhances all men and women's efforts to increase gender diversity and equality have their importance, whether men or women, employer/employee, colleague, individual or else. Actions such as mentoring women, debates on policy improvements in companies, participation or development of surveys can support the creation of knowledge and awareness raising on the topic, that are the baseline for necessary changes (IWIM, 2021). Such key lessons are worth being emphasized in this chapter since the recommendations made for this sector also apply to a variety of other sectors and to the wider supply chain field, especially regarding the lack of data and research on gender diversity, echoing Zinn et al. (2018).

Some organizations specifically focus on empowering women leadership in supply chains such as the "Achieving Women's Excellence in Supply Chain Operations, Management & Education" (AWESOME).[2] This organization created in 2013 groups about 1500 women in senior SCM positions to share their knowledge and expertise, as well as conduct several actions for encouraging women in following higher education programs in SCM. However, there is limited information provided on the benefits of such activities within supply chains and for supply chain sustainability. Such observation highlights the need for more industry organizations to become involved in these activities. Professional SC associations such as the Association for Supply Chain Management (ASCM)[3] and industrial associations could take a proactive stance and may want to focus their efforts on promoting gender diversity. Their engagement in this direction may change institutions and norms to change the common view of women as victims or as unable to perform a SC-related management job. By communicating on such engagement and the related benefits, industries as a whole may adopt mimetic approaches that will set new norms and facilitate an increased gender diversity in SC management functions.

## 8 "Self-Made Women" as Change-Makers for Sustainability in Supply Chains

A recent study has shown that women leaders in the workplace tend to stimulate change and social inclusion, especially following the COVID-19 pandemic (McKinsey & Company, 2021). They promote well-being, diversity, equity, and inclusion more than men (see Fig. 2), but although 70% of the companies surveyed recognized these efforts as being crucial, less than 25% reward this investment (MacKinsey & Company, 2021).

Although this study is not focused on SCM, transferring these efforts women make to the supply chain context would imply that more gender diversity in SCM contributes to higher social performance (i.e., well-being, work-life balance) in the supply chain.

In the SCM field, several sources highlight women as successful supply chain leaders. For instance, Kroll (2019) portrays seven female leaders in supply chain and logistics management, chosen for *"strong work ethic, a passion for supply chain and logistics, and the ability to be comfortable as one of a few—sometimes the only—women in the room."* Awards and recognitions are being created to encourage more women participation in supply chain leadership positions, such as "The Women in Supply Chain" award from the Supply & Demand Chain Executive magazine (Moralez, 2020) or the Top 100 Women in Supply Chain from the BizClik Media

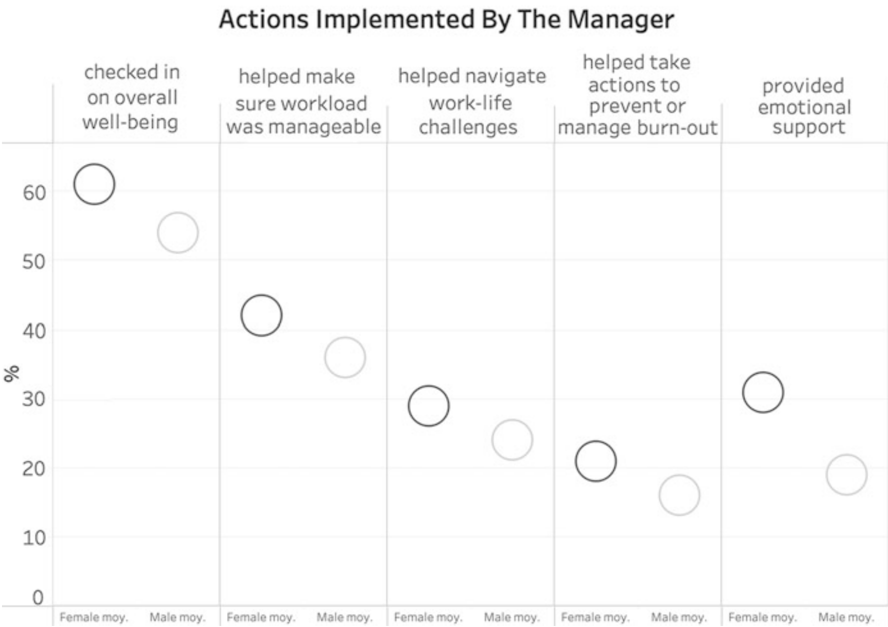

**Fig. 2** Social actions led by men and women managers during the COVID-19 pandemic. (Adapted from McKinsey, 2021)

Group (Freeman, 2020). According to BizClik Media Group's Chief Operating Officer, Stacy Norman, such recognitions are essential nowadays since *"women are playing crucial roles"* especially in supply chain, digital technology, and FinTech sectors which *"are undergoing a digital transformation and women are leading the way."*

Given the various barriers women may face in the SCM field, some women leaders take the opportunity to stimulate more diversity as pictured by Wilson (2020). For instance, Megan Smith, CEO of Symbia Logistics, revised her company's policy when reaching this position to put gender diversity at the core of its strategy. Ellen Voie, CEO of the Women in Trucking Association, gives talks worldwide to encourage more women to join the trucking sector. Still, many organizations promoting gender diversity in SCM state there is a need for more women in supply chain positions because of the great divide between the number of women compared to men (e.g., "Women in Supply Chain Initiative"[4]). However, few are able to explain further the added value of a higher share of women in top management positions, which highlights a gap to be addressed in research. Investigating with a scientific approach what gender diversity concretely brings to SCM would help develop strong arguments and make several industries invest time in attracting more women and other gender types. Furthermore, educational institutions have an increasing role to play to set a favorable ground for more gender diversity in supply chains. SCM-related jobs are historically more targeting men, so to increase gender diversity, there is a need to train and encourage women to follow-up on supply chain education and prepare them for SCM-related jobs as well as to create and develop an attractive working environment and career perspectives for women to apply to such jobs.

## 9 Future Direction on Gender Diversity for Sustainability in SCM

Several theoretical approaches could be useful to study these new aspects related to the issue of gender diversity in SCM, with an emphasis on sustainability. For instance:

– Practice theories can support the understanding of gender diversity in SCM for sustainability mainly when they challenge a static understanding of specific practices and look for deeper understanding of what can happen in terms of supply chain sustainability (Silva & Figueiredo, 2020). Further studies could look at understanding what are the meanings in developing gender diversity for supply chain sustainability as well as what kind of competences are necessary for that.
– Social justice theory. This theory works well in this debate since it can help companies and their supply chain management to ensure social sustainability.

[4] See: https://wisci.mit.edu/

Young (2011) explores through the politics of the difference how social justice may be developed to reduce discrimination and create a more distributive paradigm in which oppression is overcome. Such a perspective is not well applied to SCM and may be used to ensure supply chain sustainability, not only looking for gender diversity but stimulating further social sustainability under multiple facets.

The study of Ruel et al. (2020) also identifies several relevant theoretical frameworks for studying the issue of gender diversity in SCM. Among these:

- Gender schema theory (Bem, 1981), which explains how characteristics related to sex and gender are integrated and persistent in a group of individuals. This could enable researchers to better embrace the role of gender stereotypes in women's careers and contributions in SCM.
- Social identity theory (Tajfel & Turner, 1986), which explains behavior between different groups of individuals depending on their perceived differences of status and legitimacy, could be of interest to understand career paths in SCM and the leaky pipeline.

Other theories called "feminist theories" can contribute to address gender diversity in SCM with a theoretical background (Touboulic & McCarthy, 2019). For instance, "feminist ethics" (Crane & Matten, 2016, pp. 115–116) recognizes the differences of attitude between men and women, such as in resolving ethical conflicts. Crane and Matten (2016) highlight that almost all ethical theories have been developed by men and focus on individual interests. On the contrary, feminist ethics focuses on interrelations between individuals that are embedded in a network (Crane & Matten, 2016, p.116) and thus may be more appropriate for SCM than other ethical approaches (e.g., utilitarian, ethics of rights). In the same line, Grosser and Tyler (2021) justify the appropriateness of mobilizing radical feminism (Hooks, 2000) as a theory because the labor conditions in supply chains show many gender discriminations, sexual violence, and harassment, and this theory offers a perspective that is not individualized but rather more class-based (based on sex-class) with a focus on structures of inequality. Finally, Loosemore et al. (2020) suggest that the intersectionality theory (Crenshaw, 1991) should be mobilized as novel lenses in future research to better explain how gender and race may intersect and create an accumulation of discriminations and violence in SCM. Overall, feminist theories may be mobilized as "emancipatory" theories to shift understanding and advancement of supply chains.

These theories can create new avenues for gender diversity in SCM for sustainability. However, we cannot forget that traditional organizational theories applied to SCM can also support such a debate. They include: institutional theory (Powell & DiMaggio, 1991), stakeholder theory (Freeman, 1994), agency theory (Jensen & Meckling, 1976), intercultural dimensions theory (Hofstede, 1980), and so on. We need to advance towards a research context in which gender diversity becomes mainstream in supply chain sustainability studies, instead of being considered a marginal subject of research. By following such a perspective, scholars can better support practitioners to understand their role in SCM.

## 10 Managerial Implications

There are several implications of gender research and observations for supply chain practitioners. With this study, we encourage companies to create self-reflection on how to reduce or to eliminate the victimization approach toward a true gender diversity for sustainability in SCM. This evolution can relate to how engaged they are with education, for instance. Thus, starting from education in supply chain programs, in which women are less numerous than men, the entire sector has to promote and encourage access to supply chain training for young girls. In this sense, such an action might require that some industries have to improve their image and make their sector more attractive to women, especially heavy industries such as automotive or aviation. Supply chain actors can get involved in higher education, and even in secondary education. For instance, women leaders can share their experience and give talks or guest lectures at high schools and universities. In parallel, higher education institutions need to amplify their actions for that, pushing managers and lecturers to engage more and more with the subject.

Furthermore, for buying companies that are already engaged in promoting gender diversity in SCM, it is needed to analyze and share their knowledge regarding the benefits of an increased gender diversity in SCM. Partnerships or cooperation with researchers could help elucidate this lack of knowledge to build further arguments to promote gender diversity rather than numbers "only." This can support the gender diversity practice to increase and become a mainstream theme. Companies engaged with gender diversity in SCM should ensure that this is not a subject centered in top management involvement of different supply chain members, but a real matter in gender diversity in multiple levels. One way for that is developing sourcing or purchasing programs that engage supply chain members on the subject. Another way is to revise human resources policies and practices (e.g., hiring criteria).

Indeed, the buyer-supplier relationship seems key to develop sustainable practices along the supply chain. Research shows that more women at the supplier's side support the social pillar and foster both interorganizational collaboration and innovation towards sustainability. This characteristic implies that procurement managers should consider improving the diversity of their teams. Then, some MNEs, such as L'Oréal, are already reflecting on how to cascade their sustainable practices to their suppliers (Wilhelm & Villena, 2021) which are globally located. As part of those sustainable practices are social inclusion practices. We believe that MNEs have a big role to play in setting up cascading mechanisms that will empower their suppliers and lead them to have sustainable practices, such as including more women in their operations. In turn, these women working at suppliers can foster the emergence of new responsible practices, sometimes in connection with their own suppliers (tier 2). However, it is important to highlight again the need to align such practices with the socioeconomic and cultural contexts of suppliers.

Finally, this chapter provides practitioners with a reflection on the practices of human resources management applied to SCM regarding gender diversity. First, the SCM function is recognized as being male-dominated. Increasing the number of women would have important consequences for sustainability decisions along the supply chain, as depicted in the chapter. Also, in a world disrupted by the COVID-19 pandemic, it appears that building more resilient supply chains is desired. However, supply chain resilience requires different capabilities (Pettit et al., 2013), including organizational capabilities that rely on human resources and skills. The skills of both women and men are needed to achieve this goal. In addition, this chapter could also support women with their career path and limit the glass-ceiling issue: the more women there are in the function, the more likely they are to be considered when it comes to moving up the hierarchy.

Furthermore, increasing the number of women in the SCM function could help the entire company to increase diversity and its related positive impacts on sustainability. Finally, this chapter also allows practitioners to realize that in order to end the "talent war," considering hiring women into the role would help limit the shortage of such talent. To do so, employers are recommended to set up support for women – e.g., mentorship from supply chain leaders; making mandatory to have women in short list for an internal promotion process; facilitate distance working and increase the use of videoconferencing to limit long business trips; better recognize soft skills in recruitment ads for SCM positions; and create favorable conditions for women to participate in professional networking activities.

## 11 Summary and Conclusion

In this chapter, gender diversity in SCM has been explored from multiple lenses: victim-approach, positive discrimination, and self-made women. This review of literature and current trends among businesses highlight that gender diversity is underexplored, although some contributions show the added value gender diversity can bring to sustainability in the supply chain. Due to limited research and knowledge sharing on the topic, no generalities can be made. However, this chapter provides some hints on what can be done or what is missing by putting forward several theoretical perspectives that could help to better embrace this vast subject. Moreover, the chapter highlights rich contributions for the managerial world.

Nevertheless, these could be strengthened if more empirical research with the great involvement of practitioners would be conducted. In the same line, the involvement of practitioners in education would be appreciated to support the feminization of SCM educational programs. Probably, including gender diversity more thoroughly in business education programs would also help train more "gender-aware" supply chain managers. Finally, this chapter is a contribution to the fifth SDG which refers to achieving gender equality and empowering all women and girls.

# Integrated Thinking of the Construction Supply Chain and Project Management

## Performance Domains and Delivery Principles

## Contents

**Abstract**

The construction industry contributes to social development and the economy. However, the industry encounters numerous challenges that pertain to construction supply chain management (CSCM) and construction project management (CPM). Multi-stakeholder structure-based construction projects can challenge construction project management processes making them difficult to handle. Significant effort has been made to enhance the performance of CSCM and CPM. Despite these efforts, the construction industry still experiences challenges and problems. This chapter examines project delivery and project performance relationships within the construction supply chain. The chapter evaluates the construction supply chain from a project management perspective. The chapter emphasizes the need for integrated thinking to achieve value-oriented goals.

## 1 Introduction

Construction is among the most comprehensive, and dynamic industries worldwide. The global construction market is anticipated to grow by approximately $4.5 trillion in the 2020–2030 period (Marsh, 2022). Construction activities are complex, involving many stakeholders. Construction contributes greatly to economic development. Despite construction's economic significance, many problems remain, including low employee satisfaction levels, construction delays, and quality deficiencies. There are many uncertainties that also exist – for example, supply of raw materials, market demand, finished products, price of raw materials, production processing time, transportation and delivery budget and time, challenges due to vertical and horizontal competition, and collaboration between various parties. These challenges increase complexity, making optimal decisions even more difficult (Zhuang et al., 2014).

As construction projects are problem-, claim-, and dispute-intensive, it is critical to establish and manage competent and competitive construction supply chains starting from the early stages of construction project management (CPM). Many studies (e.g., Dubois & Gadde, 2000; Riley & Clare-Brown, 2001) emphasize the importance of improved construction supply chain (CSC) performance for achieving business objectives and gaining competitive advantage (Eriksson, 2010). Industrial supply chains are critical to organizational success (Aloini et al., 2015). Strategic supply chain management helps to facilitate organizations in improving their key outcomes (Hult et al., 2004). Project management within the supply chain can help increase efficiency, minimize risks, and minimize disruptions – but it may also result in complex activities.

Supply chain and project management are related and can be integrated. There are a number of ways for integrating supply chain strategies and with project management principles. Production and supply chain-related processes can set the stage for this integration (Tatlici & Sertyesilisik, 2019). Supply chain and project management integration has been investigated for many years (e.g., Fewings & Henjewele, 2019; Wei et al., 2021).

Various supply chain and project management models have been developed to define, explain, and obtain solutions to practical issues the industry faces (Zhuang et al., 2014). Examples of these models include input-output models and closed-loop supply chain network equilibrium models. The construction literature has also emphasized the need for an integrated supply chain and project management (Hu, 2008; Wei et al., 2021).

In this chapter, we focus on integrating supply chain and project management using the Project Management Institute (PMI) (2021)'s delivery principles and performance domains for the construction industry. Specifically, we use the project management body of knowledge (PMBOK) with its latest structure based on 12 project delivery principles (PDPs) and 8 project performance domains (PPDs) (PMI, 2021).

The importance of project management (PM) and SCM integration with relation to value creation, enhancing CPM, and construction company competitiveness are emphasized. This chapter emphasizes the importance of performance- and principle-based project management (PMI, 2021) and supply chain integration. This chapter discusses how construction project value can have the potential to be supported through effective and strategic integration based on the PMI (2021)'s PDPs and PPDs. We also discuss how this integration can be further integrated with and supported by lean, sustainable, and agile approaches.

The remainder of the chapter includes background, current concerns in the construction supply chain, PPDs and PDPs. It also provides recommendations for supporting the integration of CPM and construction supply chain management (CSCM) section with a summary and conclusion.

## 2 Background

Construction competition requires construction projects to be efficient, effective, and smart. Construction's fragmented supply is a shortcoming (Department for Business and Innovation Skills (DBIS), 2013). Many studies (e.g., Egan, 1998; Latham, 1994; Wolstenholme, 2009), strategies, and policies (e.g., UK's Construction 2025: Strategy (HM Government, 2013)) have focused on and called for construction performance improvement. For example, Latham (1994) emphasized the construction industry's under-performance related concerns and the need for improving performance without losing time.

The reports emphasized common and similar concerns and targets, including reductions in cost (Latham, 1994; Egan, 1998; DBIS, 2013); quality improvement and defect reduction (Latham, 1994; Egan, 1998); value for customer (Latham, 1994; Egan, 1998; Wolstenholme, 2009); and the need for partnering in the supply chain (SC) (Egan, 1998) and integrated SCM (DBIS, 2013).

Egan (1998) identified key drivers for change in construction with a focus on customers, integrated processes, and teams. Wolstenholme (2009) focused on business and economics, capability, delivery, and industrial structure and emphasized leadership, holistic thinking, integration, and value. In support of these studies, the HM Government (2013) emphasized "people, smart, sustainable, growth and leadership" keywords as main constructs of the Construction 2025 Strategy. Furthermore, the European Union has established the Construction 2050 Alliance, focusing on the construction value chain.

DBIS (2013)'s report on SC in the construction industry, highlighted construction industry's delay in taking relevant steps. Even if the reports and strategies (e.g., Egan, 1998; Latham, 1994; Wolstenholme, 2009; UK's Construction 2025: Strategy (HM Government, 2013)) have been prepared in different dates, these reports and strategies have common focuses and concerns. The timeline of the reports reveals that there is still a need for enhancing CPM and the construction industry, and for dealing with the construction industry and SC-related concerns.

PM guides the project to attain the desired outcomes through the application of skills, techniques, knowledge, and tools to project activities so that project requirements can be achieved (PMI, 2021). The objectives of reducing the cost, increasing quality, and improving all processes have fostered the widespread of SCM in the construction industry (Akboga & Baradan, 2011). Furthermore, the intensive use of outsourcing in the construction industry supports the adoption and implementation of SCM (Akboga & Baradan, 2011). Effective SCM can provide advantages to companies. SCM, as a structure formulated around a customer-oriented corporate vision, has its objective to manage the internal and external relationships of an organization (Min and Zhou, 2002). Contractors can get benefits from SC collaboration through reduced bureaucracy and cost, and increased profitability and market competitiveness (Akintoye et al., 2000). When PM and SCM are integrated, the value added to the project and the improvement in performance have been noted in various studies (e.g., Fewings & Henjewele, 2019; Wei et al., 2021). Furthermore, effective SC can support resilience of the PM. For example, 57% of the companies consider that diversification in their SC can prevent future disruptions (Hubs, 2021).

Egan (1998) asserted that goals and effective measures of performance are critical to improvement. SC plays a vital role in innovation and sustained performance improvements (Egan, 1998). SCM incorporates ways of eradicating waste and adding value to the SC (Saad et al., 2002; Amade et al., 2016). Latham (1994) and Egan (1998) suggested that the construction industry should implement SCM techniques (Amade et al., 2016). The construction industry should seek to develop conditions that support SC growth and encourage investments in the latest technology and employees (HM Government, 2013).

## 3 The Construction Supply Chain, Project Performance Domains (PPD), and Project Delivery Principles (PDP)

PMI's 8 PPDs and 12 PDPs comply with SC objectives (see Table 1). Companies willing to retain their competitive advantage should consider CPM and CSCM in an integrated way, relying on PMI (2021)'s PDPs (Table 1). The relationship among and importance of the PPDs of the PMBOK7 and the PDPs of the PMBOK7 (PMI, 2021) are examined from the SC and SCM perspectives under the PPDs headings using various relationships identified in Table 1. This section summarizes each PPD category and some of the major relationships and contributions to SCM.

**The stakeholders PPD:** Various stakeholders are involved in different project phases. Stakeholder impact, authority, and values may change as the project

progresses (PMI, 2021). Integration of SC stakeholders into the process can affect SC success (PMI, 2021). Success in the SCM necessitates the integration of business processes into the SCM's main objective, which is to create value for the SC (Lambert & Cooper, 2000).

The relationship between the stakeholder PPD and the team PDP needs to be considered and well-managed in the CSCM and CPM. Even if stakeholders are prioritized by team members, it can become difficult for the project team to effectively and directly engage with all stakeholders (PMI, 2021).

Integrating the SC into the project implementation process can enable improvement in the project outcomes through clearer objectives, stakeholder involvement, and result-oriented efforts (Børve et al., 2017; Erkul et al., 2020). The relationship between stakeholder PPD and stakeholder PDP needs to be considered in CSCM and CPM. As stakeholders differ from each other with respect to their power, interest, and involvement in projects (Erkul et al., 2020), each stakeholder's position related to the project needs to be analyzed (PMI, 2021).

Various aspects are involved in assessing stakeholders – for example, project interest, project proximity, influence degree, expectations, beliefs, attitudes, impact, power, and other features associated with the stakeholder and project interaction (PMI, 2021). Stakeholder PDP has effects on the project, performance, and results (PMI, 2021). Stakeholder performance can be improved by SC transparency in construction projects.

The relationship between the stakeholders PPD and holistic thinking PDP needs to be managed in the CSCM. Soft skills – such as interpersonal skills, conflict management, listening, and leadership skills like critical thinking and creating a vision – are needed to ensure that stakeholders are and remain engaged (PMI, 2021). Moreover, it is important to understand how requirements can influence integrated projects where stakeholders and teams are expected to work together (Karim Jallow et al., 2014).

**The team PPD:** The entire CSC needs to support the team PPD. The "project team" PPD involves creating a culture and atmosphere to create and establish a high-performing project team (PMI, 2021). This PPD involves identifying the steps required to encourage project team development and to motivate all staff to serve as leaders (PMI, 2021).

To improve process performance, PM can be delivered through teams (Larsson et al., 2018). The establishment of an effective and competent SC in compliance with the team PPD is important for CPM success. Lack of sufficient, effective, and robust project team integration among clients, the SC, and the supplier team is among the common reasons for project failure (Office of Government Commerce, 2005; Karim Jallow et al., 2014).

The team PPD, the stewardship PDP, and the team PDP can be considered together to enhance CSCM. The stewardship PDP is an indispensable principle for the team PPD (PMI, 2021). The establishment of the SC consisting of accurate and competent teams based on the stewardship PDP can support the PM process.

Relationships between the team PPD and the team PDP can be managed to support CSC and CSCM. The construction project team is established through the establishment of the SC. It may be difficult to manage teams (Oppong et al., 2017). Furthermore, the teams to be integrated into the SC must be selected, appointed, and assigned carefully so that the project can be accomplished successfully (PMI, 2021).

Team harmony, capacity equivalence, and their communication tools need to be considered in establishing the teams in the SCM (PMI, 2021). Furthermore, the relationship between the team PPD and the holistic thinking PDP can enhance the effectiveness of the CSCM. Fragmentation in project teams needs to be substituted by integrated teams working in collaboration (Sinclair, 2012; Karim Jallow et al., 2014). This integrated work environment can enable companies in the CSM to work complying with the holistic thinking PDP.

CSC needs to be established based on the competencies of the CSC companies. This necessity is supported by *HM Government (2013)'s Construction 2025 Strategy*, which emphasizes that multidisciplinary competencies are required by the construction industry so that integration throughout the SC can be achieved. Furthermore, as project teams and their members should be able to analyze each action's impacts on the construction process objectively (PMI, 2021), the holistic thinking PDP is needed. Holistic thinking involves critical thinking, disciplined thinking, as well as the evidence-based thinking (PMI, 2021).

Chan et al. (2003) highlighted the importance of a comprehensive system-thinking perspective to support SC performance and comply with SCM.

CS and CSM can be enhanced by the team PPD and the leadership PDP. Effective leadership's objective is to establish project teams that perform efficiently (PMI, 2021). Through the "effective leadership" PDP, project teams can introduce an adaptable and ethical environment (PMI, 2021). PMI (2021) recommends shared leadership in the SC. Shared leadership based on the fields of interest and experience in SC can support success in the PM.

**The life cycle PPD:** CSM and CSC need to comply with and support the life cycle PPD. The life cycle PPD is about all phases through which the project passes (PMI, 2021). According to the performance measurement perspective, the notion of life cycle is multifaceted (Suomala, 2005).

Relationships between the life cycle PPD and the holistic thinking PDP need to be considered in the CS and CCSM. Many changes can arise when the project progresses throughout its life cycle (PMI, 2021). It is important to manage information on client requirements throughout different life cycle stages and among all stakeholders (including designers and clients) (Karim Jallow et al., 2014). There have been project failures because of the inability to meet stakeholder requirements throughout the project life cycle (Chan & Oppong, 2017). Therefore, stakeholders should be involved in project delivery so that their expectations are systematically incorporated into the project policies and plans (Li et al., 2013; Chan & Oppong, 2017).

**The planning PPD:** CSCM needs to support the planning PPD. Project deliverables, development approach, organizational requirements, legal or regulatory restrictions, and market conditions are among the essential factors that determine the manner of executing project planning (PMI, 2021).

Weak project planning due to insufficient planning and risk assessment can result in a weak business case where there is a lack of consistency between organizational objectives and the project (Suomala, 2005). SC actors are linked to each other throughout the construction network, and they are brought together in the CSC planning and operations phases (Luong Le et al., 2021).

Relationships between the planning PPD and the team PDP need to be managed in the CSCM. It is vital to recognize areas to be modified so that the teams can anticipate changes and proactively formulate their responses to these changes (Ibbs et al., 2001). Adaptive approaches to the changes often use timeboxes so that the work quantity managed within a specific time-box can be determined (PMI, 2021).

SC integration and compliance among SC participants can enhance Construction planning and development productivity (Bankvall et al., 2010; Luong Le et al., 2021). The planning PPD needs to be considered in an integrated way with the stakeholder's PDP. Effective management can support shared understanding and consistency, leading to the attainment of project outcomes (PMI, 2021), which can be supported by SCM.

Project managers should know stakeholder-related opportunities and threats, accomplish social responsibilities, formulate shared goals, design relevant strategies, and increase stakeholder satisfaction to ensure effective management (Chan & Oppong, 2017).

Relationships between the planning PPD and the holistic thinking PDP need to be considered within the scope of the CSCM. When planning physical resources, many aspects – such as storage, movement, and disposition of materials – each being SCM activities – need to be considered, and the project team needs to make plans regarding the timing of materials (PMI, 2021). Using a holistic technique, it can be possible to describe emergent properties, which could not be identified through analysis and planning (Kraft & Steenkamp, 2010).

Planning PPD and tailoring PDP relationships need to be managed in CSCM. Through planning and tailoring, projects can achieve benefits such as reduction in waste, increased productivity, and efficiency in the use of project resources (PMI, 2021).

The planning PPD and the adaptability and resilience PDP can jointly support CSCM. Few projects can be performed exactly as they have been planned due to changes in estimates, information, and conditions (PMI, 2021). Furthermore, natural and man-made disasters foster the need for and importance of SC's resilience. For this reason, foreseeing possible scenarios and being prepared for different circumstances with the help of planning skills may make the project and SC process successful (PMI, 2021). For example, the pre-disaster as well as the post-disaster stages of construction depend on the SC disaster resilience (Sertyesilisik, 2017).

The SC needs to be adaptable to the changes. Supply change is a significant component of PM, where the following factors have an impact on supplier resilience: variations in cost and supplies, supplier geographical location, unpredictable quality parameters, supplier technical expertise, supplier flexibility, and inconsistencies in lead time (Shishodia et al., 2019).

Relationships between the planning PPD and the change management PDP can affect CSCM. Modifications may have to be made throughout the PM phases for a variety of reasons, including customer requests, the occurrence of a risk event or a change in the project environment, or understanding the requirements extensively (PMI, 2021). Various processes like change control processes, backlog reprioritization (re-arranging the list of pending project processes), or project re-baselining (updating the project baseline with respect to changes in cost, time, or goals of the project) need to be considered in the development approach (PMI, 2021). As a result, project change management should not be considered separately from the CSCM, as each decision made in this process is related to the project teams in the CSC.

**The project work PPD:** CSCM needs to enable SC to support the project work PPD. Project work is related to the development of processes and the performance of tasks to ensure that the project team delivers the estimated deliverables and results (PMI, 2021).

Jabarzadeh et al. (2021)'s study revealed a positive impact of supplier integration and organizational internal integration on the performance of the project-based organization. Managers should pay attention to supplier integration and internal integration so that project-based organizations can be successful, and their organizational performance can be improved (Jabarzadeh et al., 2021).

The relationship between the project work PPD and the team PDP plays a role in CSCM. Balance within the project team needs to ensure that business and stakeholder value are attained (PMI, 2021). The project work PPD and complexity PDP need to be carefully managed within the scope of the CSCM. Extensive complexity may be involved in SC (HM Government, 2013). As materials and supplies from third parties are required in many projects and as the planning, transportation, ordering, storing, tracking, and managing these resources require time and effort (PMI, 2021), an integrated logistics system and a logistics plan are required (PMI, 2021).

The project work PPD and the adaptability and resilience PDP in CSCM mean regular inspection of project work to identify improvement opportunities that can support project adaptability and resilience (PMI, 2021). Uncertainty may increase from scope changes. Organizations and managers need to make an assessment of the new risks emerging from these changes in scope (PMI, 2021).

It is vital to integrate resilience to the policies, codes, culture, and work traditions in the SC (Sertyesilisik, 2017). A robust and resilient SC can help attain the vision of the industry, along with a reputation for efficiency (HM Government, 2013). Sustainability of construction industry can be enhanced by its efficient project delivery technique, supported by integrated and robust SCs and efficient long-term associations (HM Government, 2013). Furthermore, as SC resilience is vital to ensure smooth flow of operations, construction SC resilience can improve the construction industry resilience (Sertyesilisik, 2017).

**The Delivery PPD:** CSCM needs to support the delivery PPD. Quality expectations, requirements, and scope should be fulfilled to attain the required deliverables that can help achieve the desired delivery PPD outcomes (PMI, 2021).

The delivery PPD and the value PDP jointly are integral to CSCM. The value PDP focuses on the outcome of the deliverables, and the focus of project teams shifts from deliverables to the desired outcomes to support achieving value in the projects (PMI, 2021).

The delivery PPD and the quality PDP relationships also require CSCM consideration. SCM is a critical success factor to meet the expectations on quality and deliveries. Ensuring quality of project processes and project deliverables can support SC integration, enhanced cost control, and reduced scrap and rework (PMI, 2021). From the logistics perspective, for example, the idea of quality management and waste reduction was stressed by Solaimani and Sedighi (2020). Materials are frequently damaged in transportation and material handling, causing write-offs and waste (Solaimani & Sedighi, 2020).

The delivery PPD and the complexity PDP relationship are integral to CSCM. For example, requirements elicitation, evolving and discovering requirements, and managing requirements are important items to deal with project complexity (PMI, 2021). The relation between the delivery PPD and the change management PDP needs CSCM management. To deal with the scope change, project teams can use a change control mechanism to examine all changes and the value these changes can add to the project (PMI, 2021). This change control mechanism needs to be at the SC level.

**The measurement PPD:** CSCM needs to support the measurement PPD. The extent to which the work carried out in the delivery PPD fulfills the metrics recognized in the planning PPD is determined by the measurement PPD (PMI, 2021). Common categories of metrics include business value, resources, delivery, deliverable metrics, forecasts, baseline performance, and stakeholders (PMI, 2021).

The measurement PPD and the value PDP relationship are important for CSC and CSCM. Value management is a PM approach that offers a structured way of assessing and designing a project to fulfill or surpass stakeholder requirements and improve the possibility of meeting benefits (Kliniotou, 2004; Karim Jallow et al., 2014). Use of the business value measurements can support the project deliverables to stay consistent with the business case and the benefit realization plans (PMI, 2021).

The measurement PPD and the holistic thinking PDP relationships provide the CSC and CSCM with how the data are used to take accurate action and as system interactions can support positive results (PMI, 2021). This relationship can support accurate and timely action in the CSCM.

Relationships between the measurement PPD and the tailoring PDP can be managed for enhancing effectiveness of the measures in the CSC. Effective measures can help to track, assess, and report information on project status, enhance project performance, and decrease the risk of weak performance (PMI, 2021). As measurement requires time and effort, it is important for project teams to measure relevant things and use correct metrics (PMI, 2021). The use of performance measurement approaches can enable measurement of the performance's efficiency and effectiveness (Yang et al., 2010). Further advancements in technologies and commercial models can provide benefits through transparent data sharing abilities throughout the SC (Construction 2025, 2013).

The measurement of PPD and the opportunities and threats of the PDP relationship can support CSCM. Performance measurement can provide effective results in the SCM process. With the help of various (e.g., the SCOR Model) performance measurement systems (PMS) in SCM, project opportunities can be assessed, and project risks can be minimized.

Different objectives for the advancement of a PMS in SCs include, but are not limited to: recognizing enhancement prospects, challenges, waste, bottlenecks, and accomplishment; enabling clear coordination and interaction, monitoring, and enabling growth; offering decisions based on facts, comprehension of business operations, and recognizing satisfaction of client needs (Gunasekaran & Kobu, 2007). Furthermore, Gunasekaran and Kobu (2007) determined the primary performance measures of SC to select cost-effective and accurate performance parameters (Najmi et al., 2013).

A complete analysis of a construction SC's efficiency is required for accurate monitoring of enterprise and cost (Tatlici & Sertyesilisik, 2019). The Supply Chain Council (SCC) created SCOR in 1996 as one of the performance evaluation models to evaluate four main factors (i.e., committed capital turnover, SC cost, flexibility/responsiveness, and commercial performance dependability) to make strategic and functional decisions about a firm's strategy development (Estampe et al., 2013). SCOR can be employed to assess, enhance, and standardize SC (SCC, 2008).

**The uncertainty PPD:** CSCM needs to support the uncertainty PPD. Uncertainty is related to inadequate understanding and awareness of events, issues, methods to follow, or solutions to attain (PMI, 2021). The uncertainty that a project may have to experience may be ascertained by the SC (Schlittgen et al., 2016).

Information is important in dealing with uncertainty. For example, when there is a lack of accurate and real-time as-built information, the managers can be unable to keep track of schedule, cost, and other indicators of performance, and they can encounter difficulty in managing uncertainty and variability involved in project activities (Zhang et al., 2009).

Many causes of SC complexity can contribute to the uncertainties, which can lead to vulnerability factors (Simangunsong et al., 2012; Thomè et al., 2016; Wei et al.,

**Fig. 1** PMI (2021)'s PDPs 12 principles based SCM to achieve PMI (2021)'s 8 PPDs

2021). The relation between the uncertainty PPD and the opportunities and threats PDP needs careful consideration in CSCM. Risks are an aspect of uncertainty (PMI, 2021). As different projects involve different degrees of risks and uncertainties due to their unique nature, the emerging risks must be carefully detected by the project team to capitalize on the opportunities and prevent threats at the same time (PMI, 2021). Threats and opportunities are integral parts of project implementation, and they are presented by uncertainty examined and investigated by project teams, who then can determine solutions to address them (PMI, 2021). Project managers need to concentrate on managing the time-use of important sources, greater clarity of task-to-task interfaces, and eliminating unpredictability from every SC member and specific project activities to avoid those threats that imperil project efficiency (Wei et al., 2021).

The project team must have a proactive plan of response ready to deal with threats and opportunities in case of risk emergence (PMI, 2021). The relation between the uncertainty PPD and the adaptability and resilience PDP needs to be managed within the scope of the CS and CSCM. An organization can strategize its SC resilience by developing innovation, technological, and collaborative efficiency (Chatterjee & Chaudhuri, 2021). SC resilience can facilitate PM by handling unpredictable SC disruption, which can support competitiveness of the organization (Wei et al., 2021).

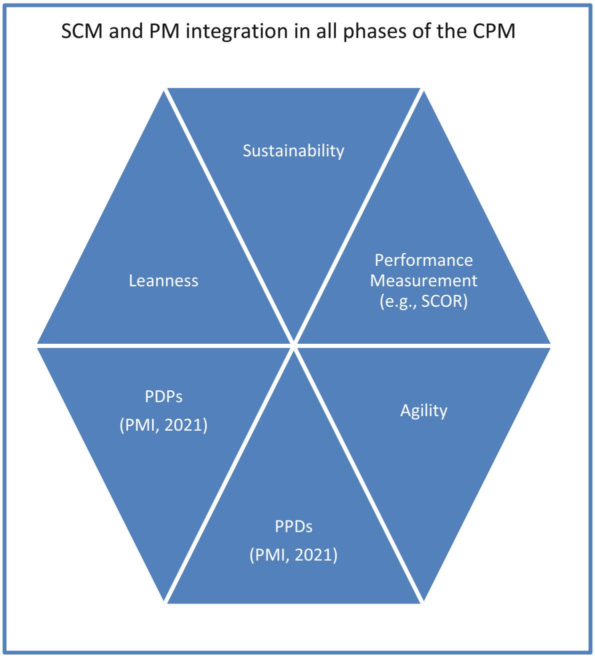
### 3.1 CSCM's Contribution to PM Principles and Performance Areas

SC and their SCM need to be based on all 12 PDPs of PMBOK7 (PMI, 2021) to achieve the 8 PPDs of the PMBOK7 (PMI, 2021) (Fig. 1). In other words, the 12 PDPs, which are indicated in the PMBOK7 (PMI, 2021), need to be considered as fundamental principles of the SCM. Furthermore, success and effectiveness of the SCM need to be considered in correlation with the achievement level of the 8 PPDs indicated in the PMBOK7.

## 4 Recommendations for Supporting the Construction Project Management (CPM) and the Construction Supply Chain Management (CSCM) Integration

The main constructs of integrated SCM and PM in all phases of the CPM in compliance with PMI (2021)'s PDPs and PPDs are highlighted in the Fig. 2. The PDPs and PPDs of the PMBOK7 are important and need to be considered for the

**Fig. 2** Main constructs of integrated SCM and PM in all phases of the CPM



establishment of effective, sustainable, agile SC in the construction industry. Waste in the processes can be removed by agile and lean (agilean) PM. Agilean PM has been described by Demir et al. (2013). Universal PM approaches, like those from the PMI, reinforce agilean PM at the strategic level (Demir et al., 2013). Sustainability, lean, and agile approaches can be used to enhance PM and SCM in compliance with PMI (2021)'s PPDs and PDPs. SCM performance measurement needs to be performed throughout the CPM phases. With the use of the SCOR paradigm in SCM, it may be possible to increase the efficiency of lean, agile, and sustainable systems as well as to reduce PM issues in the construction industry (Tatlici & Sertyesilisik, 2019).

The PPDs of the PMBOK7 (PMI, 2021) emphasize the importance of value creation (e.g., the delivery PPD), which complies with the lean management principles. Lean approaches can support the achievement of the PMI (2021)'s PPDs, as lean construction (LC) is mainly value-focused. LC takes lean production system's goals (i.e., maximization of value and minimization of waste) and implements them to procedures in project delivery approach (Marhani et al., 2013).

Fawcett et al. (2008) and Rausch-Phan and Siegfried (2022) have emphasized benefits – such as risk mitigation, better collaboration, reduced uncertainty and construction waste, enhanced communication, project flow and quality control, and project value creation – from integrating SCM to PM and SCM to obtain project value.

Lean establishes sustainable utilization of assets to enable the company to cut expenses, remove waste, and accomplish projects on time (Lim, 2008). Hence, LC is a significant milestone in the construction industry, ensuring value delivery to clients (Marhani et al., 2013). Advantages offered by LC to the construction industry have been identified by many researchers, including Lim (2008) and Koskela (1992), Abdullah et al. (2009), and Jørgensen and Emmitt (2008), who have emphasized that LC can support project planning and lead to enhanced project quality and sustainability (Marhani et al., 2013).

Lean principles and value-oriented work are in compliance with the goals of PM and SCM. Lean should be considered as an integral part of SC, especially due to the many benefits of lean approaches (e.g., resource management and waste reduction) (Suresh et al., 2011). Lean SCM can be effective for achieving PM performance and principles.

The PPDs of the PMBOK7 (PMI, 2021) emphasize the importance of agility (through the uncertainty PPD). All PMBOK editions had a narrative based on the predictive and waterfall methods, which is a traditional PM approach. Agile PM frameworks have emerged since the 2000s due to many reasons, including technological development, and increasing competition (Guvenatam, 2021). Agile concepts and methodologies offer the prospect for a better pre-design strategy (Owen et al., 2006). Application of agile PM (APM) concepts in the design phase is suited to the construction industry requirements (Owen et al., 2006).

To be agile, an organization or a project must be designed in such a way that it can accept the disruption effectively embracing possibilities to augment value outputs (Galankashi & Helmi, 2016). Most agile development methodologies divide work into little chunks to reduce cumulative threats and help the project to respond to modifications (Straçusser, 2015). Furthermore, agile allows users to provide prompt input to the team and to introduce or change functionalities (Straçusser, 2015).

Environmental, social, and economic sustainability are the three main pillars of sustainability (Purvis et al., 2019). These three pillars can support sustainability and serve as a guide for standards and certifications that assess the sustainability of businesses, goods, and services. Therefore, sustainability is among the main constructs of integrated CSCM and PM in all phases of the CPM in compliance with PMI (2021)'s PDPs and PPDs. Incorporation of sustainability considerations into fundamental business plans can support sustainability practices in companies (Elmualim et al., 2012). Adherence to sustainable practices necessitates the inclusion of sustainability into the corporate plan (Ikediashi et al., 2012).

## 5 Summary and Conclusion

This chapter examined PMI (2021)'s PDPs and PPDs from the CSC perspective, emphasizing the importance of integrated thinking of PM and CSCM and the relationship among PDPs, PPDs, and SC.

PMBOK v7 has evolved the PM approach into performance and principles and prioritized the competencies of each team involved in the project – including working with team, adaptability to changes, and quality of work (PMI, 2021). Furthermore, PMI (2021)'s PPDs and PDPs are value-focused, and their integrated thinking with CSCM can improve CSCM. Thus, it is important to integrate PM and CSCM for value- and success-oriented, sustainable, and agile projects.

This chapter, focusing on the PMI (2021)'s PPDs and PDPs, draws attention to the need for integrated thinking of CSCM and PM to achieve CPM's value-oriented goals supported by the main constructs – specifically sustainability, lean, agility, PMI (2021)'s PPDs, PMI (2021)'s PDPs, and performance measurement (see Fig. 2).

This chapter focused on project management and SCM integration based on PMI (2021)'s PPDs and PDPs. Furthermore, this chapter emphasized the necessity of understanding the importance and benefits of the widespread use of the PDPs based on sustainable, resilient, agile, and lean SC, which enabled agilean PM to achieve PMI (2021)'s value-based PM (Fig. 3). This use complies with and supports construction industry-related main reports (e.g., Latham, 1994; Egan, 1998) and their recommendations. CSCM is essential for enhancing PM's performance and PMI (2021)'s PPDs. Effective CSCM, in compliance with PMI (2021)'s PDPs, can support project performance and PPDs in compliance with the project's goals.

PMI (2021)'s PPDs are the basis of SCM to achieve value-based PM. The PPDs are the criteria surrounding the SC. Relations among PMI (2021)'s PDPs and PPDs need to be managed throughout the entire CPM processes to enhance the value creation capacity of the PM and CSCM (Fig. 3). For project success, the SC must become an intrinsic component of the project ecosystem.

Main constructs of integrated SCM and PM in all phases of the CPM (Fig. 2) can act as supporters of the CSCM and PM integration. Leanness, agility, and sustainability principles/tools/topics should be integrated with the consideration of the PPDs of PM to enhance the performance of the SC. Identifying the accurate performance tools to support the SC strategy is important for sustainable, lean, and agile approaches for the success in the CSC performance. The SCOR model can be used together with the other main constructs (Fig. 2) of integrated CSCM and PM in all phases of the CPM. PM's success can be enhanced by establishment of a successful and competitive SC.

This chapter's emphases are in compliance with the emphases in construction industry-related reports (e.g., Egan, 1998; Latham, 1994). Construction project value can be enhanced by effective and strategic PM and SCM integration based on the PMI (2021)'s PDPs and PPDs, which can be further integrated with and supported by the lean, sustainable, and agile approaches in the CPM to gain competitive advantage in the construction industry.

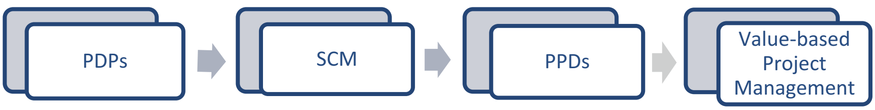


**Fig. 3** Relationship among SCM, PPD, and PDP

Researchers, academics, students, and professionals in the relevant field can benefit from this chapter. Future research is recommended to be performed on artificial intelligence's and industry 4.0 technologies' potential contributions to enhance CSCM and PM integration and performance.

# Conceptualizing Circular Supply Chains: A Theory Building Approach

## Contents

**Abstract**

Integrating circular economy (CE) principles into supply chains and operations is generating a lively debate among scholars and practitioners. However, while this literature stream is becoming abundant, there are still ambiguities in the adopted terminologies. While the established terms in the supply chain management domain, such as closed-loop and open-loop supply chains, are frequently used in the CE context, the term "circular supply chains (CSCs)" is gaining

prominence on its own. Hence, the purpose of this study is to provide clarity on this terminology while conceptualizing CSCs through a theoretical approach. We conceptualized CSCs as complex adaptive systems, with supply chain actors in physical and support supply chains who ensure the flow of products, End-of-Life products and materials, and, at the same time, considering the critiques on CE. We introduce three different CSC archetypes, closed-loop supply chains, open-loop supply chains, and CSCs – combining characteristics of both closed- and open-loop supply chains – aligning these archetypes to the current CE debate. The regenerative and restorative approaches and the application of value retention options – such as reduce, repurpose and recycle – in these archetypes are further illustrated through industrial examples. Other than traditional supply chain actors' commitment to successfully managing CSCs, collaboration with stakeholders beyond the boundaries of supply chains is crucial. When designing and planning CSCs, it is essential to understand the compatibility among resource flows to ensure improved sustainability. Scholars and practitioners can benefit from this conceptualization by comprehending the potential and boundaries of CSCs. Further, future research and understanding can empirically validate this work.

## 1 Introduction

In the last decade, the circular economy (CE) discourse has gained momentum, with increasing attention paid mainly by policymakers and think tanks. Despite the scholarly introduction of CE more than 30 years ago (Pearce & Turner, 1990), the concept is further developing around background notions such as energy consumption, resource depletion, life cycle assessment, waste, and emission generation (Korhonen et al., 2018b). At the same time, CE can be characterized as an essentially contested concept, with many disagreements over its definition and conceptual cornerstones (Korhonen et al., 2018b). Hence, it is vital to bear these different viewpoints in mind when integrating CE into any practical application.

The discourse on integrating CE into operations and supply chains is recent among scholars and practitioners. There are various approaches and strategies linked to CE implementation (Yang et al., 2018). In this regard, it is crucial to understand how circular thinking can be integrated into operations and supply chains (Seuring et al., 2022). While practitioners are initiating new projects to ensure CE implementation in supply chains, scholars are probing deep into these programs and investigating how and what aspects of operations and supply chains need to be different from traditional supply chains. Some of these scholars view these practices in the CE context as modified versions of existing operations (Genovese et al., 2017), while others highlight new practices such as industrial symbiosis integrated through other fields such as Industrial Ecology (De Angelis et al., 2018).

As a result of these differences, there is an ongoing debate over supply chain terminology in the CE context. For instance, new terminology is emerging as circular supply chains (CSCs) to denote the supply chains in the CE context (Batista et al., 2018; De Angelis et al., 2018). However, the supply chains in the CE context are commonly referred to as closed-loop supply chains (CLSCs) in the operations and supply chain management (OSCM) discourse (Taghikhah et al., 2019). Amidst all these terminologies, some have introduced another archetype called open-loop supply chains (OLSCs) (Kalverkamp, 2018), which is also embedded in OSCM discourse (Gou et al., 2008). Given the inconsistency in the use of CE-related terminology in the supply chain literature, it is important to establish a clear taxonomy of supply chains in the CE context. As such, by drawing on current knowledge on supply chains in the CE context and the theoretical foundations of OSCM, we provide an overview on:

1. Integrating circularity into supply chains while identifying and clarifying critiques on CE
2. Identify different supply chain archetypes in the CE context that can form the foundation of CSC terminology

This chapter is structured as follows. First, we will introduce the critiques toward CE and discuss how we can potentially overcome these limitations through our conceptualization. Secondly, we will conceptualize CSCs based on the OSCM theory development by Carter et al. (2015) while addressing the critiques on CE. We will further illustrate this conceptualization through practical applications of CSCs. Finally, while identifying different supply chain partners engaged, a comparison among probable CSC archetypes is presented, elaborating their similarities and differences to view the supply chains in the CE context comprehensively.

## 2 Critiques of the CE

When conceptualizing supply chains in a CE context, it is noteworthy to consider the critiques of the CE concept. One of the main critiques of CE is based on its thermodynamic limits. Even though cyclical resource flows create waste and emission, Korhonen, Honkasalo, and Seppälä (2018a) argued that product reuse, remanufacturing, and refurbishment should be prioritized over recycling as these strategies still offer an opportunity to make material and energy cascades sustainable in a global economy. Agreeing with this argument, Reike et al. (2018) also asserted that short- and medium-term loops should be favored over long-term loops. They categorized these value retention options (also known as Rs) under short-term loops (e.g., reduce, resell/reuse, repair, refuse), medium-term loops (e.g., remanufacture, refurbish, repurpose), and long-term loops (e.g., recycle, recover, re-mine). However, it is still essential to evaluate the contribution of each circular approach to sustainability (Korhonen et al., 2018a), especially given the criticism pointed toward CE regarding its unclear contribution to environmental and social sustainability performance (Corvellec et al., 2021). Hence, we integrate value retention options representing these loops and highlight their contribution to improving sustainability performance in the CSC conceptualization.

The CE is also critiqued for spatial system boundary limitations (Korhonen et al., 2018a). The materials and energy flow through different boundaries of organizations, administrations, and geographies. As a result, sustainability issues in CE approaches can be displaced and shifted across these boundaries. Hence, to overcome the critique on the limitations of spatial system boundaries of CE, we selected examples with local and regional level applications where boundary crossing is limited. We further ensured the sustainability impact of each example while reducing the concerns relating to problem displacement and shifting.

Similarly, there are concerns relating to intra- and inter-organizational management strategies when implementing CE practices. For instance, it is unclear who leads the implementation of CE practices in a network of actors, who takes the responsibility, and how these actors contribute to this network (Korhonen et al., 2018a). Hence, in this study, we considered the viewpoint of the focal firm (mainly the brand owner) as an attempt to overcome this limitation. The focal firm can be characterized by three criteria: (1) designs the product, (2) owns the related brand, and (3) organizes the supply chain (Seuring & Müller, 2008).

The unclear applicability is another critique of CE (Corvellec et al., 2021). This is mainly due to the misalignment among three pillars: policies, organizations, and individual consumers. Hence, when conceptualizing CSCs, we exemplify CE-practices implementation through real-world scenarios. These examples are mainly derived from the case studies published by the Ellen MacArthur Foundation, given the comprehensive and detailed nature of the presentation. We further validated and improved the content of these examples through grey literature. Additionally, we emphasize how these three pillars have been successfully aligned for the CE implementation through each example. As a result, this chapter focuses on understanding how supply chains can be designed by addressing certain limitations toward CE implementation.

## 3 Basis for Conceptualization

The conceptualization of CSCs is based on the following foundational premises presented by Carter et al. (2015) relating to the structure and boundary of supply chains. These premises provide a good starting point for CSC theorization with a comprehensive approach.

- A supply chain is a network with nodes and links, which acts as a Complex Adaptive System (CAS). While a node is an establishment referring to the agent's ability to make decisions and maximize gains within the constraints in which it operates, a link comprises transactions consisting of the flow of materials, finance, and information between nodes. Hence, a node is considered a "supply chain actor," and a link is regarded as a "product/End-of-Life (EoL) product/material flow."

- A supply chain is relative to a particular product/agent. This particular agent related to the supply chain is defined as a focal firm, and a product represents an input to or an output of the agent, which has a physical substance (product/EoL product/material).
- A supply chain is a combination of physical and support supply chains. A physical supply chain consists of "agents with a permanent, physical location where activities occur that add form, place, and/or time utility" to the product flow (Carter et al., 2015, p. 91). In a physical supply chain, there are different agents to be considered, as follows:
  – Traditional supply chain actors (e.g., manufacturers, suppliers, retailers, and end consumers)
  – Nontraditional supply chain actors (e.g., nongovernmental organizations [NGOs], community members, local authorities, and competitors) (Pagell & Wu, 2009; Rodríguez et al., 2016)
  – Supplementary supply chain actors who gather, make changes, or add values to the product/EoL product/material flows (e.g., waste pickers and recyclers)
  – Other manufacturers who are capable of using recovered products/materials other than the original equipment manufacturer (OEM) (Genovese et al., 2017)
- A support supply chain comprises "nodes through which a product (relative to the focal agent) does not flow, but which supports the physical supply chain of that product" (Carter et al., 2015, p. 91), such as financial institutions, brokers, and truckload transportation. Furthermore, actors such as policymakers, industry associations, and research institutes can also be identified under the support supply chain (Liao & Kuo, 2014).
- A supply chain is bounded by the visible horizon of the focal agent. Carter et al. (2015) refer to the agent's awareness (visibility) of "the physical nodes and links that move and add value to the product and the corresponding support nodes" (p. 93). Furthermore, it is noteworthy that the focal agent's visibility can be attenuated due to physical distance, cultural distance, and lack of centrality/closeness.

Based on these premises, we conceptualized the CSCs in the next section identifying the nodes and links in the combined physical and support supply chains as a CAS.

## 4 Conceptualizing CSCs

Different approaches are taken to ensure the efficient use of resources while eliminating waste creation in the CE. One main approach is to improve the circularity of product and resource flows. For example, Bocken et al. (2016) introduced three options: slowing (extending use), closing (reusing), and narrowing (reducing) loops.

These approaches lead to new business models, such as shifting from product ownership to services (De Angelis et al., 2018). Similarly, the focus on how to change the existing linear models to circular models is also gaining attention. As a result, the integration of circularity into supply chains has become inevitable.

Geissdoerfer et al. (2018) defined CSCs as “the configuration and coordination of the supply chain to close, narrow, slow, intensify and dematerialize resource loops” (p. 713). Linking to the already existing terminology in OSCM discourse, Batista et al. (2018) defined CSCs as “the coordinated forward and reverse supply chains via purposeful business ecosystem integration for value creation from products/services, by-products and useful waste flows through prolonged life cycles that improve the economic, social and environmental sustainability of organizations” (p. 446). Other scholars such as Farooque et al. (2019) also acknowledged this definition, given that this work has integrated the regenerative and restorative processes of CE to understand the circularity of supply chains. This chapter’s conceptualization is also in line with this definition, where CSCs can be considered a combination of forward and reverse supply chains (RSCs).

CSC terminology has been criticized due to its clashes with the well-established CLSC discourse. For instance, Mishra et al. (2018) proposed that CSCs can be used “for cases where circular economy principles are explicitly incorporated in CLSC for value creation” (p. 509). De Angelis et al. (2018) further argued that CSCs should be expanded beyond CLSCs, opening opportunities for materials to flow across supply chains. Hence, considering this conflicting scholarly discussion in literature, this chapter’s conceptualization includes the integration between forward supply chains and RSCs.

## 4.1 Integration of Forward Supply Chains and RSCs

Forward supply chains, also known as traditional supply chains, accomplish their mission once the end consumer owns the product (Guide et al., 2003). However, RSCs extend the forward supply chains by bringing the used products back into the system. Hence, RSCs act as “the effective and efficient management of the series of activities required to retrieve a product from a customer and either dispose of it or recover value” (Prahinski & Kocabasoglu, 2006, p. 519). These series of activities performed to retrieve a product can be identified as the key processes in reverse logistics: product acquisition, collection, inspection and sorting, and disposition (Agrawal et al., 2015).

The discussion on integrating forward supply chains and RSCs is well established in the OSCM discourse as CLSCs and OLSCs. OSCM literature primarily focuses on CLSC, where the discussion on OLSC is narrowly addressed (Govindan & Popiuc, 2014). Guide and Van Wassenhove (2009) defined CLSC as “the design, control, and operation of a system to maximize value creation over the entire life cycle of a product with the dynamic recovery of value from different types and volumes of returns over time” (p. 10). Furthermore, over the years, scholars segregated the difference between CLSCs and OLSCs based on the value recovery process in the RSC. The recovery of the used or EoL products by the OEM is categorized as CLSCs, whereas third parties or other manufacturers engaging in this process are classified as OLSCs (Govindan et al., 2013; Islam & Huda, 2018; Rahman & Subramanian, 2012).

If the RSC can bring the EoL products to the source of their production, it can create a closed loop. On the other hand, when the RSC brings these EoL products to different destinations, they create an open loop. Hence, it is evident that the RSC plays a crucial role in closing existing loops and opening new loops. Consequently, based on the recovery activities of the RSC, the engagement of different parties becomes crucial. To overcome most of the uncertainties entailed with the RSCs, such collaborations play a pivotal role (Agrawal et al., 2015).

The crucial role of RSCs is emphasized in the early scholarly attempts to integrate CE into OSCM scholarly discussion. For instance, Genovese et al. (2017) introduced RSCs as both CLSCs and OLSCs in the CE context. While the attention that should be paid to RSCs in the CE context is lacking (Mokhtar et al., 2019), the most commonly used terminology is limited to the term "CLSCs." Therefore, it is clear that a good understanding of the role of RSCs in the CE context is required to reduce conceptual confusion and dive deep into the understanding of supply chains in the CE. Hence, we propose three probable archetypes for CSCs based on three types of RSCs designed for CE implementation drawn upon the value retention options proposed by Reike et al. (2018).

## 4.2 *CSC (Type 1)* with *RSC (Type 1)* Where the EoL Products Are Returned to Their Origin

### Close the Loop with CE motivation – Restorative Approach Through Reduce and Reuse (Short-Term Loops)

We illustrate *CSC (Type 1)* through Example 1 on the universal bottle introduced by the Coca-Cola company and its bottling partners in Latin America (Ellen McArthur Foundation, 2018a). Coca-Cola introduced a reusable plastic bottle that can be used to fill their different soda brands. With the reuse of plastic bottles, the use of virgin materials to produce plastic bottles is reduced. Hence, the life cycles of plastic bottles are extended. Furthermore, with the introduction of the reuse principle, Coca-Cola has *retrofitted* its supply chain; that is, Coca-Cola adopted a new set of practices aligned with CE.

Once the consumers finish the drink, they can hand the empty bottle to the retailer or the point of sale. Consumers will have to pay an indirect deposit for the bottles, which will be received as a discount on their next purchase once they return the empty bottles. The retailers will store these empty bottles and hand them over to Coca-Cola when delivering new orders. Then Coca-Cola will bring these empty bottles and hand them over to the bottling partners to clean the bottles, wash off the paper labels of different brands, and refill and rebrand the bottles with new labels. All parties involved in the physical product flow in the forward supply chain – also known as traditional supply chain actors – are also involved in the reverse process.

Even though this operation seems straightforward, the commitment of various parties to accomplish this approach was quite exhaustive. While the internal departments of Coca-Cola have dedicated themselves to the design process of this universal bottle, the immense support from both supply chain partners and external parties has been crucial. Bottling partners of Coca-Cola have committed to understanding the specific requirements of the universal bottle manufacturing, packaging, merchandising, and distributing while investing in required infrastructure changes. Similarly, external consultancy firms were also involved in bringing in outside expertise. For example, TriCiclos, a Latin American social enterprise, focused on designing and implementing solutions to eliminate waste, provided an independent life cycle assessment of this new production system. Hence, these external consultants assist the product flow and become a part of the support supply chain.

Interestingly, apart from the consumers who return the plastic bottles to the retailers, waste pickers will return the thrown-out or disposed of plastic bottles to the retailers. These waste pickers are also known as *scavengers* who are essential external parties in supply chains. These scavengers can be informal or formal. Informal scavengers are mainly poor and marginalized people collecting waste for survival purposes with inefficient and unhealthy methods, while formal scavengers provide centralized and efficient waste management systems (Zerbino et al., 2021). These scavengers play a major role in collecting waste plastic bottles (Asim et al., 2012). Hence, these waste pickers become a part of the physical supply chain while providing such supplementary support.

We further illustrate this example in Fig. 1, which depicts how the loop is closed. Further, as presented in Table 1, we identify physical and support supply chains

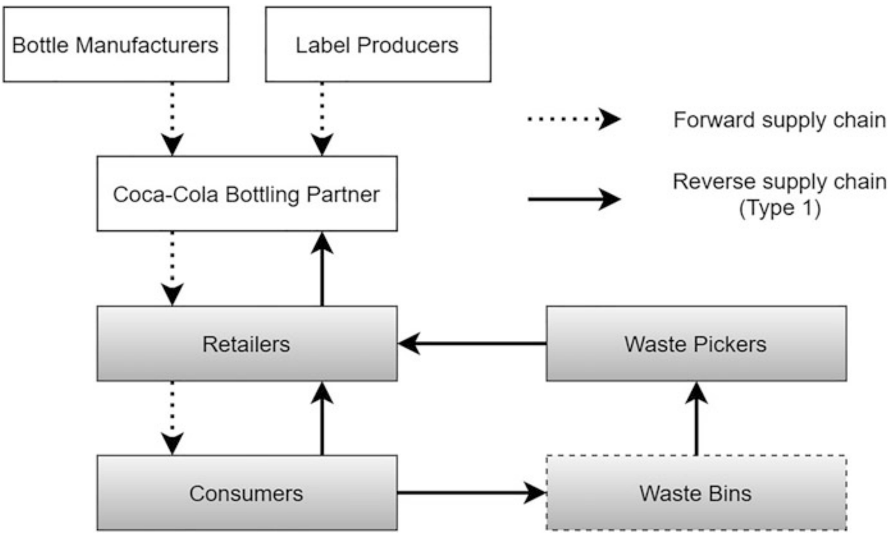

**Fig. 1** Product/EoL product/material flow in CSC (Type 1) in Example 1

along with the defined nodes. Besides the waste pickers, Coca-Cola, as the focal firm, has the visibility of other supply chain actors in the *RSC (Type 1)*.

## 4.3 *CSC (Type 2)* with *RSC (Type 2)* Where the EoL Products Are Returned to Another Supply Chain as a Resource

### Open a New Loop with CE Motivation – Regenerative Approach Through Repurpose (Medium-Term Loops)

*RSC (Type 2)* is illustrated through Example 2 on BioPak. BioPak manufactures compostable food service packaging using renewable plant-based materials (Ellen McArthur Foundation, 2018b). This example illustrated how a supply chain can be *circular by design* as the supply chain has already been designed to improve sustainability in CE. Apart from the product design contributing to the CE implementation, BioPak also provides collection and composting services to ensure that circularity is further extended. This service is mainly established in Australia and New Zealand and recently started in the UK. Even though this is a nonprofit effort, BioPak is deemed to understand its extended producer responsibility.

BioPak provides an online platform called Compost Connect, connecting restaurants and locals with composting services in different states in Australia and New Zealand. This service collects compostable packaging along with food waste. The company provides separate bins to collect all the organic wastes without separation. A restaurant or an individual can simply look for a composter in its postal code area, enter the details of the location, and agree on a pickup schedule. While the involvement of restaurants indicates the involvement of traditional SC actors, the engagement of individuals in local communities highlights the active presence of a nontraditional member of the supply chain in the product flows (physical supply chains).

In addition to the businesses such as restaurants and locals engaged in reversing their landfill food waste to compost, BioPak is working with various organizations. Especially, local and industrial composting services, waste management industries, and local governments play a prominent role in improving the composting

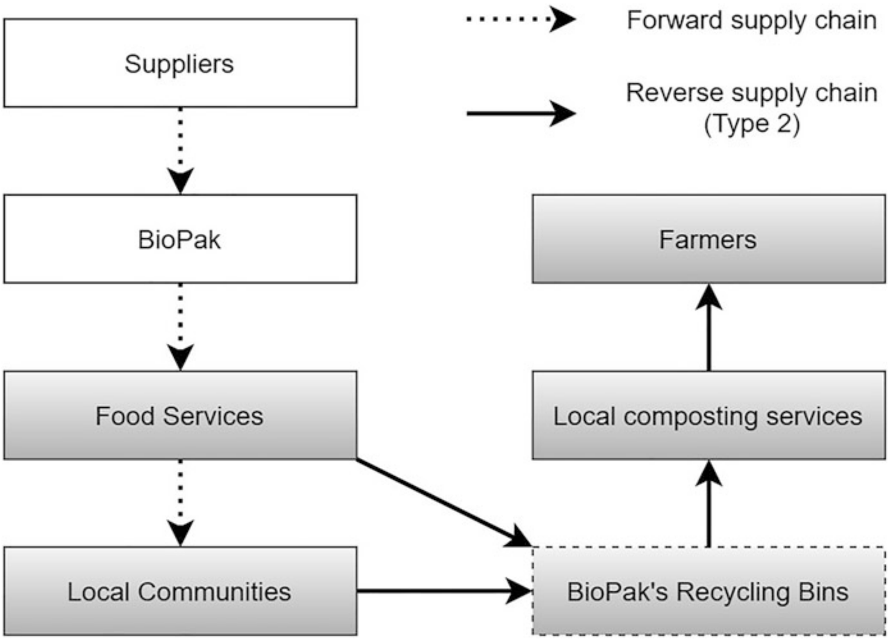

**Fig. 2** Product/EoL product/material flow in CSC (Type 2) in Example 2

infrastructure while scaling up operations. These actors support the reverse flow while being a part of the physical supply chain. Further, these initiatives are already receiving the support of the Australian Organic Recycling Association (AORA), which is a part of the support supply chain.

This scenario is illustrated in Fig. 2, and the nodes are defined in Table 2. BioPak, as the focal firm, knows the supply chain actors in the *RSC (Type 2)*, other than the farmers directly connected to the local composting services.

## 4.4 *CSC (Type 3)* with *RSC (Type 3)* Where the EoL Products Inside and Outside of the Own Supply Chain Are Returned as a Resource

### While Closing Its Own Loop, Several Resources Are Also Brought in Through Another Open Loop – Restorative Through Recycling (Long-Term Loops)

Example 3 is from Renault Group and illustrates the *CSC (Type 3)* with its factory dedicated to CE in mobility. This case is also an example of a *retrofitted* supply chain where Renault has adopted CE-oriented practices to achieve its CE strategy.

**Table 2** Identifying nodes in CSC (Type 2) in Example 2

| **Physical supply chain** | Traditional supply chain actors | Suppliers, BioPak, Restaurants | High visibility to the focal firm |
| | Nontraditional supply chain actors | Local communities gathering waste in BioPak wastebins | High visibility to the focal firm |
| | Supplementary supply chain actors | Compost partners (local and industrial composting services along with waste management industries) | High visibility to the focal firm |
| | Other manufacturers | Farmers | Low visibility to the focal firm |
| **Support supply chain** | Support supply chain actors | Industry Associations (e.g., Australian Organics Recycling Association) | High visibility to the focal firm |

Re-factory has changed Renault's manufacturing processes (Ellen McArthur Foundation, 2020). One such initiative is recycling copper retrieved from electrical wiring in End-of-Life Vehicles (ELVs), collaborating with its subsidiaries and partners (Communication Department – Groupe Renault, 2020).

INDRA, one such subsidiary, partnered with Suez, which recovers secondary materials for ELVs. Boone Comenor is another company that collaborated to recover metallic scrap materials (e.g., copper wiring) from the automotive industry. These recovered materials are then sent to the recyclers by another Renault wholly-owned subsidiary, Gaïa (Curt, 2018).

MTB Recycling is one such recycler producing 99.9% pure copper out of these wirings (Tse et al., 2016). This recycled copper is then sold internally and externally in Renault's supply chain. Internally, Fonderie de Bretagne (Groupe Renault) uses this recycled copper to produce pearlitic cast iron (Renault Group, 2016). The external parties, such as other auto part manufacturers, also become a part of this supply chain as they get their recycled copper supply for aluminum processing.

The legislative lead from the European Union (EU) was paramount to making this operational change possible with the European Directive on dismantling and recycling ELVs (European Commission, 2000). Similarly, this approach was supported by the research effort of the EU under the EU LIFE Research Program named ICARRE95 (European Commission, 2015).

This product flow within Renault's supply chain and outside in other automobile supply chains is illustrated in Fig. 3. The involved parties are shown in Table 3. As the focal firm, Renault Group has the visibility of most supply chain actors illustrated in Fig. 3, except for the other ELV owners directly linked to INDRA and other auto suppliers who are the customers of MTB Recycling. In this case, the focal firm is missing the knowledge of second-tier suppliers. As a result, this type of supply chain is characterized, overall, by a lower degree of visibility.

## 4.5 Comparison Among Three CSC Types

Based on the abovementioned three examples, comparisons among the three CSCs can be made in two different ways. Firstly, we make the comparison based on the different parties involved in each CSC archetype, as illustrated in Fig. 4.

Figure 4 depicts how the supply chain partners can be involved in CSCs. When focusing on the circular resource flows, at least one member of the traditional forward supply chain is involved in ensuring the EoL product is returned to the same or any external system. Mostly, this traditional supply chain actor is the end consumer. However, this can even be a producer who implements rigorous, extended

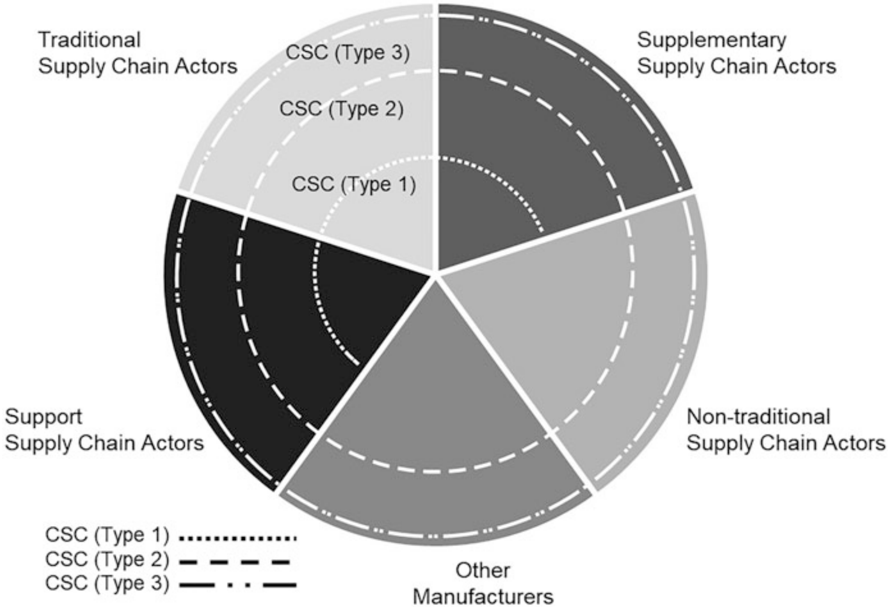

**Fig. 4** Comparison of nodes among three CSC types

responsibility practices. Similarly, it is apparent that when the product or resource flows outside one supply chain (opening new loops), the role of external parties such as nontraditional partners and other manufacturers is crucial. This illustration further proves the importance of collaboration among different parties in the CSCs.

Secondly, we compare the characteristics of these three types, as shown in Table 4.

*CSC (Type 1)* is designed to bring the supply chain's own waste back as resources to the system. Hence, with a restorative approach (return to a previous or original state) within the CE perspective, *CSC (Type1)* aims to develop the product with long-lasting approaches while following effective recovery practices. Whenever one value retention option is no longer feasible, *CSC (Type 1)* can be retrofitted to include an alternative option. *CSC (Type 1)* is driven by the *extended producer responsibility* and direct engagement of the OEM. Hence, the primary return flows are well structured, limiting the knowledge of other supply chain actors.

*CSC (Type 2)* is designed to carry the waste from one CAS to another as resources. As a result, *CSC (Type 2)* is *circular by design* to maintain resource value as long as possible. With a regenerative approach, this is driven by product stewardship. According to Jensen and Remmen (2017), product stewardship evolved from responsible management of hazardous wastes toward a broader focus on resource conservation. Product stewardship agreements have either been driven by government or industry or have involved in some form of collaboration between these two actors. In the CE, product stewardship can help manufacturers to minimize

the environmental impacts of products throughout their life cycle (Jensen & Remmen, 2017).

As illustrated in the *CSC (Type 2)* example, BioPak has already aligned its operations with CE approaches by designing the products. Still, the firm goes beyond its immediate responsibility and tries to link with another supply chain through cascading approaches. As BioPak provides only a digital platform to connect different parties, it is indirectly involved in this CSC as the OEM. However, when studying other examples of opening loops, it is crucial to pay attention to the compatibilities of the connecting loops, given their ultimate impact on sustainability.

For instance, plastic bottle recycling for the apparel industry is getting popular (Cai & Choi, 2020). However, whether this is a sustainable CE loop connection is under discussion. When PET bottles are downcycled to tires, fabric, or toys, the cycle is disturbed as their life extension is limited to a single round before sending to landfills. As a result, the European nonalcoholic beverage industry has already requested amendments to the EU's Packaging and Packaging Waste Directive to give them priority access to the waste PET bottles compared to other industries (Poole, 2021). Hence, it is crucial to remember the inherent goal conflicts to ensure successful circularity in such a resource loop combining approach.

Indirectly, we can identify *RSC (Type 3)* as an amalgamation of *RSC (Type 1)* and *RSC (Type 2)* based on their characteristics. Hence, *CSC (Type 3)* is designed in such a way as to bring the waste in the whole system (in a particular industry) into a CAS and return the restored products not only to the CAS but also to the system. Hence, this CSC type focuses on both long-lasting and cascading approaches driven by the extended producer responsibility and product stewardship. As a result, the direct engagement of the OEM is crucial. Similar to *CSC (Type 1)*, *CSC (Type 3)* can also be retrofitted to include other value retention options.

Hence, it is clear that all the RSC types mentioned above fulfill the requirements to ensure the circularity of supply chains. Thus, this answers our question that a CLSC is a CSC, but CSCs are not limited to CLSCs. CSCs can be based on OLSCs or a combination of CLSCs and OLSCs. Similarly, several parties involved in a CSC profoundly differ from conventional linear supply chain actors. Hence, the visible horizon of the CSCs needs to be expanded even outside the supply chain boundaries to integrate unrelated and new partners such as governmental agencies.

## 5 Discussion

The main issues covered in this chapter are three-fold. Firstly, we identify the distinctive features of CSCs while clarifying the confusion on the terminology. There is no hard and fast rule to define CSCs. However, CSCs should be designed considering the overall sustainability improvement achievable through the circular flows (Korhonen et al., 2018a). Hence, RSC plays a major role in hinting that the circularity can be improved even beyond the boundaries of CLSCs. Especially, the different parties involved in these supply chain archetypes to improve the physical flow of goods and support this process emphasize the importance of collaboration among these parties.

Secondly, we further detailed the CE discourse, hinting at how to design CSCs while addressing the critiques toward CE. Understandably, there is no one way to design a CSC. Each CSC is unique, given the way it addresses the limitations of the CE concept. However, it is equally important to remember that not all limitations can be overcome simply by designing the CSCs with certain boundaries. For instance, a consumer behavior change is required to overcome the rebound effect of CE discussed by Korhonen et al. (2018a). Albeit such hurdles, CE implementation can still be successful with an appropriate CSC design to improve sustainability performance.

Thirdly and finally, a focus on the collaborative perspective in CSCs and the vital role played by the nontraditional supply chain actors in the physical supply chains and supportive actors in the support supply chain are made clear. These non-traditional actors, such as local communities and NGOs, are gaining special attention even in the OSCM discourse (Sudusinghe & Seuring, 2022). Their involvement in CSCs is critical given their direct involvement in the product flows in the RSCs. In addition, supportive actors such as governmental agencies and industry associations are also equally important, given their special knowledge-sharing role in ensuring successful CE implementation (Veleva & Bodkin, 2018). Hence, the engagement of external parties who are not generally part of the traditional supply chains is crucial in designing CSCs, which are truly coherent to an ambitious view of the CE agenda.

## 6 Managerial and Policymaking Implications

Several useful managerial and policymaking implications for CE implementation through CSCs can be drawn from this chapter. Through the comparison among CSC archetypes, this chapter can assist practitioners in deciding which CSC configuration is more suitable for implementing CE practices in their supply chain. This chapter can offer some insights to practitioners in designing their CSC, in order to match with their CE implementation strategies. Furthermore, the detailed illustration of the pros and cons of each CSC archetype can make the practitioners aware of the opportunities and challenges they may face when implementing CE practices in their supply chains.

Similarly, this study elaborated on how supply chain loops can be closed, in a creative manner, in order to ensure the circularity of product flows. Especially in the presence of multiple CE implementation options, the overall effects in terms of environmental performance need to be considered. This is particularly relevant when recycling solutions are involved in closing the loops, as illustrated in the chapter. The awareness and knowledge of such implications can assist managers in making better decisions in the long run to improve the overall sustainability of CSCs.

Similarly, this chapter can provide some guidelines to practitioners regarding the need to expand the visible horizon of the focal firm. This is especially the case when integrating new partners, who are beyond the supply chain boundaries, into the operations in order to implement CE practices. Practitioners should also engage with supportive supply chain partners and other stakeholders, such as NGOs, to share knowledge. Managers can identify such crucial, out-of-scope partners, and pay special attention to them, given their crucial role in the supply chain transformations in the CE context.

Finally, this chapter can also provide useful advice to policymakers on how their intervention could nurture or disrupt CE implementation patterns in supply chains. Clear, up-to-date, strict rules and regulations can lead the progress of linear supply chains to CSCs. Consequently, this progress can thrive with extended support to supply chain partners through collaborative approaches to master the needed knowledge and skills.

## 7 Conclusion

Enhancing the circularity of supply chains requires integrating appropriate product loops to improve sustainability. As a result, with the crucial role of RSCs to ensure the circularity of product flows, engaging different parties who are generally not involved in traditional or linear supply chains is crucial to smooth these circular flows. Hence, CSCs can be designed after modifying the existing supply chains accordingly. While CLSCs and OLSCs ensure the circularity of supply chains, their integration can also be modified to improve the sustainability of CSCs. It is noteworthy to consider the characteristics and limitations of each CSC archetype before employing it.

This chapter has some limitations, and the foundation presented here can be expanded. When selecting the examples, we employed cases with the best illustration. This decision was in line with the need for case-by-case analysis to understand the circularity of application in the CE (Korhonen et al., 2018a). Yet, there are cases where failure and improvements are required, as in most cases, the complexity of CE needs careful evaluation with all the potential contingencies that exist. Future direction and understanding are needed and can be accomplished by empirically testing this conceptualization.

Similarly, CE has many additional critiques and concerns. We do not mention additional ones and do not have frameworks for each critique raised toward CE, such as concerns relating to the possibility of rebound effects (Zink & Geyer, 2017). Hence, further investigation can be conducted addressing such major critiques in more detailed expositions of these issues.

# Remanufacturing and the Supply Chain

Senlin Zhao, Yunting Feng, and Qinghua Zhu

## Contents

**Abstract**

Remanufacturing offers the advantages of energy consumption reduction, cost savings, and waste reduction. However, barriers exist along remanufacturing supply chains, from the supply of used products to consumers' acceptance/preferences for remanufactured products. Thus, support and coordination activities are needed from supply chain members and related stakeholders. This chapter first introduces the background of remanufacturing, discussing current topics and issues with great concerns by practitioners and researchers such as

governments' efforts for remanufacturing, and collection of used products. Then, we introduce the topic of "competitiveness and uncertainties," which explores how practitioners in a remanufacturing supply chain should face competition and how to coordinate remanufacturing supply chain players to ensure the stability and development of the remanufacturing supply chain. On the topic of "market acceptance," we introduce how to measure consumers' preferences, use government subsidies more efficiently, and provide an innovative service mode for remanufactured truck engines. This chapter ends by providing an overview of the evolving remanufacturing supply chain concept, significance, and practice.

## 1 Introduction

Seeking to recover value, reduce waste, and mitigate carbon emissions from products at the end of their life cycle, remanufacturing with a reverse supply chain is one mode of pursuing sustainability. Remanufacturing is pollution-preventive with low-carbon emissions, material-savings, and thus it attracts great attention in both the industrial and academic worlds. The economic, social, and environmental benefits are accrued by participants involved in remanufacturing activities.

Remanufacturing has been an issue of interest in academia and industry in recent years. At present, many human activities are at the cost of consuming natural resources and sacrificing the natural environment. Balancing economic requirements and environmental issues has become an important requirement for enterprises. Remanufacturing increases the value of used products by replacing nonfunctional parts or reprocessing broken parts. Remanufacturing processes help reduce environmental burden by reducing natural resources consumption and waste of used – end-of-life – products. However, remanufacturing faces barriers within supply chains and supply chain management.

The second section of this chapter introduces the importance of remanufacturing to enterprises and countries. This chapter first explains the importance of the remanufacturing industry, and what laws and actions have been implemented to facilitate the remanufacturing industry. Then it further illustrates how enterprises make profits through remanufacturing and how to obtain used products from consumers.

The third section of this chapter introduces the competition and uncertainties of a remanufacturing supply chain. Firstly, in most situations, the original equipment manufacturers (OEMs) prefer high-quality new products if they carry out a trade-in policy. A higher quality level could be harmful to consumer surplus because the cost is directly passed to them. Moreover, if consumers are willing to replace their original products, there exists a competition between the OEM and the third-part remanufactures (TPRs) through a trade-in policy. Interestingly, when the consumer's replacement intention is sufficiently low, the TPRs could be more profitable due to the implementation of the trade-in policy too.

Secondly, knowing remanufacturing uncertainty a coordination contract in a remanufacturing supply chain is introduced. Today's market is constantly changing, and how to deal with the change in the market has posed a great challenge to enterprises. The remanufacturing market may be affected by various factors, so the remanufacturing supply chain should be prepared to deal with market fluctuations. Enterprise attitude toward risk plays an important role during decision-making processes. The stability of the supply chain needs the coordination of different participants, and so does a remanufacturing supply chain. An effective way to achieve coordination among the various participants is to design appropriate contracts. Appropriate contracts can help the different participants of the supply chain make efforts for remanufacturing supply chain stability.

The fourth section of this chapter introduces the issue of consumer acceptance of remanufactured products. Firstly, we introduce how remanufacturers make decisions considering both consumer environmental preferences and government subsidy policies. Remanufactured products have a lower environmental impact. Unfortunately, at present, many consumers are less likely to accept and purchase remanufactured products.

Global markets and governments have realized that remanufactured products play a significant role in environmental protection and energy-saving. Promoting the development of remanufacturing, many governments have formulated relevant policies and provided subsidies for the healthy and sustainable development of remanufacturing supply chain. However, remanufacturers need to make decisions according to consumer environmental preferences and government subsidies.

Secondly, as there are two concerns of remanufactured products – one is after-sales service and the other is the quality of remanufactured products – we discuss the redesign of remanufacturing product service modes, which aims to improve consumer acceptance by alleviating or even eliminating their two concerns. Proposed innovative service modes could be adopted for remanufactured products to meet consumer needs. We describe the development of two after-sale service modes including the extended warranty mode and the free replacement mode, based on the existing conventional product innovation service mode.

The last section of this chapter identifies future research directions for remanufacturing supply chain management. The main content of this part includes some possible research directions in the future and the prospect of remanufacturing supply chain management in the future.

## 2 Business Practices and Policy Support for Remanufacturing

A remanufacturing supply chain at least consists of three parts – (1) collection of used products, (2) a remanufacturing process (including Inspection, Disassembly, Cleaning, New components replenishment, Reassembly, and Testing), and (3), remarketing (including estimation for market acceptance of remanufacturing products and impact of government subsidies) – each having its different questions and challenges.

## 2.1 Get Moving: Collection of Used Products

Collection of used products is the first step in remanufacturing, and people need to build a collection channel and develop reverse logistics before remanufacturing.

Several studies on closed-loop supply chains explored a proper reverse channel for remanufacturing collection activities in different contexts (Atasu & Souza, 2013; Savaskan et al., 2004). The results suggest that the retailer-managed collection channel is the most effective way under certain conditions. However, many manufacturers prefer to outsource the collection activities of used products to third parties (3Ps) (Atasu et al., 2009).

Hosseini-Motlagh et al. (2019) considered a case where a remanufacturer outsources the collection of used products to duopolistic 3Ps under perfect cost information. Zou et al. (2016) studied the performance of remanufacturing outsourcing and authorization, and they found that remanufacturing outsourcing is superior to remanufacturing authorization for a manufacturer. From the retailer's point of view, Wang et al. (2017) evaluated whether a retailer should engage in remanufacturing by itself or authorize this activity to a TPR.

Trade-in is another way for used products collection, as trade-ins can be used to offset the purchase price of new equipment. If the equipment does not have trade-in, or salvage, value, it can be recycled for free. Trade-in rebates involve returning used products, obtaining a price discount, and repurchasing the latest version of the durable products (Zhang & Zhang, 2018; Li et al., 2019). Traditionally, the core collection activity (i.e., returning used products), firms taking back the used products from customers, was generally separated from the repurchase decision. In contrast, trade-in policies naturally connect both the core collection and sales activities. It is, thus, clear that trade-in would enhance the OEM's competitive edge in two ways. Trade-in rebates can encourage customers to change their used products (Van Ackere & Reyniers, 1995) and alleviate the negative effect of customers' mental cost of retiring their used products (Okada, 2001).

Currently, many firms carry out trade-in rebates to improve market demand. More companies are implementing a trade-in policy for durable goods (Xiao & Zhou, 2020). Rao et al. (2009) found that a trade-in policy can soften the negative effects of the lemon problem and increase a firm's profit. Therefore, they attempt to examine the incentives for producers of new durable goods to accept trade-ins as part of the payment. Trade-in rebates to some extent can facilitate consumers to write off the mental cost of retiring their used products (Okada, 2001) and then encourage consumers to re-purchase new products (Van Ackere & Reyniers, 1995). The existence of trade-in policies has also been accepted by consumers. For instance, Xerox implements a trade-in policy as a marketing strategy and covers its collection and disposal expenses (Xerox Inc, 2016). Likewise, Apple's trade-in policy allows consumers to trade in their used equipment offline or online (Apple Inc, 2019).

Moreover, Deloitte Global predicted that there were 80 million smartphones traded with a value of $11 billion in 2015, and 120 million smartphones traded with a value of $17 billion in 2016 (Deloitte Global, 2016).

## 2.2 Governmental Efforts for Remanufacturing Systems Support

Remanufacturing is profitable for manufacturers due to the reclaimable value of used products and reduced energy use (Fang et al., 2020). Many countries are aware of the deteriorating environment, so they have established policies and regulations to facilitate remanufacturing. Europe is one such place where the population and government generally have a strong awareness of environmental protection, and they believe that remanufacturing used products can reduce energy consumption and protect the environment. Therefore, various European countries actively promote remanufacturing activities, and it is estimated that Germany has the largest remanufacturing industry in Europe.

Before 2008, the remanufacturing industry had barely developed in China. Currently, the remanufacturing industry is developing rapidly in China due to policy support. To accelerate the development of remanufacturing, the Chinese government provides at least four kinds of subsidies, which are "subsidy in the initial stage," "subsidy for used products collection," "subsidy for R&D," and "subsidy for remanufactured products."

"Subsidy in the initial stage" is a one-time subsidy that helps to cover the investment in remanufacturing operations and equipment for a new remanufacturer. "Subsidy for used product collection" is a subsidy for the collection agent which helps to ensure a sufficient supply of used products. For example, in December 2008, a "home appliances going to the countryside" policy was announced by the Chinese government. A certain percentage (13%) of financial subsidies will be given to low-income people in poor areas to buy household appliances in the subsidy scope so as to activate those low-income people's purchasing power, expand rural consumption, and promote the coordinated development of domestic and external demand.

"Subsidy for R&D" is a subsidy for remanufacturing enterprises that help to develop remanufacturing technologies, such as dismantling, cleaning, surface repair, and structural strengthening, assembling, and testing.

"Subsidy for remanufactured products" is a policy of the government to reduce the retail price of remanufactured products and increase the remanufacturing capacity. For example, the Chinese government subsidizes 2000 RMB (about 298.6 USD) per remanufactured Steyr engine (336 horsepower).

# 3 Competitiveness and Uncertainties for a Remanufacturing Supply Chain

Increased human awareness of environmental protection has supported rapid remanufacturing industry development with more enterprises entering the remanufacturing industry. Therefore, the competition in the remanufacturing industry is increasing, which brings new challenges for enterprises in a remanufacturing supply chain. This section mainly introduces how enterprises in the remanufacturing supply chain should face competition and how to coordinate remanufacturing supply chain enterprises to ensure the stability and development of a remanufacturing supply chain under an uncertain environment.

### 3.1 Competitiveness Between an OEM and a Remanufacturer

The choice of product quality is an important part of an enterprise's competitive strategy. It is well known that OEMs have to compete with dozens of TPRs that typically have low production cost and attractive price advantages. As a German carmaker said, the quality of their remanufactured products equals that of new ones but at half the cost. In reality, remanufacturing is almost always beneficial for the environment and society, but original equipment manufacturers (OEMs) prefer to prevent any kinds of recovery value by TPRs or refurbishers due to the recovery products decreasing OEM's profit (Chen & Chen, 2019).

According to Rao et al. (2009), a trade-in policy can allay inefficiencies arising from the *lemon* (low-quality vehicles) problem. Hence, OEMs can ward off competition from TPRs through trade-in policies, particularly by offering price discounts to attract existing customers who may be willing to pay for the affordable remanufactured products in the secondary market. For an OEM that also remanufactures used products, it should also determine the quality of remanufactured and new products. Remanufactured products are made from used products, and their quality usually is the same as new products. Therefore, the OEM's quality decisions affect product recovery.

A trade-in policy can stimulate consumer demand and expand product sales. However, this operation also creates additional problems for its offering firms in terms of quality choice and trade-in rebates. On the one hand, a higher quality choice can not only increase consumer perceived value of new products but may also result in high selling prices and low sales volume (Atasu & Souza, 2013). As a result, there is a lower supply of used products that can be collected in the market. Alternatively, high product quality has high durability so that the products can last longer. This situation indicates that a firm's quality choice may directly result in consumers being reluctant to replace their current version of a durable product. Even though a trade-in policy can lure consumers to repurchase new products early, a higher trade-in rebate is needed to compensate for the negative effect of a higher quality choice on a consumer replacement decision. Hence, firms should investigate how to choose new product quality when they intend to adopt a trade-in policy.

Apart from considering the effect of the trade-in policy on quality choice, an OEM needs to consider cannibalization of TPR's remanufactured products. OEMs can vary their product quality to eliminate the TPR's competitive threat (Orsdemir et al., 2014). The quality level of remanufactured products is associated with new ones. Hence, an OEM's decisions on the new product quality can affect a TPR's remanufacturing cost.

While a few papers consider the quality decision of OEMs regarding TPR competition (Orsdemir et al., 2014; Wu, 2013), they do not take the implementation of trade-in policies on the OEM's quality choice into consideration, which is slightly divergent from reality. For example, Apple recovered more than 66% of its devices by trade-in policy and sold them to new consumers, and Apple devotes itself to design for easy recovery (Apple Inc, 2019). In addition, the extant literature assumes that consumers buy new products once (Ferrer & Swaminathan, 2006, 2010; Orsdemir et al., 2014). However, according to research made by Fernandez (2001), the replacement rate of household appliances in America, like washing machines and fridges, accounts for around 75% of annual sales. In 2019, Apple had approximately three-quarters of iPhone online trade-in brand loyalty (BankMyCell, 2019).

It is important to consider consumer replacement decisions for durable goods regardless of whether or not OEMs carry out trade-in policies, which is a significant difference from previous research (such as Feng et al., 2020). Organizations could investigate thoroughly how the OEM quality choice is affected by the trade-in policy, as well as examine how the OEM takes the quality choice as a lever to enhance its competitive advantage in the trade-in policy.

From an OEM viewpoint, the implementation of a trade-in policy often results in a higher product quality in most cases, which is more likely to improve revenues for its offering firms. Under a monopoly situation, the OEM is more sensitive to consumer mental depreciation (the perceived depreciation of the product value) than recovery efficiency. Thus, it is necessary for the OEM to help former consumers accurately understand their used product salvage value. If a consumer's mental depreciation is low, the primary value of the trade-in policy is to achieve better price discrimination, which is much more significant than the purpose of exploiting repeat consumers. In the meantime, under a duopoly situation, the trade-in policy can generally consolidate the OEM's competitive position.

From the TPR viewpoint, implementation of a trade-in policy does not mean TPR profits necessarily decrease, which is more relevant to consumer mental depreciation degree. In particular, when former consumers are less willing to buy remanufactured products, the trade-in policy is also beneficial to the TPR. Alternatively, a higher consumer mental depreciation may lead to a negative effect on TPR revenue if they implement a trade-in policy. Managerially, TPRs should investigate and understand consumer mental depreciation before making decisions regarding quality if they intend to implement a trade-in policy.

From a consumer surplus perspective, consumer replacement intention plays a significant role in evaluating the impact of trade-in policies on consumer surplus. For example, if consumers are hesitant in making their replacement decisions, then the trade-in policies are most beneficial to consumer surplus. For a wide range of mental depreciation, the trade-in policy may be a detrimental factor to consumer surplus.

## 3.2 Uncertainties for a Remanufacturing Supply Chain

### Uncertainties and Contract Coordination

Supply chain uncertainty in remanufacturing supply chain management is noticeable and it poses great challenges. The uncertainty often results in low supply chain performance. In this topic, a comprehensive set of sources related to remanufacturing supply chain uncertainty has been identified and reviewed (Simangunsong et al., 2012); these uncertainties are divided into three dimensions:

1. Uncertainties from the internal organization, which come from the enterprises, such as (Re)manufacturing process, organization issues, multi-dimensions in decision-making, and the wrong use or threats of IT technical error (Sridharan et al., 2005)
2. Uncertainties from the internal supply chain, such as terminal customer demand (Mishra et al., 2009), and demand amplification, which cause the bullwhip effect (Ouyang & Daganzo, 2006), and quality problems
3. External uncertainties, such as government regulations or natural disasters

Deriving from complexity in remanufacturing supply chain management, multi-uncertainty factors could be involved at the same time. Coordination of a remanufacturing supply chain can help the stability and sustainable development of a remanufacturing supply chain, which is very important for today's competitive market environment.

Li et al. (2015a, b) established two pricing strategies for remanufacturing: (1) The FRTP pricing strategy (First-Remanufacturing-Then-Pricing), and (2) The FPTR pricing strategy (First-Pricing-Then-Remanufacturing). They analyzed the sequential decision strategies by considering the remanufacturing production and the demand for remanufactured products as stochastic parameters. They assumed that one firm acquires and remanufactures used products altogether. Supply chain coordination between old products collector and remanufacturer is not considered in retailer-collects-mode in their work. Used products collected have different statuses of use, so accordingly, the remanufacturability rate affects the decisions of participants a lot.

The retailer faces remarketing risk, for example, shortage or overage in uncertain remarketing demand. Considering multi-uncertainty factors in a remanufacturing supply chain, (1) the uncertainty demand when remarketing in remanufacturing market and (2) the remanufacturability rate of old products when they remanufacture products are two uncertainty factors that need to be considered simultaneously. These two factors cause significant difficulty to remanufacturing supply chain management.

Each participant in a remanufacturing supply chain is primarily concerned with optimizing their objectives, and usually, those objectives are different or even conflicting with each other. A coordination mechanism, such as contract design, needs to be designed to deal with those challenges in a remanufacturing supply chain. A reasonable coordination activity like the negotiation for a revenue-sharing contact could be established.

We now briefly discuss the contract coordination issue. Designing a proper contract to coordinate the supply chain is an effective way to improve channel performance. Govindan et al. (2013) overviewed supply chain coordination. Without a properly designed motivation mechanism, the retailer does not have an incentive to order enough products to maximize the profit of the whole supply chain (Li et al., 2013). This is the well-known problem of "double marginalization" (Spengler, 1950).

A contract allows decentralized decisions of supply chain members to perform a centralized decision for the whole supply chain. Studies have explored variety of contract forms (Cachon, 2003) such as wholesale price (Bresnahan & Reiss, 1985), revenue-sharing (Cachon & Lariviere, 2005), quantity discount (Zhang et al., 2014), sales rebate (Taylor, 2002), buyback (Wang & Choi, 2014; Pasternack, 1985; Zou et al., 2008), and quantity flexibility (Tsay, 1999). A revenue-sharing contract can increase economic profits in reverse logistics along with reverse supply chains (Govindan & Popiuc, 2014). Moreover, previous research proposed a dynamic leader-follower game model to examine how a reverse supply chain system for remanufactured printer ink cartridges responds to changes (Mafakheri & Nasiri, 2013).

## Risk Attitudes for Uncertainties

Facing remanufacturing uncertainties, supply chain participants have different risk attitudes including being risk-averse, risk-seeking, or risk-neutral. To address a risk-averse agent coordination problem, Gan et al. (2004) developed contracts under three cases: (1) a risk-neutral supplier and a profit-maximize retailer who are subject to a downside constraint on risk; (2) a supplier and a retailer who both maximizes a mean-variance trade-off; (3) a supplier and a retailer that are both utility-maximize players. In the latter case, they found a contract that yields a Nash Bargaining equilibrium (Explanation of Nash Bargaining equilibrium: Two players demand a portion of some good. If the two proposals sum to no more than the total good, then both players get their demand. Otherwise, both get nothing), and in each case, the set of Pareto-optimal solutions (Explanation of Pareto-optimal solution: Given a set of alternative allocations and a set of individuals, a movement from one allocation to another that can make at least one individual better off, without making any other individual worse off) is provided.

In the area of the Nash-bargaining game, Ma et al. (2012) found a Nash-bargaining equilibrium for a risk-averse retailer and risk-neutral manufacturing under a stochastic demand assumption. They found if the retailer becomes more risk-averse, then the retailer's bargaining power increases. Assuming suppliers are risk-averse, Li et al. (2013) studied the impact of competition intensity and risk attitude in the context of two sequential-moving supply chains. They showed that the retail prices under the wholesale price contract are higher than in the revenue-sharing case. They also compare the Nash-bargaining equilibriums between hybrid and symmetric subgames.

Standard revenue-sharing and buy-back contracts don't necessarily coordinate a supply chain that consists of a risk-neutral supplier and a downside risk-averse retailer (Gan et al. (2005)). To address this issue a risk-sharing contract and providing an agent's respective reservation profits may solve the issue. Wang and Webster (2007) used behavioral principal-agency theory to analyze a supply chain composed of a risk-neutral manufacturer and a loss-averse retailer in a newsvendor environment. Xu et al. (2014) provided a two-way revenue sharing contract under a mean-variance model and show how the risk attitude changes contract parameters. They found that a win-win situation could be achieved.

Choosing the Conditional Value-at-Risk criterion as a measurement index for a retailer's risk-averse level, Li et al. (2014a, b, c) investigated a Nash bargaining problem on the wholesale price, the retail price, and the order quantity between the manufacturer and the retailer who have equal bargaining power. They found that the profit shares under the Nash equilibrium are affected by the retailer's risk-aversion level. Xiao and Xu (2014) show the pricing and product line strategy of risk-averse players and identify the conditions under which the risk-averse players extend product lines or replace the used products with new ones.

#### Information Asymmetry Among Practicers

Currently, many recycling regulations require manufacturers to collect used products and properly dispose of them through recycling, such as remanufacturing or recycling. In order to comply with recycling regulations and take advantage of economies of scale, manufacturers often outsource collection activities to third-party providers (3p's). However, 3p collection efficiency is private information, and the manufacturer only knows how to follow the two-point distribution.

A fundamental challenge of collection outsourcing is the lack of perfect information about 3p collection efficiency and collection cost structure. The challenge is that manufacturers need to understand the collection efficiency of 3p's before signing a contract with a 3p in order to make better decisions. Therefore, manufacturers are motivated to obtain private information from 3p's about their real collection efficiency.

Asymmetric cost information makes consumer surplus worse. This worsening is because, in the case of asymmetric information, the information rent provided to 3p's with low collection efficiency is transmitted to consumers. Worse, setting a higher collection target will damage consumer surplus under certain conditions, that is, remanufacturing is relatively unprofitable for manufacturers. Finally, the emergence of information asymmetry magnifies the adverse impact of the collection target on consumer surplus. Solving the problem of information asymmetry in the remanufacturing supply chain is of great help to improve the efficiency of the supply chain.

Asymmetric information research tends to focus on testing the impact of asymmetric information on enterprise decision-making by using nonlinear pricing contracts. For example, Cao et al. (2013) proposed a wholesale contract to reveal a retailer's true internal variable costs for the manufacturer. Li, Gilbert, and Lai

(2015b) explored the effect of supplier encroachment on firm optimal strategies when the information about the market size is monopolized by the reseller.

Given that process innovation efficiency is a manufacturer's private information, Ni et al. (2021) explored how a supplier designs a nonlinear pricing contract to mitigate the loss caused by asymmetric information.

There are a few studies on asymmetric cost information in closed-loop supply chains. Zhang et al. (2014) considered a manufacturer that outsources the collection activities to a retailer while the collection effort is non-common information for the manufacturer and the retailer. Under an extended producer responsibility legislation, there has been work on extending the collection outsourcing to a situation where an independent collector provides the collection activities to the manufacturer that does not know the information about collection cost (Li et al. (2013).

Manufacturers can make better decisions by effectively collecting private information about efficiency. Thus, manufacturers should be motivated to obtain private information about their true collection efficiency from 3P. A manufacturer may wish to provide nonlinear pricing contracts that have two options for 3Ps with different collection efficiency, where the collecting quantities and purchasing prices of used products are fixed. In practice, many firms offer nonlinear pricing (e.g., quantity discounts) to coordinate their supply channels (Li, Gilbert, & Lai, 2015b). In the literature, nonlinear pricing was also widely used to examine the effects of asymmetric cost information on firms' decisions (Cao et al., 2013; Huang & Yang, 2016).

The collection rates of used products can be regulated by take-back regulations in many countries or regions. These regulations should also be considered in a manufacturer's contract design problem. For instance, the European Waste Electrical and Electronic Equipment (WEEE) Directive sets the collection target at 45% of the electronic products in the market for member states (Esenduran et al., 2016). Lobbying by stakeholders is the main driving force behind the current collection and recycling targets of the WEEE Directive, and whether and how manufacturers can satisfy the targets need more in-depth studies (Atasu et al., 2009; Chen et al., 2019). These factors and concerns have been investigated, for example, in how social planners can set the proper collection and recycling targets for manufacturers under perfect information (Atasu et al. (2009)).

The environmental and economic influences of take-back regulations have been studied (e.g., Atasu et al. (2009)). For example, the collection targets to maximize the total welfare under perfect information can provide insights into influences. However, few studies examine the effect of asymmetric cost information about 3p collection efficiency from an optimal collection target strategy. Esenduran et al. (2017) investigated how a manufacturer utilizes the quantity strategies to compete with an independent remanufacturer in the context of take-back regulations. They demonstrated that the increased collection targets have a positive effect on social welfare when remanufacturing can bring significant environmental. However, this finding may not be true if there is asymmetric cost information among supply chain members.

There are situations when multiple regulatory policies interact to affect remanufacturing. For example, joint consideration of the cap-and-trade and take-back regulations were considered by Chen et al. (2018) who explored a manufacturer's optimal quantity decision in a monopoly situation and the environmental impact of these two regulations. Chen et al. (2020) considered a monopolist manufacturer faces both mandatory carbon emission capacity and take-back regulations. Pazoki and Samarghandi (2020) examined how the take-back regulation influences the manufacturer's eco-design decisions.

### Analytical Models for Uncertainty

Twenty-first-century globalization has resulted in a tightly integrated global economy. Market fluctuations triggered by a single country, economic region, or industry are ever-changing, random, and unpredictable, such as the 2008 global financial crisis in the USA, the "the 311 earthquake in 2011" caused by the tsunami in Japan, and the conflict in Russia and Ukraine in 2022. These uncertainties also influence remanufacturing market uncertainties.

Obviously, the market fluctuation in remanufacturing is random and it is difficult for players in a remanufacturing supply chain to balance supply and demand. Changes in the economic cycle at the macro level or shifts in consumer acceptance or preferences could bring about drastic fluctuations in the remanufacturing market demand. Therefore, the efforts regarding the collection policy of the retailer or the trade-in policy of the manufacturer are difficult to formulate. This uncertainty results in management challenges for practitioners and researchers in the remanufacturing industry. In addition to focusing on increasing profits, an effective market strategy also seeks to eliminate risk, the volatility of profits, which is important for remanufacturing supply chain. For instance, in China, due to broader macroeconomic malaise in 2015, heavy truck sales plummeted by 26%, and the demand fluctuation in the heavy truck engine remanufacturing supply chain is significant (Zhao et al., 2018).

There are different kinds of uncertainties in reverse logistics activities. The main reason for the uncertainty of reverse logistics is that the traditional inventory management models or the pricing and ordering strategies do not apply to reverse logistics. Usually, the remanufacturing capacity is stochastic because the quality of used products and the handling time for used products are uncertain in reverse logistics (Fathi et al., 2015). In a location-allocation problem, Soleimani et al. (2014) assumed that the risk-neutral assumptions are not efficient for uncertain and volatile markets in designing a closed-loop supply chain network. Therefore, they model three risk criteria (i.e., Mean Absolute Deviation, Value at Risk, and Conditional Value at Risk) as the objective function.

Han et al. (2016) examined a remanufacturer's reverse channel selection problem from the perspectives of both robustness and profitability, and they proved that the indirect reverse collection channel has higher robustness than the direct reverse collection channel if the remanufacturing process has operational and disruption risks. As an extension to the traditional risk-neutral inventory models, Chen et al. (2007) incorporated risk aversion into multi-period inventory and pricing models. They proved that the optimal policy for a risk-aversion decision-maker is the same as the case in risk-neutral inventory and pricing models.

Zhao and Zhu (2018) used an actual case to show the game results of a revenue-sharing contract. In their study, mean-variance is the risk measurement parameter, and both the remanufacturer and the retailer are risk-averse. Because of the uncertainty in the remanufacturing market, the remanufacturer and the retailer's risk tolerance prevents them from participating in the cooperative game contract. Their study tried to propose a decision-making strategy for the risk-aversion agents in an uncertain remanufacturing market environment. Apparently, risk attitude or risk tolerance greatly affects the game results of remanufacturers and retailers, and because their risk attitudes are different in the face of severe market fluctuations, they add a risk-aversion factor for both the remanufacturer and the retailer's objective function; considering both perspectives is relatively innovative.

One of the popular areas of remanufacturing is large vehicles, especially heavy truck engine remanufacturing. There are a variety of remanufacturer and the retailer risk attitude or risk tolerance impacts on the number of used products collected, consumer surplus, overall supply chain profit, and revenue-sharing contract parameters. Risk-averse agents gain lower expected profit than "maximum profit" risk-neutral agents when the market demand for remanufacturing is not volatile. For revenue-sharing cooperative contracts, the risk-averse agents could get higher expected profit than "maximum profit" risk-neutral agents for heavily fluctuating remanufacturing demand. Revenue-sharing cooperative game contracts can serve as guides on how to better manage all the remanufacturing supply chain agents under market fluctuations, especially when facing uncertainties from both the demand and supply sides.

Thus overall, managerially considering, and modeling for remanufacturing could consider many dimensions – especially uncertainty and the acceptance of this risk and uncertainty – for the remanufacturing industry. Dozens of models across multiple characteristics were reviewed in this section to show the richness of issues and influences from the variety of game theoretic and analytical models to address these issues. There are additional concerns related to market acceptance, modeling, and organizational concerns that we now discuss in the next section.

## 4 Market Acceptance Issues of Remanufactured Products

Remanufacturing helps enterprises to fulfill extended producer responsibility and support their eco-efficiency throughout their life cycles. However, the market acceptance for remanufactured products is still low, and there exists bias toward remanufactured products, especially among consumers in developing countries with low purchasing power. Areas of importance to address some of these issues include determining how to measure consumer preferences, using government subsidies more efficiently, and finding a suitable business model for after-sales service mode. These issues are difficult to grasp and control for the remanufacturers and policymakers. In this section, we consider some of these issues and what has been addressed.

### 4.1 The Impact of Consumer Preferences and Government Subsidies

Various remanufacturing implementation barriers such as ignorance of consumer preferences and inefficient use of government subsidies make engine and gearbox remanufacturing unprofitable in China (Zhu et al., 2014). These concerns are likely to occur in other places as well.

Previous studies focused on characterizing consumers who are willing to pay for remanufactured products and tried to identify different consumer clusters with similar preferences and acceptance of remanufactured products. The segments among consumers regarding level of green values (environmental values held by the consumers) could affect the profitability of remanufacturing operations. Remanufacturers have little guidance in identifying different types of consumer segments: including price-sensitive, quality-concerned, or green-concerned consumers (Atasu et al., 2008).

A consumer or customer could also belong to multiple consumer clusters or greenness segments. Studies have been completed to evaluate consumer clusters. One example is a survey of 1600 households in Devon, Canada; Gilg et al. (2005) investigated how different sustainable lifestyles relate to each other and whether different consumer preferences could be identified. They found at least four different types of environmental values regarding consumer environmental awareness. There is no doubt that an environmentalist with high purchasing power is willing to pay for remanufactured products. In fact, a properly implemented marketing strategy of environmental friendliness could generate a positive public image, which benefits the shareholders. Yet, it has also been found that a large proportion of consumers prefer to buy traditional-but-new products with attributes such as lower prices, higher quality, and better performance than the green/remanufactured products (Ginsberg & Bloom, 2004).

To increase the market for remanufactured products and general concern for the environment, the governments across the world including the USA, European Union, China, Japan, and Canada have enacted regulations and provided subsidies for remanufacturers. Government subsidy is often seen as an incentive tool that helps enterprises to enter the remanufacturing industry, especially in developing countries.

Initially, subsidy incentives from the government played an important role in remanufacturing market development – a needed influx of investment for the remanufacturing industry. As an example, within China, 14 remanufacturing companies were announced as pilot agents of the truck engine and gearbox by the Chinese government. Since then, the Chinese government has been focusing on auto parts remanufacturing, and a large quantity of remanufacturing of the truck engine was subsided (Wang et al., 2014b).

There are also possibilities for shifting incentives. If subsidies for remanufacturing incentives are transferred to consumers, the cost of collection and remanufacturing may not be reduced. Therefore, an allocation pattern of "subsidy for remanufactured products" among remanufacturers, recyclers, and consumers is a growing and important area of operational and policy studies.

Relatedly, the proportion of green and non-green consumers and their respective willingness to pay for remanufactured products further complicates the subsidy allocation problem. A better sharing of the government subsidy among remanufacturers, recyclers, and consumers may reduce the remanufacturing cost, increasing the supply of used products, and attracting more consumers or growing the market, especially non-green ones.

### Modeling

In the early stages of remanufacturing market development, a remanufacturer faces barriers from used product collection, limitations in the remanufacturing process, and after-sales service. Subsidy policy incentives can help to overcome barriers and uncertainties at the initial stage of industry development (Zhu et al., 2014). With this concern in mind, and using a modeling perspective, Ma et al. (2013) introduced a government consumption-subsidy policy and evaluated its influences on a closed-loop supply chain. They found that the consumers who buy new products, the manufacturer, and the retailer all benefit from the consumption-subsidy policy simultaneously, but the e-retailer, who sells their products or services online, won't necessarily benefit from this consumption-subsidy policy.

Remanufacturers also face channel choices. It was found that offering too much and too few subsidies could make the remanufacturer compete with the manufacturer, rather than cooperate (Wang et al., 2014a, b). Interestingly, higher consumer acceptance of remanufacturing can result in greater competition between manufacturers and remanufacturers.

Some studies went beyond just competitive games to evaluate the remanufacturing decision. The effect of government subsidies on green technology adoption was evaluated using an extension of a price-setting newsboy model with an analysis of the interaction between the supplier and the government (Cohen et al., 2016).

Remanufacturing promotion policies and also be studied as alternative approaches. For example, cash subsidies and carbon regulation can both affect remanufacturing (Zhu et al., 2019). Cash subsidies from the government reflect the direct role of the government in promoting the consumption of specific products, while carbon regulation indirectly promotes the manufacturing of low carbon emission products. The implementation of these two policies both affect the demand for remanufactured products and corporate profits, but the carbon regulation could not work if consumer acceptance is low.

## 4.2 Remanufacturing Supply Chain Service Modes

The last discussion of remanufacturing practices in this section introduces innovative service modes of remanufactured products. Quality guarantees and after-sales service for remanufactured products are often barriers to remanufacturing (Zhu et al., 2014). While developing remanufacturing product service modes, remanufacturers should better learn from the innovative service mode of new products in order to improve their financial results (Chesbrough, 2010). Fierce competition has caused remanufacturers not only to care about the classical 4 Ps (product, price, place, and promotion) of marketing but also other modes such as after-market service.

### Sales and Service Modes for Remanufacturing

By learning from innovative sales and service modes for new products, remanufacturers can reduce or even eliminate such concerns. Within this competitive context, we provide an overview of sales and service modes that can be also used for remanufactured products.

Mode 1: *Leasing instead of selling service mode*. Leasing instead of selling indicates that a manufacturer leases rather than sells to his customers, together with providing repair and maintenance for the product. This mode was used for durable products at the beginning, which can eliminate the possibility of price decline and overproduction by a company (Bhaskaran & Gilbert, 2005). If a product is sold through a distributor, such a mode can be that a manufacturer sells its products to a dealer while the distributor leases the products to customers (Bhaskaran & Gilbert, 2009).

Mode 2: *Free replacement warranty service mode.* In the beginning, the free replacement warranty mode was adopted for expensive products such as aeromotor and armarium that requires specialized labor for maintenance and a malfunction can cause serious losses (Darghouth et al., 2012). During the free replacement warranty period, the OEM replaces any components or the entire equipment with potential malfunction free of charge. If the free replacement warranty period ends, the OEM still provides inspections and replacements service, but the costs are covered by the customer. During the whole life cycle of the product, losses due to product malfunction and their detection are totally or largely covered by the OEM.

Mode 3: *Extension of warranty length service mode*. The extension of warranty length service mode is the mode by which a company provides an extended warranty length if a customer purchases the warranty extension for products, which helps establish an image of good product quality for the OEM. In this case, the company would perform better preventive component maintenance in the warranty period to maximize the total profit and lessen the maintenance cost (Chang & Lin, 2012). Warranty extension does not guarantee better profitability, because the profitability is related to the malfunction rate (defect rate) in the warranty extension period (Kim & Park, 2008).

Mode 4: *Renewable free replacement service mode*. The mode of renewable free replacement can be identified as a combined mode of Modes 3 and 4. For this mode, if a product has a malfunction during the basic warranty period, the OEM guarantees a free replacement with a new one. Meanwhile, the OEM would generate a new warranty called the pro-rata warranty for the customer. When a malfunction occurs within the pro-rata warranty period, the customer needs to pay pro-rata money to the OEM.

In these modes the producer must know or predict the cost of maintenance/ replacement and the malfunction rate during those three service periods, that is, the basic warranty period, the pro-rata period, and the post-pro-rata period (Chien, 2010). The major goal of new sales and service modes is to improve customer acceptance of remanufactured products. If a remanufacturer provides good maintenance service or even a long-term replacement warranty, the concerns about the quality of remanufactured products can be lessened, if not totally, relieved. Therefore, the demand for remanufactured products will increase and more customers are willing to pay a higher price.

Profit optimization is always an organizational and supply chain goal. For a profit-maximizing problem, it was found that in a leasing the product-service bundle along with maintenance control-remanufacturing savings the pricing decision and the length of the leasing duration highly rely on the duration of the product's lifecycle (Robotis et al., 2012). For example, remanufactured truck engines in China are mainly sold to self-employed individual truckers, and the leasing instead of selling service mode (Mode 1) can be impractical. Considering that these drivers need better control of driving time and distance, the renewable free replacement service mode (Mode 4) is also impractical and expensive. Therefore, Modes 2 and 3 can be referred to as new sales-service modes for remanufactured truck engines.

On the basis of previous studies, according to China's heavy truck remanufacturing engine market sales, having extended warranty periods and replacement periods are two reasonable heavy truck remanufacturing engine sales modes. Through empirical analysis and mathematical models, it has been shown that the two sales models are better for remanufacturing engine sales market feasibility of implementation from the qualitative and quantitative levels.

## Observations and Recommendations on Sales-Service Modes for Remanufacturing

A number of observations and recommendations can be made in many remanufacturing contexts. Some of these are now provided.

First, consumers accept the practice that remanufacturers raise prices on the basis of extended warranty and replacement service. Extending warranty service and replacement service solves consumer concerns about the quality of the remanufacturing engine and after-sales service. Additionally, remanufacturers can also provide warranty (replacement) service and improve the sales price, and increase their earnings as a whole. This is a win-win for both remanufacturer and consumer.

Second, for heavy truck engine manufacturers, it is not that the longer the extended warranty period (replacement services), the more the remanufacturer's profit. Although remanufacturers can increase revenue by improving prices, remanufacturers also have to bear the risk of remanufactured engine increased production costs and repair costs due to providing warranty (replacement) service. The remanufacturers must weigh the maintenance costs and sales benefits and set up reasonably extended warranties and replacement service periods to achieve optimal economic returns.

Third, on the premise of remanufacturer profits, extended warranty (replacement services) will likely have a negative correlation with the cost rate. Within the same malfunction rate (defect rate), both under linear and nonlinear demand assumptions, the truck engine remanufacturer economic returns in the replacement service sales mode are more than that in the extended warranty service sales mode. Care should be taken given the demand environment and type of mode.

Last, considering the production cost has a significant impact on remanufacturer earnings, remanufacturers need to improve the level of technology and engine quality standards and reduce the production cost of remanufacturing engine. The failure of components of the remanufactured engine are usually identified and specific parts such as a turbocharger, air compressor, and other components. Vulnerable parts are the main factors influencing the consumer purchase decisions. Manufacturers should focus on extending these vulnerable part warranty periods. Remanufacturers have a choice and should take careful investigation of which mode to invest in and pursue based on product, consumer, market demand, and other characteristics. Many times the answer is not always so clear cut on mode selection.

## 5 Future Prospects and Concerns

Many developments and concerns continue to arise as culture, society, and technology continue to evolve. Different forces will play different roles related to remanufacturing markets, products, and other characteristics. There are many that exist, we identify a few with the knowledge that some things will require quick change and response, while others may take many years to emerge. We now overview some of these emergent concerns and topics.

With continuous development of e-commerce and logistics technology, the transformation from a remanufacturing supply chain to an e-supply chain has become an inevitable trend. A remanufacturing supply chain can rely on the e-commerce platform to realize product sales and recycling. In addition, with the improvement of people's living standards, people replace electronic products more frequently.

For remanufacturers, collecting used products is a very important link in the remanufacturing supply chain, but remanufacturers also face competition from third-party recycling platforms. In the future, the best decision-making for remanufacturers whether to sell products and recycle second-hand products on a third-party platform, and whether to entrust the third-party recycler to collect second-hand products in the fiercely competitive environment is of practical significance. How these decisions relate to providing help for the actual operation of enterprises is necessary to understand.

If remanufacturing enterprises choose to sell remanufactured products on e-commerce platforms, they can improve the popularity of remanufactured products through advertising, but this will also result in additional costs.

Moreover, green/non-green consumers' preferences/acceptance for remanufactured products (so-called used products) are different and ever-changing. so the effect of advertising is also different. Remanufacturers need to consider whether and how to advertise according to the information collected by consumers on e-commerce platforms. This will be related to the asymmetric information between e-commerce platforms and remanufacturers. Considering asymmetric information there is a concern about whether and how much remanufacturers make advertising investments when selling products on e-commerce platforms is a serious concern.

The remanufacturing process can effectively reduce resource consumption and protect the environment. The amount of carbon emission reduction can be used as an indicator to measure the contribution of a remanufacturing supply chain to environmental protection. At present, most studies on the environmental impact of a remanufacturing supply chain only consider the carbon emissions generated in the process of product production, ignoring the carbon emissions generated in the reverse logistics process of second-hand product recycling and the logistics process of the new and remanufactured products. Therefore, expanding understanding and knowledge on the problem of carbon emission reduction to the transportation and sales process can be important for future competitive and market needs. In addition, the remanufacturing supply chain should reasonably lay out the logistics network according to the characteristics of remanufactured products, including warehouse location and inventory control.

Operations management is a vital dimension of supply chain management. The management of a remanufacturing supply chain can be more complex than that of a traditional supply chain. The complexity of remanufacturing supply chain operation and management mainly comes from the uncertainty of second-hand product recycling quality and quantity.

Determining the demand for remanufactured products according to the remanufacturing market is difficult and more complex than ordinary products, because different consumers have different acceptance of remanufactured products. It is very important to study the production, recovery, and inventory plans of the remanufacturing supply chain. These studies can facilitate the remanufacturing supply chain more efficiently and stable so that they will be an important direction of future research.

Remanufacturing enterprises are also very involved in developing their service models according to the characteristics of remanufactured products. These service models are after-sales service models, formulated according to the characteristics of their products. The existing understanding on remanufacturing supply chain service models considers the supply chain consists of a single manufacturer and retailer. At present, most of the after-sales services of remanufactured products are provided by remanufacturing manufacturers. However, with the continuous development of remanufacturing industry, some enterprises will join to provide warranty services, improving competition for the after-sales services in a remanufacturing supply chain. Therefore, future market considerations and complexities that consider the after-sales service mode of remanufacturing under the condition of after-sales service market competition are needed.

A service model is integral to enterprise business model. A good business model can improve the profit of the enterprise, the sales volume of products, and the acceptance of consumers. Constantly improving the business model of enterprises is an inevitable trend of enterprise development. Enterprises have started to incorporate the development of remanufacturing into the formulation of enterprise business model. But many uncertainties exist in remanufacturing, each causing obstacles. How to overcome the influence of various uncertainties and further develop the business model of remanufacturing are important developments and opportunities for further understanding, research, and management practice.

The design of after-sales service mode of remanufacturing enterprises still requires significantly more understanding and development. Yet, remanufacturing enterprises also need to consider the simultaneous impact of product warranty timing, government supervision, government subsidies, remanufactured product quality, and other factors on consumer consumption preferences. As seen in the discussion in this chapter, much of what is being developed and used is still relatively immature. Advances in each of these areas are still needed.

Currently, many modeling efforts on a remanufacturing supply chain assume that remanufacturing enterprises only recycle one product—mainly to keep models tractable. But in practice, remanufacturing enterprises will simultaneously recycle and remanufacture multiple products. Some of these products can be used for remanufacturing, and some do not meet the requirements for remanufacturing, but some parts meet the requirements of remanufacturing. These parts can be used for remanufacturing, which will improve the profitability of the enterprises.

Characteristics of different products and the material requirements of remanufacturing, a remanufacturing supply chain model requires careful consideration in development and implementation of new models. But there are aspects that go beyond basic modeling of costs and operational dimensions.

The impact of consumer behavior and remanufactured product quality level on the remanufacturing supply chain also need further considerations and development. The main dimension of remanufacturing supply chain management is the uncertainty of remanufacturing productivity and the uncertainty of remanufacturing product demand. However, for different second-hand products and remanufactured products, remanufacturing productivity and product demand are certainly not the same, so a more detailed and nuanced understanding on the uncertainty of these two influencing factors is required. In addition, other uncertainties, such as cost, are different for different products. Finally, these factors are linked with the demand for remanufactured products for modeling and analysis.

With the continuous improvement of people's awareness of environmental protection, remanufacturing has attracted more attention. The development of a remanufacturing supply chain needs the coordination of various stakeholders in the remanufacturing supply chain. The development of the remanufacturing supply chain needs to conform to the business model of remanufactured products, and it needs a recycling mode in line with product characteristics. The development of the remanufacturing supply chain also needs to consider government subsidies and consumer preferences. Therefore, the research on remanufacturing and the supply chain needs to explore how the remanufacturing enterprises adopt a reasonable strategy of collecting second-hand products to the selection of determining product quality, from a macro business model to a micro remanufacturing technology.

In the future, the development of the remanufacturing supply chain needs the joint efforts of researchers, remanufacturing enterprises, recyclers, and the government, to continuously develop, better save resources, and protect the environment.

# Supply Chain Strategizing in New Product Development

## An Interplay of Practitioners, Activities, and Practices

Ewout Reitsma and Per Hilletofth

## Contents

**Abstract**

During the last few decades, supply chain (SC) strategy has become an important focus for manufacturering companies (hereafter referred to as “manufacturers”). This has resulted in the implementation of a wide variety of SC strategies, including, for example, lean, agile, and leagile – the latter being a combination of the first two. All these and other SC strategies aim at achieving a certain level of responsiveness to customer needs. Since the level of responsiveness should match the characteristics of a product, this chapter discusses how manufacturers can engage in SC strategizing in the context of new product development (NPD).

Through the theoretical lens of "strategy-as-practice" (SAP), SC strategizing in NPD is conceptualized as a dynamic interplay of "practitioners," "activities," and "practices." The chapter also explains that, while managing this interplay, manufacturers should be aware of challenges caused by uncertainty, politics, and learning. Finally, the chapter opens the door for future research that utilizes the SAP lens in order to empirically explore SC strategizing in NPD.

## 1 Introduction

Manufacturing supply chains (SCs) have become increasingly complex due to globalization, outsourcing, modularization, shorter product life cycles, and an explosion in product variety. In many cases, manufacturers have changed from sourcing only a few, simple, and separate components from local suppliers to sourcing a high variety of components/systems from globally dispersed suppliers (Handfield et al., 2020; van Hoek, 2020). This development has made manufacturers vulnerable to disruptions. For example, the Swedish home furniture manufacturer IKEA faced SC challenges due to the COVID-19 pandemic (BBC, 2021). IKEA uses suppliers in Asia and is dependent on container ships for distributing its products to warehouses across the globe. The COVID-19-induced lockdowns led to container ships being taken out of service, resulting in an overall reduction in shipping capacity. This caused massive bottlenecks at ports and low product availability at IKEA stores.

This and other examples (e.g., Brexit, the war in Ukraine) have led to SC strategy becoming an important focus area for manufacturers. A wide variety of SC strategies exist, including, for example, lean, agile, and leagile – the latter being a combination of the first two (Mason-Jones et al., 2000). The main challenge of implementing any of these or other SC strategies is achieving the "right" level of responsiveness to customer needs (Richey et al., 2021). Solving this challenge and implementing an adequate SC strategy may thus present two opportunities. First, it can enable manufacturers to optimize their own material flows, which increases both efficiency and customer satisfaction (Harland, 1996). Second, it can allow manufacturers to leverage the capabilities of other SC actors, which reduces inventory requirements in the SC, while also increasing customer satisfaction (Harvard Business Review, 2006).

According to Fisher (1997), it is crucial for a manufacturer's SC strategy to "match" the characteristics of its products. This match requires engaging in SC strategizing in new product development (NPD) (The terms "NPD" and "NPD project" are used interchangeably throughout the text of the chapter.) (Melnyk et al., 2014; Reitsma et al., 2021). Drawing on the literature, the present chapter discusses how manufacturers can engage in SC strategizing early in the product life cycle. This discussion is guided by the theoretical lens of "strategy-as-practice"

(SAP), which conceptualizes strategizing as the dynamic interplay of practitioners, activities, and practices (Whittington, 2006).

The remainder of the chapter is structured as follows. First, the background to the topic is provided in Sect. 2. Second, the theoretical lens of SAP is presented in Sect. 3. Third, through the theoretical lens of SAP, Sect. 4 discusses how manufacturers can engage in SC strategizing in NPD. Fourth and finally, the conclusion and future research direction are given in Sect. 5.

## 2 Background

To provide a background to the topic at hand, this section first discusses SC strategy and then illustrates the importance of manufacturers engaging in SC strategizing in the context of NPD.

### 2.1 SC Strategy

Strategy can be defined as the pattern in the stream of activities that characterizes the match an organization achieves with its environment and that constitutes a determinant for the attainment of its goals (Mintzberg & McHugh, 1985). Many different types of strategy are possible at different levels within a manufacturer.

*SC* strategy can be regarded as an extension of operations strategy. While operations strategy generally focuses on the competitive priorities pursued by a single manufacturer (Miller & Roth, 1994), SC strategy focuses on the objectives pursued by a manufacturer when interacting with other SC actors (Harland, 1996). As stated by Narasimhan et al. (2008, p. 5234), SC strategy can be viewed *as the pattern of decisions related to sourcing products, capacity planning, conversion of raw materials, demand management, communication across the supply chain, and delivery of products.* Thus, when correctly formulated and executed, SC strategy supports manufacturers in coping with operations that involve a variety of internal (i.e., within organizational boundaries) and external (i.e., beyond organizational boundaries) SC actors (e.g., suppliers). SCs have the same distinct life cycle stages as products: emergence, growth, maturity, and decline (MacCarthy et al., 2016). This implies that SC strategy is dynamic and evolves throughout the SC life cycle. For example, while technology and innovation are essential components of SC strategy during SC emergence and growth, enhanced efficiency is important when an SC matures.

There are different typologies of SC strategy (e.g., Fisher, 1997; Mason-Jones et al., 2000), and Narasimhan et al. (2008) suggest that they can have three underlying dimensions. The first concerns SC integration, which includes strategic alliances, collaborative integration, and long-term relationships between SC actors (Anderson et al., 1994). The second concerns just-in-time, which relates to using supplier relationships and contracts to implement a material flow system without excess inventory (Chapman & Carter, 1990). The third concerns SC linkage facilitated by the electronic exchange of information. This relates to using electronic linkages to shift the customer-order decoupling point upstream in order to deal effectively with demand uncertainty while maintaining the ability to respond quickly to customer demands (Berry et al., 1994).

An example of an SC strategy typology is provided by Mason-Jones et al. (2000). The SC strategies associated with this typology include lean, agile, and leagile – the latter being a combination of the first two. First, a lean SC strategy refers to developing a physically efficient value stream focused on eliminating all kinds of waste (Naylor et al., 1999). The main objective of this strategy is to reduce cost and enhance efficiency in SC processes (Womack & Jones, 1997). Lean is typically associated with stable customer demand, mass production, just-in-time, and long-term supplier relationships (Reitsma et al., 2020).

Second, an agile SC strategy refers to *the successful exploration of competitive bases (speed, flexibility, innovation proactivity, quality, and profitability) through the integration of reconfigurable resources and best practices in a knowledge-rich environment to provide customer-driven products and services in a fast-changing market environment* (Yusuf et al., 1999, p. 37). By leveraging capacity buffers and relationships with other SC actors, an agile SC strategy aids manufacturers in providing customer-driven products with unique features to the market quickly, so as to maintain a competitive advantage in a rapidly changing environment (Christopher, 2000; Mason-Jones et al., 2000).

Third and finally, as indicated, a leagile SC strategy refers to combining elements of lean and agile (Bruce et al., 2004). As stated by Bruce et al. (2004, p. 155), *leagile takes the view that lean and agile approaches shall be combined at a decoupling point for optimal SC management.* This means that the leagile strategy involves adopting very different approaches to managing the upstream and downstream activities in a manufacturer's SC. For example, upstream activities can be managed in a cost-effective (lean) manner, whereas downstream activities can be managed in a highly responsive (agile) manner (Bruce et al., 2004).

Despite their individual differences, what all SC strategies and their typologies have in common is that they are linked to the theme of "responsiveness." As Richey et al. (2021) argue, SC strategies revolve around manufacturers pursuing certain levels of responsiveness to customer needs when interacting with other SC actors. Drawing on prior literature, Richey et al. (2021, p. 2) define SC responsiveness as *the process and outcome of organizational adjustments achieved as individual organizations within a SC alter behaviors, norms, and/or policies to help place a SC and its members in a favorable position to achieve customer value under dynamic environmental conditions.*

Similarly, Holweg (2005, p. 605) defines responsiveness as *the ability to react purposefully and within an appropriate timescale to customer demand or changes in the marketplace.* In other words, responsiveness is the ability to modify a course of action through organizational adjustment in response to market and environmental conditions.

## 2.2 The Importance of SC Strategizing in NPD

As the preceding discussion reveals, a core theme of SC strategy concerns achieving the "right" level of responsiveness to customer needs. But what level of SC responsiveness should be achieved? The literature (e.g., Chopra & Meindl, 2007; Fisher, 1997) suggests that the answer to this question depends on the product that flows (or will flow) through the SC.

For example, the "zone of strategic fit" concept argues that the level of SC responsiveness should match the innovativeness of a product (Chopra & Meindl, 2007; Fisher, 1997). Otherwise, significant problems can occur in SC operations. Moreover, Selldin and Olhager (2007) found that manufacturers that match SC strategies with products outperform those that do not. The zone of strategic fit is illustrated in Fig. 1 and subsequently discussed.

Figure 1 includes horizontal and vertical axes. On the horizontal axis, products with low levels of innovativeness have predictable demand patterns, long life cycles, low product variety, low contribution margins, or long lead times. Conversely, products with high levels of innovativeness have unpredictable demand patterns, short life cycles, high product variety, high contribution margins, or short lead times.

On the vertical axis of Fig. 1, SCs with low levels of responsiveness supply predictably and efficiently at the lowest possible cost. Alternatively, SCs with high levels of responsiveness react quickly to customer needs so as to minimize stockouts, forced markdowns, or obsolete inventory. Based on these axes and the zone of strategic fit in Fig. 1, Table 1 lists examples of matches between SC responsiveness and product innovativeness.

The next question that arises naturally is: when to match SC strategies (i.e., level of responsiveness) with products? The literature (e.g., Hilletofth et al., 2018; Reitsma et al., 2021) suggests starting this matching process already in NPD, which is the moment when most product life cycle costs are determined (Dowlatshahi, 1996).

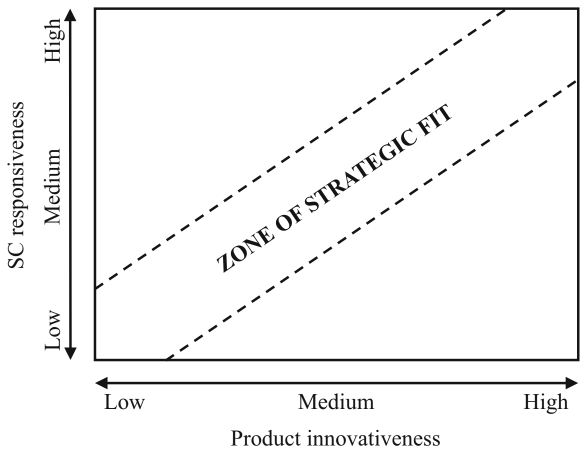

**Fig. 1** Matching SC responsiveness with product innovativeness. (Adapted from Fisher (1997, p. 109) and Chopra and Meindl (2007, p. 35))

**Table 1** Matching products with SCs

| Level of product innovativeness | Level of SC responsiveness | Example |
|---|---|---|
| Low | Low | Products such as toothbrushes require a highly efficient SC, with minimal waste and loss, while retaining the ability to adapt to unexpected delays |
| Medium | Medium | Products such as trucks require an SC that is both efficient and flexible enough to respond swiftly to the changing needs of customers |
| High | High | Products such as new computer chips require a highly responsive SC, with minimal shortages, while retaining the ability to minimize stocked inventory |

Failing to adequately engage with an SC strategy in NPD may lead to problems such as low product performance, low SC performance, and ultimately market failure (Browning & Ramasesh, 2007; Dowlatshahi, 1996; Reitsma et al., 2021). The causes of these problems can be illustrated with an example.

Consider the following situation: a new product is designed based solely on customer needs, thus independently of a chosen SC strategy. After the new product has been designed, SC operations are ramped up and examined for their level of responsiveness. If the performance of these operations is not within acceptable limits, the design of a product may need to be revised until satisfactory performance is achieved.

However, toward the end of NPD, it is not always possible to make product design changes. For example, strict NPD deadlines may prevent exchanging scarce components for ones for which there is abundant supply. In the long term, this can result in an unnecessarily long time-to-market and high product cost due to dependency on a few expensive suppliers with long lead times (Dowlatshahi, 1992; Gokhan et al., 2010).

There are also examples of the benefits of considering SC strategies in NPD. For example, Microsoft intentionally creates a sense of product scarcity when launching a new Xbox by limiting product availability (van Hoek & Chapman, 2006). This is done to create a consumer rush for a product while minimizing tied-up capital in inventories and expensive express shipments.

Furthermore, a globally leading gas turbine manufacturer ensures that a new product's point of differentiation is positioned after the customer-order decoupling point (Bäckstrand et al., 2014). This avoids increasing the level of tied-up capital in inventory through having to manufacture different product variants based on forecasts.

### 2.3 Summary of Sect. 2

This section provided a background to the present chapter by discussing SC strategy and its importance in NPD. This included discussing different SC strategies and "responsiveness," which is the core theme connecting these strategies. Hereafter, the "zone of strategic fit" concept showed that a manufacturer's SC strategy (i.e., level of responsiveness) should match its products. Finally, it was argued that a good match requires engaging in SC strategizing in NPD, which is as early in the product life cycle as possible.

## 3 SAP

Before discussing how manufacturers can engage in SC strategizing in NPD, this section presents the theoretical lens – SAP – that is used to organize the discussion.

### 3.1 Dimensions of SAP

The SAP literature provides a guide for discussing how manufacturers can engage in SC strategizing in NPD. Inspired by practice theorists (e.g., Bourdieu, 1990), this literature proposes practice-based theories of strategy (Fenton & Langley, 2011; Vaara & Whittington, 2012). These theories take issue with the more traditional view of strategy as a "static" property of manufacturers.

Instead, they propose that strategy should be thought of as something continuous that practitioners do (Johnson et al., 2003; Whittington, 2006). Following this rationale, Whittington (2006) introduces the concept of strategizing and its three interrelated dimensions: practitioners, activities, and practices. These dimensions are summarized in Fig. 2 and subsequently discussed.

#### Strategizing "Practitioners"

Strategizing "practitioners" are the actors who shape the construction of practice through who they are, how they act, and what resources they draw upon (Jarzabkowski et al., 2007; Whittington, 2006). Moreover, practitioners are those who make, shape,

**Fig. 2** Strategizing as the interplay of practitioners, activities, and practices. (Adapted from Johnson et al. (2011))

and execute strategy and play an important role when they perform activities that draw upon socially defined practices (Jarzabkowski et al., 2007).

Practitioners disclose a certain understanding of what constitutes good action when conducting strategy work driven by a particular collective end (Tsoukas, 2018). This suggests that practitioner characteristics have major implications for the daily strategy work (Jarzabkowski et al., 2016). Specifically, what can be achieved during this work depends on the practical or social-political skills of practitioners (Rouleau, 2005). For example, they may require cross-functional skills and working knowledge of all areas of the organization in order to understand the collective end driving strategizing.

Furthermore, practitioners from all levels of the organization (e.g., shop floor employees, middle or senior managers) can make a difference in strategizing (Jarzabkowski et al., 2016; Vaara & Whittington, 2012). Practitioners who are external to the organization, such as consultants and regulators, can also make a difference. Thus, strategizing can include practitioners from beyond the managerial ranks and organizational boundaries.

### Strategizing "Activities"

Practitioners do not just think; they act individually or collectively in a world where the object of the activity is related to the needs of the individual (Leontiev, 1978; Vygotsky, 1980). Based on this logic, strategizing "activities" represent practitioner activities with regard to the formulation and implementation of strategy (Reckwitz, 2002; Whittington, 2006). Examples of such activities include recognizing and acting upon business opportunities or threats, analyzing an organization's weaknesses or strengths, and setting or evaluating long-term goals.

Strategizing activities are situated (Whittington, 2006), which means that their ideal performance depends on the particular context in which they are embedded. For example, activities should follow certain standards of excellence (Tsoukas, 2018).

Furthermore, strategizing activities can be planned or unplanned, temporary or long-term, routine or nonroutine, and formal or informal (Adams, 2004). For example, Tsoukas (2010) states that strategizing activities are often not interpreted as "strategic." Practitioners rarely pause to think about strategies or engage in deliberate strategizing, indicating that strategy often simply emerges over the course of routine activity (Jarzabkowski et al., 2016).

In other words, strategies are often merely the result of organizational activities, instead of the rational decision-making process used by senior managers as they develop a strategic plan (Mintzberg & Waters, 1985). This implies that even though strategizing benefits from intention or purposeful goal orientation, it sometimes just happens.

### Strategizing "Practices"

Strategizing "practices" support practitioners in performing strategizing activities (Reckwitz, 2002; Whittington, 2006). Whittington (2006, p. 619) defines practices as *shared routines of behavior, including traditions, norms, and procedures for thinking, acting, and using 'things', this last in the broadest sense.* This implies that practices act as instrumental problem-solvers, information generators, inspirers of social interaction, or constructors of strategy (Jarzabkowski & Kaplan, 2015). Thus, practices include any structured aids, managerial or technical in nature, used for structuring or influencing the management and effective execution of strategizing activities (De Waal & Knott, 2010).

In other words, practices can be conceptualized as instruments of mediation between the varied purposes and interests of practitioners (Jarzabkowski, 2003). Specific examples of practices include cross-functional meetings/teams, routines, decision-making tools, frameworks, or process models (Jarzabkowski & Kaplan, 2015; Whittington, 2006).

Practices can be used at individual, interpersonal, and organizational levels and support different practitioners simultaneously (Stenfors, 2007). Moreover, multiple practices or multiple enactments of the same practice (e.g., repeated meetings of cross-functional teams) may be used for long-term strategizing activities.

When used, practices facilitate continuity or change of strategy by aligning the different practitioners engaging with strategizing activities (Jarzabkowski, 2003; Johnson et al., 2003). While continuity is facilitated by aligning practitioners and activity in the organization, change is facilitated by identifying and mediating contradictions between past and future activity.

### 3.2 Summary of Sect. 3

Using the SAP literature, this section discussed strategizing involving the interplay of three dimensions: practitioners, activities, and practices. First, strategizing practitioners shape the construction of practice and strategy through who they are, how they act, and what resources they draw upon. Second, strategizing activities are practitioner activities regarding the formulation and implementation of strategy. Third and finally, strategizing practices are the mechanisms that support practitioners in performing strategizing activities.

## 4 SC Strategy-as-Practice in NPD

Through the theoretical lens of SAP, this section discusses how manufacturers can engage in SC strategizing in NPD. The section is divided into three subsections. First, the dimensions of SC strategizing in NPD are discussed individually, using the literature. Second, the interplay among these dimensions is examined. Third and finally, challenges of engaging in SC strategizing in NPD are considered.

### 4.1 Dimensions of SC Strategizing in NPD

The SAP literature (e.g., Whittington, 2006) suggests that practitioners, activities, and practices are the key dimensions of strategizing. The present section follows these dimensions to discuss how manufacturers can engage in SC strategizing in NPD.

### SC Strategizing "Practitioners" in NPD

A diverse set of practitioners can play an important role in SC strategizing in NPD. Practitioners from different organizational functions – product design, logistics, demand management, procurement, and transportation – need to share their situated knowledge to achieve an adequate level of responsiveness to customer needs. This knowledge sharing is challenging and requires practitioners with different backgrounds, knowledge, and interests to understand each other and pursue an effective approach to communication.

Practitioners such as product designers need to take a broader perspective than that of product functionality and performance in NPD. They also need the capability to link product design with SC strategy-related challenges such as responsiveness to customer needs. However, such a broad perspective is not one that product designers are trained to use in NPD (Lee & Schmidt, 2017).

In turn, practitioners in more SC-oriented organizational functions – logistics, demand management, procurement, and transportation – are also not trained to fully grasp the implications of product designs on SC strategy. Practitioners need to possess a broad set of skills including behavioral skills, business acumen, and the appropriate engineering knowledge (Lee & Schmidt, 2017). These skills require training, coaching, and possible tag-teaming with peers or even job rotation.

Van Hoek and Chapman (2007) suggest that this expanding knowledge scope should ultimately enable practitioners to:

1. Refrain from unnecessarily using jargon and technical language.
2. Move toward using shared business language that expresses initiatives in terms of shared output objectives and in terms of benefits and priorities in other organizational functions.
3. Communicate the case for initiatives up front, and frequently update peers on progress and results against the shared output objectives.
4. Come to the table proactively with constructive questions and solutions to enhance NPD effectiveness and value.
5. Avoid being perceived as a showstopper for innovation.
6. Ensure that the starting point of discussions related to SC strategies is founded on corporate objectives.
7. Inform about considerations and opportunities related to SC strategies and advance the relevant thinking.
8. Be positive and have expertise about relevant themes (e.g., product design, logistics, demand management, procurement, transportation) that can contribute to NPD.

### SC Strategizing "Activities" in NPD

Section 2.1 explained that SC strategy is a broad concept that, in its widest form, can be understood as the level of responsiveness a manufacturer aims to achieve toward customer needs. Following this conceptualization, practitioners can perform a wide range of different SC strategizing activities in NPD.

These activities have two aims. The first is to identify the desired level of responsiveness to customer needs; the second is to develop and implement the resources, processes, and relationships (within the manufacturer and across the SC) that seek to make the attainment of the desired level of responsiveness inevitable over time (Melnyk et al., 2014).

SC strategizing activities typically relate to a manufacturer's supplier base, supplier relationships, and internal or external material flows. To define a set of SC strategizing activities that can be performed in NPD – while recognizing that this list is not exhaustive – Table 2 draws on the work of Reitsma et al. (2021) and Min and Zhou (2002).

## SC Strategizing "Practices" in NPD

When engaging in SC strategizing in NPD, there is plenty of room for practitioners of one organizational function – for example, product design – to promote its interests as taking priority over that of another, such as procurement. Therefore, carefully chosen practices that facilitate collaboration are needed when practitioners perform SC strategizing activities that require discussion, negotiation, and iteration. Examples of practices discussed in this subsection include decision-making tools, specialized roles, cross-functional meetings/teams, and process models.

***Decision-Making Tools*** The literature (e.g., Blackhurst et al., 2005; Fine et al., 2005) proposes several quantitative decision-making tools that support SC strategizing practitioners in NPD. These tools aim at designing a product together with its SC. In many cases, this reduces the cyclic procedure of designing a product, designing the SC, evaluating the SC, and redesigning the product to a single iteration (Gokhan et al., 2010). This may lead to benefits such as more efficient and effective SC planning, ultimately optimizing the delivery of products to customers (Arntzen et al., 1995).

For example, Blackhurst et al. (2005) propose a tool that stores product, process, and SC data. This enables practitioners to evaluate the lead time consequences of certain product design choices. Similarly, Chiu and Kremer (2014) propose a tool for evaluating different SC scenarios (i.e., centralized and decentralized) during product design. This includes consideration of SC costs such as transportation and inventory costs.

Furthermore, Fine et al. (2005) propose a weighted goal-programming tool that simultaneously solves for the best combination, for each product version, of product design, assembly plan, and SC design. As a final example, Claypool et al. (2015) propose a simulation tool that designs an SC parallel to designing a new product. This tool obtains the optimal product and SC designs while simultaneously analyzing time-to-market and supplier-dependency risks.

***Role Specialization*** The literature (e.g., Lakemond et al., 2001; Van Hoek & Chapman, 2007) further proposes the introduction of a specialized role in NPD, which is responsible for coordinating collaboration between different SC

**Table 2** SC strategizing activities in NPD. (Based on Reitsma et al. (2021) and Min and Zhou (2002))

| Activity (determining the. . .) | Description | Example |
|---|---|---|
| Sourcing approach | Determining the balance between internal and external sourcing in NPD by prioritizing the areas on which to devote internal resources. This includes determining and examining the ideal geographical sourcing locations and balancing single and multiple sourcing | A manufacturer may prefer externally sourcing product items (e.g., components, systems) when suppliers are relatively cheap but highly responsive, flexible, and innovative. In turn, these items can be single sourced when benefits from the use of economies of scale outweigh the risk of supplier dependency |
| Collaboration approach | Determining the extent of collaboration with SC actors in NPD and deciding with which SC tiers to collaborate | Close collaboration with suppliers is recommended when they are responsible for product items or workloads critical for a manufacturer's success. It may also be desirable to collaborate directly with critical lower-tier suppliers |
| Postponement approach | Determining the balance between forecast and demand-driven activities in NPD. This includes positioning the customer-order decoupling point in the SC while simultaneously balancing inventory and service levels | When operating in a configure-to-order context, a manufacturer delays the configuration of final products until orders arrive and customer requirements become known. This increases the flexibility to respond to changing market conditions |
| Network structure | Determining which SC nodes (e.g., suppliers, manufacturing plants, warehouses, and consolidation points) should be utilized in NPD and serve which customers, market segments, and suppliers. This includes selecting transportation modes and their routes | When outsourcing product items or workloads, it is necessary to evaluate and select suppliers based on their capabilities. It may also be necessary to design multiple supply or distribution channels in terms of their length in both distance and time |
| Internal material flow | Determining the material flow layout within SC nodes utilized in NPD. This includes selecting the equipment (e.g., stations and forklifts) needed for material handling (i.e., moving, storing, packing) and allocation of storage areas | A manufacturer can tailor the layout of the manufacturing process to product items. This requires evaluating different process layouts (e.g., job shop or cellular) when setting physical properties (e.g., geometries) of product items |
| Packaging | Determining the packaging needed for inbound product items, work in progress, and outbound products in NPD | Even though a manufacturer is encouraged to use existing packaging formats, it may be necessary to choose new packaging. For example, special packaging may be needed when product items are sensitive and at risk of damage |

(continued)

**Table 2** (continued)

| Activity (determining the. . .) | Description | Example |
|---|---|---|
| Capacity plan | Determining the optimal production (and transportation) capacity at each SC node utilized in NPD to meet changing demands for both new and old products | A manufacturer can plan capacity by setting overall planning objectives and determining appropriate time horizon(s). It is also relevant to consider the product's manufacturing characteristics (e.g., setup time, throughput time) |
| Inventory levels | Determining the levels and locations of stocks throughout the SC in order to maintain an appropriate trade-off between customer service and costs in NPD | When product items are critical for a manufacturer's success and have a short life cycle, the physical efficiency of the just-in-time inventory model can be combined with the responsiveness dictated by product items |

strategizing practitioners. For example, SC performance can be improved by creating the role of new product-introduction forecasting manager (Van Hoek & Chapman, 2007). This role is dedicated to working with various functions in NPD to drive alignment around the forecast. It involves flagging forecasting differences, spotting potentially wrong assumptions, and working across the organization to arrive at appropriate SC capacity plans (Van Hoek & Chapman, 2007).

Similarly, Lakemond et al. (2001) suggest introducing the role of a dedicated SC coordinator when NPD involves a high degree of innovation and a wide variety of product items or workloads. Such a role should focus on ensuring that SC constraints (i.e., possibilities and limitations) are considered in NPD (Lakemond et al., 2001).

As another example, Zolghadri et al. (2008) suggest establishing three roles that focus on SC strategizing in NPD. The first role coordinates the identification of potential critical suppliers, selection of suppliers, and negotiation of supplier contracts. The second role is an independent entity that oversees the work of product designers. The third role works together with the other two to ensure consideration of SC constraints in NPD.

***Cross-Functional Meetings/Teams*** Collaboration between SC strategizing practitioners can be further increased by using cross-functional NPD meetings/teams. Specifically, the literature (e.g., Brewer & Arnette, 2017; Di Benedetto et al., 2003; Dowlatshahi, 1992) suggests that practitioners from all relevant functional areas should be represented in NPD meetings/teams. For example, Di Benedetto et al. (2003) propose permanently including practitioners from SC-oriented organizational functions in NPD.

Similarly, Noori and Georgescu (2008) advise including practitioners from product design, marketing, finance, procurement, operations, transportation, and logistics in NPD meetings/teams. SC-oriented practitioners should especially be permanently included when NPD success is dependent on actors beyond organizational boundaries (Lakemond et al., 2001).

Cross-functional NPD meetings/teams can improve SC performance through facilitating early consideration of SC strategizing activities related to procurement, manufacturing, distribution, and marketing (Brewer & Arnette, 2017). This enables identifying and solving potential problems before SC strategizing activities are initiated. To realize such benefits, a manufacturer must welcome new ways of thinking, encourage high levels of communication, ensure a joint understanding of company goals and strategies, and locate teams in close proximity (Guy & Dale, 1993).

However, in globally operating manufacturers, it may be inevitable that practitioners or functions are geographically dispersed. Therefore, there may also be a need for information technology tools that foster virtual collaboration (Duranti & de Almeida, 2012).

***Process Models*** The work of SC strategizing practitioners in NPD can also be coordinated with process models. Specifically, these models can be used to structure NPD around various stages and gates (Cooper, 2008). The stages reflect the points in time at which NPD activities – including SC strategizing activities – are performed, while the gates act as quality control checkpoints.

This type of activity-based process models links NPD activities to input (objects necessary to carry out an activity) and output (objects produced in an activity) (Nicholas & Steyn, 2008). This way, it becomes possible to establish input-output relationships that provide coordination and interaction of activities.

Process models tend to be either sequential or iterative in nature (Browning & Ramasesh, 2007). When NPD is conceived as a set of planned iterations through all of the major NPD stages and gates, an iterative model is more applicable than a sequential one (Browning & Ramasesh, 2007). Furthermore, different NPD projects do not necessarily pass through the same stages or gates, which means that a process model may require adjustment to individual NPD projects (Cooper, 2008).

## 4.2 Interplay Among Dimensions of SC Strategizing in NPD

Having individually described the dimensions of SC strategizing in NPD, their possible interplay is summarized in Fig. 3 and then discussed.

Figure 3 shows that SC strategizing practices at one level interact with SC strategizing activities in NPD at another. As suggested by De Waal and Knott (2010), a key distinction between these levels is that SC strategizing practices are to some extent generic, whereas the type and number of SC strategizing activities depends on the specific NPD project under consideration.

Within the manufacturer's internal context, the drivers for institutionalizing practices are potential improvements in terms of efficiency and legitimacy (Westphal et al., 1997). Within the manufacturer's NPD context, practitioners tend to select and apply existing or emerging practices based on their knowledge and how suitable the practices are for performing SC strategizing activities.

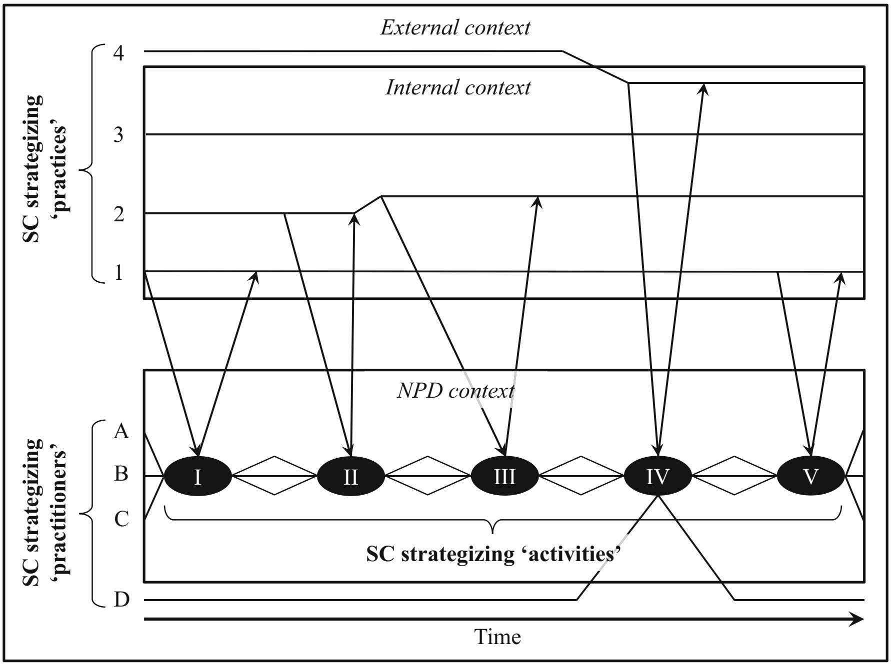

**Fig. 3** Interplay among SC strategizing practitioners, activities, and practices in the context of NPD. (Adapted from Whittington (2006))

The bottom rectangle in Fig. 3 represents the manufacturer's NPD context, which includes a set of SC strategizing activities (I, II, III, IV, V). These activities are performed by three practitioners of the same organization (A, B, C) and one external practitioner (D) in the case of activity IV. Practitioner D can be a partner or consultant from the manufacturer's external context. Figure 3 simplifies reality, since NPD can include more than five activities and more than four practitioners.

The top rectangle in Fig. 3 includes the set of accepted and institutionalized practices that are drawn upon by practitioners as they engage in SC strategizing activities in NPD. Figure 3 simplifies reality by only showing four practices. These practices can be generated locally (within the manufacturer's internal context) or originate from the external context (e.g., introduced by outside partners or consultants) (De Waal & Knott, 2010).

Sometimes practitioners want to modify existing practices in order to perform their activities optimally (Jarzabkowski, 2004), which is depicted by the kink at practice 2 in Fig. 3. On other occasions, practitioners may need to draw upon practices that are new to the manufacturer (practice 4) to successfully perform a certain activity (activity IV) in NPD. These newly introduced practices can be reapplied and amended in the future. Finally, it is also possible that an institutionalized practice is not relevant to a specific NPD project (practice 3).

## 4.3 Challenges of Engaging in SC Strategizing in NPD

Many challenges can occur when managing the interplay of SC strategizing practitioners, activities, and practices in NPD. Three often mentioned challenges relate to uncertainty, politics, and learning.

### Uncertainty Challenges

Several sources of uncertainty can challenge SC strategizing in NPD. For example, products tend to exhibit "emerging" properties in NPD, leading to unexpected interactions when designing and integrating items (e.g., components, systems) into a final product (Hobday et al., 2000).

Demand and supply uncertainties are additional challenges that SC strategizing practitioners may face in NPD. Demand uncertainty occurs when changing customer needs cause unclear goals and increased risks (Davies et al., 2011). For example, panic buying during the COVID-19 pandemic caused unforeseen customer demand spikes in certain industries (Handfield et al., 2020; van Hoek, 2020). Such situations make it difficult to accurately predict demand for new products, plan capacity in the SC, and create supplier contracts for secure and stable supply.

Furthermore, supply uncertainty occurs when manufacturers have become dependent on high-risk suppliers (Vanpoucke & Ellis, 2019). For example, the last two decades have seen the pursuit of lower landed cost, which resulted in many manufacturers switching to suppliers in low-cost regions such as China and Southeast Asia (Handfield et al., 2020). Even though this brought many cost benefits, it also lengthened SCs and exposed NPD to the risk of delivery delays from remote suppliers (Handfield et al., 2020; van Hoek, 2020).

All the identifiable sources of uncertainty that can challenge SC strategizing in NPD should of course be addressed in the best possible way. As Mason-Jones and Towill (1998) argue, *those companies which cope best with uncertainty are most likely to produce internationally competitive bottom-line performances.* In general, uncertainty can be reduced by actively sharing information throughout the SC (Wagner & Bode, 2008). This may require technologies (e.g., RFID, ERP, blockchain) that accelerate information sharing and increase the transparency of material flows (Reitsma & Hilletofth, 2018).

### Political Challenges

As discussed in Sect. 4.1.1, SC strategizing in NPD can involve a diverse set of practitioners. This leads to the need for a political process that involves practitioners with different backgrounds, knowledge, objectives, or orientations (Esper et al., 2010). Throughout this process, there is considerable latitude for practitioners of one organizational function (e.g., product design) to promote their interests as taking priority over that of another (e.g., procurement).

A major reason for this behavior is that functions provide unique resources to an organization, tend to pursue their own goals, do not always share a common understanding, and tend to hold different values (Ellinger et al., 2006). As a result, any change imposed by a function can meet resistance, especially if those changes unfairly disadvantage or threaten the incentive system of another function.

This situation can result in functions protecting their local autonomy and coherence at the expense of other functions' initiatives aimed at reinforcing organization-wide coherence (Narduzzo et al., 2001). Thus, the risk is that SC strategizing practitioners become self-referential, at the expense of relating the outcomes of their work to the changing needs of other practitioners and to the manufacturer's SC goals.

Consequently, cooperation between practitioners from different functions requires tackling the issue of self-referential behavior (Tsoukas, 2018). This issue is also referred to as the social dilemma of individual self-interest versus group efficiency (Gintis, 2014). As Gintis (2009, p. 47) states, *all gain when all cooperate but each one has a personal incentive to defect, gaining at the expense of the others.*

Self-referential behavior can be discouraged by establishing an authority structure and mutually reinforcing expectations among practitioners, so that cooperation becomes the norm (Gintis, 2014). For example, practitioners are keener to cooperate when believing that others are also committed to cooperation.

### Learning and Knowledge Acquisition Challenges

Another challenge when engaging in SC strategizing in NPD relates to learning. Manufacturers should find a way to systematically promote learning within and across different NPD projects and the broader business organization (Prencipe & Tell, 2001). Even though NPD projects can be unique and thus unlikely to be repeated in the future, the challenges faced by practitioners are often similar (Davies & Brady, 2000).

Therefore, the more frequently similar NPD projects are completed, the greater the possibility to predict outcomes based on previous experiences and use learning to preempt problems (Davies & Brady, 2000). This phenomenon is referred to as "economies of repetition" (Davies & Brady, 2000) and enables conducting SC strategizing work more efficiently and effectively.

However, the temporary nature of NPD creates an obstacle to learning and capability development related to SC strategizing. As Davies et al. (2011, p. 12) observe, *[NPD] project teams typically break up after a project is completed and there are no project silos to capture this crucial learning. All too often, commercial pressures to utilize resources fully during the life of the [NPD] project and to reallocate them quickly when a project finishes, prevent systematic learning within phases of a project and from one project to the next.* Thus, NPD is associated with the risk of "learning closure" (Hobday, 2000), which refers to the act of prioritizing the start of a new project over learning from its predecessors.

The risk of learning closure can be mitigated by developing practitioners who learn to think in terms of systems, work purposefully toward a vision, and learn how to collectively and iteratively develop frameworks for thinking (Senge, 2006). As such, learning becomes an intrinsic aspect of the work of practitioners, not something extra that is added. This may ultimately lead to the creation of a "learning organization" (Senge, 2006). In such an organization, practitioners obtain, share, and use accumulated knowledge and transfer it within and across projects in order to meet strategic goals.

### 4.4 Summary of Sect. 4

Through the theoretical lens of SAP, this section discussed how manufacturers can engage in SC strategizing in NPD. This started with individually discussing the three dimensions of SC strategizing in NPD: practitioners, activities, and practices.

First, SC strategizing practitioners in NPD can originate from different organizational functions and have different backgrounds, knowledge, or interests. Second, SC strategizing activities in NPD typically relate to determining the manufacturer's supplier base, supplier relationships, and internal or external material flows. Third, SC strategizing practices are the mechanisms that support practitioners when they perform SC strategizing activities which require discussion, negotiation, and iteration.

Having individually discussed these dimensions, their interplay was exemplified. This revealed that the interplay among the dimensions of SC strategizing in NPD is dynamic and may change over time.

Finally, the section discussed three challenges of engaging in SC strategizing in NPD: uncertainty, politics, and learning. First, uncertainties related to product design, demand, and supply may challenge SC strategizing in NPD. Second, SC strategizing in NPD involves a complex political process in which there is plenty of room for practitioners to promote their interests as taking priority over that of others. Third and finally, the temporary nature of NPD creates an obstacle to learning and capability development related to SC strategizing.

## 5 Conclusion and Future Directions

This chapter discussed how manufacturers can engage in SC strategizing in NPD, by touching upon several topics. First, different SC strategies were introduced. After concluding that these strategies aim at achieving a certain level of responsiveness to customer needs, it was argued that manufacturers should engage in SC strategizing in NPD. Thereafter, through the lens of SAP, it was shown that this engagement can be achieved by managing the dynamic interplay of SC strategizing "practitioners," "activities," and "practices." Finally, while managing this interplay, manufacturers were warned to be aware of challenges related to uncertainty, politics, and learning.

The present chapter also opens the door for future research and practice that utilizes the SAP lens in order to empirically explore SC strategizing in NPD. Such research can create reflexive knowledge by – instead of looking for structural invariants, normative rules of conduct, or predetermined cognitive schema – investigating practitioners, activities, and practices within a community of interpretation (Whittington, 1996).

Future directions for practice and research include further investigating the unfolding nature of SC strategizing in NPD as the interplay of practitioners, activities, and practices. This investigation and integration should provide an interpretative framework in which a particular approach to SC strategizing in NPD "makes sense" in a manner that may be unique to that time and place. Instead of searching for theories of general validity, future research can contribute particularly meaningfully by stating the context and conditions in which a particular approach to SC strategizing might be appropriate in NPD.

As suggested by Tsoukas (2009), the value of such work lies *not* in its generalizability but in the understanding provided of the means and mechanisms through which SC strategizing in NPD occurs in a specific situation and in practice. Even though the goal is not to generalize in a statistical sense, the provided insights can be of considerable interest for other contexts. By presenting the results in such a way that readers may interpret the relevance of the findings in other contexts, the notion of "transferability" (Lincoln & Guba, 1985) rather than "generalizability" becomes more relevant in future research.

Despite not delivering "actionable knowledge" (Jarzabkowski & Wilson, 2006) in the sense of providing (deterministic) guidelines for acting, the proposed type of research should be capable of helping practitioners do their work differently. Utilizing the SAP provides an opportunity to focus attention precisely on what is easily taken for granted by practitioners (Vaara & Whittington, 2012). This understanding may contribute to the creation of "reflective practitioners" (Schön, 2017), who will hopefully become more subtle and sensitive when engaging in SC strategizing in NPD. Thus, future research is invited to provide practitioners with resources enabling them to consider their work in a different light, thus creating new or alternative ways of working.

# Viewing Supply Chain Ambidexterity (SCX) Through Paradox Theory and an Innovation Framework

Mehmet G. Yalcin and Muhammad Hasan Ashraf

## Contents

**Abstract**

Ambidexterity explains why companies engage in seemingly contradictory strategies in their effort to improve competitiveness. In supply chains, the literature provides neither a generally accepted definition of supply chain ambidexterity (SCX) nor a proper measure of relevant constructs. In addition, scholars have argued that ambidexterity is only an academic concept with no practical implications. This chapter evaluates supply chain integration (SCI) and supply chain agility (SCA) as antecedents to SCX. A conceptual framework consisting of four theoretical components, concept of ambidexterity (CoA) in conjunction with

paradox theory (PT), theory of constraints (TOC), institutional theory (IT), and resource-based view (RBV) – resource-advantage theory (R-A), is proposed as a meta-theoretical guide for research, teaching, and practice. The chapter first introduces this Sustainable Innovation Capability Framework (SICF), explains its components, and then outlines the relevance of SCX in supply chains. A concept of an ambidextrous growth mindset (AGM) is also introduced with relevance to sustainability and innovation.

# 1 Introduction

> Traditional approaches to business will collapse, and companies will have to develop innovative solutions. That will happen only when executives recognize a simple truth: Sustainability = Innovation. (Nidumolu et al., 2009, p. 9)

Establishing a strong scholarly connection between innovation and sustainability from the perspective of supply chain management (SCM) motivates this chapter, where efforts are directed to develop a practical framework for guiding theory development around sustainable innovation. Numerous theories provide an opportunity to show how supply chain ambidexterity (SCX) could be employed toward *creating value sustainably* in all aspects – i.e., social, environmental, and economic. We present a general framework that consists of four select theoretical components that link to creating value sustainably: the concept of ambidexterity (CoA) in conjunction with paradox theory (PT), theory of constraints (TOC), institutional theory (IT), and resource-based view (RBV)/resource-advantage theory (R-A) where the latter two theories are nested within TOC. This guiding framework offers an overarching meta-theoretical pathway for research, teaching, and practice toward sustainability and innovation (see Fig. 1).

Over the past few decades, all aspects of sustainability – such as the triple-bottom-line (TBL), corporate social responsibility (CSR), and environmental, social, and governance (ESG) metrics – revealed fresh challenges for organizations around the globe. Supply chains have become intertwined with one another to create a spectrum of smoothly-to-haphazardly dovetailed networks, and therefore, managers are concerned more than ever regarding matters beyond their supply chains. Translated into organizational processes as constraints, these challenges are root causes for continual assessment of risk faced by supply-demand networks (Arlbjørn & Paulraj, 2013) amid increased connectedness through enhanced technologies. Once addressed and adopted, the sum of all outcomes relating to these constraints is transformed into competitive/comparative advantages that sustain the networks

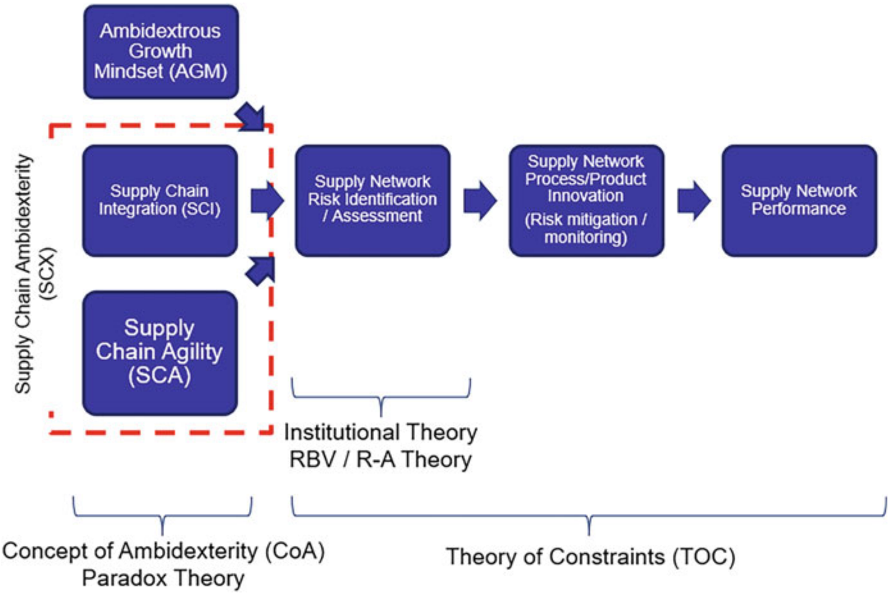

**Fig. 1** Sustainable Innovation Capability Framework (SICF): A meta-theoretical guide for research, teaching, and practice. (Source: Authors)

into the future. In this chapter, these outcomes are synonymous with innovation – defined within a broad spectrum where even the slightest (incremental) and the most leap-frogging (radical) improvements are acknowledged as innovations.

TOC states that networks tend to focus on challenges perceived as bottleneck/constrained processes. Defining the scope of SCM as an end-to-end phenomenon that extends from the first supplier to the consumer – including all the stakeholders along the way – and back, assessing where constraints reside now or could possibly appear in the future, requires impactful use of available resources and continuous effort by network players. A critical and plausible assumption can be made where constraints are defined as *uncertainties that matter* for a supply chain/network. In other words, anything that affects supply chain goals has the potential to become a relevant constraint and, therefore, may need to be addressed within the supply chain risk management context. The following sections briefly explain each component in the proposed framework – from Fig. 1.

## 2 Theory of Constraints (TOC) and Risk Management

Kern et al. (2012) define supply chain risk management using three sub-components – risk identification, risk assessment, and risk mitigation (Wagner & Bode, 2009; Kleindorfer & Saad, 2005; Tang, 2006). They suggest that continuous improvement and risk management need to occur simultaneously over the long term because of the vulnerabilities that arise upon changes in the environment. In their empirical study, the authors find that superior identification of risk leads to subsequently better risk assessment and mitigation performances (Kern et al., 2012). Without proper risk identification, supply chains might manage irrelevant risks. If supply chains continue to integrate their operations and exercise agility simultaneously – which we define as SCX – their supply chain's risk identification ability can improve.

TOC (Goldratt & Cox, 1984; Goldratt, 1990) prescribes identifying the constraint – the process creating a bottleneck – in a system and then exploiting it. All other processes should play a subordinate role to the bottleneck process, then elevate the capacity of the constraint as needed, and restart the cycle by identifying any new constraint or bottleneck process. Global efforts toward exercising more sustainable solutions require operations to incorporate new constraints into their organizational strategies as they are expected to perform under conditions that are more stringent.

Trying to operate under such conditions, acquiring the right resources, and managing them in an efficient and effective manner have become more challenging due to increased competitiveness. Organizations are continuously evaluating their supply chain networks in conjunction with the constraints that they confront. This evaluation creates a link where the supply chain performance is influenced by risk management, with potential threats and opportunities to an organization being identified and addressed to maximize future gains. Whether imposed through rules and regulations or due to self-motivation for improvement, the new constraints – or new constraint combinations – trigger action and help improve processes and product-service offerings.

Thinking of a firm or a supply chain network as an entity that has unique characteristics, any new venture for improvement could be assumed to be an innovation – for example, implementation of best practices, importing practices from other industries, innovating with resources that reside within. Adding more constraints to firm or supply chain network operations introduces additional challenges for managers.

TOC explains the overall procedure of selecting the relevant constraint that is ripe for improvement and advises eliminating its bottleneck status. The focus of this chapter is not to explain the innovation process but to examine the nature of "bottleneck constraint selection" by identifying its determinants. Strategically, a firm will want to pick a constraint that will either pose a threat or opportunity – since both are uncertainties with risks – for mitigation, evaluation, and further improvement. Determinants of this selection procedure would talk much about the firm's intent. However, some firms might be forced to select certain improvement programs.

## 3 Supply Chain Ambidexterity (SCX) for Risk Identification

CoA explains why companies engage in seemingly contradictory strategies when seeking to improve competitiveness. CoA's theoretical support comes from paradox theory – where contradictory elements are termed *paradoxes* (Schad et al., 2016;

Smith et al., 2017). CoA explains why operational activities within the same organization appear to be diametrically opposed but collectively improve performance (Andriopoulos & Lewis, 2009; Raisch & Birkinshaw, 2008; Smith & Lewis, 2011; Birkinshaw & Gupta, 2013; O'Reilly & Tushman, 2013; Turner et al., 2013).

This chapter uses Schad et al.'s (2016) interpretation of paradox and defines ambidexterity as a "persistent contradiction between two interdependent elements." While interdependent and contradicting elements appear to collectively create value, this dynamic is a dilemma for practitioners and researchers. CoA includes various paradoxical dichotomies such as adaptability and alignment, integration and responsiveness, exploration and exploitation, differentiation and low-cost strategic positioning, and global integration and local responsiveness (Gibson & Birkinshaw, 2004).

These dichotomies describe drivers of seemingly irreconcilable operational tensions (Adler et al., 2009) that exist between short-term efficiency and long-term adaptability (Abernathy, 1978). These paradoxical tensions are what operations and supply chain managers must routinely address (Adler et al., 2009; Ashraf et al., 2021; Zhang et al. 2020) – including flexibility versus efficiency (Adler et al., 1999), exploitation versus exploration, and just-in-time versus traditional manufacturing (Quinn & Cameron, 1988). Organizations that successfully manage these tensions use them to improve and sustain performance (Raisch et al., 2009; Birkinshaw & Gupta, 2013; Schad et al., 2016; Smith et al., 2017).

Most of the CoA discourse focuses on the exploitation and exploration dichotomy (Birkinshaw & Gupta, 2013; O'Reilly & Tushman, 2013; Turner et al., 2013; Zimmermann et al., 2015; Smith et al., 2017) and posit that when organizations employ both exploitation and exploration type activities in their operations, they achieve greater levels of performance than companies that focus on a single dimension.

Ambidextrous SC strategy is often described and measured through the simultaneous existence of exploitative and explorative SC activities (Kristal et al., 2010; Lee & Rha, 2016; Rojo et al., 2016). No generally accepted definition of ambidexterity within supply chain context exists (Yalcin, 2017). However, an operational definition of ambidexterity through the lens of paradox theory and supply chain management can be developed. Identifying antecedents of SCX can assist practitioners and researchers in creating it in their organizations. Additionally, while the literature anecdotes that ambidexterity can provide tangible benefits, Birkinshaw and Gupta (2013) argue that it is currently only an academic concept. As a result of this issue, operationalizing SCX by creating measures to examine the concept empirically is important (Yalcin, 2017).

To extend SCX application beyond just being an abstract concept requires that it be useful to SC scholars and practitioners. To do so, SCX requires a greater level of definition, measurement, and experimentation. The exploitation and exploration ambidextrous relationship is conceptually close to supply chain integration (SCI) and supply chain agility (SCA) in the SC context. SCI and SCA can be jointly examined to investigate their relationship to SCX. Similar to exploitation and exploration, an overemphasis on either SCI or SCA, to the detriment of the other, can weaken organizational competitiveness. SCA refers to the adaptability of the supply chain to capitalize on new opportunities. SCI refers to the level of cooperation and collaboration among supply chain partners to increase efficiency. Both concepts have been treated separately in the literature and have individually shown to improve competitiveness. This individual treatment suggests that the two concepts are distinct due to their differing activities and effects on competitiveness (Yalcin, 2017).

Paradox theory suggests that positive synergies between apparently opposing activities can create interactions that are complementary to competitiveness. This suggestion may not be evident superficially, but it provides conceptual support for testing the concepts together. For example, SCA increases adaptability to new opportunities, which in turn can improve efficiencies through SCI. Alternatively, SCI can free up resources and capacity that support greater adaptability through SCA. The presence of both factors indicates SCX.

Since SCI and SCA are concepts used in practice, this suggests that SCX is more than an abstract academic concept and can explain many of the practical industrial outcomes. The SCX term may not be well-known among practitioners, but SCI and SCA are well-known and have been shown empirically to individually improve SC performance. No studies have examined SCI and SCA for their combined effect on performance – also known as *combinative competitive capabilities*, which CoA suggests (Yalcin, 2017).

Similar to exploitation and exploration activities, SCI and SCA together can increase SCX. As a result, identifying antecedents to SCX at the firm level is important. In this chapter, a measurement model is proposed. For practitioners, identifying SCX drivers could lead to better SC management and performance (Yalcin, 2017).

## 4 Concept of Ambidexterity (CoA) and Paradox Theory

Smith et al. (2017) arguably tie the concept of paradox to ancient philosophy while citing that paradox research increased by 10% per year between 1990 and 2014. It is built on early scientific research conducted in psychoanalysis, communications, and macro sociology disciplines. Demonstrating the continuing debate about paradoxes, Harris (1882) analyzes Hegel's deep commitment to his way of paradoxical thinking as a philosopher.

More recently, the paradoxes and complexity are recognized in works such as Stacey et al. (2000) that draw from Hegel, Mead, and Elias by focusing on a better understanding of organizing instead of organizations as human-made tools in their discussions about stability and change. While Nilsson and Gammelgaard (2012) elaborate on the increasing advantages offered by complexity approaches over the systems approach, Nilsson (2019) explains how the complexity paradigm helps generate research through the study of paradoxes (Nilsson & Christopher 2018) that are better aligned with real-life logistics.

Smith et al. (2017) also add a collection of studies that advance the paradox theory. These studies are rich in the explorative nature of paradox and posit that interdependent contradictions are inherent in human nature, its environment, as well as the constructs that humans build – for example, life-death, knowledge-ignorance, self-other, expansion-constriction, independence-dependence, time-space, particles-waves, stability-change, empowerment-alienation, flexibility-control, diversity-inclusion, exploration-exploitation, social-commercial, competition-collaboration, learning-performing, profits-purposes, and novelty-usefulness.

Johnson (2014), through a *polarity map*, practically illustrates how each paradox dimension (e.g., group cohesion and individuality) brings something positive to the innovation process and how each dimension becomes a liability without the other dimension to complement it.

In the context of SCM, paradox theory is still in its early stages but is gradually gaining popularity. For example, Maalouf and Gammelgaard (2016) identify organizational paradoxes that emerge when firms implement lean practices and present a range of managerial responses used for dealing with the emerged paradoxes. Similarly, Ashraf et al. (2021) identify paradoxes that became salient during COVID-19 in the logistics industry and propose managerial responses to address them. Xiao et al. (2019) show how purchasing and sustainability managers make sense of and respond to paradoxical tensions in sustainable supply chains. Van der Byl and Slawinski (2015) show the potential of paradox theory to understand the nature of tensions in corporate sustainability and generate creative approaches to address them. Jarzabkowski et al. (2013) develop an empirically grounded process model and show how managers experience paradoxes and their approach to cope with them over time. Sandberg (2017) explores the applicability of the paradox theory in the global sourcing context, and Zhang et al. (2020) apply the paradox lens to identify the elements of paradox in the literature. Ashraf et al. (2022) introduced the concept of the Braess Paradox in the supply chain domain, arguing that capacity building counterintuitively may lead to a decrease in performance.

From another viewpoint, Duncan (1976) found that to be competitive; successful organizations need to possess two separate structures; one that encourages exploitation and the other, exploration. In the 1990s, the term "ambidexterity" was coined to describe these structures, and its use gained momentum in organizational behavior (i.e., March, 1991; Levinthal & March, 1993; Ghoshal & Bartlett, 1994; Tushman & O'Reilly, 1996). In the 2000s, the literature began to describe it as the CoA (i.e., Gibson & Birkinshaw, 2004; Birkinshaw & Gibson, 2004; Raisch & Birkinshaw, 2008; Raisch et al., 2009; Simsek, 2009; Lavie et al., 2010). Recent scholars began a consolidation of CoA (i.e., Birkinshaw & Gupta, 2013; O'Reilly & Tushman, 2013; Turner et al., 2013) and applied it to firm and SC performance (i.e., Tokman et al., 2007; Im & Rai, 2008; Adler et al., 2009; Kristal et al., 2010; Blome et al., 2013; Narasimhan & Narayanan, 2013; Lee & Rha, 2016; Rojo et al., 2016; Eltantawy, 2016; Yalcin, 2017; Aslam et al., 2018).

CoA's dominant utility has a time dimension that is perceived as performance, hinging on an organization's ability to manage exploitation vs. exploration activities simultaneously (Gibson & Birkinshaw, 2004). While CoA is primarily studied within organizational science, it has been gaining attention among SC scholars. Recent research has investigated CoA by using elements of cooperative relationship portfolios of small-to-medium-sized enterprises (Tokman et al., 2007), long-term inter-organizational relationships (Im & Rai, 2008), and supply management sustainability performance (Eltantawy, 2016). Also, CoA has been applied to explain a manufacturer's *combinative competitive capabilities* (Kristal et al., 2010), SC disruptions via SC sensing (an approach to visibility), SC seizing (a form of agility), and SC reconfiguring (their term that is synonymous with flexibility) (Lee & Rha, 2016). More recently, CoA has been used to explain SC flexibility and SC competence (Rojo et al., 2016); supply chain efficiency and responsiveness (Aslam et al., 2018); supply network knowledge and innovation (Narasimhan & Narayanan, 2013); organizational governance and innovation (Blome et al., 2013); and supply chain ambidexterity (SCX) (Yalcin, 2017). This extensive use demonstrates that CoA is an emerging area of study in SCM.

## 4.1 Relevance of Ambidexterity in Practice

The work of Birkinshaw and Gupta (2013), O'Reilly and Tushman (2013), and Turner et al. (2013) provide the basis of a contemporary view of CoA. While all three studies provide valuable insights regarding CoA, Birkinshaw and Gupta (2013) provide the broadest perspective with an *efficient frontier* approach similar to that used by Boumgarden et al. (2012) and Porter (1996). They find that CoA is not necessarily opposing but includes orthogonality with relationships that are interactive – less than 180° angles between vectors – instead of diametrically opposed relationships (180° relationships). This observation suggests that an interaction between two interdependent elements in supply chains may explain the benefits of SCX as long as they have some degree of persistent contradiction between them – not fully parallel and thus interactive.

Birkinshaw and Gupta (2013) admit that despite it being a vital and attractive phenomenon, CoA is ill-defined, and its applicability to organizational research is primarily anecdotal. While the authors assert that CoA offers another theory to explain organizational behavior, they highlight the difficulty in measuring competing objectives that must be traded off, reconciled, managed, or balanced in the industry (Yalcin, 2017). The current literature is not clear on which opposing or complementary objectives exist.

Upon developing a new construct called ambidextrous SC strategy, Kristal et al. (2010) discover odds with the "tradeoffs scenario" between exploitation and exploration and propose that ambidextrous SC strategy may describe a complementary relationship between realizing efficiencies and concurrently evaluating new prospects. In support, Birkinshaw and Gupta (2013) argue that measuring exploitation and exploration as separate dimensions is crucial, but treating them as opposing points a priori as a strict trade-off is unwarranted. Applied to the broader SC, the work by Kristal et al. (2010) captures constructs that are loosely defined and not SC-specific. Lee and Rha (2016) introduce a plausible model, but their factors are not SC-specific, and the linkages have not been examined within an SC context (Yalcin, 2017). Because CoA has been treated as an academic construct lacking demonstrated industry relevance, Birkinshaw and Gupta (2013) have concerns about CoA becoming a fad. They argue that refocusing and rethinking the direction of the current literature is needed.

## 4.2 Supply Chain Ambidexterity (SCX)

Ambidexterity theorists acknowledge the definitional issues as the main source of uncertainty in meaning and measurement (O'Reilly & Tushman, 2013; Turner et al., 2013). So far, the literature provides neither a generally accepted definition of SCX nor a proper measure of relevant constructs.

Simsek (2009) classifies CoA definitions under three views: structural, behavioral, and realized. The *behavioral view* examines organizational CoA under a single entity, whereas the *structural view* approaches CoA from higher abstract levels. While there are issues with all three viewpoints, they show an especially poor consensus on the definition of the *realized view*, which focuses on attainments through duality's actions. The realized view applies not only to single organizational units but also to SCs. Unlike the behavioral and structural views, the realized view is about a state where CoA behavior is actually taking place and not just the endeavor to achieve a hypothetical, idealized level called *ultimate ambidexterity*. The realized view captures the entire spectrum of levels of CoA.

It is risky to apply CoA to a wide variety of contrasting concepts because the theory can lose its meaning (O'Reilly & Tushman, 2013), especially from the SC perspective. Birkinshaw and Gupta (2013) and O'Reilly and Tushman (2013) recognize that the unit of analysis should be moved from the firm level to an SC level; however, this might not be possible unless SCX occurs at the firm level first. Therefore, by focusing on a definition from the realized view, a transition of CoA is necessary from the firm to the SC level to claim that SCX exists. Recent CoA-related research in SC supports this argument (Yalcin, 2017).

Aslam et al. (2018) conveniently incorporate SCX without developing the construct. Although the elements, supply chain efficiency and responsiveness, in this construct are plausible, they are haphazardly put together to carry on their analysis of a bigger model. Because the SCX strategy is a relatively new construct, SC researchers began to develop measurement items built around the commonly used exploitation and exploration variables. The ambidextrous SC strategy, developed by Kristal et al. (2010), is the only construct that synthesizes CoA with SC. It encompasses the simultaneous pursuit of both supply chain exploitation and exploration practices from a manufacturer's perspective.

While SC exploitation practices refine and extend existing skills and resources, exploration practices pertain to the development of new supply chain competencies through experimentation and acquisition of new knowledge and resources. SC exploitation mainly focuses on obtaining lower costs and higher reliability through improved efficiencies. In contrast, the goal of SC exploration is to seek new knowledge and ideas within SC relationships to better support organizational decision-making.

Flynn et al. (2010) define SCI with three factors in a manufacturing setting as opposed to other forms (e.g., Wiengarten & Longoni, 2015; Yuen & Thai, 2016): customer, supplier, and internal integration and show linkages to operational and financial performance. Flynn et al. (2010) show that supplier, internal, and customer integration all have different effects. Further, in their findings, Flynn et al. (2010) explain that the best-performing manufacturers were effective with internal, customer, and supplier integration. Consensus in measuring SCA is not as further-established (i.e., Fayezi & Zomorrodi, 2016) as in measuring SCI.

Gligor et al. (2015) provide details on measuring SCI and building on SCA items developed in earlier studies (i.e., Christopher, 2000; van Hoek, 2001; Swafford, 2003; Li et al., 2009; Braunscheidel & Suresh, 2009; Gligor, 2013; Gligor et al., 2013). Gligor (2013) conducted an empirical study on the effects of firm SCA on performance outcomes from an efficiency and effectiveness perspective. Until then, Gligor (2013) suggests that the theory development for SCA had been limited, evident by the underdeveloped elements and linkages related to agility. For instance, agility and flexibility were used synonymously (i.e., Giachetti et al., 2003; Li et al., 2008; Almahamid et al., 2010). While their research led to a consensus definition for agility, Gligor et al. (2015) established a measurement instrument by identifying the dimensions of agility within the SC field. They reveal five distinct dimensions of SCA that are categorized under cognitive (alertness, accessibility, decisiveness) and physical (swiftness, flexibility) classifications. The former is linked to information processing, and the latter is linked to action-taking.

Tse et al. (2016) find that SCI positively influences SCA, which then positively influences a firm's performance by fully mediating the SCI's effect on firm performance. This observation suggests that an interaction effect may be present on SCX. Gligor (2013), while investigating the effect of "alertness," stops short of acknowledging possible confluence of SCI such that after being "alert," the failure of internal integration might appear as the root cause holding back the firm's decision-making process. Birkinshaw and Gupta (2013) suggest that this situation may indicate a relationship that is similar to the efficiency-frontier-like idea within these dualities. Whether through reconciling, balancing, or trading off, the components of dualities influence one another (Yalcin, 2017). It is possible that further agility might bring new resources into and make them an operational component of the organization and thus help the organization exceed a certain threshold with its integration efforts. Similarly, SCA could possibly enable further SCI.

## 5 Linking Supply Chain Integration and Supply Chain Agility via Paradox Theory

Employing a multi-method approach that uses a Literature Review, Expert Panels conducting Q-sorts, Semi-structured interviews, and a Grounded Theory (GT) type approach, a study was conducted, incorporating academics and practitioners, to

develop a new theory by linking the SCI and SCA constructs (Yalcin, 2017). Table 1 summarizes the main steps of the process used and some outcomes.

Reconciliation between SCI and SCA activities is important. For instance, a recent decision to push for further vertical integration efforts with their suppliers in a company was presented with caution by some practitioners in the study, mentioning the need to monitor and nurture the existing agility efforts that are already in place with the fear of slowing down supplier innovation (Yalcin, 2017).

Many times, organizations have to sacrifice either SCI or SCA activity for the sake of the other. Examples include a limitation of resources such as funds, time, and human resources rather than the strategic ability that the managers or the organizations possess themselves. The intensity of the argument for lack of resources seems to vary depending on the functional departments, organizational units, or initiatives. There is a strong appeal to the trade-off perception in the SCI and SCA interaction by practitioners (Yalcin, 2017).

Balancing SCI and SCA activities is significant to scholars who seem to be more comfortable articulating their views of the applicability of balancing organizational activities. Practitioners seem to refrain from being able to strike a proper balance between SCI and SCA. While the statements of academics with industry experience resemble those views of the practitioners, they believe in the achievability of balancing more than the practitioners. Arguments revolve around different SCI and SCA activities occurring in proper amounts and importance, such as nurturing existing customers and gaining new customers. In lieu of persisting over time, the contradictions are observed to display a temporary nature (Yalcin, 2017).

## 6 Future of Supply Chain Ambidexterity (SCX)

Per the typology of conceptual contributions suggested by MacInnis (2011), "*integration*" represents the connections among previously unconnected phenomena that are explained; in this case, the relationship between SCI and SCA through CoA. By operationalizing the relevant constructs and extending (Kilduff, 2006) the CoA into SCM, further empirical research can be enabled and linkages established.

With the introduction of the proposed SCX model, not only the theory-practice gap is bridged (Waller et al., 2012), but also the scientific community is helped to anticipate an important need that the business and social organizations have (Corley & Gioia, 2011). Using established constructs and procedures to achieve clear definitions and relations between constructs, the model elaborates on the operating conditions of these relationships and explicates with reasons as to why these relationships exist (Hedström & Ylikoski, 2010; Suddaby, 2010). CoA in the SCM context improves the explanation of orthogonal dualities via SCX (Yalcin, 2017). It increases the legitimacy of SCM discipline and advances interdisciplinary connectivity, and contributes back to CoA.

This chapter focuses on bringing about the relationships between SCI and SCA constructs and explaining them with similar underlying mechanisms that lie in CoA (Chen et al., 2005). Overcoming the confusion over deciding which SC activities should be considered exploitative and which ones are explorative, academics and practitioners could have a better idea of how to manage SCX (Yalcin, 2017). It seems that the level of SCI can better measure one aspect of the SCX, while the degree of SCI depends on the degree of SCA, which represents the other aspect of SCX (Yalcin, 2017). SCI and SCA interaction enables an operational definition of SCX through the lens of paradox theory and SCM. This operationalization would allow further examination of the SCX concept empirically and help fine-tune the definition and measurement and related experimentations.

## 7 Supply Chain Ambidexterity (SCX) Outcomes and Observations

Paradoxical elements in strategies and activities do exist in the industry, and using the term ambidexterity, as it is defined in this study, is appropriate. Paradoxical elements can be complementary, although this is usually only recognized after-the-fact, suggesting that companies are not yet viewing SCX strategically. Significant resources are required to reconcile SCI and SCA activities. This involves not only internal operations but also extending to suppliers and customers. The efforts to reconcile the paradoxical elements must be intentional but are often conducted below the strategic level. There can be several opportunities where SCI and SCA activities can be non-contradictory in nature.

On the other hand, managers moving beyond the consensus of the coexistence of SCI and SCA activities rarely encounter a situation where some form of trade-off is not required. Even when complementary, the sacrifice of SCI or SCA activities is common. These may be in the form of trade-offs between human resources versus technology, short-term versus long-term benefits, or limitations due to deadlines. Again, these tradeoffs hold below the strategic level, which the theory of SCX indicates, leading to sub-optimal competitiveness. The intensity of the argument for lack of resources varies depending on the functional departments, organizational units, or initiatives, further suggesting that companies need to recognize this at a strategic level. This shows that SCX is a concept used in industry and applies to real organizational processes and resources, although the SCX terminology is not used.

It is evident that SCI and SCA are antecedents to SCX, meaning that companies must seek greater integration and agility simultaneously to achieve a level that can be described as ambidextrous (Yalcin, 2017). To achieve this at an SC level, SCX must occur when a firm incorporates it internally and with external partners with customers and suppliers. In relating SCX to the efficiency-frontier idea, the interaction effect of SCI and SCA is perceived in four stages by the practitioners, i.e., (i) as reconciliation, where firms only acknowledge the need to simultaneously pursue both the elements of SCX, (ii) as a trade-off, where firms are forced to sacrifice either element of SCX for the sake of the other, (iii) as balance, where firms pursue both the elements of SCX in proper amounts and importance, and (iv) as maximizing, where firms proactively manage the elements of SCX toward innovation and growth. Figure 2 shows the four emerging perceptions.

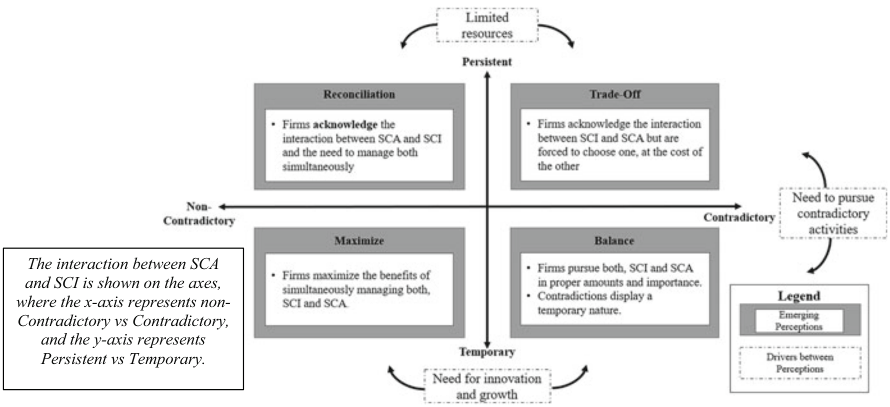

**Fig. 2** Emerging perceptions of how the interactions between SCI and SCA occur. (Source: Authors)

Practitioners who strictly focus on either SCI or SCA are intentional with their unidirectional approach, even though it may stifle innovation and further growth. Reconciliation starts with the vision of putting SCI and SCA on a Cartesian plane, and then accommodating tensions that emerge between the two. Balancing requires action on addressing the emerging tensions, where the practitioners develop proper means and methods to keep the tensions balanced. Maximizing would entail proactive management of these tensions toward innovation and growth.

Following the introduction of the measurement model for SCX, there is a need to elaborate on how this duality is achieved or practiced by managers in the industry (Yalcin, 2017). For instance, it is possible that many established firms try to capture either SCI or SCA perspectives through mergers and acquisitions. Rather than developing the needed capability in-house, they try to fill the gap that they see via the purchasing mechanism. Also, there is a need to investigate and test the measurement model that is proposed and developed in this chapter in a follow-up large-scale empirical study. The proposed linkages in the measurement model need to be hypothesized. Statistical significance ought to be established to verify and strengthen the SCX theory and then generate further insights for developing a meaningful analytical model.

## 8 Ambidextrous Growth Mindset (AGM) and Supply Chain Ambidexterity (SCX) Management Model

Based on the explanation of Birkinshaw and Gupta (2013), when the management capability is analyzed within the ambidexterity context, leadership and human resources-related studies reveal further insight into the construct that seems to have an influence on the dynamics between interdependent yet contradictory elements. It is suggested that ambidexterity generally represents successful management of both sides (Anderson et al., 2014). This perspective, therefore, holds potential for future studies, most notably into leadership effects in innovation processes (Rosing et al., 2011).

Mom et al. (2007) investigate the relationship between different knowledge flows in conjunction with management ambidextrous activities. Zimmermann et al. (2015) attempt to answer the reason behind this behavior by showing that the bottom-up version of the ambidextrous behavior of frontline managers can complement the top-down ambidextrous behavior of upper-level managers. This combined ambidextrous behavior enables organizations to be more responsive due to the frontline action in lieu of awaiting orders for action from top levels of management. Havermans et al. (2015, p. 1) "show that in responding adaptively to environmental stimuli, leaders shift between practices. . .and their enactments are bounded by the conditions of keeping. . . *them* simultaneously high" (paraphrased in italics), suggesting an optimum balance between the ambidextrous elements with the analogy of "approaching a moving target."

Since proper measures do not exist in the literature, the focus should be to invest efforts into developing the managerial capability/human resources construct to

**Ambidextrous Growth Mindset (AGM)**

1. What is the combined organizational belief/culture system that dominates the firm's supply chain: more of a fixed or a growth mindset? (Dweck, 2006)
2. What are some of the different ways for managing an ambidextrous relation between supply chain integration (SCI) and supply chain agility (SCA)? Based on potential answers as following (Yalcin, 2017):
   a) The managers' abilities to manage an ambidextrous dynamic between SCI and SCA in a maximizing manner.
   b) The managers' abilities to manage an ambidextrous dynamic between SCI and SCA in a balancing manner.
   c) The managers' abilities to manage an ambidextrous dynamic between SCI and SCA in a trade-off manner.
   d) The managers' abilities to manage an ambidextrous dynamic between SCI and SCA in a reconciling manner.

ensure its contributing/complementing influence within the SCX model. Dweck's (2006) research suggests that the growth mindset (as opposed to a fixed mindset) enables continuous improvement in self, through the teams, and then organizations by utilizing the power of people's beliefs. Synthesizing the above arguments present the ambidextrous growth mindset (AGM) construct (see Fig. 3). Dweck states that the growth mindset is based on the belief that an individual's basic qualities are things that she/he can cultivate through her/his efforts. In contrast, individuals with a fixed mindset believe that their qualities are carved in stone, which creates an urgency to prove themselves repeatedly.

Here, the growth mindset is a prerequisite of an AGM. At the same time, the other dimension focuses on addressing solely the management style of an ambidextrous dynamic between SCI and SCA (see Fig. 4).

## 9 Sustainability, Supply Chains, Theories, and AGM as a Resource

Sustainable supply chain management (SSCM) helps in further refining SCX and AGM. Here a parsimonious approach is preferred with two theories that function as opposite sides of the same coin, namely, institutional theory (IT) and resource-based view/resource-advantage theory (RBV/R-A theory) in addressing sustainability (going back to the framework in Fig. 1). The premise for the two-pronged approach is that depending on a variety of SCM-related factors, the sustainability phenomenon could either be perceived as a strategic resource that can be embraced and leveraged by a firm or a burden that the firm has to tackle or eliminate based on the market segment(s) that the firm is servicing. The degree with which the AGM dovetails with the SCI and SCA efforts (i.e., SCX) helps determine the organization's path toward

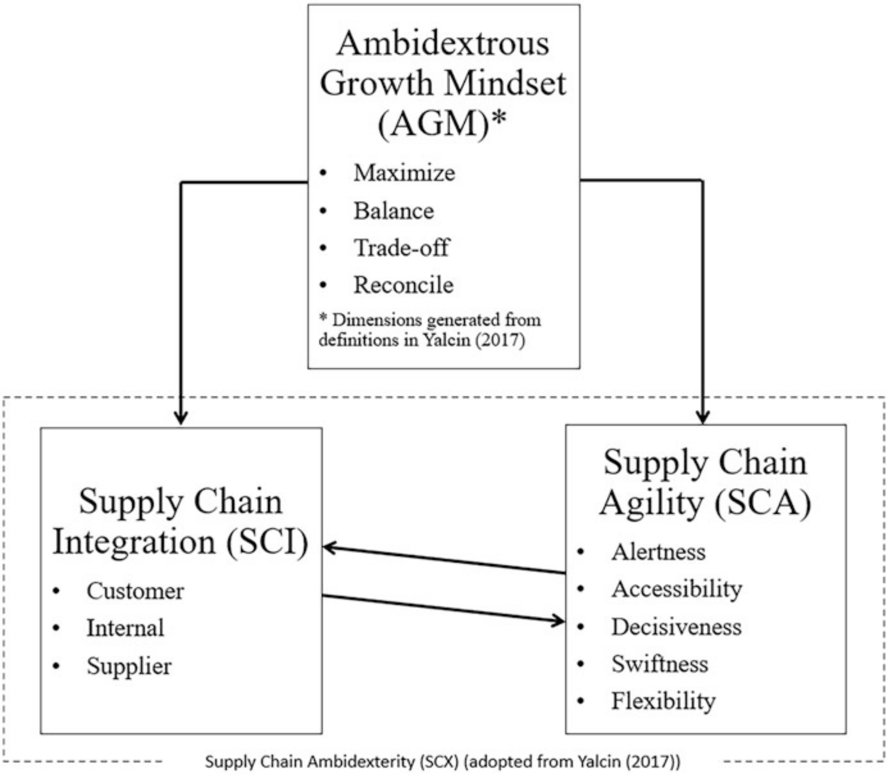

**Fig. 4** Proposed SCX management model. (Source: Authors)

robustly identifying "the uncertainties that matter" as well as boldly internalizing those relevant risks that are identified in their strategic and operational plans and activities. The reason for this lies behind the main assumption that the supply chains cannot improve indefinitely in isolation from their supply networks. While some organizations opt to wait/survive until networks improve, others choose to take on a more active role to influence the networks around identified risks (i.e., uncertainties that matter).

The dynamism in sustainability practices and the rapid evolution in the markets force firms that are at the extremes (i) to eventually adopt sustainable practices due to institutional pressures or (ii) to proactively embrace the foresighted up-and-coming AGM. Between these two extremes, firms straddle and navigate through the change with different speeds and techniques depending on the characteristics of the imposed change, some firms with fear of entrapment over time in mind and some others with no concern for long-term survival at all.

AGM is not only instrumental in ensuring that SCX is enacted but also weighs heavily in exploiting and elevating the bottlenecks (i.e., risks/uncertainties that matter) during the improvement/innovation process. Value creation through innovation motivated via AGM is a central theme. Arlbjorn and Paulraj (2013) define innovations within the supply chain network as “an incremental or radical change in process, structure, and/or technology that takes place in the supply chain network so as to create value for all stakeholders” (p. 4).

“The Discipline of Innovation,” a Harvard Business Review classic by Drucker (2002), outlines the potential sources of innovation within a firm or its industry as (i) unexpected occurrences, (ii) incongruities, (iii) process needs, and (iv) industry and market changes; while demographic changes, changes in perception, and new knowledge are considered as additional sources of opportunities for innovation that reside outside the firm. AGM reveals itself as a comprehensive phenomenon encompassing all internal and external potential sources of innovation that Drucker presents.

With every additional consideration or constraint that is included in optimization or decision-making process, supply chains devise new ways of realigning themselves in order to move forward. Therefore, “The discipline of innovation” by Peter Drucker establishes a solid foundation for an opportunity to relate sustainability from all three of its pillars (environmental, social, and economic) to systematic innovation. Based on this view, additional nodes of stakeholder requirements or perspectives within the supply chains serve as individual opportunities for motivation to innovate. It is at this juncture where “AGM” is operationalized.

Importing the resources into any operational setting invites the adoption of the definition that Hunt (2000) provided because it includes the demand-side perspective with an assumption of heterogeneous and dynamic nature (Hunt & Davis, 2008, p. 13): “the tangible and intangible entities available to the firm that enable it to produce efficiently and/or effectively a market offering that has value for some market segment(s).” AGM (tangible with sustainable inputs, production, output and intangible via knowledge, strategy) can be considered as an entity that “at times” can enable the firm to produce efficiently and/or effectively a market offering (manage its supply chains) that has value for the market segment(s) in which the firm is competing. For those other times when AGM is not valuable for the firm under the above conditions, as the resource definition would not apply, and for convenience, AGM is labeled as a burden.

Two paths seem to exist for organizations for handling uncertainties: those firms that are active and embrace the AGM along with its practices and develop competitive advantages, and others that are relatively reactive or manipulative and consider the AGM as a burden which only reduces the flexibility of the firm by squeezing the incumbent resources that feed competitive advantages. Relevance is a “competitive advantage” perspective; however, it is worth elaborating on the “burden” perspective to assist with clarifying/setting boundaries in the sustainable value creation spectrum. While institutional theory would view AGM as a burden, we focus on AGM as a competitive advantage in this chapter. Timing and the operational details of introducing the sustainability constraints are often unpredictable, proven by rich historical evidence (loss of market shares, competitive advantages, and bankruptcies). The economic pillar of sustainability is usually portrayed as the dark side; however, cost consciousness prevents resources from being expended prematurely if sufficient premiums are assigned to the resources. The real reason holding back genuine sustainability efforts is simply not knowing enough about the uncertainty; in other words, the inability to define the “uncertainties that matter” or the relevant risks to organizational processes. Through abductive reasoning, SCX offers a plausible alternative to assist supply chain managers in identifying uncertainties that matter to them the most.

## 10 Conclusion

The purpose of this chapter is to explicate Supply Chain Ambidexterity (SCX) and Ambidextrous Growth Mindset (AGM) in conjunction with Sustainable Innovation Capability Framework (SICF): A Meta-theoretical Guide for Research, Teaching, and Practice. In doing so, a thorough review of ambidexterity in SCM is also provided for proper grounding of the concepts employed.

In other words, we explained how SCX is operationalized via AGM through risk identification and theoretical considerations at the interface of sustainability constraints and innovation performance. While definitional concerns about ambidexterity are addressed from an SC perspective, we propose a definition that can be used as a practitioner construct, so the improvement claim by the ambidexterity researchers is better understood by practitioners (Yalcin, 2017).

Adams et al. (2016, p. 199) think that the managers need to be equipped “with tools for innovative solutions to sustainability challenges” and reveal that the relevant academic literature have been too diverse and fragmented. In a similar vein, while it is believed that succeeding against the sustainability challenges introduce different operating models by adding complexity to the supply chains, Simpson et al. (2015, p. 94) assert that “Sustainability will cease to be seen as some sort of specialism by ‘tree-huggers’ and will instead be a central point within the range of operations and supply chain managers’ many tasks,” therefore the need is critical “for managers to be experts in making the best possible use of very limited resources within globally competitive environments.” To that extent, we hope that our efforts in this chapter via introducing SICF offer some help to move the needle forward.

**Abstract**

Supply chain planning is a crucial factor for operational excellence and competitive advantage. Related concepts and approaches were already designed in the last century and are now implemented by most firms in almost every industry sector. Advanced planning systems that provide decision-support for supply chain planning were conceptualized and developed several decades ago and are still in place and used by planners in their daily work. However, progress in information technology and megatrends of sustainability and digitalization as well as global crises and disasters considerably change the business environment in which companies and supply chains operate. Supply chain planning processes and systems must be extended, adapted, and amended to reflect these developments and transitions. This chapter summarizes the fundamental concepts of supply chain planning and advanced planning systems and outlines which changes and advancements are needed to ensure that processes and tools remain

## 1 Introduction

Supply chain planning is decisive for operational excellence and financial success of a firm. For several decades, researchers have developed and amended supply chain planning concepts which are used worldwide by firms from all industry sectors to execute planning processes efficiently and effectively. In parallel, software vendors and scholars have designed and developed sophisticated software packages and advanced planning systems (APS) that support supply chain planning and decision-making. These information technology (IT) tools are implemented by many companies and now represent global state of the art.

However, the area of supply chain planning still emerges. Progress in IT and radical innovations in computers and software offer potential for substantial improvements and enhancements of APS. Sustainability as a global megatrend affects supply chains worldwide and is reflected comprehensively in concepts and tools for supply chain planning. In addition, firms and supply chains are exposed to new challenges and threats that arise from human-made crises including political instability or wars and from natural disasters such as global pandemics or climate change.

Supply chain planning approaches have to reflect these changes in the business environment. Therefore, continuous improvements and advancements of related management concepts, business processes, and system solutions are needed. Hence, the relevance of supply chain planning for scientific research and management practice remains unbroken. The chapter at hand introduces the fundamentals of supply chain planning and suggests possible directions for the future development of this topic.

The remainder of this chapter is structured as follows: Sect. 2 lays the terminological basis and provides a brief introduction of supply chain planning concepts and characteristics and an outline of properties and functionalities of IT systems for supply chain planning. Section 3 reveals existing gaps and points toward future directions of supply chain planning from a scientific perspective as well as from a practitioner's point of view. It tackles issues of how to augment processes and enhance models and systems for supply chain planning and elaborates on the question how supply chain planning concepts should emerge due to global changes in the business environment. Section 6 discusses practical issues with regard to supply chain actors that execute supply chain planning processes and software vendors that develop and distribute IT systems for supply chain planning. Section 7 ends the chapter.

# 2 Background

## 2.1 Terminology and Foundational Concepts

A supply chain is a network of organizations that are linked by internal and external relationships and flows of goods, finances, services, and information (Stock & Boyer, 2009). In today's business, competition has shifted from the company level of single firms to the network level of supply chains (Christopher, 2005). Such networks comprise not only a company and its immediate suppliers and customers – the *direct supply chain* – but also subsuppliers and customer's customers – the *extended supply chain*. Organizations involved in upstream and downstream flows of goods, finances, and information from ultimate suppliers to ultimate customers – an *ultimate supply chain* – represent the broader perspective (Mentzer et al., 2001).

Supply chains exist whether they are managed or not (Mentzer et al., 2001). However, supply chain management has gained attention for business practice and has become an important factor of competitive advantage and a strong lever for competitiveness of firms and their supply chain partners (Brandenburg, 2013). Characterized by process orientation, customer focus, and collaboration, supply chain management strives to improve efficiency and effectiveness of functions and activities which add value to a firm and its customers and partners up- and downstream in the supply chain (Stock & Boyer, 2009).

Temporally, the tasks of supply chain management are split into present-related supply chain execution and future-oriented supply chain planning. Supply chain execution comprises all processes that have to be carried out at the present time to operate the supply network (Shu & Barton, 2012). The Supply Chain Operations Reference (SCOR) Model distinguishes between six major management processes for *Plan*, *Source*, *Make*, *Deliver*, *Return,* and *Enable* (APICS, 2017), where planning is the first major process.

Supply chain planning covers all preparatory activities that have to be executed to configure or operate the supply network in order to meet future customer service requirements by coordinated release of materials and resources (de Kok & Fransoo, 2003). Supply chain planning is closely related to sales and operations planning, which is performed as a "process to develop tactical plans that provide management with the ability to strategically direct its businesses to achieve competitive advantage on a continuous basis by integrating customer-focused marketing plans for new and existing products with the management of the supply chain" (Pittman & Atwater, 2019).

## 2.2 Concepts and Characteristics

Using categories of decision relevance and planning horizon length, the tasks of supply chain planning can be grouped into three categories (Fleischmann et al., 2015, p. 72): First, **strategic decisions** on the supply chain configuration are made in **long-term planning** of several years. Second, **tactical decisions** on operating the supply chain are made in **midterm planning** over several months or quarters. Third, **operational decisions** on supply chain execution in the near future are made in **short-term planning** for a few days or weeks.

Strategic supply chain planning determines how the supply chain is configured, i.e., which organizations form the network and which property, plant, and equipment are available and located at which place. Tactical and operational planning determines which processes and activities the supply chain actors shall perform at which point in time in the mid and near future. These tactical and operational decisions determine rough quantities and times for the flows and resources within the network and may, in the midterm horizon, reflect effects of seasonality.

Long-, mid-, and short-term supply chain planning represent different levels of a holistic supply chain-planning concept. Trying to solve a monolithic supply chain planning problem in which all required decisions are made simultaneously would not be feasible due to the high complexity of the numerous decisions that have to be made and the various constraints that have to be considered (Stadtler & Fleischmann, 2012, p. 22). Instead, a **hierarchical planning** approach **decomposes** the overall supply chain problem into smaller (sub-)problems on the strategic, tactical, and operational level in such a way that the (sub-)problems can be solved independently.

Adequate **coordination** of hierarchical planning ensures that the results of the planning (sub-)problem of one level are reflected when solving the planning (sub-)-problems of the other planning levels – for example, network configuration decisions made in strategic supply chain planning are considered in the subsequent planning runs of tactical and operational supply chain planning. In addition, feedback mechanisms ensure that results obtained from planning at the lower level serve as input for the higher-level plan execution. This divide-and-conquer concept is adequate to handle the complexity of supply chain planning which is reduced further by **aggregation** performed on the dimensions of time and entities (Stadtler & Fleischmann, 2012, pp. 21–24).

The planning horizon is split into different time buckets with larger time buckets occurring at higher planning levels, such as monthly buckets for strategic long-term planning. Smaller time buckets occur at lower levels – daily buckets for tactical mid-term planning. For example, product variants for operational short-term planning are aggregated to products for tactical mid-term planning and furthermore clustered to product groups for strategic long-term planning. Similarly, supply chain equipment can be (dis-)aggregated – for example, from single trucks to transport fleets or from single machines to whole production plants and vice versa. In addition to decomposition, aggregation, and hierarchical coordination, there are two more important elements of hierarchical planning, namely, model building and

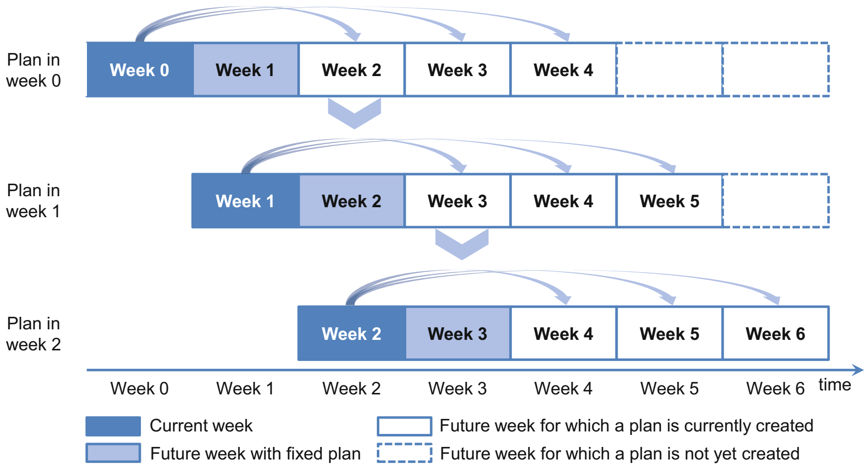

**Fig. 1** The concept of the rolling planning horizon (own representation)

model solving (Stadtler, 2015, p. 24). These elements will be described later in Sect. 2.3.

Discrepancies between reality and corresponding planning results occur frequently and have to be corrected by revised plans. For this purpose, supply chain planning is performed based on a **rolling planning horizon** (Fleischmann et al., 2015, pp. 73–74). The planning horizon, which is split into different time buckets, is iteratively shifted forward by one bucket in each planning run. For example, a planning horizon of 6 months is shifted from the months January till June to the months February till July as the planning calendar progresses. The first buckets of the planning horizon may be declared as a frozen zone in which planning decisions made in earlier planning runs must not be modified by later ones – see Fig. 1 for a rolling planning horizon (Stadtler & Fleischmann, 2012, pp. 26–28).

Supply chain planning tasks differ depending on function. Strategic supply planning, for example, determines the pool of potential suppliers while strategic production planning decides upon factory locations in the manufacturing network. However, the planning results of these function-specific planning tasks strongly affect each other. For example, decisions in manufacturing planning will remain suboptimal if the distribution plans are unconsidered and production scheduling results define planning goals (time and quantity) for raw material purchasing. **Integrated supply chain planning** reflects these interdependencies and links the different function-specific planning tasks in such a way that functional silos are overcome.

Integrated supply chain planning is conceptualized in the **supply chain planning matrix** (see Fig. 2) which is a framework that spans across the strategic, tactical, and operational levels and covers the different supply chain functions. In the horizontal dimension, it covers the different supply chain sections from supply- to demand-side in the direction of material flow downstream the supply chain while the different

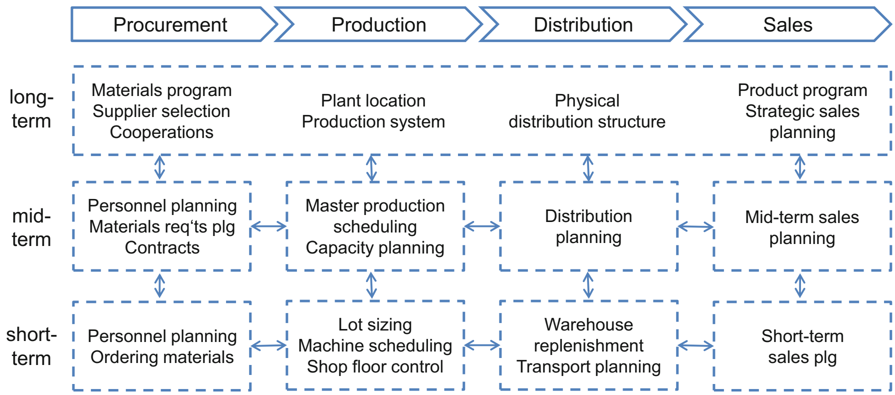

**Fig. 2** The supply chain planning matrix (Fleischmann et al., 2015, p. 77)

planning levels are reflected in the vertical dimension (Stadtler & Fleischmann, 2012, p. 29). The matrix contains the different tasks of supply chain planning and illustrates their hierarchical relationships. These tasks differ in the length of the planning horizon (long-, mid-, or short-term) and the type of decisions (strategic, tactical, or operational) and, as a consequence, in the impact of the planning results which may affect the whole company, larger parts of it, or only limited areas or single units (Stadtler & Fleischmann, 2012, p. 29). Hence, the tasks also vary with regard to their level of detail and responsibility, respectively (Stadtler & Fleischmann, 2012, p. 30): Strategic planning decisions are made by upper management based on aggregate data while local planners may be responsible for decision-making in operational planning based on detailed information.

In addition to connecting function-specific decision-makers in a centralized or decentralized decision structure within a single firm, supply chain planning should also involve suppliers and customers (Calvete et al., 2016). Hence, integrated supply chain planning crosses the organizational boundaries between different companies and ideally spans across the firms that cooperate within the supply network (Stank & Goldsby, 2000). However, due to the large complexity of today's supply networks – usually, firms are members of many different product-specific supply chains – this ideal state of integration is hardly achievable in business practice and, thus, nearly always must remain a theoretical utopia.

**Collaborative Planning, Forecasting and Replenishment** (CPFR) is a powerful approach to overcome this shortfall from the ideal state by integrating business logistics systems of different members of the supply chain (Panahifar et al., 2015). According to Seifert (2003, p. 30), CPFR is "an initiative among all participants in the supply chain intended to improve the relationship among them through jointly managed planning processes and shared information."

CPFR is enabled by a high level of trust and information sharing between the collaborating supply chain partners and inhibited by various factors including uncoordinated or disrupted information flows, lack of budget and expertise in information technology, or missing partner trust (Panahifar et al., 2015). Adequate partner selection and incentive alignment are crucial success factors for CPFR which – if implemented successfully – considerably increases the performance of all involved firms (Panahifar et al., 2015). An event study conducted by Hill et al. (2018) illustrates that CPFR has substantial positive impacts on inventory levels and sales and that it may improve operational and even financial performance of companies and supply chains.

In addition to the discussed functional, organizational, hierarchical, and time-based links, supply chain planning has process **interfaces to supply chain execution**. On the operational level and at a certain point in time, the supply chain plan must be executed by operations and execution activities: Planned purchase orders lead to receiving transactions, planned shipments result in transportation of products and pallets, and planned changes in inventory levels are realized by goods movements in warehouses. Supply chain planning ends when supply chain execution begins.

The business environment of functions, firms, and supply chains is highly dynamic and shows many, sometimes radical and dramatic, changes over time. As a consequence, supply chain planning is exposed to considerable **uncertainties** which cause **risks** in supply, demand, information, and products (Tang, 2006). Deviations between plan and reality most often lead to slight disturbances of operational processes and, thus, cause minor efficiency detriments and value losses. Typical examples include demand uncertainty and forecasting errors or the vagueness of fluctuating product yield (Fildes & Kingsman, 2011).

Unpredicted or unwanted events can also result in strong supply chain disruptions that cause long-lasting supply shortfalls, manufacturing breakdowns, and delivery failures which in turn may end in large losses in sales and market share (Norrman & Wieland, 2020). Major supply chain glitches often show considerable negative impacts on shareholder wealth (Zsidisin et al., 2016). To encounter challenges of uncertainties and risks, supply chain planning strives for incorporating aspects of resilience and robustness (Durach et al., 2015).

Jonsson, Rudberg, and Holmberg (2013) analyze the **prerequisites and effects** of supply chain planning. Their case study of a global furniture company shows that functional products, vertical integration, implementation-enforced organizations and their management, and the use of critical planning data and information are imperative for successful supply chain planning. Benefits include improvements in supply chain integration, standardization, and specialization as well as learning effects while human and organizational factors as well as software and data issues represent major obstacles for supply chain planning.

## 2.3 IT Systems, Models, and Solution Approaches

Although supply chain planning concepts follow complexity-reducing divide-and-conquer approaches, the numerous tasks are too difficult to be solved manually. Moreover, planning data and results must be exchanged rapidly to fully leverage the advantages of transparency and information exchange. These aspects call for IT systems to enable supply chain planning processes and to support related decision-making.

Progress in computer technology enabled the development of IT-support for supply chain planning which comprises systems for **materials requirement planning** (MRP), **manufacturing resource planning** (MRP II), and **enterprise resource planning** (ERP) (Kurbel, 2013). ERP systems are accounting-oriented information systems for enterprise-wide resource planning and controlling in manufacturing, distribution, and service companies which can considerably improve firm performance (Hendricks et al., 2007).

SAP AG, a German business software firm headquartered in Walldorf-Baden, developed the market-leading ERP system which consists of several modules for SC-related applications in procurement, manufacturing and logistics, and other business functions including finance and accounting or marketing and sales (Kurbel, 2013). SAP-based system solutions for supply chain management support planning, execution, and analysis of processes and activities to design the supply chain, to manage demand, supply, and service parts, and to facilitate transactions for procurement, manufacturing, warehousing, order fulfillment, and transportation (Knolmayer et al., 2009).

**Software packages for supply chain execution** complement the ERP systems. These tools comprise manufacturing execution systems (MES), logistics execution systems (LES), and warehouse management systems (WMS) that support company internal transactions. There are also software planning and execution systems for supplier relationship management (SRM) and customer relationship management (CRM) which help manage the inter-organizational flows of information, material, and finance within the supply network (Haulder et al., 2019).

The set of IT systems for supply chain management is complemented by **advanced planning systems** (APS), which support decision-making activities in supply chain planning at the long-term strategic, mid-term tactical, and short-term operational level (Stadtler, 2005; Stadtler & Fleischmann, 2012). An APS is a hierarchically structured system for integrated planning of the entire supply chain with exact or heuristic optimization methods of various planning problems that are defined by alternatives, objectives, and constraints (Fleischmann et al., 2015, p. 74). APS model the physical planning problem, use an engine to calculate the consequences of planning decisions based on the model, and depict the use of resources and materials over time via a graphical user interface (de Man & Strandhagen, 2018). Moreover, APS allow supply chain planners to modify the plan and make the implications of these changes transparent (Berning et al., 2002). As illustrated in Fig. 3, APS consist of different software modules which correspond to the different planning tasks of the supply chain planning matrix (Stadtler, 2005).

To solve the highly complex planning problems, commercial APS incorporate **mathematical models** and sophisticated solution algorithms which determine the quantities to be produced, stored, transported, and procured in the supply network (Stadtler, 2005, 2015). For each planning unit, mathematical models formally describe the decision situation by (i) variables that represent the different decision

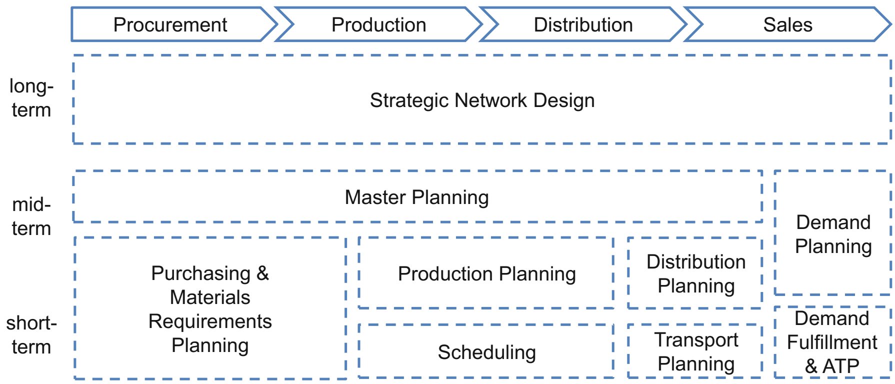

**Fig. 3** The APS modules covering the supply chain planning matrix (Meyr et al., 2015, p. 100)

options, (ii) constraints that specify the limits of the decision options, (iii) objective functions that express the planning goals and targets, and (iv) parameters that formalize the constraints and objective functions (Stadtler & Fleischmann, 2012, pp. 24–25).

APS comprise prescriptive models to determine optimized planning decisions, descriptive models to simulate different planning scenarios and their performance implications, analytic models to evaluate different supply chain plans, and statistical models to predict future product demands and to forecast future sales (Shapiro, 2007). Problem instances for the specific planning situation are parameterized by master data, such as parameters that remain unchanged over a longer time period, and transaction data, such as parameters that vary from planning run to planning run. Data have to be managed carefully, because the data quality strongly affects the quality of the planning results (Haug & Stentoft Arlbjørn, 2011).

APS contain **algorithms** to solve the complex instances of the supply chain planning problems and to execute calculations in supply chain planning routines. These mathematical procedures range from simple heuristics to sophisticated meta-heuristics to exact optimization algorithms (Stadtler & Fleischmann, 2012, pp. 25–26). If solving a large and complex planning problem to optimality is impossible – this is the most common case – nature-inspired metaheuristics come into play to determine a good or at least feasible supply chain plan (Turken et al., 2020).

In addition to metaheuristic approaches, various other methods of artificial intelligence (AI) such as expert systems, machine learning (ML) techniques, neural networks, or fuzzy logic are applied for supply chain planning (Rodríguez et al., 2020). These techniques have proven their suitability to cope with uncertainty, vagueness, or often changing information (Rodríguez et al., 2020). Simulation approaches, which unlike optimization techniques do not determine an optimized solution to a planning problem but mimic the behavior of a supply system over time, complement the catalogue of mathematical procedures that are applied for supply chain planning (Almeder et al., 2009). Simulation and optimization techniques can

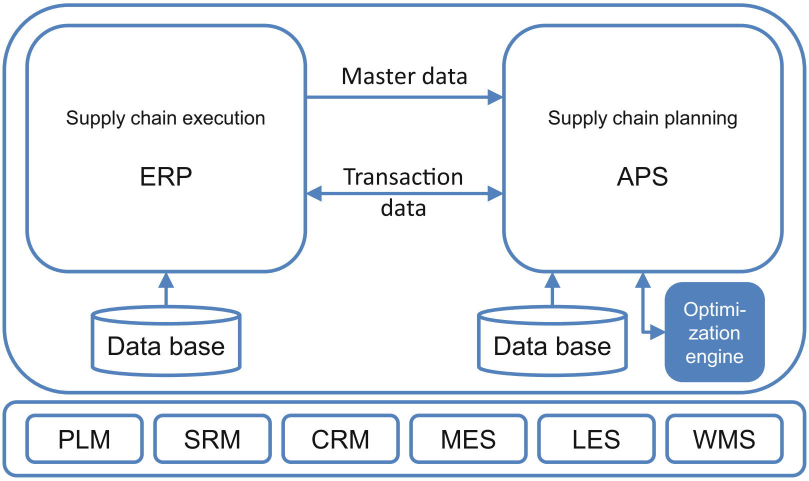

**Fig. 4** The IT system landscape for supply chain planning (own representation)

be combined to hybrid approaches in order to leverage the full potential of both methods (Figueira & Almada-Lobo, 2014).

As depicted in Fig. 4, ERP and APS are embedded into an **IT system landscape** for supply chain planning that is complemented by software packages for supply chain execution. A core interface enables the required exchange of master and transaction data between ERP and APS. In addition, an optimization engine is employed to solve the mathematical planning problems.

The application of APS for supply chain planning has considerable **positive impacts** on operational and firm performance. Case examples illustrate that applying APS has numerous substantial advantages in business practice (Jonsson et al., 2007). Rudberg and Thulin (2009) list three main benefits of employing an APS. First, higher throughput is achieved at lower cost and improved delivery reliability with reduced capacity and less inventory. Second, coordination and communication are improved due to increased visibility and transparency within the supply chain. Third, more time-efficient and proactive supply chain planning processes can be executed at a higher level of cross-functional integration.

Using APS considerably reduces the number of exceptional situations and helps to maintain business in a standard mode of operation thereby achieving swift and even flows of material, cash, and information (Schmenner & Swink, 1998).

## 3 Concerns, Outstanding Research, and Future Directions

For several decades, scientific research and business practice have conceptualized, developed, and implemented sophisticated approaches and advanced systems for supply chain planning. Many approaches currently represent a global standard in numerous industry sectors. However, from a research perspective as well as from a practitioner's point of view the topic of supply chain planning is far from being closed. New management concepts and progress in IT development offer opportunities to enhance planning processes and systems. Changes in the business environment force the need to consider additional factors and altered frame conditions of supply chain planning or to substantially refine planning processes and procedures. The following subsections will outline related future research perspectives and give practical guidelines.

### 3.1 Augmented Processes for Supply Chain Planning

The overall task of supply chain planning is to design the supply network and to decide how it shall be operated. In most cases, decision-making in supply chain planning is limited to determining future quantities and times of purchasing, production, storage, and distribution (Stadtler, 2005). Since a supply chain plan that violates cash constraints cannot be executed (Lainez et al., 2009), the exclusive focus on operations needs to be complemented by the finance perspective which considers investments, cash, and other financial factors in supply chain planning (Hahn & Kuhn, 2012b). Volume-based supply chain plans need to be translated into financial terms, adjusted for cash and budget constraints, and aligned with the financial targets of a firm.

Enhancing the well-known volume-based concepts to more comprehensive **value-based approaches for supply chain planning** would link supply chain planning to financial performance management and strengthening the integration of different yet separate planning processes within firms and across supply chains (Brandenburg, 2013). Such a value-based supply chain planning process would combine demand and supply planning with business planning thereby enabling improved managerial decision-making (Dougherty & Gray, 2006).

Integrating supply chain planning with **supply chain performance management** and **supply chain risk managemen**t is a key lever to substantially increase shareholder value (Hahn & Kuhn, 2012c). However, related concepts and processes are scant. Development perspectives include risk-aware or uncertainty-focused supply chain planning or the risk evaluation of supply chain plans based on risk measures such as VaR or CVar (Brandenburg et al., 2014).

The most comprehensive reengineering of supply chain planning would lead to **integrated business planning** which links sales and operations planning more closely to CPFR and financial planning (Willms & Brandenburg, 2019). Integrated business planning is an advanced form of sales and operations planning which embeds cross-functional planning of sales, operations, marketing, and finance into corporate strategy and combines it with inter-organizational integration up- and downstream the supply chain (Schlegel et al., 2021). Since integrated business planning enables substantial improvements of financial and operational performance, its implementation may be interesting for managers from business practice (Kepczynski et al., 2018, pp. 9–10). From a research perspective, comprehensive concepts need to be developed that seamlessly connect isolated application for volume- or value-based supply chain planning to holistic approaches for truly integrated business planning.

## 4 Changes in the Business Environment

Megatrends of sustainability and digitalization as well as megathreats arising from global crises and natural disasters substantially change the business environment in which firms and supply networks operate. These events have to be adequately reflected in supply chain planning. New challenges and technological advancements may also trigger or enable progress in concepts, processes, and tools for supply chain planning.

**Sustainability** is one of the megatrends that definitely alter supply chain planning. Supply chain sustainability requirements to which a firm is exposed are propagated from customer markets and constrained by technical possibilities (Seuring & Müller, 2008). To meet these requirements and to manage and improve supply chain sustainability, environmental factors and social criteria need to be integrated into supply chain planning approaches and models (Boukherroub et al., 2015).

The imbalance between the three sustainability dimensions in supply chain planning has to be resolved, because social aspects are strongly underrepresented in related models (Brandenburg et al., 2013). Supply chain planning needs to assess decision options and analyze resulting plans under consideration of sustainability objectives, and supply chain planning decisions must be consistent with sustainability performance criteria and the related goals and targets (Boukherroub et al., 2015; Stindt, 2017). For this purpose, supply chain planners and their decision-support systems need to orchestrate different mathematical methods including multiobjective programming, simulation, and analytic models (Stindt, 2017). Concepts for sustainable supply chain planning can comprise methods to capture customer and technological requirements which enable planners to conduct analyses under consideration of socioenvironmental aspects (Zhang & Awasthi, 2014). Consideration of broader stakeholder needs and requirements should be integrated into planning systems within a sustainability-focused environment.

Concepts like the supply chain planning matrix that are designed for the downstream material flows in forward supply chain have to be extended to approaches that reflect reverse material flows upstream the supply chain (Das & Posinasetti, 2015). To enable truly sustainable supply chain planning in business practice, these extended concepts and sophisticated mathematical approaches need to be implemented in processes, tools, and IT systems. Models and algorithms for planning in reverse and closed-loop supply chains may be helpful in this regard (Akçalı & Çetinkaya, 2011).

**Digitalization** is another megatrend that affects concepts and tools for supply chain planning. Digital technologies such as AI and ML or big data and business analytics allow companies to improve and enhance their planning, sourcing, and procurement planning and execution (Bigliardi et al., 2022). Logistics 4.0, for example, enables planning by digital technologies that lead to changes in automation, connection, and decision-making (Bigliardi et al., 2022).

Business analytics and in particular supply chain analytics can improve supply chain planning and increase the quality of supply chain plans thereby strengthening supply chain performance (Chae et al., 2014). Application examples in supply chain planning include the analysis of market data to predict trends of product and service demand or inventory replenishment activities that are supported by business analytics (Trkman et al., 2010). Big data, for example, allows real-time information collection concerning movements of goods, customer preferences, or purchasing habits thereby improving the data base for supply chain planning (Bigliardi et al., 2022). Big data analytics may also enable integrated business planning (Schlegel et al., 2021). These powerful approaches need to be leveraged to enhance supply chain planning performance.

AI is a powerful technique that can make a substantial difference in future supply chain planning. AI applications are suitable to improve supply chain network design and supplier selection as well as inventory and demand planning (Sharma et al., 2022). Moreover, manufacturing planners can predict seasonal effects and mitigate the bullwhip effect by improved resource planning based on AI (Sharma et al., 2022). AI technology may also help reflecting the social dimension of sustainability and considering pandemic situations in supply chain planning (Rodríguez et al., 2020). New developments at the human-machine interface improve the communication between supply chain planners and the APS, e.g., by ML methods which enable the APS to learn from plan adaptations made by human planners (Willms & Brandenburg, 2019).

In times of **global crises and disasters**, supply chain planning may also help obtain agility, contingency, resilience, and robustness of global value chains and supply networks. In the event of a global pandemic, supply chain planning needs to broaden the perspective from the resilience to the viability level which ensures the mere survival of the supply chain (Ivanov & Dolgui, 2020).

Time-series analyses and AI/ML methods may help predict the growth of a pandemic and the resulting supply chain disruptions (Nikolopoulos et al., 2021). Moreover, supply chain planning must consider the availability of labor during times of a pandemic (Nagurney, 2021). Supply chain planning should also reflect the relationships between firms and the state representatives, governmental organizations, and legal authorities that govern global supply networks (Siebert et al., 2020). Recent examples have shown that political instability or war may considerably disrupt global supply chains (Simchi-Levi & Haren, 2022). In such cases, global supply chain scenario planning may be conducted to understand the impact of commodity inflation in supplier and customer contracts, to update inventory policies and planning parameters for critical materials and to prepare for disruptions in operations in the conflict region (Kilpatrick, 2022). In addition to these short- and midterm disasters, supply chain planning should also reflect impacts and risks that arise from the long-term climate change (Ghadge et al., 2020).

## 5 Enhanced Models and Systems for Supply Chain Planning

In model-based supply chain planning, optimization techniques dominate while the potential of **simulation modeling** remains underexplored (Ivanov, 2017). To perform sensitivity analyses in supply chain planning, usually several optimization runs are executed for separate planning versions with minor variations of selected problem parameters. Since simulation models are more capable of capturing the behavior of complex systems (Peidro et al., 2009), simulation can be used for what-if analyses of various planning scenarios with major differences in the overall setting (Terzi & Cavalieri, 2004). This analysis would help evaluate and quantify the benefits and issues of decision options when the overall frame conditions of business-making (seem to) undergo substantial changes – such as in cases of worldwide disasters or major disruptions in global business and trade (Ivanov, 2017). These approaches would enrich the intersection of supply chain planning and supply chain risk management.

For optimized supply chain planning, **goal programming** could be applied to attain prespecified performance target values instead of optimizing plans according to selected objectives (Broz et al., 2017). This modeling approach of satisficing instead of optimizing would strengthen the connection between supply chain planning and supply chain performance management. Possible applications include, but are not limited to, strategic supply chain planning (Broz et al., 2017), tactical supply chain configuration for new products (Brandenburg, 2015), and operational production planning (Broz et al., 2019).

Despite the fact that ERP and APS are developed, offered, and used for several decades, practitioners still need to be encouraged to **adopt, implement, enhance, and complement** the **available system solutions** for supply chain planning. First and foremost, spreadsheet applications still dominate over ERP and APS as the main support for planners in their daily work (de Man & Strandhagen, 2018). Taking into account that employing ERP and APS for supply chain planning substantially contributes to operational and firm performance, this observation is surprising.

With regard to system enhancement, the perspective to reflecting the economic, environmental, and social dimensions have to be addressed comprehensively and holistically. Decision-support systems for supply chain planning need to be redesigned and developed further to enable value-based management (Hahn & Kuhn, 2012a). Moreover, extending decision-support systems by socio-environmental factors is required to fully reflect all three dimensions of sustainability in supply chain planning (Reefke & Sundaram, 2018).

## 6 Managerial Implications

Managerial implications and practical issues of supply chain planning arise for supply chain actors such as manufacturing companies, wholesalers, distributors, or retail firms who operate (parts of) supply networks as well as for software vendors who develop and distribute APS. Practical guidelines for further system development are related to joint development initiatives under participation of researchers and supply chain planning experts from academia.

**Supply chain actors** may want to advance from focused volume-based supply chain planning to combined volume- and value-based supply chain planning and even further to integrated business planning. Socioenvironmental factors need to be considered for sustainable supply chain planning. In addition, supply chain actors should establish and strengthen planning partnerships with their suppliers and customers to push forward the inter-organizational integration and collaboration in supply chain planning.

Laggards in APS implementation who still conduct spreadsheet-based supply chain planning are urgently advised to replace these outdated tools by more sophisticated system solutions in order to close the gaps to leaders who in turn should not hesitate to conceptualize, develop, and implement the next generation of APS.

**Software vendors** may want to continue their work to develop further their software packages. New digitalization techniques and methods of AI and ML could be integrated into upgraded and enhanced APS. Moreover, software vendors may want to continue and increase their effort to conceptualize and develop integrated decision support systems for supply chain planning, supply chain performance management, and supply chain risk management. The work on the human-machine interface of APS is also worth being intensified, e.g., to enable a feedback mechanism that allows the machine to learn from plan adaptations which the human planners execute frequently in their daily work.

Software vendors and supply chain actors could form **strategic development partnerships** for the next generation of APS in order to leverage the development effort. Such strategic initiatives may result in faster advancement and more sophisticated system solutions. Involving **scientific experts from academia** into the joint system development would ensure that state-of-the art concepts from academia are considered in the design, development, and implementation of the next generation of APS.

As digitalization of systems and tools may cover multiple organizations and stakeholders – such as with blockchain technology, which includes smart contracts – planning models and technologies need to consider this evolving environment. Integrating legacy systems and planning information in these multiorganizational supply chain planning systems may require training, investment, and significant collaboration across supply chain partners and external stakeholders.

## 7 Summary and Conclusion

This chapter has shown that supply chain planning concepts and systems represent powerful business solutions that contribute to a firm's success and, thus, are considered state of the art in many industries. This chapter has also illustrated that the development of the next generation of supply chain planning approaches and tools has just begun and is far from ending soon. Companies that operate in supply chains as well as system vendors that provide IT solutions for supply chain planning must not stop their efforts to develop further and implement the concepts, approaches, and systems. Researchers may find opportunities for further conceptualization and development of supply chain planning processes and instruments. Hence, a new phase of scientific research and management practices invites to participate.

This chapter may be helpful to gain a basic understanding of fundamentals, developments, and trends in supply chain planning, but the topic is too broad and comprehensive to be fully covered in a single book chapter. Hence, the interested reader is referred to a large body of literature that will not stop growing continuously in future.

**Abstract**

Digitalization not only improves individual performance but also helps orchestrate supply chain partners to serve a bigger goal. To fully benefit from supply chain digitalization, a high level of integration across supply chain activities is required. This chapter introduces major interactions between production management decisions and the supply chain strategy, structure, and performance to explore supply chain integration (SCI). For this purpose, the design and development issues of production management are first investigated. On this basis, decisions with a strategic nature, including product design (what), material and technology selection (which), process design (how), and facility layout (where) optimization are analyzed. Next, the planning and control issues, including production scheduling (when), quality management, resource management and supervision (who), and planning for disruptions are explored, which have a rather

## 1 Introduction

The fourth industrial revolution, widely known as Industry 4.0, has transformed research and practice in many fields; supply chain management is no exception to this trend. Industry 4.0 is formed around digitalizing processes, making them interconnected, and interoperable, while ensuring that they occur in a smart environment enabled by real-time data-driven decision-making (Gunnarsson et al., 2006). Industry 4.0 and its enabling technologies have the potential to improve individual performance in every corner of the supply chain by improving productivity and flexibility, resource and energy efficiency, as well as waste reduction. However, the effective integration of processes and activities is essential to fully exploit the advantages of supply chain digitalization at a systemwide level (Ghobakhloo et al., 2021).

Achieving greater degrees of integration requires considering the impact of individual decisions on the performance of other players. Individual decisions can be well-informed and aligned with the bigger goal of visibility across supply chain collaborators. In addition to reduced costs and response time, enhanced integration has implications for improving supply chain quality, flexibility, and resilience (Danese et al., 2020; Tiwari, 2020).

Supply Chain Integration (SCI) refers to the extent to which a company and its supply chain collaborators work together to more effectively manage intra- and interorganizational processes and improve the flow of products, material, information, and funds (Zhang et al., 2015). In this definition, the activities, and processes from the acquisition of raw material and sourcing to those involved in producing and distributing the final goods interact. Some of the interactions are more notable than others, making it necessary to simultaneously plan/optimize their associated operations.

As a major process in the manufacturing supply chain, production interacts with many logistical functions – inventory, facility, transportation, and sourcing. Questions regarding what to deliver, who, when, where, and how to complete the operations should be answered considering both supply chain and production management aspects of operations.

Whether an organization strategically targets cost-effectiveness, responsiveness, or it wants to differentiate its products and services from those of rivals, production management decisions can help adjust the operational capabilities to establish strategic fit. Production management decisions should also be aligned with the supply chain strategy. For example, a cost-effective supply chain is mostly concerned with enabling low-cost operations. In this situation, the way the production operations are handled influences the performance of downstream players and the supply chain cost as a whole. Production operations can also be significantly impacted by the performance of the upstream collaborators, which may have a different competitive strategy. This interaction manifests itself in both macro- and micro-managerial decisions. Therefore, it is important to understand the underpinnings of production management decisions and the way they influence supply chain operations.

This chapter elaborates on the interactions between the major production management topics and supply chain structure, strategy, and performance. For this purpose, the managerial decisions pertinent to the development and design issues, as well as planning and control issues are considered to investigate the possible interdependencies. Section 2 discusses the design decisions and the way they interact with supply chain strategy, structure, and decisions – that is, when and why to enter a market and what to produce (product development), how to produce the products (process design), which technologies and materials to use (technology selection), and where to do the operations (facility layout and location planning). Section 3 elaborates on the question of when to conduct the operations (production scheduling), quality control issues, who should conduct the operations (resource management and supervision), as well as planning for possible disruptions. The chapter is concluded in Sect. 4 with major remarks and managerial insights.

## 2 Development and Design Issues Relationships to Supply Chain Management

### 2.1 Product Development

Supply chain performance depends on many factors – one of the factor relates to product characteristics (what). A continuous evaluation of the efficiency and effectiveness of the products portfolio and adjusting them is necessary to maintain the supply chain's competitiveness. Well-informed product design or redesign decisions are a managerial tool to help improve supply chain performance by reducing inventory times (e.g., the use of standard modules), transportation volume (e.g., the postponement of assembly operations), and, overall, the operational cost (Handfield et al., 2020).

Product development and supply chain management capabilities counterbalance each other (Morita et al., 2018). In addition to product design elements for mass customization, such as modularity and multi-skill employees, high supplier involvement and the supply chain design are required to ensure the best outcomes (Ye et al., 2018). For example, companies can reduce the time-to-market if they include supply chain partners in the product development process. On the other hand, the bargaining power of suppliers and customers (Porter, 2008), as well as the strategic partnerships, should be considered in the product development process.

It is also suggested that new product development (Reitsma et al., 2021), and other product management decisions, such as product revitalization and discontinuation, should be made considering supply chain-related factors (Pourhejazy, Thamchutha et al., 2021). These interdependencies emphasize the impact of product management decisions on supply chain strategy and performance.

Supply chain operations are influenced by product design decisions both at the network and node (entity) levels (Reitsma et al., 2021). From a network-level perspective, the product design decisions interact with the supply strategy: whether to outsource certain parts or services to a third party or keep them in-house. They also define the extent supply chain partners, particularly suppliers, should be involved in the design process. If the parts or products are planned to be outsourced, certification or training of third-party actors will be necessary. Otherwise, if the operations are decided to be completed internally, which manufacturing facilities should produce the product and what operational capabilities are needed for these facilities should be determined. Additionally, companies should select the most appropriate transportation mode considering the product features, compartments, and needs.

Overall, these aspects both directly and indirectly influence supply chain fixed and variable costs. Supply chain reconfiguration for managing risks in time of new product development is another strategic topic at the intersection of product development and SCI (Sabzevari et al., 2019).

From the node-level perspective, packaging operations are impacted the most by the product design. For example, a fragile product requires more rigorous packaging; in this situation, alternative material and design approaches that increase the robustness of the product reduce packaging costs.

Taking IKEA's approach to product design as an example, postponing the final assembly until the point of consumption is a paradigm shift in the supply chain of furniture and home appliances. In addition to reducing the transportation cost and inventory times enabled by increased modularity, the downstream supply chain nodes do not require assembly-related capabilities, such as space, machine, or workforce further reducing fixed costs.

In addition to the node- and network-level activities, product design decisions have an impact on supply chain planning, in particular demand forecasting, capacity planning, and inventory management (Reitsma et al., 2021). For example, the use of common parts in the design of products reduces the variety of required inventory, which alleviates the warehousing complexities and reduces sensitivity to the forecasting outcomes (Jha et al., 2017).

In addition to improving organizational financial performance, integrating product development and supply chain management helps improve less-tangible aspects of supply chain performance, such as open innovation, supply chain trust (Rahmanzadeh et al., 2020), visibility, responsiveness, and risk (Khan et al., 2016). This integration also has implications for a circular economy (Burke et al., 2021), and the adaptation of Industry 4.0 (Benzidia et al., 2021), among other examples. Alleviating profit-loss due to remanufacturing and improving environmental performance were recognized as major advantages of integrating product design into green supply chain management (Liu et al., 2019).

There are barriers to integrating product development and supply chains. These barriers include loss of intellectual property, which may be worrisome for companies who seek vertical integration, especially high-tech and sensitive products, like chip manufacturing. The situation may be a challenge for international companies with offshore production activities in distant locations to take full advantage of product design and SCI. New technologies such as virtual reality and 3D printing can help to bridge the gap.

Product design has an impact on technology and material selection and the design of production processes (Marsillac & Roh, 2014), like handling and storage of the incoming and outgoing materials and the flow of materials on the shop floor, which are the determinants of internal logistics performance. I will delve deeper into these subjects in the next subsections.

## 2.2 Technology and Material Selection

Given the characteristics of a company's products, production managers are responsible for selecting the right technology and material before designing the production processes. As a strategic production management decision with long-term implications, technology selection should be done considering the capabilities and requirements of the supply chain partners (Farooq & O'Brien, 2012). These requirements are pertinent to the cost of the material/parts, their quality, delivery speed, the flexibility of the technology to adjust to the changing market needs, and the commitment of the corporations for innovativeness. Additionally, the selected technology should be compatible with those of the partners, their technical constraints, and the available supply chain infrastructure.

A production (or logistics) technology alternative that best serve the supply chain strategy and goals should receive a higher priority than the technology that maximizes individual performance. A cost-effective supply chain benefits from well-established and mature technologies that reduce fixed and variable costs. An original part manufacturer that selects expensive technologies, which produces high-end parts but cannot offer a competitive price, may not fit in a cost-effective strategy. Alternatively, responsiveness and differentiation-oriented supply chain strategies require new technologies with higher degrees of innovativeness to stay ahead of the competition.

Depending on the corporate strategy and the type of product or market, organizations may prioritize their technology investment plans for a particular supply chain function; this may limit the budget for the rest of the company-owned facilities. From the perspective of the competitive forces (Porter, 2008), the supply chain players should be concerned about what technologies are used by the existing and potential rivals, otherwise, it may be hard to stay competitive.

Depending on the market, customers may be willing to pay for the products and services that are produced using the latest technologies. The type of technology used in production and logistics processes also plays a major role in the sustainability of supply chains; a supply chain with old technologies may have a higher overall carbon footprint than supply chains with state-of-the-art machinery. Selecting greener technologies is especially important for corporations seeking to promote a green image. Overall, technology is an enabling factor for the supply chain's competitiveness regardless of the competitive strategy.

Adaptation to new technology may require a change in the supply chain structure, especially when it emphasizes a disruptive innovation. In this situation, delivery time, cycle times, labor cost, manufacturing cost, inventory levels, and required production capacity are impacted (Coronado Mondragon et al., 2017).

As an example, with additive manufacturing (3D printing), production sites can be more distributed and located closer to the point of consumption or in remote areas. These technologies can change supply chain partnerships. For example, 3D printing service providers can have shorter supply tiers and be involved in the production of semi-finished materials, components, and structures. Blockchain technology for regulating the information and funds flow is another prime example of disruptive technology with implications for SCI. In particular, the adaption of smart contracts can streamline procurement formalities, time, and address the legal issues and partnerships. These examples further highlight the role of technology selection in SCI.

Technology selection literature has been well supplied by decision-making frameworks including supply chain-related considerations (Xia et al., 2017). Relatively limited attention has been directed toward incorporating technology selection variables in supply chain optimization. Supply chain network design considering location and technology selection (Marvin et al., 2013) may be the most relevant integration scheme considering that both decisions have a long-term and strategic nature.

Supply chain tactical decisions, like planning and coordinating demand and supply, as well as managing inventories in a supply chain are also interrelated with manufacturing technology selection decisions but require additional investigation. For example, the optimal level of product availability may vary across production technologies where the speed at which a unit of product is produced and the required skilled staff for running the processes are different.

Material selection has received relatively more attention in the supply chain context, especially because it is closely relevant to supplier selection. The characteristics of the selected material determine the operational requirements. For example, distribution and warehousing facilities should be equipped with refrigeration gear for handling perishables; selecting materials with milder requirements reduces the supply chain fixed costs and its operational complexities.

Packaging and storage costs may be minimized by selecting the material with the right physical state. In the upstream supply chain, selecting materials that are subject to less supply process complexity, like tariffs, local and international regulations, and those with alternative supply sources are likely to be preferred. The power of suppliers is another relevant aspect that emphasizes the role of material selection decision variables in supply chain optimization; selecting material from monopolized markets increases supply risk and reduces the control of the focal company over price and quality aspects.

Similar to technology selection, material selection should be well aligned with the supply chain strategy. Cost, quality, and delivery speed of the final product are directly impacted by the material type, while it also can hinder or facilitate operational flexibility and innovativeness. From a supply chain sustainability perspective, selecting materials with a lower carbon footprint and avoiding materials with negative environmental and health impacts have become a necessity.

Material selection also has implications for supply chain structure and reverse logistics activities. As an example, selecting recyclable materials facilitates closing the supply chain loop, making it easier to take them back into the production cycle (Ndiaye, 2012). In contrast, the use of non-sustainable materials may exacerbate the complexities involved in the corporate social/environmental responsibility in the supply chain. The characteristics of the selected technology, material, and the requirements determined by the product development and design process are used as inputs to *process design*, which is discussed in the next subsection.

## 2.3 Process Design

Activities that add value – and their associated preparations – represent the production process. The overall goal of the production process is to transform inputs, such as raw material and energy, into outputs, products, and services. Conversion, fabrication, setup and preparation, machining, assembly, and quality control are some typical operations for production processes.

Production process design considers the following inputs to decide the sort of required operations and sub-processes: flexibility of the available equipment, labor, the selected technology, inputs from product development and management, the required variety of the products or services, and the expected sales volumes from the forecasting department.

Selecting processes to be executed in a facility is a strategic production management decision with implications for supply chains. This decision is influenced by physical limitations in the upstream supply chain. For example, access to raw materials and suppliers, skills and knowledge, technology, and low wages can make a location more desirable for certain production processes (Pourhejazy & Ashby, 2021). Technical requirements may necessitate certain processes to be performed together, within a certain time period, or in a certain climate condition due to product characteristics. Intellectual property-related factors are other examples that influence the selection of processes and their location.

Process structure, or production setting, is another strategic-level decision production process design. This decision is based on operational characteristics such as product variety and volume. Selecting the process structure determines the pattern of material movements in the manufacturing plants. Job shop, flow shop, and open shops are seminal examples of different process structures. The flow shop category requires all the items to go through an identical sequence and number of machines and processes; it is suitable for high-volume production of similar or standard items. When the product variety is high and the required production volume is low, a job shop may be the best alternative. Under the job shop setting, the items should be processed on every machine but in a different order. Finally, in an open shop, the items can be processed in an arbitrary order – there are no fixed precedence constraints and may have a different number of machines or processes. Other production settings, like hybrid and flexible flow shops, combine the above major categories to better match the case-specific industrial needs; they will be discussed in more detail in Sect. 3.1.

The logistical requirements for the above production settings may vary. For transportation on the shop floor, the production process in open shops is subject to irregular movements, which is in contrast with flow shops where less intensive and more regulated material movements are prevalent. That is, internal logistics in flow shops can be handled using more automated means of transportation while this level of automation may be infeasible or economically less viable in the job shop and open shop settings. It is not clear that there is a significant difference in the inventory level on the shop floor for different production settings.

In terms of external logistics, given that flow shops deal with a high volume of standardized products, the economy of scale plays a significant role in their supply chains when compared to the job shop and open shop productions. In this situation, the continuous flow of inbound and outbound logistics highlights the need for advanced decision synchronization, information sharing, and collaborative performance systems (Simatupang & Sridharan, 2008) and more effective supply chain collaboration and coordination.

Each of the production process structures has different facility investment requirements. In a job shop, general-purpose machinery is required to ensure the flexibility of the operations and the labor should be multi-task and highly skilled. Flow shops do not require these but may need a higher process continuity and automation level. Overall, flow shops require relatively higher investment (Mohammadi & Forghani, 2017); therefore, they are economically viable when a highly stable market in terms of demand and variety is targeted.

If the production process is designed in isolation, small fluctuations in the supply and demand sides of the supply chain can be amplified as they progress along the chain (Blackhurst et al., 2005). Given the significance of this amplification effect, integrating the production and supply chain process design elements should be mainly investigated from the material flow perspective. In the upstream supply chain, extreme demand fluctuations may put pressure on the manufacturing and procurement cycles. In the downstream supply chain, delays in the production process can interrupt the replenishment and customer order cycles.

Disruption propagation across the supply chain (i.e., the *bullwhip effect*) emphasizes the interdependencies among supply chain operations and entities, suggesting that the supply chain-related decisions, like the number of deliveries– both inbound and outbound – and the time interval between them (Chung & Wee, 2012) should be considered when designing the production process structure. Such integration helps reduce inefficiencies (Geismar et al., 2008), improves organizational performance, and environmental factors (Khanuja & Jain, 2019), and facilitates supply chain digitalization (Tiwari, 2020).

In addition to the above considerations, the process design should account for less-tangible tactical and operational factors like maintenance and the inspection mechanisms. These factors should consider logistical elements within the supply chain – including inventory management and distribution operations. For example, production downtimes can be planned considering the state of the logistics elements and in coordination with the supply chain partners.

The integration of production process design and supply chain can also be investigated from a quality perspective. Traditionally, logistics operations are designed assuming that the products are perfect while, imperfect quality items are hard to avoid. Reworking the imperfect quality products helps reduce the total costs (Ouyang & Chang, 2013). However, returned items may be burdensome to the supply chain if the reworking processes and logistics are not well coordinated. Alternatively, the quality of raw materials may be deteriorating, which makes it necessary to manage them in an integrated manner.

Another relevant aspect is the integration of reverse logistics and the design of the production process. In particular, an integrated design of the collection and disassembly processes helps alleviate the impact of the uneven and uncertain flow of returned materials in the production continuity and cost.

## 2.4 Facility Layout Design and Optimization

Material movement affects the productivity of manufacturing and logistics operations, design [and optimization] of facility layout impacts supply chain performance. This impact is mostly related to the connectedness of individuals in the supply network, where improving the efficiency of the individuals results in reduced supply chain time, cost, and enhanced agility in the long run. Industry 4.0 and the need for higher degrees of automation further highlight the importance of connecting the internal and external material flows in smart facilities. Despite the benefits of including facility layout variables in the supply chain context, it is largely overlooked by academics and practitioners.

Facilities should be designed considering the production process, selected technology/machinery, expected production capacity, and the supply chain strategy. The first three determine the material flow while the last specifies the broader objective and needs a facility should serve. Recalling the process design subsection, a *flow shop* setting is best suited if high-volume standardized products are produced, otherwise, other production settings may be preferred. Within this general framework, the details of positioning may differ depending on the company's desire to run a cost-effective system or seek high levels of responsiveness and flexibility. Having designed the facility layout, the managers can determine the optimum level of product availability and the aggregate plan based on the actual production capacity, the available inventory-carrying space, as well as the market situation.

In manufacturing facilities, buffer zones for storing raw material, parts, and work-in-progress are limited. Sound layout design decisions help maximize the space utilization and make room for keeping inventories. Additionally, an optimum layout helps smooth material flow on the shop floor, which, in turn, reduces the operational cost and improves agility. This situation helps avoid bottlenecks in the supply chain network where an interruption in material inflows to one value-adding entity due to lack of space or inefficient movements inside the facility may spread downstream in the supply chain. Integrating the facility layout variables into supply chain risk and optimization models helps address disruption among other operational uncertainties caused by poor synchronization.

As another supply chain network element, warehouses are often necessary to provide the right quantity of materials, parts, and products available at the right time and location. Otherwise, managing supply and demand mismatches in a volatile market becomes a prohibitive task. Simultaneous determination of warehouse layout and inventory control policies, such as storage policies and inventory routing, have implications for supply chain performance improvement (Roodbergen et al., 2015).

Internal material handling – movements and storage – have increasingly used automatic guided vehicles, optical guidance systems, and robots to load-unload incoming and outgoing trucks. In this situation, the major facility elements, like the unloading gates, recharging stations, sorting, and buffer areas, as well as waypoints and optical paths for the navigation of automatic guided vehicles, should be optimized. This optimization should consider inbound and outbound flow variables to reduce avoidable delays (Ribino et al., 2018).

More advanced supply chain practices, such as *cross-docking* have been used in certain industries to streamline the response time to customer orders. Given the dynamics in cross-docking facilities, real-time data collection, synchronization, and analysis should be used for dynamic reconfiguration of the storage area to better integrate the inbound and outbound flows (Vis & Roodbergen, 2011).

From a supply chain information flow perspective, considering historic data on supplier performance and customer demand patterns facilitate well-informed layout optimization in the upstream and downstream supply chain facilities, respectively. For example, the layout design of retail stores, as the interface component between customers and goods in a supply chain, can be dynamically adjusted by investigating less-tangible operational needs extracted from historic demand data (Ozgormus & Smith, 2020). This situation may call for strategic positioning of products in the store.

Another example relates to the seasonal supply chains or those expected to experience occasional but dramatic changes. Massive demand variations for a company with many products necessitate operational strategic adjustment of the production processes for which updating the facility layout may be necessary. Layout redesign considering supply chain parameters and product demand variations for disaster relief operations is a good example of this type (Tayal & Singh, 2019).

Finally, decisions for resizing, repurposing, or moving strategic functioning blocks across the existing supply chain facilities are another relevant production manager responsibility. The location-allocation and network optimization problems are well addressed in the supply chain context (see (Eskandarpour et al., 2015)) but assigning departments to different supply chain facilities and moving them has received limited attention.

The Research & Development and Engineering Design departments are prime examples of more intangible units of a corporation; they are often located in closer proximity to the production sites and the focal company. Intellectual property, access to state-of-the-art technologies, knowledge, and resources, as well as geopolitical considerations may be in favor of relocating or decentralizing sensitive departments. Such decisions result in long-term and sustainable outcomes if made considering wider optimization goals. Overall, layout design and determining the location of the departments within and across facilities require both financial and nonfinancial supply chain considerations in addition to optimizing cost and productivity.

This section discussed the major design and development topics and their interactions with supply chain management. Planning and control issues and their supply chain implications are presented in Sect. 3.

## 3 Planning and Control Issues Relationship to Supply Chain Management

Long-term supply chain strategy integrates aggregate planning, which is required to direct the business activities over an intermediate time horizon. Aggregate planning sets a tactical framework for demand fulfillment decisions; it uses forecasting to determine the production, inventory, outsourcing, and backlog quantities to manage costs and profitability (Chopra & Meindl, 2015). Production managers use aggregate plans to determine production schedules, organize available resources, and address quality control issues at the factory level. This section elaborates on these production management topics and the way they interact with supply chain structure, strategy, and decisions.

### 3.1 Production Scheduling

Once an aggregate plan is developed by supply chain managers, production managers are responsible for scheduling the operation at the level of individual production units. Production scheduling consists of determining the order of jobs to be dispatched to production such that the available time and resources are used efficiently. Production scheduling can be categorized into single-machine, parallel-machine, flow shop, job shop, and open shop settings; several other variants combine two or more of these production settings, which would be considered hybrid settings. There are many extensions to each of the main production configurations, which are proposed to address case-specific industry situations, and practical needs, and facilitate the real-world applications of scheduling theory.

Given a set of jobs to be completed on a set of different machines (production stages), all jobs in a flow shop require an identical sequence of operations. In a job-shop environment, jobs go through a prespecified but different sequence of operations with precedence constraints. In an open shop, the sequence of operations for every job is different but arbitrary with no precedence constraints. In the job- and flow-shop constructs, each operation should be completed on a specific machine while in the flexible variant of these production settings, the operations can be assigned to any machine from a given set. Finally, in the parallel machine setting, machines are either identical or uniform and jobs should go through one of the available parallel machines for a certain number of stages, which can be different from one job to another.

In addition to the operational characteristics that determine the type of production setting, supply chain considerations may have an impact. For example, the supply chain may require assembly operations to occur within the same facility where the parts are manufactured, which can be modeled as distributed two-stage assembly scheduling (Pourhejazy, Cheng, et al., 2021). Otherwise, assembling at a separate facility should be modeled using the distributed assembly permutation flow shop scheduling (Ying et al., 2020). As another example, a responsive supply chain may require a set of machines in each production stage – redundant capacity instead of a single machine – to better respond to demand surges. This situation may make flexible flow shop and job-shop more viable settings. The desired flexibility in the production process – single versus multi-purpose machines – is another relevant supply chain factor with implications for scheduling.

Recent studies recognized the need for a supply chain-oriented view toward production scheduling. These models can be categorized into distributed scheduling problems and production routing problems. In the distributed scheduling situation, production operations across distributed manufacturing facilities are scheduled simultaneously. Extending production scheduling from an isolated optimization approach to an integrated one, this category emphasizes coordination between different production units for fulfilling global demands while optimizing system performance. Distributed blocking flow-shop, distributed no-wait flow shop, distributed no-idle flow shop, distributed parallel-machine, distributed job shop, and distributed flexible job shop scheduling problem are some of the recent variants of supply chain-oriented scheduling problems. Such models can incorporate order assignment variables for better integration of customer order and manufacturing cycles. In so doing, the possibility of rejecting an order and backlogging them may be of interest to certain use cases. Alternatively, procurement-related decision variables can be incorporated into distributed production scheduling with release dates to take into consideration the possibility of delays in receiving raw materials and parts.

Production routing problems focus on the concurrent planning of sequential – and heterogeneous – operations along the value chain, that is, across production and distribution activities. In the traditional approach, production scheduling solutions are used as inputs for optimizing distribution operations, which may result in a number of planning issues. First, distribution operations may be planned based on infeasible input data, for instance, the delivery may be scheduled for an order that is experiencing a production delay. Second, a lack of coordination between the two processes may result in suboptimal solutions. For example, a customer order with less urgency may be prioritized in the production stage earlier than more urgent ones, which results in poor responsiveness, operational burden, and unnecessary cost. Third, integrated planning of the production and distribution processes is important for maintaining product quality in the supply chain of time-sensitive and perishable products (Ullrich, 2013), while a stand-alone approach may not effectively account for this requirement.

Scheduling variants are predominantly developed in response to case-specific and technical production requirements. For example, the no-wait setting indicates that a work-in-progress job should proceed to the next operation immediately after finishing the current one. In the no-idle setting, the focus is on the idle time of resources, where machines must start processing new jobs immediately after completing a current task without delays. In addition to these technical features, operational requirements, such as setup time and due dates, are considered in form of mathematical constraints to better reflect the real situation.

The optimization criterion for distributed scheduling models is directly influenced by supply chain objectives. The maximum completion time of all jobs – also known as the *makespan* – determines the response time for new demand. The number of tardy jobs and maximum lateness are service-oriented measures, and total weighted tardiness prioritizes more urgent demands. These measures support the strategic management of responsive supply chains. Alternatively, total completion time performance metrics emphasize better resource utilization and total flow time concerns minimizing the work-in-process inventory. These various objectives and related functions are suitable for supply chains with a cost-efficiency goal.

There are other opportunities for extending production scheduling to improve SCI. From a market perspective, the product mix and the demand size in various regions are dynamic. An optimal location-allocation solution for a certain period may not remain optimum in a dynamic multi-period environment. In this situation, facility transfer is a possible option for adjusting the supply chain.

Facility transfer adjusts the factory cell formation and production capacity, which have an impact on production schedules in different planning periods. Given the mutual relationship between facility location – using a supply chain network optimization decision – and the production planning considerations, that should be optimized simultaneously (Liu et al., 2018).

From an operational viewpoint, make-to-stock supply chains require real-time coordination between production and inventory management (Dong & Maravelias, 2021). That is, producing additional units of products should be subject to inventory variables and limitations. On the other hand, rescheduling might be necessary to boost production and reload the product inventory. Finally, production scheduling can be extended to consider product defects and account for possible reworks, in particular, considering its interactions with the transportation variables (Gheisariha et al., 2021).

Tactical plans, such as production scheduling, provide production managers a boundary of control for managing their operations and determining whether operations are being performed as tactically planned. Another control topic that interacts with supply chain decisions, quality management issues, is discussed next.

### 3.2 Quality Management

Quality is the main determinant of supply chain strategy. A cost-effective supply chain may not emphasize high-quality materials, parts, and services. A cost-effective strategy favors minimizing investment in resources and selecting less costly logistics operations – such as slower modes of transportation and less frequent replenishments – which may have negative consequences for quality. Product quality and safety may be compromised if the supply chain overemphasizes responsiveness, for example by relaxing the quality control measures. Downstream and upstream supply chain partners should adopt a coordinated quality control system that serves as a supply chain competitive strategy (Jraisat & Sawalha, 2013).

From a supply chain structure perspective, more distributed facilities may be better for the quality of perishable goods, where a shorter distance to the supply and demand nodes reduces the odds of spoilage and degradation. In other cases, centralized facilities may benefit from economy of scale and more delicate quality control tools and approaches. The absence of integrated quality control/visibility over the supply chain partners may put supply continuity at risk. Quality assurance may favor supply chain vertical integration and in-house production of parts and components – such as using additive manufacturing – where the manufacturer has better control over the quality of raw material and parts.

The quality of products a supply chain offers depends on various aspects including input materials, workforce skills, the state of machinery, tools, and production processes. Continuous evaluation and improvement of these elements facilitate better design, optimization, and management of supply chains (Grenzfurtner & Gronalt, 2021). The interactions between quality management and supply chain should consider the roles of material, man, machine, and methods in production management.

*Material.* When it comes to the procurement of raw materials and parts, the main interaction happens between the quality control aspect of production management and the pricing element – both of which are regulated by the supply chain strategy. As an intersection between production and supply chain management, material quality has been well investigated in the academic literature (Chen et al., 2014). Integrating quality control variables into inventory optimization models allows for addressing uncertainties from an operational perspective. New inventory management strategies (e.g., consignment stock and vendor-managed) have been introduced as a result of this integration; such strategies extend the supplier's responsibility for the quality of the product until the consumption point (Alfares & Attia, 2017). The cost (time) of quality control operations is another production management aspect that is investigated from a supply chain optimization perspective (Cogollo-Flórez & Correa-Espinal, 2019).

Expectedly, less attention has been directed toward the intersection of quality control with the transportation and facility elements of the supply chain. This situation is particularly relevant for the logistics of consumer goods and perishables, where time and ambient conditions impact the product quality. Supply chain information technology and quality relationships require access to real-time data on the status of materials, parts, and products to help improve quality control. The role of blockchain in confirming the source of the material (i.e., suppliers of suppliers) is a prime example of disruptive technologies with implications for quality control and counterfeit issues.

*Machine.* In addition to the quality of incoming materials and parts, using calibrated and well-maintained equipment for processing these inputs has a positive impact on the quality of the final product. There is a bidirectional interaction between the reliability of different supply chain stages and product quality, which should be considered in the maintenance of machinery in multi-stage systems (Zhou & Lu, 2018). Channel coordination in machine maintenance practices by individuals in a supply chain enhances the machine capacity, and product quality, and reduces production costs (Chong et al., 2012). These, together, increase supply chain profitability under certain coordination strategies (Jiang et al., 2020). More rigorous preventive maintenance operations may be required in supply chains with a responsiveness strategy. Alternatively, emphasizing reactive maintenance may decrease the individual short-term costs – when compared to preventive maintenance – but can hurt supply chain performance even if the supply chain pursues a cost-effective strategy. From a supply chain structure perspective, centralized production reduces the cost of maintenance services; this may improve the effectiveness of quality control activities and enhance product quality.

Integrating maintenance decisions in supply chain tactical planning improves optimization outcomes (Fatehi-Kivi et al., 2019). Additionally, supply chain optimization can benefit from integrated quality control and maintenance (Jiang et al., 2020). From an information viewpoint, the recent advances in big data analysis and machine learning help predict possible failures by early detection of anomalies in the real-time data collected using sensors (Cheng et al., 2021); this situation facilitates quality control along the value chain. Maintenance information and quality history of material or parts from across the supply chain can also be used for optimizing product quality and lifecycles (Madenas et al., 2015).

*Methods.* Production processes along the value chain are another determinant of the quality of materials, parts, and products. Process control and improvement are necessary for maintaining quality to the desired expectation. The production manager in each manufacturing unit is responsible for reacting to anomalies detected through process information analysis (Schiefer, 2002).

The complexities of the process control system depend on the supply chain structure. In a highly distributed manufacturing setting, coordinated process control is necessary to enable the supply chain managers to trace anomalies to prevent the propagation of quality loss and delays in a timely fashion. As a means of improving process and product quality, *lean* and *six-sigma* concepts have been widely adopted for process improvement in supply chains (Chugani et al., 2017).

Classical supply chain optimization models and methods have been extended to account for process control-related variables. For example, inventory models are improved by including the variables pertinent to production process adjustments (e.g., stopping production and performing setups) in case of quality issues (El Saadany & Jaber, 2008). From an information flow perspective, radio frequency identification (RFID) technologies can assist lean production to further improve the transportation, storage, and retrieval processes in a supply chain (Chen et al., 2013). In addition to improving product and service quality, process improvements reduce scrap, and reworks, among other types of waste, which help the company to stay competitive by lowering the final prices they offer in the market.

*Manpower*. There is consensus on the positive impact of supplier development programs on the quality of materials and parts (Karaer et al., 2020). As production management practices, employee training, development, and performance management within company-owned facilities have seen little progress in the supply chain context despite its significant impact on supply chain quality and innovativeness (Haq et al., 2021). With a strategic view towards quality, the integrative, exportive, or adaptive human resource practices help create synergy and improve individual performance should it follow a supply chain-oriented approach (Lengnick-Hall et al., 2013).

Regardless of supply chain strategy, successful SCI requires training, development, and performance management of the employees (Menon, 2012). The objective of these human resource practices may vary depending on the supply chain strategy. Overall, integrating human resource and supply chain management helps boost the competitive strategy and organizational performance (Jena & Ghadge, 2021). The next subsection elaborates on the organization and management of its resources.

## 3.3 Resource Management

Rapid changes in consumer preferences and shortened product lifecycles have added to demand volatilities and supply process complexities. Within this context, resources should be managed effectively to meet demand at the lowest operational cost. While material resource management is closely related to handling the physical flow in the supply chain, other resources, including the capital, manpower, machines, land, energy, and water, are managed at the factory level. How decisions on managing these resources interact with supply chain strategy, structure, and performance is now discussed.

Supply chain management is mostly concerned with managing supplier and customer relationships while manpower capital plays a pivotal role in integrating operational elements. At the factory level, production managers are responsible for the supervision and organization of workforces in close collaboration with the human resource department. Labor supply practices – such as recruitment, planning, and training – are essential for maintaining desired and necessary operations.

Shortage of skilled workers in individual production sites propagates along the supply chain and results in an array of operational issues, from quality degradation to delays. An integrated view toward manpower resources and supply chain management, therefore, improves corporate performance while being largely overlooked (Jena & Ghadge, 2021).

Supply chain strategy directs the recruitment, planning, and training programs. A cost-effective supply chain emphasizes highly repetitive routines while a responsive supply chain strategy requires multiskilling and workforce empowerment. Supply chains that compete on differentiating their products and services often tend to spend more on training programs. Supply chain structure is impacted by manpower resource considerations, like access to skilled workers, cheap labor, work culture, and social sustainability issues.

From an operational perspective, the organizational interdependencies between the workforce across supply chain entities and departments make it necessary to consider manpower resource shortage along with the physical resources to mitigate the disruption effects (Aviso et al., 2018). Given the less tangible nature of decisions on the organization and supervision of workforces, limited integrations of such variables can be found in the supply chain optimization context. Integrating decision variables related to worker types for executing certain production tasks – by considering their competencies – into supply chain network planning and optimization models (Paquet et al., 2008) and reverse logistics operations (e.g., electronics waste collection (Pourhejazy, Zhang, et al., 2021)) are examples.

In managing machinery and equipment, resource redundancy – excess capacity – is a safe way of coping with demand fluctuations. Supply chains with a responsiveness agenda typically use excess resource management strategies while cost-effective supply chains are mostly cognizant of maximizing the utilization of the available resources. *Line balancing* can be used to balance machine time and adjust the production rate for demand fulfillment – especially when the production system has tight utilization rates and constraints on machinery resources. For line balancing, the number of machines (and operators) assigned to each task is rebalanced to adjust the production rate. This kind of optimization approach provides decision support to production managers, but it can result in better outcomes when coordinated with supply chain variables.

Integrating assembly and disassembly line balancing variables into the supply chain network optimization and closed-loop models is a good example of a broader supply chain integration (Yolmeh & Saif, 2021). New technologies, like additive manufacturing, make it easier to manage resources and adjust to demand changes. Besides, the use of big data analysis and machine learning approaches helps improve resource management by reducing non-value-adding activities and addressing less-tangible aspects of operations.

Land, energy, and water are basic resources required for any supply chain activity. The required amount of these resources is a matter of technical requirements – for example, semiconductor production sites require huge water reservoirs. Access to such resources is considered one of the essential criteria for selecting the location of production facilities as strategic supply chain decisions.

Production managers are responsible for managing the available land, energy, and water resources at the operational level. Managing such resources at the factory level has indirect interaction with supply chain strategy but it directly impacts the supply chain structure. For example, limited land, energy, and water may encourage extending the supply tiers to find alternative sources for the products that cannot be produced in-house due to land, energy, and water limitations. Additionally, distributed and geographically dispersed facilities or relocation decisions may be triggered by resource limitations.

A holistic view of the long-term requirements, as well as the profile of available resources across the supply chain, are prerequisites for informed resource management decisions (Taherzadeh, 2021). At the factory level, the availability of land resources may influence inventory management decisions as well as the production level. Adaptive resource planning may be required to adjust to the changing operational conditions. In particular, dynamic adjustment of the available spaces is a relevant decision that can be considered to best manage such resources in volatile times.

The planning and control issues discussed up to this point of Sect. 3 are meant for routine operations – that is, when everything goes as planned. Disruptions, especially those impacting the factory level operations, change the situation, hence, require decisive actions and alternative solutions to mitigate the adverse supply chain effects as much as possible. Planning for disruption is discussed in the next subsection.

## 3.4 Planning for Disruption

Unexpected events that impact resources availability – availability of power, machines, material, and manpower – can interrupt the production processes at the factory level and can result in major supply chain disruptions. Planning for disruptions consists of preparing for unexpected situations, finding alternative solutions for maintaining the production facilities' operations, and having strategies for a quick recovery after a major disruptive event. Digitalization and SCI improve connectivity, transparency, and effective information flow between different departments within and outside of the factory, which enables a timely and well-informed course of managerial actions in times of disruption (Treber & Lanza, 2018). Training programs, which are discussed earlier in the chapter, and drills are some of the initiatives for labor-based disruption preparedness at the factory level.

Operationally, production processes can be impacted by disruptions in: (1) supply – material, parts, and components; (2) manpower, machines, energy, and water; and (3) demand. Supply and demand disruptions relate to supply chain management level activities. Supply chain decisions, such as location and volume of redundant inventory in the network can help alleviate the negative impact of material disruptions. For example, purchasing's time for finding alternative resources and addressing the shortage problem are additional activities.

At the factory level, a production manager could consider the severity of disruption and its root cause(s), which requires current knowledge on the state of the system at the time of disruption. The manager would need to decide to delay the operations, outsource them, or renegotiate the accepted orders for possible backlog or cancellation. Production rescheduling is a possible production management solution in response to production disruptions (Katragjini et al., 2013). Production management decisions, like rescheduling, have implications for supply chain performance (Rao & Ranga Janardhana, 2014). In addition, rescheduling the production operations is the most common way of minimizing the losses after disruptions (Paul et al., 2015). In either case, the company may have to employ additional machines and manpower or adjust the working hours of the existing ones – such as using additional shifts or overtime – to fulfill the backlogged demands. Such decisions should also be made in coordination with the supply chain partners to ensure a smooth flow of raw material and finished products.

Production managers may take advantage of alternative solutions – such as the application of new technologies – for producing the delayed parts or components in-house. For example, additive manufacturing can be used as an alternative production method in times of supply disruptions.

Possible changes in the production methods on the shop floor impact the supply chain structure. Taking the alternative manufacturing methods for producing parts or components as an example, the company may have to seek material suppliers or third-party 3D printing service providers, which can shorten or extend the partnerships, supply tiers, and alter the network configuration. This decision also has implications for supply chain performance in terms of cost, quality, speed, and flexibility. Dual-channel supply chain optimization models should be developed to account for the possible shift between the regular and alternate production approaches considering various disruption scenarios.

During market disruptions, the shop floor may not be required to operate at normal capacity due to the physical limitations in the factory and supply chain. Slowing down operations and reallocating resources in response to addressing demand disruptions are some of the possible production management solutions. These factory-level decisions should be made in coordination with downstream entities, in particular warehouses, distribution centers, and retail stores, to pursue optimum outcomes.

As another example, a disruption in outbound distribution operation due to accidents, vehicle breakdowns, and weather conditions may impact production operations. In this situation, integrated planning of production and distribution activities provides better outcomes than an isolated optimization approach (Li & Li, 2020). Production management decisions, such as production scheduling and line balancing on the shop floor, will interact with supply chain activities such as transportation modes, inventory, sourcing, and pricing policy decisions. Integrated optimization models may be helpful for well-informed decisions. Integrated optimization of the production and inventory variables considering the possible disruption risks in the production process (Malik & Sarkar, 2020) is a recent example.

Using redundant – excess – resources is a common strategy for dealing with disruptions caused by labor limitations and machine breakdown. From a planning perspective, employing additional manpower and machines reduces dependency on individual resources. The main tradeoff is between the costs of redundant resources and the ability of the system to remain operational in times of disruption.

Crucial resources and bottleneck operations should receive a higher priority for building redundancy. Identifying the cost break-even point of using redundant resources varies depending on the supply chain strategy. That is, a cost-effective supply chain may not use many redundant resources when compared to a responsive one. Cost-benefit analysis for deciding the use of redundant resources should consider a systemwide perspective. Decisions should not be only focused on the optimality of an individual production facility, or, more generally, a supply chain entity.

From a technical perspective, informed maintenance of machinery and equipment is necessary to prevent unplanned breakdowns. In the case of reactive maintenance, 3D printers can be used to facilitate repair and maintenance activities by producing machinery components and tooling equipment that may require weeks or months to be supplied in a regular situation. Energy source disruptions can have alternative solutions like the use of solar panels, which are becoming more viable and resilient options. The geographical characteristic of the production facility is an enabling factor for the selection of alternative energy sources.

Overall, different combinations of production management and logistics measures result in different outcomes when reacting to disruptions (Peukert et al., 2020). In this situation, a standalone planning approach may result in either infeasible or suboptimal solutions. Alternatively, possible disruptions in the system are usually reflected through parameter changes in the optimization models. In addition to stochastic optimization approaches and dynamic programming that can account for such features, applications of simulation-based optimization models help address the underlining uncertainties effectively, especially when planning for possible disruptions.

## 4 Concluding Remarks

SCI requires that possible interactions between individual units and their operations are taken into consideration for design and planning purposes; this integration will help achieve a global optimum when improving the operations. The integration between supply chain elements has seen developments in both academic literature and practice.

Production management topics including shop floor decisions and their interactions with the supply chain have received relatively less attention. To investigate the major links between the topics, design and development issues, including product design (what), material and technology selection (which), process design (how), and facility layout (where) are first studied. Planning and control issues, including production scheduling (when), quality management, resource management and supervision (who), and planning for possible disruptions are then considered.

The chapter discussed the interdependencies between the subject matter and the supply chain strategy, structure, and elaborated on the impact of the respective decisions on the supply chain performance. Each subsection concluded by providing insights into some of the latest technological and/or academic developments and suggestions for future works on the subject.

Overall, there are many opportunities for improving the supply chain performance beyond current norms by considering production management-related decisions. This includes joint optimization of production and supply chain variables as well as decision-making considering the factors integrating shop floor considerations. Given the tradeoff between the complexity of an optimization or management decision model and its practicability, the sort of integration should be determined considering the targeted competency and the core interactions. For example, integrating production scheduling and inventory management variables should be targeted when achieving a short product shelf-life is an optimization priority.

Broader supply chain perspectives such as end-of-life disassembly and reverse logistics variables should be optimized simultaneously when the supply chain emphasizes the use of recycled material and closed-loop operations. Operational mandates may impact the sort of integration, for instance, just-in-time production requires an advanced level of connectivity between the production and distribution operations. From a methodological perspective, simulation-based optimization frameworks should receive more attention in SCI. This is particularly relevant for integrating the micro and macro processes at the intersection of production management and SCI. Reducing modeling assumptions, generating more accurate model parameters, more realistic performance evaluation, and the effective inclusion of various uncertainty sources are some of the major advantages of simulation-based optimization methods.

Supply chain integration with production management will always be a prerequisite for broader strategic competitiveness.

# Supply Chain "Flows" Management

Muhammad Hasan Ashraf and Mehmet G. Yalcin

## Contents

**Abstract**

This chapter provides an overview of the concept of Supply Chain Flows (SCF). While the normative literature in Supply Chain Management (SCM) emphasizes the importance of three primary flows – material, information, and finance – recent challenges, notably the COVID-19 pandemic, have highlighted the

prominence of likely additional flows. This chapter delves into four such flows – human, knowledge, equipment, and technology – that significantly impact supply chain performance. This exploration prompts a reevaluation of traditional SCF scope. Theoretical approaches for effectively managing the interactions among SCF are also proposed. The chapter concludes by suggesting future directions in establishing a consensus-based SCF framework. Overall, this chapter provides a foundation for ongoing efforts to enhance SCF understanding and develop additional theoretical insights for SCM researchers and practitioners.

## 1 Introduction

The concept of flows was first introduced into the management domain by Forrester in 1958. He emphasized the importance of effectively managing five key flows – information, materials, money, manpower, and capital equipment – as they significantly impact an organization's performance. Supply chain management (SCM) is an interdisciplinary concept focusing on optimizing flows in most cases. Therefore, Forrester's initial conceptualization about flows for organizational success integrates with modern-day SCM (Mentzer et al., 2001).

Despite Forrester's conceptualization of five flows, SCM has traditionally focused on the flow of materials. As supply chains globalized, research on Supply Chain Flows (SCF) revealed many more flows as part of effective supply chain processes. Yet most SCM research focuses on three SCF – materials, finances, and information. Various other flows that play a significant role in effective supply chain performance have been overlooked. The limited acknowledgment of flows restricts SCM actors from thoroughly analyzing and integrating numerous crucial flows, thereby impeding the potential to expand the scope of SCF.

COVID-19 brought to the attention of practitioners and theorists the emergence of various lesser-acknowledged flows that became dominant or influential in SCM. For instance, the transportation sector encountered disruptions in human flows, struggling to retain essential workers such as drivers, sorters, pickers, material handlers, etc., mainly due to an upsurge in sickness cases. Similarly, the shipping industry witnessed a disruption in equipment flow, with firms facing challenges in securing empty containers due to extended transit times at ports. These examples underscore the importance of incorporating flows often overlooked in normative SCM literature into consideration, a point also emphasized in research and practitioner magazines and articles.

Most SCF research studies have centered on definitions and concepts from a functional viewpoint. They recommend implementing resources to improve specific flows in particular contexts but often overlook the simultaneous management aspect of all flows. Similarly, the current SCM frameworks present solutions on how to design and manage a particular SCF but do not address the theoretical foundations to manage the full spectrum of the flows (Ashraf, 2023). In most instances, SCM research perspectives are overly simplified and fail to align with real-world complexities (Carter et al., 2015). Consequently, SCM research has not adequately depicted how to efficiently manage the SCF. Given the extent of SCF disruptions during COVID-19, several researchers and practitioners have been calling for more advanced SCM knowledge – knowledge capable of addressing elaborate SCF interactions.

This chapter provides insights and initial steps to guide SCM scholars in building and extending their knowledge around various flows critical to ensuring effective and efficient supply chains. These flows, despite their significance, have been overlooked in normative literature. This chapter also provides potential SCM theories that can be utilized for effective SCF management. Theoretical underpinnings are necessary to manage the full spectrum of the SCF. For practitioners and learners, the content of this chapter can be used to recognize flows in their supply chains and provide guidance in selecting an appropriate theoretical lens to manage these flows efficiently.

## 2 Background

In 1985, the Council of Logistics Management (CLM) defined SCM (logistics) as "the process of planning, implementing and controlling the efficient flow and storage of raw materials, in-process inventory, finished goods, services, and related information from point of origin to point of consumption (including inbound, outbound, internal and external movements) for the purpose of conforming to customer requirements" (qtd. in Mentzer et al., 2001, p. 16). Flows are the core of SCM, and their significance is well acknowledged in the literature and the textbooks. For this reason, numerous researchers have defined SCM in terms of SCF. Table 1 provides an overview of a few such definitions.

In the early days of SCM, researchers primarily focused on the flow of materials as the most crucial aspect of the SCM. However, it wasn't until the late 1990s that they began to recognize the significant value of information in managing SCM processes. As a result, the boundaries of the SCF were expanded to encompass this new understanding. Despite this expansion, some researchers still emphasized the importance of material flow as the only integral flow needed to achieve desirable SCM performance. Nevertheless, with the advent of globalization, various forces emerged, such as economic factors (e.g., cost-cutting initiatives), political factors (e.g., war on terror), and technological advancements (e.g., automation) (Zhang et al., 2020). These factors compelled researchers to further extend the boundary of the SCF, leading them to include the flow of information and finances as a critical element on the list.

**Table 1** Definitions of SCM in terms of SCF in literature. (Source: Adapted from Mentzer et al., 2001 and updated for this chapter)

| Source | SCM Definition |
|---|---|
| Jones and Riley (1985) | "Supply chain management deals with the total **flow of materials** from suppliers through end users." |
| Stevens (1989) | "The objective of managing the supply chain is to synchronize the requirements of the customer with the **flow of materials** from suppliers in order to effect a balance between what are often seen as conflicting goals of high customer service, low inventory management, and low unit cost." |
| Mentzer et al. (2001) | "Supply chain is a set of three or more entities (organizations or individuals) directly involved in the upstream and downstream **flows** of **products, services, finances, and/or information** from a source to a customer." (p. 4) |
| Anderson et al. (2007) | "The supply chain includes all the links involved in managing the **flow of products, services, and information** from their supplier's suppliers to their customer's customers." (p. 3) |
| Stock and Boyer (2009) | "The management of a network of relationships within a firm and between interdependent organizations and business units consisting of material suppliers, purchasing, production facilities, logistics, marketing, and related systems that facilitate the forward and reverse **flow** of **materials, services, finances and information** from the original producer to final customer with the benefits of adding value, maximizing profitability through efficiencies, and achieving customer satisfaction" (p. 706) |

The renewed understanding of SCF was confirmed by numerous industry initiatives as well. Walmart's downstream supply chain serves as a perfect example. The Arkansas-based retailer initially operated brick-and-mortar stores where customers would walk in to purchase everyday low-priced goods. The flow of materials was of immense significance for the retailer to ensure that customers found the desired goods on the shelves. However, with the advent of smart technology, such as smartphones, the flow of information became equally relevant. Customers began to prefer buying online or, at the very least, staying updated with the inventory in the store. This shift in consumer behavior gave rise to the phenomenon of e-commerce. Consequently, innovative payment methods became essential, making the flow of finances critical to the Walmart supply chain. Today, Walmart has successfully connected the supply and demand sides by integrating the flow of material, information, and finances. Several other firms, such as Amazon, eBay, United Airlines, McDonald's, and Coca-Cola, have also achieved efficient supply chains by effectively integrating these three flows.

During the mid-1990s, studies in SCM experienced a significant increase, and this trend has continued to grow up to the present day. A review conducted by Zhang et al. in 2020, focusing on five major Operations and SCM journals, found that a majority of papers published between 1997 and 2018 were centered around the flow of materials. Moreover, there was an increase in the number of papers addressing the flow of information and finances during this period. Table 2 provides an overview of some of the studies that highlight these flows in SCM literature.

| Type of flow | Articles | Summary |
|---|---|---|
| Information | Pedroso and Nakano (2009) | Effective information sharing can be achieved by using information and communication technology-based tools (such as SAP, Oracle, Salesforce, etc.) which allow supply chain partners to get real-time information about the products. |
| | Sucky (2009) | When information does not flow promptly, it may lead to supply chain disturbances, resulting in sudden order quantity changes, overemphasized production lots, and excessive inventory. |
| | Cachon and Fisher (2000) | Supply chain costs are 2.2% lower on average for actors that share full information than the ones that work on traditional style and hold onto some information. |
| Material | Childerhouse and Towill (2003) | The route to achieving the goal of a fully integrated and effective supply chain is based on the principles of simplified material flow. |
| | Ashraf et al. (2022b) | Increasing the capacity to process high package volume in a third-party logistics hub might lead to a counterintuitive phenomenon called Braess Paradox. |
| | Grover and Ashraf (2023) | To achieve superior performance, autonomous and IoT-driven intralogistics systems are increasingly being deployed in warehouses to process the ever-increasing package (material flow) volume. |
| Finance | Stenzel (2003) | Introduce the term "logistics financing," where the logistics firms actively market the financial services in addition to logistics services to initiate another stream of competence. |
| | Steinmüller (2003) | Examine the financing and leasing of the logistics real estate (e.g., Penske rentals). |
| | Pfohl et al. (2003) | Locate the financial flow at the interface between logistics and finance and terms it a "financial supply chain." |

## 3 Impact of COVID-19 on SCF

COVID-19 was declared as a pandemic by the World Health Organization (WHO) in March of 2020. This prompted countries worldwide to take significant measures to comprehend and evaluate the pandemic's impact. The responses included widespread quarantines and lockdowns, which had a profound effect on supply chains, causing substantial disruptions. The virus originating in China caused a significant disruption in economic activity across various supply and demand channels.

In the U.S., the supply chain disruption had immediate and far-reaching consequences, particularly leading to a widespread shortage of crucial medical supplies like personal protective equipment (PPE). As a result, frontline health workers found themselves ill-equipped to properly care for Covid-19 patients. Similarly, hospitals faced difficulties in procuring lifesaving ventilator machines. Most of these machines were manufactured in foreign countries, leaving the U.S. healthcare sector dependent on already disrupted global supply chains. Federal and state governments had to collaborate with the private sector to ramp up domestic manufacturing and distribution of critical health-saving equipment to hospitals. However, producing these complex machines proved to be a challenge as they were composed of parts sourced from firms around the world.

The impact of the lack of PPEs and other safety equipment extended beyond the healthcare sector, affecting labor-intensive facilities like warehousing, manufacturing, and food processing plants. Employees in these industries faced the challenge of not having enough masks to protect themselves from contracting the virus, leading to the temporary closure of some facilities. In the commercial markets, demand vanished for some product categories, while others, such as toilet paper, furniture, food items, fitness equipment, and hand sanitizers, experienced a skyrocketing demand. Retailer inventory levels for these items reached near-record lows, exacerbated by the chaos in global shipping, which further fueled the ongoing disruption crisis. Additionally, the shortage of all-important semiconductor chips – vital components for electronics and automobiles – worsened the situation. Initially, the scarcity of chips resulted from plant closures during the first wave of COVID-19. Later, the plants faced challenges in meeting the surge in demand when global production resumed operations.

The disruption in material flow was directly correlated with the disrupted flow of information among supply chain partners, making it challenging for them to accurately communicate their demands to upstream providers. Additionally, the lack of visibility into the suppliers' network further exacerbated this issue. Most focal firms had no information regarding their suppliers' suppliers. Similarly, the disruption in financial flows also impacted the availability of material flow. For example, many fashion brands canceled their orders with suppliers due to perceived drops in demand, leading to delayed or withheld payments. This cascaded effect on deep-tier suppliers, most of which were small and medium enterprises, forcing some of them out of business. When the markets reopened, these suppliers had already closed down, significantly impacting production. Similar situations were experienced in other industry sectors, such as airlines, automotive, and the hospitality industry, where firms suspended or postponed payments to their suppliers.

COVID-19 exposed vulnerabilities in supply chains that significantly impacted the flow of goods, information, and finances. It became evident that these three flows were intertwined, and any disruptions in one flow affected the others. Table 3 illustrates the short-term and long-term impact of these three flows across five industry sectors – logistics, airlines, food, manufacturing, and healthcare.

While it is evident that the three most acknowledged flows in SCM experienced disruptions during COVID-19, the pandemic also brought about new threats that triggered interactions among several other flows. In this chapter, we identify and discuss four such flows that played a vital role in supply chain performance during COVID-19 – suggesting the need to reconsider the traditional boundaries of supply chain frameworks. The following sections delve into each flow in detail, providing

| *Information* | *Information* |
| **Logistics**: Distorted information from suppliers due to unexpected e-commerce boom (Sargent, 2020). | **Logistics**: Border restrictions and port delays would impact the real-time information sharing (Gui et al., 2022). |
| **Airline**: Lack of information collected by third-party booking sites impacted passenger tracing (Kitroeff & Silver-Greenberg, 2020). | **Airline**: Lack of information regarding customer behavior and preferences would impact pricing, and scheduling (Dichter & Riedel, 2021). |
| **Food**: Dramatic shift to online, digital food ordering (Aday & Aday, 2020). | **Food**: Restaurants to move for cloud kitchens and online-to-offline takeout (Aday & Aday, 2020). |
| **Health**: Overwhelmed by the information demands and the challenges encountered. No information regarding source of PPEs and other medical devices (WHO, 2020). | **Health**: AI Diagnostic equipment will enhance the ability of providers to do remote virtual care (Bestsennyy et al., 2021). |
| **Manufacturing**: Lack of information from overseas suppliers led to uncertainty (Yavar & Pratt, 2020). | **Manufacturing**: Unpredictable demand trends impact information for finished goods and inventory needs (Yavar & Pratt, 2020). |
| *Material* | *Material* |
| **Logistics**: Record volume causing backlog, hence delays in package delivery (Condon, 2020). | **Logistics**: People are embracing e-commerce; package volume is expected to grow; longer transit times due to port congestions (Bhattacharjee et al., 2021). |
| **Airline**: More than 20 airlines suspended operations by 100% in March 2020 (Statista, 2020) | **Airline**: Flight delays expected due to pilot shortage and retirements (Dolinger, 2022). |
| **Food**: Restaurant closure, plant shutdowns, dumped milk and euthanized livestock lead to food shortage. Further exacerbated by panic buying (Jeffery & Newburger, 2020). | **Food**: Less in-store dining will push food service toward smaller stores. Demand for organic items will increase. Logistical challenges may continue (Aday & Aday, 2020). |
| **Health**: Shortage of PPEs and other medical supplies. Patients unable to access care at the primary care and community care levels (WHO, 2020). | **Health**: More COVID-19 variants would lead to medical devices shortage, complemented by chip shortages and product recalls (Van Houten, 2022). |
| **Manufacturing**: Supply disruptions due to lockdowns in China. Service impacted due to delayed deliveries and cancelled orders (Yavar & Pratt, 2020). | **Manufacturing**: More delays expected due to n-tier suppliers' issues (Yavar & Pratt, 2020). |
| *Finance* | *Finance* |
| **Logistics**: Reduction in potential revenues due to lack of work force, delayed deliveries and cancelled orders (Bhattacharjee et al., 2021). | **Logistics**: Revenue to be impacted due to social distancing protocols, disinfecting of large facilities, delayed deliveries and high financial investments in automation (IFC, 2020). |
| **Airline**: Revenue fall by as much as $113B in 2020 due to lack of passenger traffic (IATA, 2020). | **Airline**: Bankruptcies or mergers and acquisitions among large airlines (OECD, 2020). |

## 4 Human Flows

Human flows are underrepresented in the supply chain research literature. One possible explanation for this is that supply chain scholars have not emphasized human resource development as a means to enhance supply chain performance (Gowen & Tallon, 2003). In a supply chain, every link requires human involvement to ensure successful operations, reduce uncertainty, and achieve organizational goals (Farndale et al., 2010). During COVID-19, human flow emerged as a critical factor affecting supply chain functioning. The reduction in labor availability spread through the paths of the supply chain network, significantly impacting the effectiveness and efficiency of the supply chains (Nagurney, 2021).

The logistics industry, for example, was one of the hardest hit by human flow disruptions (Ashraf et al., 2022a). Amazon's fulfillment centers, as well as UPS, FedEx, DHL, and the USPS's sorting hubs, faced challenges in hiring and retaining workers during the virus outbreak in their facilities. This challenging situation coincided with a surge in e-commerce volume, prompting these companies to suspend their guaranteed delivery/money-back services. Similarly, the airline industry faced pilot and ground staff shortages as they grappled with the increasing number of air travelers. In 2022, Southwest Airlines had to cut nearly 20,000 flights, and Delta canceled almost 100 daily flights during the summer due to staff shortages (Dolinger, 2022). In the agriculture sector, farm owners faced difficulties finding and retaining workers due to the delayed arrival of seasonal immigrant farm workers. As a result, they had to rely on alternative sources, such as high school students and laid-off workers, to work on farms (Weinraub & Ingwersen, 2020). The delay in summer harvesting led to a surge in wheat, soy, and corn prices. Meat and poultry processing facilities were also affected by human flow disruptions. A report presented to the House of Representatives revealed that in 2020, more than 86,000 meat and poultry workers tested positive for COVID-19, with over 400 deaths reported (Chadde, 2021). As a result, companies like Tyson Foods, JBS, Cargill, and National Beef had to suspend operations at several plants. In the healthcare sector, workforce shortage was already a challenge before COVID-19. The pandemic further exacerbated this issue due to extensive workforce burnout and many healthcare workers contracting the virus. The shortage of workers became even more critical during the surges of COVID-19 variants, such as Omicron and Delta.

In addition to the labor shortages caused by workers contracting the virus, another major human flow disruption emerged due to massive layoffs. Take the example of the U.S. manufacturing sector. About 1.4 million employees lost their jobs during the early days of COVID-19 (Wellener et al., 2021). General Motors had to lay off 6500 employees, while Tesla furloughed approximately half of its U.S. sales and delivery staff. According to a survey conducted by the National Association of Manufacturers (NAM), even as the industry rebounded in 2021, it was only able to fulfill 63% of the jobs lost during the pandemic, despite having a record number of job openings (Hennessey, 2022). Further, the survey respondents mentioned finding talented workers was 36% harder than pre-COVID-19. NAM also forecasted that by 2030, there could be a shortage of talented workforce leading to 2.1 million manufacturing jobs going unfilled. This shortage of workers will significantly impact the sector's supply chain and could cost the industry $1 trillion or more.

Like other flows, the disruptions in human flow during COVID-19 affected nearly every industry, resulting in an unprecedented global slowdown in production volumes and services.

## 5 Knowledge Flows

Knowledge is one of the most valuable assets for any firm (Yalcin et al., 2018). Knowledge flow is the transfer of knowledge between different entities or functions for "facilitating creation, access, and reuse of knowledge, typically by using advanced technology" (Laing et al., 2001, p. 430). Knowledge flow differs from information flow because "information flow focuses on what to do and where to get resources, while the knowledge flow focuses on how to do it" (Pudane, 2013, p. 2). Yet, most SCM research considers knowledge as part of the information flow. As a result, this perspective limits the effective analysis of various SCM issues related to the flow of knowledge.

Amidst the challenges of COVID-19, knowledge became a crucial resource for organizations dealing with uncertain circumstances. Authors such as Orlando, Tortora, Pezzi, and Bitbol-Saba (2021) argue that SCM scholars have not adequately studied the role of knowledge flow for firms and their supply chains. They suggest investing in knowledge flows could have enabled firms to respond effectively to unpredictable events, such as COVID-19. Similarly, Kassaneh, Bolisani, and Cegarra-Navarro (2021) propose that a greater focus on knowledge could have helped to reduce the knowledge gaps between supply chain partners, creating a "traceable and transparent environment" (p. 2).

Due to a lack of knowledge sharing with shippers, logistics firms like UPS, FedEx, and DHL faced challenges in arranging extra capacity to meet the sudden spike in package volume, resulting in delayed deliveries. On the downstream side, the absence of knowledge flow between sellers and consumers led to shortages of essential items due to panic buying. For example, there was a surge in consumers hoarding toilet paper, hand sanitizers, cleaning bleach, alcohol wipes, and utensils and placing numerous online orders for essentials due to their limited knowledge about the available stock levels. Similarly, well-known brands like Nike, Adidas, and J. Crew encountered difficulties in finding alternative suppliers since they lacked knowledge about their deep-tier suppliers, most of whom were located in developing countries such as Bangladesh, Vietnam, and Pakistan. In contrast, companies that had meticulously mapped their supply chains were better informed about their supply network and were able to identify suppliers, plants, and sites that were facing disruptions, enabling them to secure inventory and additional capacity from alternate sources (Choi et al., 2020).

Effective flow of knowledge among supply chain partners could have significantly alleviated the impacts of supply chain disruptions caused by COVID-19. According to a study by McKinsey and Company (2022), for firms to survive any pandemic-like disruptions in the future, they must "invest in foundational, end-to-end supply chain knowledge building, coupled with advanced functional, technical, and leadership training." To achieve this, the World Bank recommends that firms establish systematic learning platforms for stakeholders in their supply chains (Lutalo et al., 2022). These platforms could enable the exchange of experiences and insights – knowledge flow – aiding in the identification and resolution of any prevailing knowledge gaps. Establishing such systems to ensure knowledge transfer is crucial because relying on informal information collected through personal relationships is often "anecdotal" and based on sheer speculation (Choi et al., 2020). Apple, for instance, has recently partnered with Digital Public Square to create a mobile platform that facilitates the exchange of knowledge, including training modules, production status, employee health, and factory preparedness (Apple, 2021). The platform translates the information into the native languages of suppliers in Asia, making it easier for them to comprehend the content.

Modern-day supply chains are intricate, and COVID-19 has highlighted vulnerabilities within these interconnected networks. Recognizing the significance of knowledge flow can empower firms to discover solutions and mitigate challenges associated with processes within these complex networks, ultimately leading to improved supply chain performance.

## 6 Equipment Flows

Similar to the flow of humans and knowledge, the flow of equipment emerged as a critical flow during COVID-19. Equipment refers to any assets a firm utilizes, including transportation equipment like trucks, trailers, and containers, as well as industrial equipment such as forklifts, dollies, and conveyors. These assets are crucial in maintaining the smooth and efficient flow of materials within a supply chain. For companies such as UPS, FedEx, DHL, Walmart, Coca-Cola, and others, equipment flow holds significant importance. Therefore, investing in equipment flow might constitute one of the most substantial long-term capital investments for these firms.

A distinctive characteristic of equipment flows is the variations in their demand, which are directly influenced by changes in material flow or shifts in end-user expectations. These changes can significantly alter the flow of the equipment. For instance, when there is a surge in package volume during peak seasons, logistics companies like UPS etc., often opt to rent delivery vehicles from rental companies such as Penske, U-Haul, etc. This helps ensure the smooth continuity of equipment flow without any disruptions.

During COVID-19, the disruption in equipment flow became evident. To illustrate, The Washington Post reported a significant cause of disruptions to be the shortage of freight-handling equipment in ports (Lynch, 2021). Notably, the ports of Los Angeles and Long Beach experienced delays in container movement due to a shortage of trailer chassis. Similarly, a report by UNICEF (2021) highlighted a global shortage of shipping equipment as a primary factor behind disruptions in sea freight operations. Companies, particularly those that didn’t possess their transportation equipment, were affected by this situation. Acquiring containers became a challenge. In the food industry, small farm owners encountered difficulties obtaining containers and trucks to ensure the timely delivery of their produce to markets.

In addition to transportation equipment, there was a noticeable flow disruption of various equipment within the medical field. For instance, medical devices like blood collection tubes, which facilitate the movement of blood specimens, experienced shortages. These shortages led to disruptions in the blood supply chain, subsequently causing delays in obtaining COVID-19 test results. Consequently, the US Food and Drug Administration issued guidelines to healthcare providers, including laboratory operatives and phlebotomists, advising them to implement strategies for conserving collection tubes to reduce usage (USFDA, 2022). Likewise, in the UK, the National Health Service (NHS) temporarily halted blood testing for non-emergency illnesses (Kent, 2021). On the pharmaceutical side, vaccine production was affected by a shortage of crucial equipment like vials and disposable bioreactor bags, which were essential for transporting the vaccine (Bown, 2022). In the airline industry, infestations in mothballed aircrafts affected instrument accuracy, resulting in rejected takeoffs and in-flight turn-back events during their reintegration into service (Allianz, 2021).

The effective and efficient functioning of supply chains heavily relies on equipment flow. This flow typically necessitates coordination among various internal departments within a company, including purchasing, manufacturing, and planning. With the amplified volatility in supply chains, exacerbated by challenges brought about by COVID-19, the ability of firms to meet customer demands is closely linked to their adeptness in managing equipment flows.

## 7 Technology Flows

Like knowledge, technology flow has largely been examined within the context of information flows. However, it's important to recognize that these two types of flows are distinct. The information focuses on what to do and where to get resources, whereas technology enables coordination across departments, teams, and companies through a high integration amongst the key stakeholders in the network. Putnam and Evenson (1994) describe technology flow as the technological capability developed in one sector of the economy – or by one firm in the supply chain – spilling over to other sectors. The scope of technology flows may extend beyond organizational limits and include all the supply chain partners. For a focal firm to gain the most out of the technological flows, it must ensure that technological alignment is achieved among its supply chain partners.

During COVID-19, the fragmented technology landscape between the focal firms and their overseas partners was one of the major drivers for supply chain disruptions. A World Bank report highlighted that approximately 47% of companies within Bangladesh's manufacturing sector lacked the technological infrastructure to effectively monitor key performance indicators (Gu et al., 2021). This limited the focal firms' visibility into the manufacturers' operations. In another survey conducted by IBM, which involved over 3000 executives representing 22 different industries, the findings highlighted a clear imperative for improved technological alignment among the supply chain partners (Straight, 2020). Companies like Apple, for instance, encountered prolonged periods of reduced production due to insufficient technological integration among its supply chain partners in China.

Even locally, a noticeable disruption in technology flow emerged among supply chain partners. For example, many manufacturers and retailers had no coordination with their local customers, resulting in panic buying. Likewise, the absence of technological integration between logistics firms and vaccine producers posed substantial hurdles in vaccination deployment. The U.S. logistics sector was ill-equipped to handle such integration demands. As a result, healthcare providers and vaccination clinics lacked visibility into vaccine distribution operations.

Amid the repercussions of the COVID-19 disruptions, the technology flow stands out as one of the most influential factors in mitigating the impact on the supply chains. Virtually every industry sector is now channeling investments into enhancing technological flows within their supply chains. For example, Maersk has taken the initiative by implementing an Electronic Data Interchange platform (Maersk, 2021). This platform facilitates inventory optimization, automates financial transactions with suppliers, and enables real-time adjustments to cargo flow. Similarly, third-party logistics (3PL) companies are embracing cloud technologies to consolidate data from various internal and external sources. This consolidation provides heightened visibility for both suppliers and customers. In the healthcare sector, technology is being used to offer appointments and clinical checkups through telemedicine. Artificial intelligence-supported engines are being implemented to improve the healthcare supply chain by identifying high-risk regions and delivering personalized dosage recommendations (Mace, 2021).

Technology flows make the supply chains robust and immune to crisis. It can allow for integration in the key business processes, within and outside the supply network, thereby enabling firms to achieve profits by improving the quality of their product or service and minimizing coordination efforts and transaction risks. Technology is a vital SCF and should be considered by practitioners and scholars.

This is not a comprehensive list of flows; however, the above-mentioned flows should pave the way for SCM scholars and practitioners to explore and manage SCF that impact SCM.

Some might argue that the identified flows may not be suitable in the context of SCM since a flow must add value to the whole supply chain as it moves across various entities in a supply chain. Yet, a flow can be viewed within or between firms. Also, much depends on the type of industry and how it establishes the scope of its supply chain. For instance, consider a cosmetic manufacturing company like L'Oréal. Within its manufacturing facility, the company might employ intelligent robotic systems to perform tasks such as filling, screwing, and securely sealing makeup bottles. Subsequently, these bottles will be imprinted with production-specific laser codes and conveyed to an automated cartoning unit. The cartons will then be loaded onto GPS-equipped trucks managed by 3PLs such as UPS, FedEx, and DHL. Upon reaching the 3PL hub, the cartons will be offloaded and systematically processed using advanced conveyor systems, autonomous forklifts, automated sorters, and more, all to ensure their accurate placement onto the appropriate destination trucks. Once sorted, these cartons will be reloaded onto GPS-enabled delivery trucks, ready for their final journey to the end customer. This intricate scenario underscores the pervasive presence of technological flow throughout the supply chain. It is similar to how finance flows vary throughout the chain – an initial payment might convert from cash to a cheque to an online transaction as it moves through the supply chain. Therefore, SCF should be perceived not only from a macro supply chain perspective but also encompass the various flows intrinsic to internal business functions.

## 8 Managing Supply Chain Flows – Theories in Research

Supply chain management theory has been slow to change since Forrester highlighted the association between a firm's success and a company's functional interrelationships with related flows. However, what has changed is the context with the emergence of COVID-19, that has elevated the need to proactively manage these flows. It also required a shift from traditionally disjointed silos to more effective, integrated management of flows across the overall supply chain.

SCM scholars do now acknowledge integrated SCF to achieve more resilient and sustainable supply chain performance. Interestingly, there is no theoretical framework in the SCM literature that explains the effective management of all SCF. Current SCM frameworks present solutions on how to design and manage particular SCF but do not address the theoretical foundations to manage all the flows (Ashraf, 2023). Therefore, there is a need for SCM scholars to utilize a relevant theoretical underpinning to manage all the SCF. Within this section, several potential theories are presented, which can serve to assist both SCM scholars and practitioners in this matter.

### 8.1 Paradox Theory

COVID-19's immediate impact on SCF brought unprecedented "volatility, uncertainty, complexity and ambiguity" to supply chains (Golgeci et al., 2020, p. 129). In these situations, adhering to the usual course of business was not viable. Managers consistently found themselves grappling with tensions, specifically encountering situations where various options seemed to conflict with each other. This made the process of decision-making quite challenging. Table 4 highlights some of the tensions that surfaced across various industry sectors due to the impact of COVID-19 on SCF.

Such tensions are also called paradoxes in the management literature (Lewis, 2000). Paradoxes consist of "contradictory, yet interrelated elements – elements that seem logical in isolation, but absurd and irrational when appearing simultaneously" (Lewis, 2000, p. 760). The importance of paradoxes during the COVID-19 pandemic becomes evident when considering the usage of the term "paradox" by various media outlets to characterize the crisis. For instance, a New York Times article titled "Corona Virus and the Isolation Paradox" (Shihipar, 2020) exemplifies this phenomenon.

SCM researchers have mostly acknowledged the tradeoffs when addressing the tensions. However, Paradox theory can serve as the theoretical framework to make sense of the tensions that emerge when organizations undergo a major change, such as interactions in SCF due to disruptions (Zhang et al., 2021). It is a valuable theoretical lens since it guides researchers and managers in effectively managing the inherent tensions within the SCF. According to Lewis (2000), actors often simplify complex situations into polarized distinctions – such as focusing on certain flow(s) – when under pressure and narrow their choices to elements (flows in this case) most under their control. However, supply chains cannot perform without all the flows being managed simultaneously. A focus on only a few flows can be

**Table 4** Tensions emerging due to COVID-19. (Source: Authors)

| Tensions | Industry Context |
|---|---|
| Survival versus Sustainability | Manufacturing |
| Independence versus Dependence, Commonality versus Distinction | Management |
| Centralization versus Decentralization, Cooperation versus Competition, Authority versus Trust | Organizational decision making |
| Efficiency versus Resilience | Global value chains |
| Corporate interest versus Employee interests, Employment levels versus Downsizing, Financial interest versus Sustainability | Organizational human resources |
| Interaction versus Safety, Regular versus Critical customers, Responsiveness versus Driver shortage, Revenue versus Safety | Third-party logistics |

disadvantageous to the firm and can even be an obstruction to achieving long-term goals and viability.

## 9 Complimentary Theories to Explain SCF Interactions

Using complementary theories allows scholars to investigate the interactions of SCF that are not fully explained by other perspectives. Three theories – *contingency, institutional complexity*, and *complexity theories* – can address interactions between the SCF. In the following sub-sections, an overview of each theory is presented.

### 9.1 Complexity Theory

Complexity theory addresses several elements an organization must address simultaneously (Scott, 1992). Complexity theory suggests that "some systems with many interactions among highly differentiated parts can produce surprisingly simple, predictable behavior, while others generate behavior that is impossible to forecast, though they feature simple laws and few actors" (Anderson, 1999, p. 217).

Within the SCM context, complexity theory proposes that alterations in the supply chain network's structure will occur unpredictably (Zhang et al., 2021). It has been used to examine the persistent contradictions between short-term success and long-term survival in service innovation (Chae, 2012). Nilsson (2019) argues that complexity theory can be applied to study changes, interrelationships, and paradoxical tensions in supply chains. Therefore, complexity theory's capability to explain the simultaneous management of paradoxical elements can provide an alternate lens to investigate SCF management. It provides constructs such as co-evolution, emergence, patching, and self-organization that may be relevant in understanding the interactions in SCF.

### 9.2 Institutional Complexity Theory

Institutional complexity theory addresses tensions at the institutional and/or organizational levels. The theory depicts competing demands as originating from societal-level expectations. Institutional complexity is when firms "confront incompatible prescriptions from multiple logics" (Greenwood et al., 2011, p. 317).

Institutional logics offer fundamental sets of principles that guide understanding of tensions and appropriate behavior in social situations (Friedland & Alford, 1991). Actors adhere to these logics to attain approval and cultivate the necessary resources. For instance, in SCM, institutional complexity theory can assist in recognizing how social enterprises alter particular practices for social impact (Pullman et al., 2018). This occurs along a spectrum that ranges from purely commercial to purely social. Similarly, Sayed, Hendry, and Bell (2017) explore the influence of "institutional pressures, institutional logics and institutional complexity on Sustainable Supply

Chain Management practices across mixed public and private sector supply chains" (p. 542). Additionally, Baumann-Pauly, Scherer, and Palazzo (2016) explore how firms implement strategies and procedures to respond to contradictory institutional logics in their business environment.

Institutional complexity theory highlights the existence of various and potentially contradictory institutional logics – tensions. This theory offers an alternative perspective to understand how the tensions among SCF can be managed on an institutional level.

### 9.3 Contingency Theory

Contingency theory concludes that there is no universally optimal method for managing a corporation or making decisions, as distinct environments present varying demands (Fiedler, 2005). Managers must choose between competing demands based on internal and external environments. This perspective enables the generation of more advanced "if-then" insights, helping to identify the conditions under which firms can address diverse and conflicting demands (Qui et al., 2012). For instance, Lewis and Smith (2014) note that the "contingency approach to exploration and exploitation seeks to resolve the tension by determining when and where to focus on each strategy separately" (p.131).

Pina e Cunha, Fortes, Gomes, Rego, and Rodrigues (2019, p. 715) conducted research at the interface of contingency theory and paradox theory and determined that "a contingency theory of paradox may contribute to a more granular view of paradox in organizations." Within the context of SCM, Danese (2011) focuses in collaborative planning initiatives in supply networks. The author investigates the pertinent contingency factors influencing firms' selection of a specific collaborative planning initiative. Grötsch et al. (2013) investigated the factors that encourage the proactive adoption of supply chain risk management using the lens of contingency theory. Their study revealed that previous instances of supplier insolvencies influence organizations' vulnerability when engaging with those suppliers.

Overall, contingency theory can provide insights into managing tensions within SCF based on environmental change.

## 10 Moving Forward: Future Research and Current Practice

In this chapter, we highlighted the hesitancy amongst SCM researchers in expanding SCF definitions. The chapter provided an overview of various SCM definitions for SCF over the last few decades. The extent of confusion can be observed both in academia and practice amid the lack of a unified theory of SCM.

Previous SCM definitions do not do justice to various flows that are as impactful as the three most acknowledged flows – especially given recent COVID-19 evidence. Several flows that require attention by the research fraternity could be included within the boundaries of the SCF. Future researchers can broaden their research horizon and identify more flows vital to supply chain performance

**Table 5** Limitations of proposed theories. (Source: Authors)

| Theory | Assumptions | Conflict with SCF |
|---|---|---|
| Paradox Theory | Two elements existing in relation to one another<br>Tensions persist over time | SCF are more than two elements.<br>Tensions between SCF may or may not persist over time.<br>Intensity of tensions might change over time. |
| Contingency Theory | Tensions to be solved discretely | Flows are integrated and must be managed simultaneously. |
| Institutional complexity theory | Tensions emanating from societal-level expectations | Tensions in SCF are inherent that may emerge through an act of the firm (such as implementing new technology) or through environmental change (such as COVID-19). |
| Complexity Theory | Self-organizing systems with little to no direct control<br>Chaos is a necessary condition | Firms can manage the interactions between flows with predictable outcomes.<br>Chaos is not a necessary condition. |

(i.e., resilience, sustainability, etc.). Some possible flows to look into are *value flows, ownership flows, resource flows,* and *risk flows.*

To investigate such flows, there needs to be awareness of what qualifies as SCF. SCM literature does neither clearly define the SCF concept nor discuss the attributes required to be qualified as an SCF. Therefore, the absence of a SCF definition has made it difficult to develop the concept and build a consistent stream of research, and standard practice, in this domain. Without adopting a grounded definition or a framework, confusion will continue to hamper the studies related to SCF and consequently impact the development of SCM research.

For practitioners, the absence of a SCF framework will make it more challenging to effectively identify the critical flows in their supply chains and adopt processes to manage them. Hence, a consensus definition of SCF is greatly needed to advance the field. Therefore, we suggest that future researchers should undertake studies aimed at its development.

Theoretically, a robust SCF theory can only be developed when its valid constructs are established (Stock and Boyer, 2009). Though we proposed four theories that could explain the management of SCF through their interactions, each theory has its limitations that may not fully explain the underlying characteristics of SCF. Table 5 presents some of the limitations of each theory that may not fit well with the SCF dynamics. Therefore, we suggest future researchers develop theories that consider all the aspects of SCF and provide insightful guidance in managing them.

## 11 Conclusion

Motivated by the discussions surrounding the failure of SCM research to respond to disruptions in SCF during COVID-19, this chapter is written to present a basis for debate and development around the extant concept of SCF by attempting to consolidate learning, identify possible gaps, and thereby present possible future directions for development. The nature of research in SCM and, more specifically, what would constitute the domain of SCF, and whether Paradox Theory can provide a critical lens to manage the interactions in SCF, especially amid instances that are unexpected. In doing so, this chapter also provides information on potentially using complementary theoretical approaches to investigate interactions within SCF. Limitations of each theory are presented along with future research suggestions, such as investment in establishing a consensus definition and developing a theoretical framework for SCF so that the research in this domain remains consistent and focused.

The purpose of this chapter is not to undermine the importance of material, financial, and information flows within SCM. Rather, it aims to take an initial step toward enhancing the SCF understanding. It encourages scholars and practitioners not to disregard flows that might hold significance on par with the three most acknowledged flows. This chapter provides a foundation to develop additional theoretical insights for SCM researchers.

## Contents

**Abstract**

Creating agile supply chains is of utmost importance to stay competitive. However, making supply chain operations agile or transforming networks towards an agile form is often challenging for most organizations. This chapter focuses on the agility concept in supply chains. The chapter overviews agile supply chain studies focused on developing models or frameworks for supply chain agility. A comprehensive collection of studies is summarized along with discussing the components of previously developed models or frameworks. The chapter further presents a section about the implementation of supply chain agility in different industries. Manufacturing, automotive, and construction industry examples are discussed. After discussing agility in different industries, the chapter provides emergent concerns and outstanding research areas to direct potential researchers and industry practitioners in terms of assessing supply chain agility. Main research areas on supply chain agility were demonstrated as the integration of

## 1 Introduction

The main motivation behind agility is increasing change facing organizations and supply chains. Globalization, advancements in technology, accumulation of knowledge, customer requirements, competitiveness, uncertainty, and complexity have all increased (Najrani, 2016). In these circumstances, change becomes inevitable. Hence, agility is one of the essential requirements that an organization needs to continue as an operable entity.

There are many examples of leading companies that lost their competitive advantage and failed because of their inability to adapt to changing environments or customer requirements (Najrani, 2016). Hence, agility is essential for survival. To gain and maintain a competitive advantage, supply chains rather than individual organizations have become the unit of competition (Christopher & Peck, 2004; Van Hoek et al., 2001). In that way, supply chain agility became a crucial (Swafford et al., 2006).

This chapter introduces the concept of agile supply chain management. Firstly, the supply chain is defined and the importance of supply networks for individual companies is discussed. Supply chain management is specified, and several strategies are presented based on the previously established studies. Secondly, agility is discussed based on the review of agility definitions and the historical background of agility. The level of agility is also examined. Building on the concepts of supply chain management and agility, agile supply chains are discussed based on the need for agile supply chains and existing definitions. Then, the concept of supply chain agility and other related concepts such as leanness, flexibility, adaptability, and resilience are reviewed and compared. The following section presents a collection of supply chain agility models and frameworks that have been developed so far. Then, examples of empirical studies from different industries are provided. The existing concerns in the prevalent literature are discussed, and future directions are suggested. Managerial implications considering the supply chain agility domain are disclosed. Finally, the summary and conclusions of the chapter are listed.

## 2 Supply Chain Management

Supply chains are networks of companies that are taking part through upstream and downstream linkages from design to delivery of products (Yusuf et al., 2004). It includes all parties extending from suppliers of suppliers to end customers

(Whitten et al., 2012). The supply chain is not a linear chain but a complex network that includes more than two organizations that embody indirect relations and link various organizations, industries, and economies (Christopher & Peck, 2004). It aims to produce value for customers using products and services (Iskanius, 2006).

Organizations should not consider their operations in isolation from the other supply chain parties (Naylor et al., 1999). They need links that support them to become successful (Christopher & Peck, 2004). Developing and maintaining the core competencies to meet the objectives is mostly problematic for individual companies. Hence, they are forced to cooperate and collaborate (Yusuf et al., 2004). The notion of being increasingly dependent on suppliers raised awareness of the need for the management of the whole supply chain from end to end. The dominant means of competitive advantage became supply chains rather than individual companies (Ismail & Sharifi, 2006; Van Hoek et al., 2001).

Supply chain management facilitates the integration of supply chain parties to satisfy the end-customer demand (Agarwal et al., 2007). It is one of the main domains that help companies to achieve a competitive advantage (Lee, 2002). Supply chain management provides a different approach from traditional command and control. Some supply chains are more command and control depending on the industry and conditions. It aims for mass customization rather than mass production and marketing, and also focuses on processes rather than functional, geographical, and product departments (Van Hoek et al., 2001).

Management of the supply chain is complicated and challenging, because of increasing product variety, shortening the life cycle of products, development in technology, globalization, competition, and increasing customer requirements (Christopher, 2000; Lee, 2002). Supply chains in numerous industries are faced with the problem of excessive products or scarcity of products due to difficulties in the prediction of demand (Fisher, 1997). Hence, supply chain management strategy should be determined according to the characteristics of the demand and supply (Lee, 2002).

The foundation of supply chain management is considered to be laid by Forrester (1958) that investigated and modeled the dynamics of demand and supply rates and presented an approach for supply chain management. Being one of the influential studies, Fisher (1997) suggested a framework for supply chain strategies based on the demand characteristics of products. Products can be categorized as functional and innovative. Functional products have stable and expected demand, long product life cycles, and low-profit margins. On the other hand, innovative products have variable and unpredictable demand, shorter life cycles, and higher profit margins. Fisher (1997) considered two types of supply chain processes. Efficient supply chains aim to meet foreseen demand by focusing on cost. Responsive supply chains intend to respond to unforeseen demand and focus on speed and flexibility. According to characteristics of product demand and supply chains, Fisher (1997) proposed that functional products necessitate efficient supply chains, while innovative products require responsive supply chains.

By developing Fisher's framework, Lee (2002) proposed the "uncertainty framework" to determine the supply chain strategy according to uncertainties in demand and supply of products. Differently from Fisher (1997), Lee (2002) categorized the uncertainty of supply as low (stable) and high (evolving). A stable supply process has an established foundation, lower complexity, higher automation, reliable lead time, constant and higher yields, more reliable suppliers, and long-term agreements. In contrast, evolving supply has developed and advancing processes that may cause limitations in capacity and experience. With these complexities, there is more vulnerability to breakdowns, more changes in processes, changing lead time, lower and unstable yields, and less reliable suppliers (Lee, 2002). To increase the performance of the supply chain, uncertainties in demand and supply should be minimized. In some cases, despite the stability of demand from customers, the upstream supply chain may perceive irregular demand patterns. This situation is called the "bullwhip effect" which is the increase of variability throughout upstream of the supply chain (Lee, 2002). As the number of parties in the supply chain increases, the forecasts become more error-prone (Prater et al., 2001). Information sharing, synchronized planning, collaboration, and coordination are significant methods to reduce demand and supply uncertainties (Lee, 2002).

Lee (2002) provided a framework including two dimensions of uncertainties in demand and supply to determine appropriate supply chain strategies. Low uncertainty in demand and supply requires an efficient supply chain in which competitive advantage is gained through efficiency. Industries such as basic apparel and oil and gas can be considered in this category. Functional products that have low uncertainty in demand and evolving supply that have high uncertainty in supply necessitate risk-hedging in supply chains. Hydroelectric power is an example of this category. When the products are innovative with high uncertainty in demand and supply is stable with low uncertainty in supply, companies need to devise responsive supply chains. For instance, the fashion apparel industry is in this category. On the other hand, if both demand and supply uncertainty is high, companies with innovative products and evolving supply should consider an agile supply chain as a strategy. Telecom and high-end computers industry are in this group.

Agility becomes more crucial as demand and supply become more variable and faster in most industries. The effect of natural disasters, crises, pandemics, and other macroenvironmental issues on supply chains escalates this variability given that most supply chains are global. Even though efficiency is required, efficient supply chains are incapable of responding to unpredictable demand and supply changes, as a result, fail to gain a competitive advantage. Some reasons cause supply chain breakdown. Transfer of products in large quantities is useful for cost-efficiency; however, it restricts reacting to the customer demand in a timely fashion. On the other hand, low demand causes excessive inventory, which may result in discounted prices and increased costs while reducing profit along with lowering the value of the product. Lacking buffer stock and the pressure of speed make the supply chain prone to producing defective products (Lee, 2004).

## 3 Agility

Agility is a broad, multidimensional, and complex concept including various aspects of an organization's (Li et al., 2008; Swafford et al., 2006). To make supply chain agility understandable, we first discuss agility definitions. In several studies across different disciplines, agility is defined using varying perspectives as can be seen in Table 1. Given definitions are not attempted to be comprehensive, but representative of significant studies. A review of agility definitions gives the insight to understand underlying foundations and common elements of agility.

| (Iacocca Institute, 1991) | "[. . .] a manufacturing system with extraordinary capabilities (internal capabilities: hard and soft technologies, human resources, educated management, information) to meet the rapidly changing needs of the marketplace (speed, flexibility, customers, competitors, suppliers, infrastructure, responsiveness)." |
| (Goldman et al., 1995) | "[. . .] the ability to thrive in a competitive environment of continuous and unanticipated change and to respond quickly to rapidly changing, fragmenting global markets that are served by networked competitors with routine access to a worldwide production system and are driven by demand for high-quality, high-performance, low-cost, customer-configured products and services." |
| (Yusuf et al., 1999, p. 37) | "[. . .] the successful exploration of competitive bases (speed, flexibility, innovation proactivity, quality and profitability) through the integration of reconfigurable resources and best practices in a knowledge-rich environment to provide customer-driven products and services in a fast changing market environment." |
| (Sharifi & Zhang, 1999, p. 496) | "[. . .] is the ability to cope with unexpected changes, to survive unprecedented threats of business environment, and to take advantage of changes as opportunities." |
| (Jin-Hai et al., 2003, p. 7) | "[. . .] the strategic process of responding to the competitive environment of continuous and unpredictable change by reacting quickly and effectively to changing markets. It takes multiple winners (manufacturers, suppliers and customers) as an objective, integration (of resources, methods, technologies, departments) as the means, with IT as an essential condition and core competence as the key." |
| (Sambamurthy et al., 2003, p. 245) | "[. . .] the ability to detect opportunities for innovation and seize those competitive market opportunities by assembling requisite assets, knowledge, and relationships with speed and surprise. Agility encompasses the exploration and exploitation of opportunities for market arbitrage." |
| (Overby et al., 2005, p. 296) | "[. . .] the ability of firms to sense environmental change and respond appropriately." |
| (Ganguly et al., 2009, p. 414) | "[. . .] the ability of an organization to rapidly and efficiently response to any proactive/reactive changes in the technology/industry without compromising with the cost and the quality of the product/service that it is catering." |

|---|---|
| (Charbonnier-voirin, 2011, p. 123) | "[. . .] a response capability which is intentionally sought out and developed by the organization in order to enable it to act efficiently in a changing environment characterized in particular by complexity, turbulence, and uncertainty." |
| (Lu & Ramamurthy, 2011, p. 933) | "[. . .] a firm-wide capability to deal with changes that often arise unexpectedly in business environments via rapid and innovative responses that exploit changes as opportunities to grow and prosper." |
| (Rimienė, 2011, p. 895) | "[. . .] an ability of a company in a changing market environment profitably exploit market opportunities, quickly and flexibly respond to customers' needs, and qualitatively, suffering minimum cost, satisfy them by using innovative solutions and partnership cooperation." |
| (Singh et al., 2013, p. 10) | "[. . .] the ability of a firm to sense and respond to the environment by intentionally changing (1) magnitude of variety and/or (2) the rate at which it generates this variety relative to its competitors." |
| (Teece et al., 2016, p. 17) | "[. . .] the capacity of an organization to efficiently and effectively redeploy/redirect its resources to value creating and value protecting (and capturing) higher-yield activities as internal and external circumstances warrant" |
| (Walter, 2021, p. 37) | "[. . .] a learned, permanently-available dynamic capability that can be performed to a necessary degree in a quick and efficient fashion, and whenever needed in order to increase business performance in a volatile market environment." |

Almost all definitions consider agility as dependent on environmental change (Singh et al., 2013). The environment is characterized as volatile, turbulent, uncertain, complex, and competitive, which also encompasses continuous and unpredictable external and internal changes, proactive/reactive changes, and threats and opportunities. The most prominent facets in the definitions are sensing the environment and responding to changes. Further, speed is highlighted as an essential element in most of the definitions. Flexibility is also mentioned as an element of agility. Objectives of agility are highlighted as cost, quality, performance, and customer orientation. Some benefits of agility are mentioned such as surviving, gaining competitive advantage, and increasing and maintaining performance. Jin-Hai et al. (2003) stated principle elements of agility definitions as a response to change and uncertainty, building core competencies, supplying highly customized products, synthesizing diverse technologies, and intra-enterprise and inter-enterprise integration. Iskanius (2006) listed the most cited agility attributes such as cost-effectiveness, flexibility, customer responsiveness, speed, reconfigurability, and technology innovation. The main dimensions of agility were implied as cooperation, enriching customer, handling change and uncertainty, and leveraging the impact of people and information by Meade and Sarkis (1999).

Agility is not a new concept. The usage of the term dates back to the late twentieth century (Singh et al., 2013). It has been studied in different fields such as economics, operations research management, manufacturing, strategic management, software engineering, and information technology/information systems (Seethamraju, 2006).

In the software development context, agility drew attention with the introduction of the *Agile Manifesto* proposed by 17 software developers. The Agile Software Development Alliance specified important values and principles in the *Agile Manifesto*. They revealed better ways of software development by valuing: "(1) individuals and interactions over processes and tools, (2) working software over comprehensive documentation, (3) customer collaboration over contract negotiation, and (4) responding to change over following a planned development" (Beck et al., 2001).

Agility is often considered interchangeable with the terms of flexibility, adaptability, and resilience (Li et al., 2008). This shows the overlapping nature of these concepts (Bernardes & Hanna, 2009). Agility involves elements of flexibility and adaptability, which are prior concepts. Even though these concepts have similar elements, they are conceptualized differently in terms of some aspects. Flexibility is the "ability of a system to change status within an existing configuration (of pre-established parameters)" (Bernardes & Hanna, 2009, p. 41). Flexibility helps to minimize environmental uncertainty by acting as a buffer to stabilize the processes. Alternatively, agility helps to take advantage of uncertainties by enabling competitive actions with the help of the reconfiguration (Bernardes & Hanna, 2009). Another significant difference is the management of change. Flexibility deals with predictable change; however, agility faces unpredictable changes (Iskanius, 2006). Flexibility is achieved with pre-established parameters, while agility involves flexibility by including the ability to respond to changes in which the conditions are not established a priori (Bernardes & Hanna, 2009). Another distinguishing point is that flexibility does not have a time element. Agility embeds speed response as an important capability on the contrary to flexibility (Ganguly et al., 2009).

In the context of the manufacturing industry, agility was popularized by the Agile Manufacturing Enterprise Forum by a group of researchers from the Iacocca Institute at Lehigh University in 1991 (Bal et al., 1999; Ganguly et al., 2009; Horney, 2013; Yusuf et al., 1999). The report provided the viewpoint of representatives from industry, government, and academia and presented a new manufacturing system (Iacocca Institute, 1991). This study became a center of interest in manufacturing studies (Sharifi & Zhang, 1999). The group proposed that organizations need to adapt to the dynamic environment and changing requirements like speed, flexibility, and response-ability (Seethamraju, 2006). The report included agile manufacturing organizations, their elements, and operational mechanisms (Yusuf et al., 1999). The Iacocca Institute (1991) further specified some recommendations for the industry to become agile. Another influential study was a book called *Agile Competitors and Virtual Organizations* by Goldman et al. (1995) that drew attention to agility. They emphasized agile capabilities which are enriching the customer, mastering the change, leveraging resources, and cooperation (Bal et al., 1999). However, it was criticized by some researchers that the concept was not founded on management theory (Li et al., 2008; Yusuf et al., 1999).

Early studies mostly focused on agility as a general concept or in the context of the manufacturing industry (Van Hoek et al., 2001). In earlier studies, agility was mostly studied at the organizational level as a whole (Sharifi & Zhang, 1999; Yusuf et al., 1999).

Additionally, another stream of agility research focuses on agile project management and other areas such as workforce agility, human resource agility, information systems/technology agility, business process agility, and operational agility (Seethamraju, 2006; Walter, 2021).

Some studies specified levels of agility. Jin-Hai et al. (2003) and Yusuf et al. (1999) proposed elemental, micro-, and macrolevels. The elemental level is related to individual resources (people, management, and equipment) and functions; the microlevel refers to the organizational level where the key resource is the competence of the organization, and the macrolevel focuses on inter-organizational relations where core competencies of different organizations are utilized (Jin-Hai et al., 2003; Yusuf et al., 1999).

Likewise, van Oosterhout et al. (2005) considered agility at two levels: the enterprise level (similar to the organizational level) and the business network level (similar to the inter-organizational level). Eltawy and Gallear (2017) mentioned agility within three levels: manufacturing, organization, and supply chain. An alternative view has some studies stating that agility consists of operational agility, partnering agility, and customer agility dimensions (Sambamurthy et al., 2003).

As can be seen, there is a variation in the emergence and agility definition. These are presented to provide a broad overview. We now provide some agility definitions within the supply chain context.

## 3.1 Supply Chain Agility

In the past, time, cost, and quality criteria were satisfactory for achieving success (Seethamraju, 2006). However, in current conditions, most organizations are challenged with the dynamics of operations (Ismail & Sharifi, 2006), variety of products (Verma et al., 2012), the short life cycle of products (Christopher, 2000; Rimienė, 2011; Verma et al., 2012; Yusuf et al., 2004), long supply chains (Christopher & Peck, 2004), and unpredictable demand and unreliable supply (Rimienė, 2011).

Several factors such as globalization, customer expectations, emerging markets, and advances in technology lead to strong competition (Carvalho et al., 2012; Christopher, 2000; Ismail & Sharifi, 2006; Rimienė, 2011; Verma et al., 2012; Walter, 2021; Yusuf et al., 2004). Further, other unexpected events are likely to occur such as crises, pandemics, or macroenvironmental issues. The recent COVID-19 pandemic caused disruption in supply chains, material scarcity, variability in demand, and, as a result, unstable prices. All this results in a highly volatile, turbulent, dynamic, and complex environment with an increasing rate of change and uncertainties (Christopher, 2000; Christopher & Peck, 2004; Ismail & Sharifi, 2006; Prater et al., 2001; Verma et al., 2012). These factors further create pressure on time, cost, quality, and performance (Verma et al., 2012). Considering these pressures, companies struggle to integrate and manage upstream and downstream supply chain (Yusuf et al., 2004).

With an unstable, changing, and transforming environment, agility is essential. Responding to changing conditions is mainly influenced by the capabilities of supply chain partners (Power et al., 2001). Since supply chains rather than individual organizations have become the unit of competition (Christopher & Peck, 2004; Van Hoek et al., 2001), supply chain agility became a crucial component for gaining and maintaining competitive advantage (Bal et al., 1999; Lee, 2004; Li et al., 2008; Swafford et al., 2006). Parallel developments in agility and supply chain management resulted in the foundation of the agile supply chain concept (Ismail & Sharifi, 2006). Supply chain agility was introduced in the late 1990s (Bal et al., 1999; Naylor et al., 1999). It was defined by several researchers and some of the definitions are presented in Table 2. Together with being like agility definitions, they refer to the

| (Li et al., 2008, p. 421) | "The result of integrating an alertness to changes (opportunities/ challenges), both internal and environmental, with a capability to use resources in responding (proactively/reactively) to such changes, all in a timely, and flexible manner." |
| (Braunscheidel & Suresh, 2009, p. 126) | "[. . .] the capability of the firm, internally, and in conjunction with its key suppliers and customers, to adapt or respond in a speedy manner to a changing marketplace, contributing to agility of the extended supply chain." |
| (Ngai et al., 2011, p. 233) | "[. . .] the capability of supply chain functions to provide a strategic advantage by converting unexpected market uncertainties and potential and actual disruptions into competitive opportunities through assembling requisite assets, knowledge, and relationships with speed and surprise." |
| (Shashi et al., 2020, p. 324) | "[. . .] a critical strategy for companies to manage supply network, and develop flexible capabilities to meet rapidly changing customer demands." |

level of supply chains and/or networks. Considering these definitions, agile supply chain management helps to generate the ability to respond appropriately to unexpected changes in a volatile and turbulent environment (Carvalho et al., 2012).

## 3.2 Supply Chain Agility and Related Concepts

Several concepts are highly related to the agility (Overby et al., 2005). Some terms have various meanings from different perspectives, while some terms have similar meanings based on the context (Horney, 2013). This creates inconsistencies in the usage of the terms (Li et al., 2008). Understanding the similarities and differences of these concepts with agility can clarify the meaning and implementation (Walter, 2021).

The relationship between lean and agility has been discussed in various studies, which resulted in different perspectives. Some studies argue that leanness precedes agility, and agility is founded in the lean manufacturing (Van Hoek et al., 2001). On the contrary, some studies claim that agility involves a leanness (Iskanius, 2006; Sarkis, 2001). In some studies, they were considered as mutually supporting and complementary approaches (Naylor et al., 1999; Yusuf et al., 1999). Apart from these, some researchers propose combining lean and agile paradigms and benefitting from this synergy (Christopher & Towill, 2001; Naylor et al., 1999).

Lean can be considered as doing more and maximizing value using fewer resources and minimizing waste (Sarkis, 2001). Agility can be considered as the ability to perceive internal and external changes and respond properly. Both lean and agility have similar approaches to some concepts; however, their competitive objectives are in different fields (Walter, 2021). Both paradigms focus on customer requirements and integration of the supply chain (Naylor et al., 1999). Both approaches consider time compression as a significant element; however, their main motivation is slightly different. In lean, eliminating nonvalue adding activities is a primary concern, and these activities are compressed. On the other hand, agility focuses on increasing responsiveness while compressing material and information flows. In lean, the primary goal is to minimize waste. Agility also adopts this concept, however, to the extent that its ability to respond to changes is not prevented (Ganguly et al., 2009).

Rapid configuration is desirable for lean; however, it is not as crucial as for agile. Cost, lead time, quality, and service are important metrics for both methodologies (Naylor et al., 1999). The essential difference between lean and agile is market conditions. Lean is more applicable in more stable and predictable environments, whereas in volatile and changing environments, agility is necessary (Ganguly et al., 2009; Naylor et al., 1999). Agility provides robustness and flexibility in contrast with stability in leanness. While agility focuses on competitiveness and taking advantage of future market opportunities, lean does not focus on these fields (Walter, 2021). Besides, the way of planning and controlling work is different. Lean utilizes a pull system; however, in the agile approach, planning is carried out to respond quickly focusing on the customer demand (Eltawy & Gallear, 2017).

Several researchers discussed using the combination of lean and agile together as a hybrid strategy (Iskanius, 2006). Naylor et al. (1999) proposed the integration of lean and agile concepts as a supply chain strategy which is called leagility. They discussed the decoupling point, which acts as a buffer and separates the part of the supply chain with variable demand from the part with smaller variety. Upstream from the decoupling point has smoother demand with less variety; hence, the lean concept is applicable. Downstream from the decoupling point has a highly variable demand and higher product variety; therefore, the agile concept is appropriate.

Christopher and Towill (2001) also studied lean and agile integration and suggested the following approaches: decoupling point, Pareto curve, and separation of base and surge demands. The Pareto curve approach can be used for lean and agile integration. For instance, considering that 20% of products have more predictable and stable demand, lean is suitable. The other part of the production, that is, 80%, which is less predictable and unstable, necessitates agility. Another approach is the separation of base and surge demands. Base demand can be predicted based on past data and lean is more suitable, while surge demand cannot be predicted and agile is applicable.

Agility is considered an extension of flexibility in several studies (Iskanius, 2006). Based on capability and competency relation, Swafford et al. (2006) examined supply chain agility as an externally focused capability and considered flexibility as an internally focused competency. In other terms, supply chain agility is rather considered a concept derived from the flexibilities in the supply chain processes. Hence, flexibility is viewed as an antecedent of agility. Similarly, it is considered one of the main prerequisites of agility in many studies (Bernardes & Hanna, 2009; Swafford et al., 2006). Another common approach is to examine flexibility as a characteristic of the agility (Christopher & Towill, 2001; Sarkis, 2001; Zhang & Sharifi, 2000). Other studies conceptualize agility and flexibility as distinct but related concepts (Swafford et al., 2006).

Adaptability is “the ability to change from one state to another state in a timely and cost-effective manner” (Swafford et al., 2006). An adaptable supply chain aims to adjust and modify the supply chain to meet the changes (Lee, 2004). The Triple-A supply chain approach conceptualized agility and adaptability as highly related concepts to achieving competitiveness (Lee, 2004). Adaptability is considered to be needed for the flexibility (Iskanius, 2006; Swafford et al., 2006). Even though there are different views on these concepts, flexibility, adaptability, and agility originated as a solution to deal with uncertain and unpredictable environments. As the most developed concept, agility can be considered to involve flexibility and adaptability (Bernardes & Hanna, 2009).

Responsiveness is the tendency to change states in response to altering stimuli (Bernardes & Hanna, 2009). Responsiveness can be considered a component of agility. For example, Van Hoek et al. (2001) stated that agility requires both responsiveness and flexibility. On the other hand, Qrunfleh and Tarafdar (2013) found that an agile supply chain leads to responsiveness, while lean does not. Postponement strategy was found to mediate the relation between agile supply chain and responsiveness. Strategic supplier partnership acted as a mediator in the relation of lean supply chain and responsiveness.

Resilience is "the ability of a system to return to its original state or move to a new, more desirable state after being disturbed" (Christopher & Peck, 2004). Supply chain resilience aims to prevent the undesirable states, which lead to failure by dealing with unpredicted disturbances (Carvalho et al., 2012). Both agility and resilience concepts have the same global aim to increase the performance and competitiveness of the supply chain. They both try to improve quality, enhance customer service, reduce lead time, develop collaborative relations, and work with flexible suppliers. However, their priorities are different. Agility is highly focused on responding to customer requirements, while resilience prioritizes flexibility and redundancy (Carvalho et al., 2012).

Even though agility and resilience definitions have many similarities in terms of responding to internal or external stimuli, their main difference is the stimuli type. In resilience, the organization is faced with an issue or disruption that should be responded to sustain the output capability and survive. In agility, the organization is faced with changes that can be threats but also can be exploited as opportunities. This implies that resilience is a reactive approach, on the other hand, agility provides a proactive approach. Christopher and Peck (2004) proposed that agility is an antecedent to resilience. Carvalho et al. (2012) studied the integration of agile and resilient strategies through the lens of supply chain management.

### 3.3 Supply Chain Agility Models and Frameworks

Christopher (2000) developed one of the earlier and more comprehensive conceptual frameworks explaining the characteristics of the agile supply chain, which are market/customer sensitivity, virtual integration, process integration, and network integration. He proposed a four-dimensional framework, which has been highly cited in many research studies (Iskanius, 2006). These four dimensions are market and customer sensitivity, virtual integration, process integration, and network integration.

*Market and customer sensitivity* indicates the ability to understand and react to real demand and customer requirements. *Virtual integration* pertains to the use of information and knowledge throughout the supply chain both upstream and downstream. *Process integration* relates to the management of uncertainties affecting the supply chain with the help of collaborative and cooperative working. *Network integration specifies* close, collaborative, and fluid associations with suppliers and customers in the supply chain (Christopher, 2000; Van Hoek et al., 2001). This framework assumes that supply chain parties have open relations, information sharing, and technology use (Iskanius, 2006). This framework provides an external, multiorganization focus. Processes and structures to establish an agile supply chain were highlighted across companies, but not within the companies (Gligor, 2014). The framework presented in the study of Van Hoek et al. (2001) was very similar to this framework. Further, Christopher et al. (2004) utilized and developed this framework.

Swafford et al. (2006) adopted a process-based view of supply chains including three main processes: procurement, manufacturing, and distribution. This model conforms with source, make, and delivery processes. On the contrary to Christopher (2000) and Van Hoek et al. (2001), Swafford et al. (2006) suggested a framework that has an internal and single-organization focus (Gligor, 2014). This framework has some limitations in terms of lacking elements such as process integration according to Gligor (2014).

Li et al. (2008) suggested that the main dimensions of supply chain agility are alertness to changes and response capability. They recommended that the degree of agility be measured on timeliness and flexibility. They modeled supply chain agility at episodic, operational, and strategic design levels from the perspective of work design. At the episodic level, work episodes are performed by using existing or obtained resources. The operational design focuses on adjusting available work episodes or involving new work episodes. The strategic level is involved in modifying existing operational systems or building new systems. The three levels are aligned and assumed to be positively associated. This study makes an effort to combine the elements: across organization practices from Christopher's (2000) framework and within organization practices from Swafford et al.'s (2006) framework (Gligor, 2014).

Gligor (2014) suggested a conceptual framework considering the importance of demand and supply management, and flexibility in demand and supply processes to achieve supply chain agility. Unlike studies focusing on supply only, they emphasized both demand and supply management and their integration. They also stated that organization-level strategies should be aligned with supply chain orientation.

The *Triple-A* supply chain framework was utilized by several studies. Lee (2004) introduced that top-performing supply chains have three distinct characteristics as agility, adaptability, and alignment, which were called *Triple-A* supply chains. Agility is responding to unforeseen changes in demand or supply. Lee (2004) explained some rules to create agile supply chains: continuous information and data sharing with supply chain partners, establishing collaborative relations with partners, postponement of some parts of production until customer demand is clarified, keeping inventory of some materials leading to bottlenecks, and having reliable logistics system and experienced human resources.

Adaptability is adjusting the supply chain to conform to the changes. Some necessary actions for adaptability were stated as following economic trends and changes, forecasting end consumer expectations, developing alternative supply chain partners, and considering supply chain implications at the design stage. Alignment is the arrangement of conditions to align supply chain parties towards the same goal. The ways of establishing alignment were identified as the exchange of data with supply chain partners, clear identification of roles and liabilities of supply chain partners to prevent conflict, sharing risks, costs, and savings, and giving incentives and initiatives to improve performance (Lee, 2004).

Whitten et al. (2012) evaluated the Triple-A supply chain-supply chain performance relationship through a Structural Equation Modelling (SEM) methodology. They found a significant and positive relationship that supports Lee's (2004) proposal. Dubey et al. (2018) investigated supply chain agility, adaptability, and alignment and their relationship with some antecedents to them in the auto components industry. They tested hypotheses using multiple regression analysis. They demonstrated that supply chain visibility has a positive effect on supply chain agility, adaptability, and alignment. Top management commitment was found to act as a moderator in this relationship.

Several studies conceptualized supply chain agility by considering agility drivers, capabilities, and enablers. Change is the main driver of agility. Agility drivers specify the changes, agility capabilities are essential to respond to these changes, while agility enablers help to achieve capabilities.

Prater et al. (2001) revealed the relation between external vulnerability and supply chain agility, and as a result, proposed the supply chain exposure concept. They defined supply chain agility as flexibility and speed in sourcing, manufacturing, and delivery. Weaknesses make the supply chain vulnerable internally and externally. External vulnerability is caused by complexity and uncertainty. According to the case studies they conducted, it was revealed that exposure affects supply chain agility. Christopher and Towill (2001) proposed an integrated model for the agile supply chain that explains the enabling concepts within three levels. The first level showed principles that support the agile supply chain, which is postponement and rapid replenishment. The second level specified plans that should be applied to accomplish key principles. Lean production, flexible response, and quick response were proposed to achieve postponement; agile supply, organizational agility, and demand-driven supply chain were presented to achieve rapid replenishment. In the third level, actions for realizing these plans were demonstrated.

Yusuf et al. (2004) analyzed supply chain agility based on two dimensions – range of integration (from messaging to use of the Internet) and reach of information (from personal to global). They developed a conceptual model evaluating the capability of an agile supply chain. Supply chain practices indicate the type of relationship with supply chain parties, which can be categorized as traditional, lean, and agile supply chains. This model proposed that supply chain practices impact competitive objectives, change drivers, and performance. Others identified success factors critical for agile supply chain management (Power et al., 2001). Variables were grouped as participative management, computer-based technology, technology use, resource management, continuous improvement, relationship with suppliers, and just-in-time method.

A group of researchers further focused on developing agile supply chain frameworks or models to discuss the aspects of supply chain agility. For example, Ismail and Sharifi (2006) proposed a framework revealing an approach to achieving an agile supply chain. They suggested integrating two complementary concepts: design of the supply chain and design for the supply chain. In the framework, they also presented factors that affect the supply chain strategy. These factors were grouped as being related to market and business environment, product, organization, and supply chain. Lin, Chiu, and Chu (2006) developed a conceptual model based on previous studies. The model consisted of agility drivers, agility capabilities, and agility enablers. Agility enablers were considered as collaborative relations, process integration, information integration, and customer sensitivity, similar to Christopher's (2000) study. Agile capabilities are specified as responsiveness, competency, flexibility, and speed. Jain et al. (2008) presented a framework integrating several approaches. They included external vulnerability, agility drivers, agility capabilities, agility pillars, and agility enablers on a comprehensive framework by considering the supply chain agility of organizations that appear both internally and externally. However, it was unclear whether the level at which enablers are realized was supply chain or organization level according to Gligor (2014).

In a considerable portion of studies, the impact of virtual teaming and collaborative technologies on the supply chain systems was emphasized. Among these, Bal et al. (1999) investigated the implementation of virtual teaming in supply chain agility. To eliminate uncertainty in the supply chain, information on value and demand should be conveyed upstream, and information on cost and supply should be transferred downstream. Bal et al. (1999) further explain the relationship between data, information, knowledge, and expertise. Data given in a relevant context generates information that helps to gain knowledge, then competent application of knowledge produces expertise. Turbulence is considered within design, volume, mix, schedule, and process categories. To avoid turbulence, concurrent engineering and late configuration can be used; however, they have some limitations since they provide design solutions and are not efficient in other types of turbulence. Keeping stocks is another alternative; however, it is risky, especially for products with short life cycles (Bal et al., 1999). The flow of information can be improved with the help of communication technologies.

Several studies investigated the relationships between supply chain agility and its antecedents or outcomes. Agarwal et al. (2007) developed a model including supply chain variables including market sensitiveness, speed of delivery, the accuracy of data, new product launching, centralized and collaborative planning, process integration, use of information technology, reduction of lead time, improvement of service level, cost minimization, customer satisfaction, quality enhancement, uncertainty reduction, developing trust, and eliminating resistance to change. An Interpretive Structural Model (ISM) allowed them to investigate the relations among these multiple antecedent variables.

Organizational factors are also important in terms of supply chain agility. Therefore, some studies focused on these dynamics between organizations and supply chains. For instance, Braunscheidel and Suresh (2009) revealed the relation between organizational orientation, organizational practices, and supply chain agility. Organizational orientation was conceptualized to be composed of market orientation and learning orientation. Organizational practices were internal and external integration practices and external flexibility. They conducted an SEM analysis. The study revealed that market orientation has a significant effect on all organizational practices. Learning orientation was found to affect internal integration only. Organizational practices were found to impact supply chain agility positively and significantly.

There is further evidence regarding the relationship between infrastructure and supply chain agility. In this respect, Al-Shboul (2017) examined the relationship between infrastructure framework and supply chain agility, indicating all installations such as roads, railways, airports, etc., that are required to provide a flow of products and services. They employed SEM using data collected from developing countries. It was found that the infrastructure framework does not significantly affect supply chain agility. However, delivery dependability and time to market were found to act as mediators in this relationship. In another study, Mandal (2019) studied the relationship between supply chain agility and big data analytics management that covers processing data and drawing inferences. Big data analytics planning, coordination, and control were found to have a positive and significant effect on supply chain agility. This leads to the conclusion that firms dealing with big data have to develop ways for supply chain agility.

Many studies examined the effect of supply chain agility on performance. Building on the resource-based view, Ngai et al. (2011) developed a model to explain the role of supply chain agility on firm performance. They argued that organizations should have some competencies to achieve supply chain agility. These competencies were information technology competence that includes information technology integration and flexibility, operational competence that covers supply chain integration, flexibility, and learning orientation, and management competence that encompasses top management and employee competence. They conducted multiple case studies and evaluated the relations qualitatively. The positive relation between competencies and supply chain agility was supported. Al-Shboul (2017) and Ngai et al. (2011) also inferred that supply chain agility has a positive impact on firm performance.

## 3.4 Implementation of Supply Chain Agility Across Industries

Supply chain agility is of utmost importance in terms of fast responding to the changes in turbulent markets by taking the advantage of benefits and avoiding threats (Dubey et al., 2018; Li et al., 2008). Despite the common benefits, different industries have varying agile operations and take advantage of supply chain agility in different ways.

Supply chain agility is most utilized in the manufacturing industry. Supply chain agility helps manufacturing organizations to revise their prices, specs, quantity, and quality requirements as well as delivery times (Lin, Chiu, & Chu, 2006). Multiple enablers were identified for manufacturing organizations that included practices, methods, tools, and techniques. People and organizational issues were found to be the most important practices for manufacturers (Zhang & Sharifi, 2000). The study further implied that Internet, mass-customization, and virtual organizations are less employed practices by most manufacturing organizations surveyed. This leads to the fact that manufacturing organizations are more concentrated on people and organizational issues when creating agile supply chains.

In another study, Narasimhan and Das (1999) stated that the ability to manufacture and respond to change stems from appropriate selection, development, and integration of suppliers. According to the study of Power et al. (2001), the more agile manufacturing companies are more customer-focus and practice both soft and hard methodologies to meet customer expectations. Moreover, more agile companies were reported to be more active in terms of integrating suppliers in the processes to reach higher levels of customer satisfaction and use technology to promote productivity, new product development, and customer satisfaction. Many mature industries such as manufacturing and steel supply face similar challenges in terms of agility (Iskanius, 2006). In meeting these similar challenges, supply chains must be designed to be sensitive, virtual, and network-based in terms of communication and have process integration to be truly agile.

Agile transformation is a serious concern also for the automotive industry. Baramichai et al. (2006) assessed agile supply chain transformation in a corporation producing automobile parts. After careful consideration of corporation-specific practices, they concluded that the corporation had to reduce the time for supplier selection, find ways to best integrate them into the supply chain, and consider the use of more computer-based systems for order allocation and scheduling to have agility improvement. Vinodh et al. (2013) conducted a case study with an automotive component manufacturing organization to study agile supply chain performance. They proposed a set of attributes to improve supply chain performance such as material planning, adoption of time compression technologies, elimination of paperwork by IT, streamlining of the process, and coordination and cooperation. Similarly, Bal et al. (1999) investigated a major automotive manufacturer to assess agility in the supply chain. They revealed that virtual teaming is critical for the success of supply chain agility, where collaborative supply chain partners are integrated into the processes regardless of their geographic location.

Further, supply chain agility was studied in the electronics industry. Tse et al. (2016) provided a conceptual framework and collected empirical data from electronics companies. They implied that supply chain agility components should be applied together to achieve the best benefits.

Fashion, apparel, and textiles industries require an agile supply chain due to their nature of short life cycle, low predictability, high volatility, and changing customer demand (Christopher et al., 2004). Christopher et al. (2004) implied that critical lead times of fashion supply chains are time-to-market, time-to-serve, and time-to-react.

Even though the discrete manufacturing industry has been widely analyzed in terms of agility, studies in process manufacturing are a limited. The food industry mostly includes products with low shelf-life, which requires a quick response to changing customer demand. Khalili-Damghani et al. (2011) provided a conceptual model for supply chain agility including agility capabilities and enablers in the food industry. Then, they collected empirical data from diary industry companies and measured the effectiveness of agile supply chains.

The pharmaceutical industry is another one that requires agile supply chains. It is a significant industry for health and medicine; hence, it needs to provide drugs continuously with minimum delay and error (Mehralian et al., 2015). Agile supply factors in the pharmaceutical industry include delivery speed, cost reduction, quality, market research, flexibility, and use of information technology tools, which are amongst the highest-ranked priorities in terms of affecting agile supply chains (Mehralian et al., 2015).

Oil and gas industries are characterized by small- and medium-sized companies. Companies in this industry started outsourcing rather than keeping all capacity, which made supply chain integration more important. Complexity and uncertainty are inherent in the oil and gas industries. Piya et al. (2020) studied several factors affecting agility in the oil and gas industries. They came up with a comprehensive list including strategic alignment, top management commitment and support, internal collaborations within the organization, external collaboration among supply chain partners, integration of information systems technology, and applying advanced and new technology.

Along with these industries, others also investigated agile supply chains, even though, to a limited extent. The construction industry – which relates to several other industries – has significant uncertainty and volatility in the supply of materials. It is a complex and risky industry including multiple stakeholders and complex relations (Oyegoke et al., 2008). Thipparat (2010) evaluated the agility of the construction supply chain by using agility capabilities flexibility, responsiveness and quickness, competency, and cost as measurement criteria, in levels of sourcing, construction, and delivery. Then the model was applied to companies as case studies and validated. Poloie et al. (2012) examined the agility of the supply chain in mass construction. They determined criteria for agility: technology, quality, partnership, market, information technology, financial, government, and society. According to empirical data collected, they utilized the interpretive structural model (ISM). They deduced that "government" is the key criterion for agility.

However, all criteria should be at an ideal level to achieve supply chain agility. Markets were viewed as critical based on Poloie et al. (2012) criteria with "information technology" as the least important criterion in construction industry agile supply chains. Oyegoke et al. (2008) studied supply chain management from the perspective of agile specialists. Findings showed that the agile approach helped to reduce cost and time, decrease the uncertainty, and mitigate communication problems.

## 4 Emergent Concerns, Outstanding Research, and Future Directions

The supply chain agility domain includes many studies. Yet, it still has the potential for further investigation. A majority of studies focused on definitions and conceptual models using qualitative approaches (AlKahtani et al., 2019). Several measurement criteria and agility index scales were developed in a relatively limited number of studies. An ambiguity of concepts exists across studies. For example, some studies use agility capabilities for agility assessment – others also include agility enablers. There are no generally accepted agile supply chain measurement criteria. There is a lack of studies on the effectiveness and applicability of the assessment methods (AlKahtani et al., 2019). Empirical studies have utilized varying conceptual models across different industries. In some studies, supply chain agility was integrated with other concepts especially with lean. These studies aimed to provide better ways of supply chain management by combining different perspectives. The main areas observed in supply chain agility are presented along with relevant references in Table 3.

**Table 3** Summary of the research areas of supply chain agility

| Research area | Example studies | Research directions |
|---|---|---|
| Conceptual models of supply chain agility | (Christopher, 2000; Jain et al., 2008; Lee, 2004; Lin, Chiu, & Chu, 2006; Mehralian et al., 2015; Swafford et al., 2006) | Existing studies investigated supply chain agility from various perspectives. Dimensions of supply chain agility were considered in some studies. Process-based view and dynamic capability view were taken into account by some researchers. Several studies investigated supply chain agility based on different levels such as operational, organizational, strategic, and supply chain levels. However, a comprehensive conceptual model is still needed. |
| Empirical studies of supply chain agility | (Baramichai et al., 2006; Christopher et al., 2004; Iskanius, 2006; Khalili-Damghani et al., 2011; Tse et al., 2016; Vinodh et al., 2013; Zhang & Sharifi, 2000) | Manufacturing, automotive, and textile industries mostly adopted supply chain agility. Case study, interview, and questionnaire survey methodologies were mostly employed in empirical studies. |
| Measurement and assessment of supply chain agility | (Agarwal et al., 2007; AlKahtani et al., 2019; Baramichai et al., 2006; Jain et al., 2008; Lin, Chiu, & Chu, 2006; Sarkis, 2001; Vinodh et al., 2013) | Most utilized methodologies for measurement of supply chain agility were fuzzy logic, statistical analysis, analytical hierarchy process, and quality function deployment. |
| Integration of supply chain agility with related concepts | (Gunawardhana et al., 2014; Naylor et al., 1999; Qrunfleh & Tarafdar, 2013) | Agility was combined with various related concepts, for example, leanness, flexibility, resilience, green, and sustainability. It was expected to achieve competitive advantage and better performance with the integration of different management methods. |
| Enablers of supply chain agility | (AlKahtani et al., 2019; Braunscheidel & Suresh, 2009; Lin, Chiu, & Chu, 2006; Mandal, 2019; Ngai et al., 2011; Swafford et al., 2006; Tse et al., 2016; Vinodh et al., 2013; Yusuf et al., 2004) | Most commonly mentioned enablers were: Flexibility, supply chain integration, use of information technology, coordination and cooperation, transparent information sharing, flattened organizational structure, and learning organization. |

(continued)

**Table 3** (continued)

| Research area | Example studies | Research directions |
|---|---|---|
| Barriers to supply chain agility | (Shashi et al., 2020; Zhukov et al., 2019) | Most mentioned barriers were unavailability of appropriate technology, poor partnership formation, lack of top management support, and lack of human resources. |
| Relationship between supply chain agility and performance | (Al-Shboul, 2017; Ngai et al., 2011; Tse et al., 2016; Vinodh et al., 2013; Whitten et al., 2012) | Most of the studies found that supply chain agility has a positive impact on firm performance, business performance, and marketing performance. |

Investigation of the existing studies revealed some research gaps in the area. The existing studies have a narrow view mostly focusing on manufacturing. In-depth studies for the implementation of supply chain agility are needed in most industries. Because of globalization, competition, and rapid customer change, every industry is increasingly faced with changes and more vulnerable to them, which requires supply chain agility.

The literature lacks a detailed, comprehensive, and guided study. Further, the level of investigation is also important. A comprehensive model should be able to integrate supply chain, organization, and team levels. Longitudinal studies are also lacking, most of the empirical studies examine only a cross-section over time. Studying over a period could be beneficial to investigate practices deeply and draw inferences thoroughly.

## 5 Managerial Implications

This chapter summarizes the implications of the agile supply chain and provides practical examples regarding the use of agile practices. In this respect, the chapter presents a comprehensive approach to implementing an agile supply chain in terms of including supply chain partners most effectively. Organizations might benefit from the conclusions provided in this study to set up collaborative structures – across and within stakeholder groups – to enhance the agility of supply chains and develop early action towards changes to overcome supply chain challenges.

Organizations might further benefit from the strategies provided in this study to foster the use of technology in the supply chain, enhance the process and network integration, and educate management by increasing responsiveness towards changes. A critical implication is the multiple solutions, antecedents, and outcomes. Organizations will need to be able to evaluate and implement these various elements for agile supply chains. It is unlikely that one organization or even a whole supply chain can implement all these dimensions in one pass; many times, the outcomes will not meet expectations. But at what point will investment in agility in supply chains no longer be economically or operationally feasible. These complexities need to be managed carefully, and it is not clear that one project or programmatic management approach can guarantee success.

## 6 Summary and Conclusions

Agile supply chains are important in terms of creating an environment ready to handle change. Therefore, organizations must take action towards creating agile teams, integrative processes, and a strengthened network chain. However, there is a growing interest in researching the agility of supply chains and ways to improve the effectiveness of those. Therefore, this chapter focuses on the agility of supply chains by providing the comprehensive definitions of "agility" and its meaning for the supply chains.

Previous studies are investigated in terms of the models and developed for supply chain agility. Cases are provided from different industries to assess supply chain agility. The assessment of supply chain agility indicated that there are challenges with creating agile supply chains in terms of process and network integration as well as handling changes. Therefore, it is recommended that organizations set up effective working teams with the agility concepts and tools to best manage projects and sustain continuous improvement.

# Agility in the Supply Chain

Nallan C. Suresh

## Contents

**Abstract**

Today's marketplace is characterized by intense competitive pressures as well as high levels of turbulence and uncertainty. Organizations require agility in their supply chains to better manage disruption risks, ensure uninterrupted service, and provide superior value to customers. A systematic cultivation of agility is required in all segments of the supply chain, with the ability to anticipate as well as respond rapidly, in a coordinated fashion, to supply and operational disruptions. Supply chain agility is thus of value for both risk mitigation and response. This chapter provides an updated perspective on agility, based on a summary of research conducted to date, along with current and emerging managerial and research concerns. Major gaps in the literature and shortfalls in practice are summarized, along with critical needs in both research and practice domains. The research literature on agility is covered under the categories of: (1) Supply chain disruption risk management; (2) Conceptualization and evolving

## 1 Introduction

Organizations are increasingly subject to many types of disruptions, with little or no predictability. In recent years, in addition to increasing levels of competition, greater product variety and customization, shorter product life cycles, increasing customer demands, pressures to reduce cost and improve quality, businesses have also had to deal with growing levels of turbulence and unpredictability.

Global supply chains have been exposed to a wide range of catastrophes in recent years, such as earthquakes, tsunamis, hurricanes, volcano eruptions and, as experienced still, pandemics like Covid-19. These seem to occur with increasing frequency and impact. The disruptions due to the recent Covid-19 pandemic have also proved to be different to the catastrophic events of the past two or three decades, serving to expose some fundamental inadequacies in supply chain networks. The term *common cause failure* is often used in these contexts to describe a situation where a global system failure is caused by a single event with tightly coupled system components. Common cause failures, also referred to as command mode failures, are dependent on multiple failures that can be traced to one common cause (Hagen, 1980). They are often viewed as one-in-a-billion, "black swan" events. There is now a growing recognition that organizations require a proactive approach, equipped with a structured decision process to protect themselves against disruptive events.

Given an increasingly turbulent and unpredictable environment, it has been stressed that organizations must consciously develop agility in the entire supply chain to provide superior value as well as manage disruption risks and ensure uninterrupted service to customers (Christopher & Towill, 2001; Zhang et al., 2003; Chopra & Sodhi, 2004; Kleindorfer & Saad, 2005; Swafford et al., 2006). The systematic cultivation of agility in the supply chain, adopting measures to counter various types of disruption is subject to increasing attention among both researchers and practitioners. The management of disruption risks is now recognized to be an integral part of managing supply chains. It involves both: (a) *Mitigation*: actions aimed at reducing the probability of occurrence of a disruption and

(b) *Response and recovery*: measures aimed at reducing the impact of the disruption once it occurs, ensuring fast recovery back to normal modes of operation.

As we emerge from the Covid-19 pandemic, major economies of the world have witnessed an increase in consumer demand for a wide range of products, presenting favorable demand conditions that should work towards a fast economic recovery. Yet, we have been faced with major supply-side constraints that have stifled economic recovery, besides contributing to inflation. There has been a noticeable shortage in critical components like semiconductors, which has curtailed production in automotive and other industries, congestions in the US west coast ports, disruptions in major export hubs and ports in Asia, container shortages, truck driver shortages, and disruptions in the labor market due to new, post-Covid expectations regarding work-life balance and ensuing shortage of labor across industries. The need for supply chain agility based on more diversified and disruption-free supply networks has been palpably felt by many nations.

In this chapter, we present an updated perspective based on a summary of research conducted to date on supply chain agility, along with current managerial practices. We also highlight major gaps or shortfalls in practice and summarize critical needs in both research and practice domains with a view to enhancing the agility and robustness of global supply chains amidst greater turbulence and volatility.

This chapter is organized as follows. In Sect. 2, we summarize the research literature on agility under four subcategories. In Sect. 3 regarding agility, we discuss issues of importance to practitioners. This section is followed by Sect. 4 wherein we discuss major gaps in the literature as well as future research issues and evolving managerial practices. Section 5 is the next section, which outlines specific courses of action for managers for the systematic cultivation of agility. Section 6 ends the chapter by summarizing various issues covered in the chapter.

## 2 Background: Literature Review

This section provides a summary of the research literature under four subcategories: (1) Supply chain disruption risk management; (2) Evolving definitions and conceptualization of agility; (3) Flexibility, agility, and resilience; and (4) Antecedents, drivers, and impacts of supply chain agility, with a view to exploring, in subsequent sections, the managerial actions needed to cultivate and enhance agility within organizations and supply chains.

### 2.1 Supply Chain Disruption Risk Management

The management of supply chain disruption risk has received widespread attention among researchers over the last two decades, and many types of risk faced by supply chains have been identified in all areas of supply chain activity. Figure 1 shows the basic functional domains in supply chain management. The top level involves

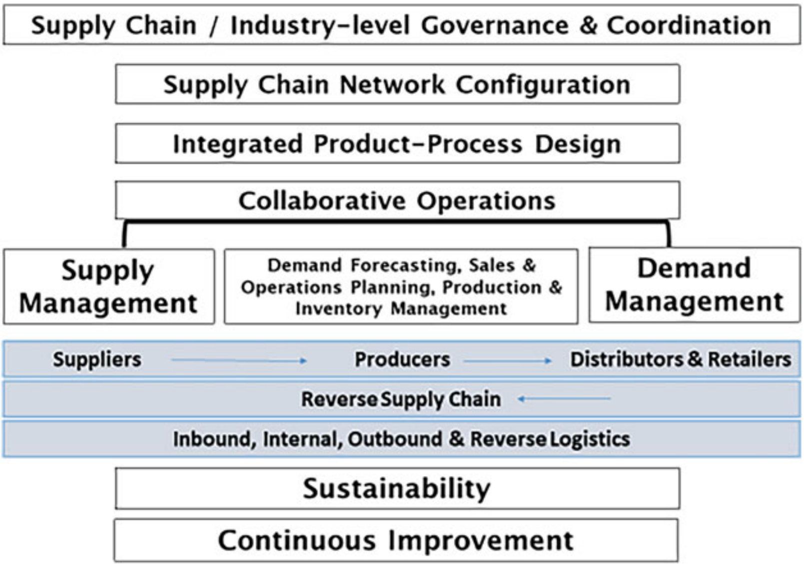

**Fig. 1** Supply chain functions

coordination among firms in a supply chain, typically via a steering committee which connects supplier firms, manufactures, distributors, and retailers. However, supply chains often tend to operate as supply chain networks, instead of linear chains, and the level of coordination among supply chain firms is often limited to a collection of individual relationships among supplier firms, manufacturers, distributors, and retailers. In addition, industry-level coordination tends to be quite inadequate, and supply chains are highly divided, as pointed out in a *Wall Street Journal* article by Smith (2020).

The next level involves supply chain network configuration decisions, often undertaken by the major manufacturers and retailers in the chain. The interorganizational development of new products and processes may be placed at the next level. For the development of new products, many firms have gone through the transition from sequential development to a process based on inter-functional integration via *concurrent engineering* over the last two or three decades. In the supply chain phase, this *inter-functional integration* has given way to an *interorganizational product and process development*, with greater involvement of suppliers and distributors in the design process via *interorganizational concurrent engineering* teams.

The fourth level involves collaborative planning and control of supply chain operations, linking supply management, production and inventory management, and demand management that are required to operate the physical supply chain, which is shown below this level. Reverse supply chain processes are seen below this, as an integral part of the physical supply chain, geared towards sustainability and circular

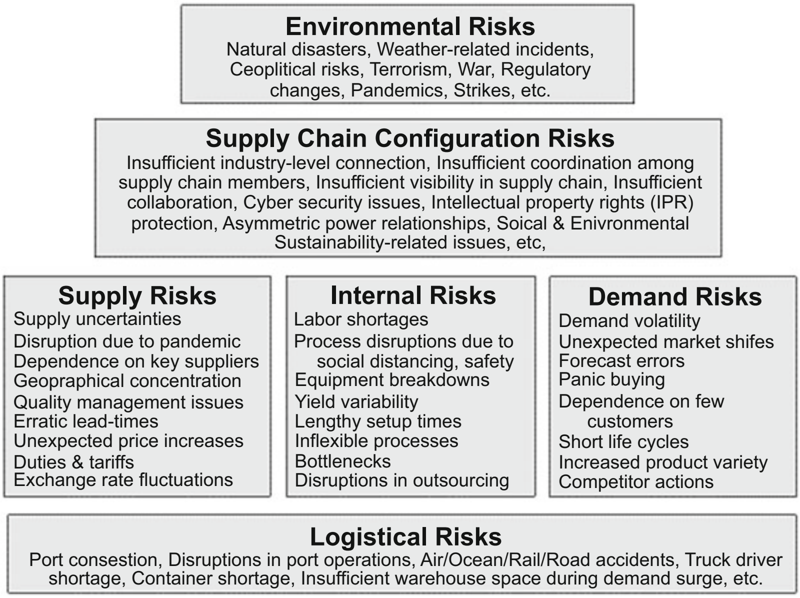

**Fig. 2** Types of disruption risks in supply chains

economy objectives. Logistics functions ensure the forward and backward flow (transportation) and storage (warehousing) of goods and services in the supply chain. Logistics activities can be categorized as inbound (procurement), internal, outbound (distribution), and reverse logistics. Sustainability goals and efforts are shown at the next level. Finally, continuous improvement efforts based on six sigma and lean-six sigma for disseminating and implementing operational performance and quality improvements appear at the bottom of Fig. 1.

Many types of risks exist in various segments of supply chain operations. These risks can be categorized as shown in Fig. 2. The supply chain, overall, is subject to, first, environmental risks which include natural disasters, weather-related incidents, geopolitical risks, terrorism, war, regulatory risks, and pandemics. At the supply chain configuration level, operational and financial risks stemming from insufficient coordination, insufficient industry-level connections, insufficient visibility in the supply chains upstream and downstream, cybersecurity vulnerabilities, weak links in the information network, and sustainability-related issues such as the presence of high carbon footprint areas in the supply chain.

In addition to the above, numerous sources of supply-side risks exist on the inbound side, stemming from supply-side uncertainties, overdependence on key suppliers, geographical concentration of supply sources, unexpected changes in duties and tariffs, exchange rate fluctuations, and other supply-related issues such as poor performance on cost, quality, delivery, flexibility, and service ("CQDFS") dimensions on the part of suppliers. Likewise, numerous sources of variability and uncertainty exist internally.

Demand-side uncertainties include unexpected market shifts, demand volatilities, and panic buying on the part consumers, as experienced by grocery supply chains during the recent Covid-19 years. As on the supply side, overdependence on key customers and geographical concentration of customers may also occur on the demand side. Finally logistical risks, shown at the bottom of Fig. 2, include the numerous sources of risk in warehousing, transportation, and other segments of international and domestic logistics, such as the recent port congestions in the US west coast ports, disruptions to export port operations in China and other Asian countries due to Covid-19, nonavailability of containers, shortage of truck drivers, customs clearance delays, to name a few.

Given the wide array of risks that global supply chains are exposed to, researchers have attempted to identify the risks comprehensively and suggested various tactics for mitigation and response. Researchers have also been developing systematic frameworks for risk management procedures (e.g., Zsidisin et al., 2005; Suresh et al., 2020) which companies can adopt to address the risks of disruption.

Table 1 summarizes recent studies that have addressed the topic of supply chain disruption risk management. Chopra & Sodhi (2004) classified supply chain risks into the risk of disruptions, delays, information systems failures, demand forecast errors, loss of intellectual property (IPR), procurement-side risks, accounts receivable risk, inventories, and capacity. These risks are summarized in Table 2. The drivers of these risks and mitigation strategies to address them have also been listed in Table 2, such as the selective provision of reserve capacity in critical areas of the supply chain, inventory buffers, multiple sourcing, provision of flexibility, and pooling of demand. Kleindorfer & Saad (2005) categorized these risks into two types: (1) risks related to supply and demand coordination and uncertainty and (2) disruption risks that are caused by such events as natural disasters, terrorism, and labor strikes. They developed a conceptual framework consisting of ten principles for supply chain risk assessment and mitigation. Tomlin (2006) makes the distinction between mitigation tactics (which are taken in advance of a disruption) and contingency tactics (response tactics which are adopted only if a disruption occurs). The adoption of volume flexibility, for instance, is viewed as a mitigation tactic that provides for the possibility of rerouting supplies after a disruption has occurred or has become imminent. The cultivation of flexibility, agility, and responsiveness has been frequently mentioned in this emerging stream of literature as a key component in the management of disruption risks. The three terms have been mentioned somewhat interchangeably. Along these lines, there have been many prescriptive articles that have identified different types of risks and different types of actions to both anticipate such risks (mitigation) and different ways by which firms can recover quickly from such disruptions if and when they occur (responsiveness).

Numerous tools and techniques for risk management, such as failure mode and effects analysis (FMEA), cause and effect (Ishikawa) charts, and Bayesian approaches, have been developed. These are applied for analyzing the causes, their possible consequence, impact analyses, and corresponding mitigation and recovery tactics. For brevity, these tools and techniques are not described here.

## 2.2 Agility: Evolving Definitions and Conceptualization

Over the years, a growing body of research, seeking to identify the defining aspects of agility, has generated valuable insights into the elements underpinning agility and, consequently, has led to an ongoing reevaluation of the definition of supply chain agility. Table 3 provides a summary of evolving definitions of agility among representative research studies, along with key elements of agility identified in the literature.

Early definitions of agility (e.g., Fliedner & Vokurka 1997, Mason-Jones et al., 2000) emphasized the importance of *sensing market opportunities* and quick understanding of customer requirements as being integral to agility, in addition to responsiveness to customer requirements. For instance, Fliedner & Vokurka (1997) defined

**Table 2** Supply chain risk categories, drivers, and mitigation tactics (From Chopra & Sodhi, 2004)

| Risk categories and drivers of risk | | Mitigation tactics |
|---|---|---|
| Disruptions | Natural disaster, labor dispute, supplier bankruptcy, war, terrorism dependency on a single source of supply | • Increase capacity<br>• Acquire redundant suppliers<br>• Increase responsiveness<br>• Increase inventory<br>• Increase flexibility<br>• Pool or aggregate demand<br>• Increase capability |
| Delays | High capacity utilization at supply source, inflexibility of supply source, poor quality or yield at supply source, increased border crossings/changes in transportation modes | |
| Systems | Information infrastructure breakdown, system integration, networking, and e-commerce systems | |
| Forecast | Inaccurate demand forecasts<br>Bullwhip effect: Information distortion due to sales promotions, incentives, lack of supply-chain visibility and consumer hoarding | |
| IPR | Vertical integration of supply chain, global outsourcing, and markets | |
| Procurement | Exchange rate risk, percentage of a key component or raw material procured from a single source, industry-wide capacity utilization, long-term versus short-term contract | |

agility to be "the ability to offer low-cost, high quality products with short lead times, varying volumes to provide enhanced value to customers through customization, utilizing: (1) enriching the customer (quick understanding of customer requirements and providing them); (2) cooperating internally and externally to enhance competitiveness; (3) organizing to master change and uncertainty; and (4) leveraging people (training and empowerment) and information." However, in later years, definitions of agility tended to focus somewhat more on the responsiveness dimension.

Swafford et al. (2006) defined supply chain agility as the capability to adapt or react to marketplace changes, or seize/exploit opportunities with speed and quickness. Fliedner & Vokurka (1997) contended that firms can no longer gain competitive advantage by positioning themselves at a particular point on the *product-process matrix*. Instead, due to the presence of dynamic markets, shorter product life cycles, and a faster pace of innovation, firms will need to become agile and simultaneously deliver on the basis of cost, quality, dependability, and flexibility. Naylor et al. (1999) advanced the notion that both lean and agile paradigms need to be adopted (as "leagility") in supply chains, separated by the decoupling point between push and pull systems.

Mason-Jones et al. (2000) asserted that organizations first need to identify and understand the requirements of the marketplace before embarking on reengineering programs. Christopher & Towill (2001) presented conceptual arguments to define agility as a business-wide capability that embraces organizational structures, information systems, and mindsets along with four characteristics vital to an agile supply chain: market sensitivity, information-based (vs. inventory-based) posture,

becoming a fully linked network, and collaboration among partners. Agarwal et al. (2006) sought to demonstrate that supply chain performance is improved if it is able to respond quickly to changing customer demand, while reducing costs. They found that supply chain agility depends on customer satisfaction, quality and cost improvements, delivery speed, new product introduction, and service level improvement. Narasimhan et al. (2006), in distinguishing between agility and leanness, defined agility as the ability to efficiently change operating states in response to uncertain and changing market conditions. This definition clearly has a response, as opposed to mitigation orientation.

In subsequent years, both *sensing and responding* capabilities came to be emphasized as essential elements of agility (e.g., Overby et al., 2006; Roberts & Grover, 2012). These later studies have argued that, in addition to being responsive, supply chains should also be alert and sensitive to market changes, requiring an explicitly defined set of routines, referred to as sensing capability. The notion of sensing has been emphasized in strategy literature as the role of market knowledge and capabilities that enable a firm to stay "ahead of the market and succeed" in fast-changing markets (Zaheer & Zaheer, 1997; Swafford et al., 2008). Gligor et al. (2013) modelled supply chain agility as a second-order construct consisting of five elements: alertness, accessibility, decisiveness, swiftness, and flexibility. These five elements were found to be operable as constituent dimensions of agility. The five dimensions were not found to be distinct dimensions of agility. Gligor et al. (2015) identified five dimensions of agility: alertness, accessibility of relevant data, decisiveness, swiftness, and flexibility.

Swafford et al. (2006) made theoretical arguments that agility is an externally facing *capability*, drawing from many types of flexibility that are internal *competences*. They found that an organization's supply chain agility is directly influenced by the degree of flexibility in manufacturing and procurement/sourcing and is indirectly influenced by distribution/logistics.

Supply chain agility was defined in terms of a *firm's* supply chain agility (FSCA) (Braunscheidel & Suresh (2009)). It is the capability of a firm, internally, and in conjunction with key suppliers and distributors, to adapt or respond in a speedy manner to changing markets, contributing to agility of supply chain. FSCA was again seen as a capability, drawn from flexibility competences to provide both mitigation and response characteristics to the supply chain.

In the work of Eckstein et al. (2015), a distinction was made between agility and *adaptability*. Supply chain agility was again seen to consist of sensing and responding dimensions. However, *agility* was viewed as a short-term capability, while adaptability was defined as a long-term capability of being able to reconfigure the supply chain in response to longer-term changes.

Based on these updated perspectives, a firm's supply chain agility may perhaps be defined as the capability, both internally and in conjunction with its supply and distribution partners, to both sense and respond in a speedy and cost-effective manner to marketplace and environmental changes in the short and long term, with the ability to reconfigure and adapt the supply network.

## 2.3 Flexibility, Agility, and Resilience

Prior to the notion of supply chain agility, many types of flexibility were identified with the advent of flexible manufacturing systems (FMSs) in the 1980s. Starting with the early work of Slack (1983), many taxonomies of flexibility were developed. Slack (1987) defined flexibility as the range of states a system can adopt, along with the ease, time, and cost with which changes can be made within the capability envelope. Based on this essential notion, many other types of flexibility were identified: machine, labor, product, mix, process, routing, and volume flexibilities, to name a few. An evolution of the notion of flexibility can be found in the works of Gerwin (1993), Slack (1987), Sethi & Sethi (1990), Gupta (1993), Upton (1997), Koste & Malhotra (1999), Vokurka & O'Leary-Kelly (2000), D'Souza & Williams (2000), and Zhang et al. (2003).

With the subsequent focus on agility, flexibility came to be differentiated with agility. Based on the *competence-capability paradigm* in strategy literature, Swafford et al. (2006) argued that flexibilities are internally oriented *competences*, while agility is an external-facing *capability* of an organization. Thus, supply chain agility came to be regarded as an externally focused capability that is derived from the many flexibilities in supply chain processes, which in turn were viewed as internally focused competencies. Based on these arguments, agility and flexibility were deemed to be distinct, yet related concepts, with flexibility being an antecedent of agility (Swafford et al., 2006).

Flexibilities themselves have been categorized as internal- and external-facing flexibilities based on the competence-capability relationship (Zhang et al., 2003). Flexibilities were established to be important antecedents of agility, but other initiatives like supply chain integration with suppliers and distributors were also seen to be antecedents of agility (Braunscheidel & Suresh, 2009). The systematic cultivation of supply chain agility has come to be viewed as an essential means for coping with the increasingly volatile conditions faced by businesses.

In addition to flexibility and agility, a third, parallel stream of literature has been aimed at augmenting supply chain *resilience*. Resilience has been defined as the capacity of an enterprise to survive, adapt, and grow in the face of turbulent change (Fiksel, 2006). Resilience involves improving the adaptability of global supply chains, collaborating with stakeholders, and leveraging information technology to assure continuity, even in the face of catastrophic disruptions. Resilience goes beyond risk mitigation, enabling a business to gain competitive advantage by learning how to deal with disruptions more effectively than its competitors, and possibly shifting to a new equilibrium (Fiksel et al., 2015) (Table 4).

The concept of resilience has a distinct orientation towards *fast recovery from disruptions*. Several antecedents for supply chain resilience have been identified, which include firm-level resilience, risk management infrastructure, and resource reconfiguration capability. Compared to agility – which may be seen as a means to an end – resilience may be argued to represent the end goal itself (Suresh et al., 2020). It has been recognized within this literature that a lack of a unified definition of resilience has contributed to ambiguity of the concept of resilience relating to supply chain disruptions (Bhamra et al., 2011; Ambulkar et al., 2015).

**Table 4** Definitions and representative studies in flexibility, agility, and resilience

It has been pointed out that in today's global business environment, supply chains have increased in both length and complexity. This increase in length and complexity, coupled with a focus on improving efficiency, such as lean manufacturing practices, may lead to higher levels of supply chain risk where the likelihood of a disruption severely impacting supply chain performance increases. Resilient supply chains have been touted as a means to reduce the likelihood and severity of supply chain disruptions. However, there is little empirical evidence relative to the factors that contribute to or detract from supply resiliency (Blackhurst et al., 2011).

There has been clearly an overlap between the notions of supply chain agility and supply chain resilience. Gligor et al. (2019) have identified the unique themes in both streams of research as well as the overlapping elements. First, they identifies six major dimensions that capture agility: ability to quickly change direction, speed/accelerate operations, scan the environment/anticipate, empower the customer/customize, adjust tactics and operations (flexibility), and integrate processes within and across firms. Similarly, six dimensions were uncovered for resilience: the ability to resist/survive disruptions, avoid shocks altogether, recover/return to original form following disruption, speed/accelerate operations, adjust tactics and operations (flexibility), and scan the environment/anticipate. Agility and resilience were found to share three common dimensions: the ability to adjust tactics and operations (flexibility), speed/accelerate operations, and scan the environment/anticipate. Thus, while the distinction between flexibility and agility has become clear, thanks to works such as Swafford et al. (2006), the concepts of agility and resilience are yet to be clearly differentiated.

## 2.4 Antecedents, Drivers, and Impacts of Agility

Besides research on conceptualization of agility, as seen above, a significant amount of research has been conducted on two other key agility aspects: (1) antecedents or drivers of agility and (2) impact of supply chain agility on operational and financial performance. A few studies have investigated both antecedents and performance outcomes. Table 5 summarizes representative studies on both themes, summarizing the independent variables (IVs), dependent variables (DVs), and key findings of each study, which may be of interest to researchers.

However, in this section, a slightly practitioner-oriented summary is presented, in order to indicate the sets of practices that may be utilized by executives to cultivate agility in their firms and supply chains, and the sets of practices that may lead to tangible performance outcomes. We categorize these antecedents and drivers broadly under the following categories: (1) internal integration; (2) external integration with suppliers and customers; (3) flexibility; (4) sensing capabilities; (5) lean management practices; (6) information and communication technologies; and (6) cultural antecedents.

## Internal Integration

Internal integration refers to cross-functional integration, representing practices that allow organizational functions to coordinate and cooperate with one another (Braunscheidel & Suresh, 2009). Internal integration involves the use of cross-functional teams, internal communication regarding goals and priorities, openness and teamwork, and the use of formal and informal meetings. Internal integration has been studied extensively in past research on supply chain performance. Several studies have suggested that internal integration is also a necessary first step before integrating externally with suppliers and customers (e.g., Vickery et al., 2003).

There is now a vast amount of research literature on the impacts of both internal and external integration measures on operational and financial performance. Useful summaries of this extensive body of literature are found in works such as Mackelprang et al. (2014). However, there have been far fewer studies on the impact of internal and external integration on supply chain *agility*, as opposed to *operational and financial performance*. We focus here on the impacts of supply chain integration on agility.

## External Integration with Suppliers and Customers

A second important supply chain initiative, external integration, represents activities and practices that coordinate the flow of information and goods with upstream and downstream members of the supply chain (Braunscheidel et al., 2010). Strong external integration enables a coordinated preparation for contingencies as well as a coordinated response on the part of the supply chain members to act in times of disruption.

There has been a significant amount of research on integration with customers and suppliers and its impact on supply chain performance, but not enough on agility. A study of German multinational firms by Blome et al. (2013) concluded that there is a direct relationship between supply-side and demand-side competences with supply chain agility.

Braunscheidel & Suresh (2009), employing a second-order construct of external integration, identified a pathway from external integration to supply chain agility. Thus, there is strong evidence that internal and external integration enable the supply chain to act in a coordinated fashion to address both mitigation and response aspects of supply chains, and hence contribute to agility.

### Flexibility

Flexibilities may be classified as internal flexibilities (deemed as competences in the work of Swafford et al., 2006) and external flexibilities, which, like agility, may be viewed as capabilities. Zhang et al. (2003) classify flexibilities thus as internal and external flexibilities within a competence-capability framework.

The two outward-facing flexibilities of mix and volume flexibility have been shown to be direct antecedents of agility in Braunscheidel & Suresh (2009). Mix flexibility is the ability of the organization to produce different combinations of products economically and effectively, given a certain capacity (Zhang et al., 2003). Mix flexibility is measured as the ability to produce a wide variety of products and different product types without major changeovers, or different products in the same plant with speed and quick changeovers. Volume flexibility is defined as the ability of an organization to operate at various levels of output without compromising the performance of the system with respect to cost, quality, or service (Zhang et al., 2003). It enables the firm to operate profitably at different levels of production and to change production quantities easily, swiftly, and cost effectively.

Thus, given a wide range of different flexibilities – such as machine, labor, process, routing, mix, and volume flexibilities – achieving the right mix and balance of these types of flexibilities within organizations is recognized to be a foundational requirement for agility in the supply chain.

### Sensing Capability

Sensing capability refers to the ability to detect or sense opportunities and threats. Sensing involves the systematic acquisition of information about buyers and competitors in target markets, and disseminating the information throughout a business and its partners. Sensing pertains to activities such as gathering market intelligence, monitoring government relations, legal, research and development (R&D), and information technologies (IT).

Many studies have emphasized the role of market knowledge and capabilities that enable firms to stay "ahead of the market and succeed" in fast-changing markets (Zaheer & Zaheer, 1997; Swafford et al., 2006). Naylor et al. (1999) argued that market knowledge helps firms to figure out proper supply chain strategies to pursue by exploiting profitable opportunities in a volatile market place. Sensing enables an organization to anticipate as well as react more quickly and effectively to marketplace volatility and other uncertainties. Firms that are more market-sensitive are also better able to synchronize supply with demand and are able to achieve higher customer service levels. A greater level of sensing also enables a firm to produce more innovative products that are better aligned with customer needs (Overby et al., 2006).

### Lean Management Practices

Lean management practices, as articulated in the seminal work of Womack et al. (1990), have been widely adopted in practice. Lean is associated with the elimination of waste from all processes within a firm and in the extended supply chain. Lean supply chains often operate with tightly coupled systems with very little slack. This goal may come at the expense of agility, rendering supply chains more vulnerable to disruptions. It has been pointed out that in today's global business environments, supply chains have increased in both length and complexity. This situation, coupled with a singular focus on improving efficiency using lean manufacturing practices, may lead to higher levels of supply chain risk where the likelihood of a disruption severely impacting supply chain performance increases (Blackhurst et al., 2011).

However, it may be noted that the bundle of practices associated with lean also includes action steps such as reduction in setup times, faster changeovers, labor flexibility and cross-trained workforce, and dynamic scheduling – each may contribute to agility in other ways. It is perhaps an injudicious and across-the-board pursuit of waste elimination through inventory reduction, limited reserve capacities, and other types of waste elimination that has contributed to the current rethink of lean practices amidst global supply disruptions.

### Information Systems and Technologies

The important role of information and communication technologies (ICT) in supply chain planning and operations is well recognized, and many important research studies have investigated the impacts of IT on supply chain performance. Focusing on agility, however, important studies in the information systems (IS) literature addressing supply chain agility include the works of Chakravarty et al. (2013), Liu et al. (2013), Lu & Ramamurthy (2011), Qrunfleh & Tarafdar (2013), Tarafdar & Qrunfleh (2017), and Vickery et al. (2010).

Information and communications systems form the glue that holds supply chains together. They contribute both towards sensing capability – for the acquisition of business intelligence information – and rapid dissemination of the information throughout the supply chain. They also contribute to fast response and recovery capabilities in the event of a disruption. Thus, the important role of ICT for both mitigation and response is clear. In addition, information systems and technologies are utilized both at strategic and tactical levels, and for both *exploitative* and *exploratory* functions. During exploitation, firms use their existing knowledge to enhance organizational efficiency. On the other hand, during exploration, firms search for new knowledge, develop new products and services for emerging customers and markets, and enhance their innovation performance (Benner & Tushman, 2003).

Works such as Tarafdar & Qrunfleh (2017) have investigated the complementary roles of supply chain practices and information systems capabilities for realizing supply chain agility. Vickery et al. (2010) have investigated two competing models wherein IT and supply chain organizational initiatives may have separate or complementary effects on supply chain performance, with supply chain agility acting as a moderator. The model with the complementary effects was seen to fit the results better. Liu et al. (2013) categorized agility into two types: *market-capitalizing agility* and *operational adjustment agility*, and demonstrated the positive impacts of IT on organizational agility. The IS literature has made important contributions towards a better understanding of agility. A better integration of IS literature and operations management (OM) literature devoted to agility appears to be in order.

### Cultural Antecedents

There has been very little investigation on organizational culture pertaining to supply chain performance and agility. In the work of Braunscheidel & Suresh (2009), the impact of two organizational culture variables, *market orientation* and *learning orientation*, were shown to be indirect antecedents of agility. Supply chain efforts clearly involve major cultural changes such as the establishment of trust, a shift from adversarial relationships to collaboration, and partnership among buyers and sellers in the supply chain. It was found that market orientation has a significant influence on both internal integration and external integration with key customers and key suppliers, and a moderate influence on external flexibility. Learning orientation was seen to strongly influence internal integration, which in turn was seen to significantly affect supply chain agility.

In Braunscheidel et al. (2010), the competing values framework (CVF) of Quinn & Rohrbaugh (1983) was utilized to test whether the four organizational culture types of *adhocracy, clan, hierarchy, and market* are related to supply chain internal and external integration practices, and their effects on delivery performance. It was found that a firm's clan cultural score had no effect on any of the integration practices. However, a firm's adhocracy score strongly affected external integration practices, while the firm's market characteristics had a mild influence on these same practices. Finally, the hierarchy score was found to strongly influence both internal and external integration practices, but in a negative way. Thus, firms exhibiting a strong hierarchical culture tended to have lower external integration. Overall, more research on organizational culture aspects on supply chain performance and agility would be fruitful.

## 3 Current Concerns

From a practitioner standpoint, some major concerns facing global supply chains include the following.

***Increasing unpredictability and a seeming inability to anticipate the next disruptive event***. Supply chain disruptions appear to be occurring more frequently, with increasing impact and unpredictability, ushering us into an *era of unknown unknowns*. This new era clearly calls for superior environmental scanning to anticipate possible climate change events, geopolitical changes, unforeseen changes in economic and global trade issues, acts of nature like earthquakes, tsunamis, volcano eruptions, or asteroid hits, and human-induced incidents like war and terrorism. But, despite the sophistication of the scanning methods used, some events may simply not be predictable. Businesses have to face that reality and plan for contingencies on that basis. No matter what the next disruptive event turns out to be, it will involve supply disruption *in one or more arcs in the network*, *one or more nodes being incapacitated*, a combination of both, or the entire network being incapacitated. Contingency planning based on risk and impact assessments on that basis, along the lines of FMEA and various other tools is warranted.

***Need for structured processes for risk management***. Numerous tools and techniques for risk management, such as FMEA, Ishikawa charts, and Bayesian approaches, have been developed. These are being applied for analyzing the causes, their possible consequences, impact analysis, and corresponding mitigation and recovery tactics. But, despite the availability of numerous tools and techniques for risk management, it is clear that organizations and supply chains are striving for a more structured approach to risk management. Business continuity management (BCM) (Zsidisin et al., 2005) and ISO 22301 of the International Organizations for Standardization (ISO) have served to provide such structured methodologies.

***Need for greater coordination at supply chain and industry levels***. This need has been particularly evident lately. For instance, when consumers could not venture out to eat at restaurants during the Covid-19 disruption, the demand for food products reduced in restaurant channels, giving way to higher demand in grocery supply chains. However, this shift of products across the channels could not be easily effected, due to insufficient coordination at the industry level, contractual rigidities, different packaging requirements, safety standards, etc. (Smith, 2020). Likewise, there is a pronounced need for greater coordination and governance of firms at the supply chain level.

***Need for diversifying global supply networks***. It is also realized that the pursuit of cost efficiencies has led to greater reliance on production in low-cost regions and, in addition, production consolidations in these regions to realize economies of scale. This consolidation has resulted in a concentration of production in low-cost countries and an overreliance on a limited set of suppliers. The recent shortages in semiconductors have been attributed to one large firm in Taiwan, namely TSMC, dominating the supply source, for instance.

***Need for balancing leanness with agility***. There is a growing sense that the pursuit of leanness, eliminating all types of waste, such as excess inventory and capacity wastage, has also rendered globally extended supply chains more vulnerable to disruptions. The disruptions in grocery and food supply chains during Covid-19 have tended to make this clear (Gasparro et al., 2020).

Many of these concerns came to the fore recently in the food supply chain and grocery industry, and the supply of medical devices. In the case of grocery chains, demand volatility, caused by panic buying and hoarding on the part of consumers, led to unexpected shortages of items such as sanitizing wipes and toilet tissues. The industry was caught by surprise, even though grocery chains have been making impressive advances in supply chain management over the years, offering a plentiful and affordable supply of a wide variety of products to consumers. However, the industry has become too lean in recent years, operating with low inventory levels, sacrificing agility and resilience (Gasparro et al., 2020).

Grocery chains found that the lessons learned from the past, the era of hurricanes, were ineffective in handling pandemic situations, which have proved to be different. In the case of hurricanes, demand surge for products can be met by shipments from other, unaffected regions. But in a pandemic, there is a demand surge across the nation, or even globally, limiting shipments from other regions. Pandemics impose constraints on the supply side as well, by having to ensure safer working conditions and social distancing, thereby reducing the ability to scale up production quickly.

The grocery chain industry has also revealed a distinct lack of coordinated response within supply chains. Such supply chain-wide organization, leadership, and coordination through steering committees at supply chain or industry levels. Other factors, such as contractual rigidities in supply chains, have contributed to the inability to redistribute supplies from restaurant channels, which experienced a downturn in demand, towards consumer channels, which faced demand surges (Smith, 2020).

Likewise, the absence of risk management procedures across the supply chain has also been evident. A systematic examination of risk, impact assessments, and contingency actions in all stages of the supply chain is warranted. The vulnerabilities in the upstream, supply network become evident in the case of supply chains for medical devices. Medical devices like ventilators, masks, and personal protection equipment (PPE) rely on a globally dispersed supply chain, originating from global regions which have themselves been affected by the virus, thereby limiting supplies. The risks emanating from overreliance on a limited number of suppliers or distributors, excessive concentration of suppliers, distributors, and other entities in distant geographical regions, etc., can be avoided by systematically examining the risks in all segments of supply and distribution.

## 4 Emergent Concerns: Research Gaps and Future Directions

On the research front, many useful contributions have been made over the years to enhance our understanding of the issues pertaining to agility. Many types of supply chain risks have been identified, numerous tools and techniques have been developed to mitigate risks and enable fast recovery after disruptions, and structured frameworks have been developed for practitioner use (e.g., Ho et al., 2015). However, there are some major gaps in the research literature, and some of these are identified below as emergent concerns, along with suggestions to narrow the gaps between research and practice.

***Dominance of cross-sectional research.*** In the research methodologies employed so far, cross-sectional survey research has tended to dominate, coupled with case study research. The limitations of cross-sectional research are well known: the results pertain to one moment in time; cross-sectional studies often rely on responses elicited from a single, key respondent within an organization; they are based on subjective assessments, with limited validation with objective data; the risk of common method bias; and the responses being limited to one firm within the supply chain.

Causal effects pertaining to agility initiatives and their antecedents may be better captured in longitudinal studies. The use of longitudinal assessments poses some challenges, and secondary data may be hard to obtain for agility and related constructs. However, there has been research employing announcements of supply chain glitches and disruptions, and the impact on financial performance has been assessed through event-study methodology (e.g., Hendricks & Singhal, 2012).

Case studies may also perhaps be employed to discern longitudinal and causal effects, and there is definitely a need to supplement current investigations with more structured, case-study investigations in this field. The extent of case study investigations on flexibility, agility, and resilience is undoubtedly limited, compared to the extent of case study usage in the sustainability field, for instance. Thus, there is a need for broadening the methodological base for empirical research in this area.

***Research silos.*** Research on supply chain agility and research on resilience have proceeded somewhat independently, and there is a clear need to reconcile, and perhaps unify both streams under a common theme. Agility research has been an outgrowth of research on flexibility, whereas research on resilience appears unconnected to flexibility literature. Studies on resilience also have a distinct orientation towards response and recovery from catastrophic disruptions. Gligor et al. (2019) have attempted to reconcile both streams of literature and have identified common themes, as mentioned earlier. However, more studies are warranted for this effort. Likewise, there is a noticeable gap between OM and IS literatures on agility, and this is another area requiring some integration.

***Need for empirical research on supply chain governance and industry-level coordination.*** Though a voluminous body of empirical research has emerged on supply chain integration and coordination, there is a significant gap in our knowledge on how firms in a supply chain are actually coordinating with each other. The advent of Covid-19 disruptions has served to identify such a lack of coordination, both among firms in a supply chain and among supply chains within a given industry (Smith, 2020).

Though the use of steering committees has been advocated by academic researchers, it is not clear to what extent firms actually use steering committees to coordinate activities in supply chains. There is also insufficient research on the organizational aspects of collaboration initiatives such as vendor-managed inventory (VMI) and collaborative planning, forecasting, and replenishment (CPFR) systems, and to what extent they may contribute to agility and resilience. The fact that real-world supply chains operate more as supply networks, than as linear chains, perhaps accounts for the insufficient amount of higher-level coordination.

***Need for research on the use of risk management techniques.*** It is also not clear to what extent firms and supply chains actually utilize the numerous risk management tools that have been developed. Though the use of stress tests and simulations has been advocated for resilience preparation, for instance, it is not clear to what extent supply chains actually use them. More research is also needed on the extent of use of structured risk management approaches like business continuity management (BCM) and implementation of standards such as ISO 22301 (Suresh et al., 2020).

***Gaps in the literature.*** Despite the proliferation of studies on supply agility, there are also some noticeable gaps. These include the dearth of studies on organizational culture and behavioral antecedents of agility. There is also a need for more studies on the use of technologies such as the internet of things (IoT) and blockchains and their impacts on the agility of a supply chain. In the event of a disruption in the food and agribusiness supply chains, it is known that blockchains enable fast traceability of the source of contamination or defects and facilitate fast remedies. Such technologies enable both mitigation and response efforts. Industries also lack guidance currently on how to design and effect the tradeoffs between leanness and agility in various parts of the supply chain. There is also an insufficient base of quantitative modeling on agility, despite a profusion of risk analysis models.

In addition, there is also a need for more contingency research on the impacts of agility in specific situations such as specific national cultures and countries or specific industries. Past research has employed cross-sectional surveys covering a wide range of industries, and it would be of interest if these generally established research results hold in specific industries and contingent contexts. The studies of Blome et al. (2013: Germany), Yang (2014: China), Fayezi et al. (2015: Australia), Dubey et al. (2018: Indian automotive industry), Yusuf et al. (2014: oil & gas industry), and Jahed et al. (2021: Bangladesh fast fashion apparel industry) may be included under this category of research on contingent effects. More such studies are warranted.

## 5 Managerial Implications

We next summarize the managerial implications as a broad set of actions needed on the part of supply chain executives to ensure agility in all segments of supply chain activity, generally in the order shown in Figs. 1 and 2.

***Environmental and Supply Chain Configuration-Level Initiatives.*** Consistent with supply chain management principles developed over the last two decades, firms are expected to actively share information with upstream and downstream partners, maintain visibility of demand forecasts, inventory information, production plans, etc., with suppliers and distributors.

A high-level steering committee, consisting of senior executives of upstream and downstream partner firms, may be created first to provide governance and overall direction to supply chain coordination and improvement efforts. Supply chain-level coordination procedures, such as the ones advocated by Lambert et al. (1998), are particularly useful at this level. The supply chain steering committee may consist of key members who are the major value-adding firms in the chain. This high-level committee systematically examines the supply chain flows to identify points of vulnerability in terms of supply and distribution. At this level, environmental scanning to anticipate potential disruptions may be undertaken to mitigate environmental risks. In addition, network decisions, such as avoiding excessive concentration of production in the hands of one or a few suppliers and avoiding excessive geographical concentration of supply sources, may be addressed.

A map of the supply chain should be examined carefully to identify redundancies in capacity and inventory buffers at critical positions to prevent possible disruptions. Sources of uncertainty must be examined systematically in all segments of the supply chain and their root causes must be addressed for mitigation, prior to developing contingency plans to react after disruptions occur. A useful tool to identify potential risks and estimate the probability of occurrence and their consequences is a supply chain vulnerability map or a subjective risk map. By employing inter-functional and interorganizational teams, a comprehensive vulnerability map can be constructed. This enables the supply chain to not only identify potential risks but also enables the preparation of contingency plans that can be implemented in advance of a disruption.

The identification of potential risks enables the prioritization of risks, the identification of controllable and noncontrollable risks, and the ability to assess the cost of mitigating risk exposure with the benefits of reduced risk exposure (Van Mieghem, 2012). The supply chain map can also be utilized to identify high-impact areas to implement supply chain improvements or identify high carbon footprint areas, as examples.

Supply chain optimization and initiatives such as form postponement (delayed differentiation) and logistics postponement have been advocated for ensuring agility and fast response to changing customer demands. Postponement strategies, by virtue of delaying product differentiation as close to the customer as possible, help reduce the supply-demand mismatch that many global supply chains have to cope with. Under normal circumstances, postponement improves the capability to manage supply, while during a disruption event, it enables a firm to change the configuration of different products quickly (Tang, 2006).

Systematic sharing of information, as part of initiatives such as vendor-managed inventory (VMI), collaborative planning, forecasting and replenishment (CPFR) systems, etc., also involves sharing of demand forecasts and operating plans with other supply chain partners, and they contribute to mitigation as well as coordinated response on the part of the supply chain members. In many situations, the integration and synchronization of planning and execution of production plans via VMI, CPFR, or similar initiatives can minimize and/or eliminate disruptions caused by demand-supply mismatches.

***Internal Integration.*** Managerial actions pertaining to internal (inter-functional) integration may lead to a connected and more coordinated response to marketplace changes and disruptions. Internal integration has often been mentioned as a necessary first step in supply chain integration process (Vickery et al., 2003). Vickery et al. (2003), in a study of the automotive supply industry, found that there is a positive, causal relationship between integrative information technologies and supply chain integration, comprising both horizontal integration (within a firm) and vertical integration (with suppliers and customers).

Firms with high levels of internal integration have cross-functional teams that include members of operations, marketing, procurement and logistics, and other functions. In addition to being knowledgeable about real and potential risks, functions must coordinate with one another to ensure a smooth flow of products to their customers in normal times as well as when disruptions occur. Thus internal integration is beneficial during normal operations as well as when disruptive events occur.

***External Integration with Upstream Suppliers.*** In order to ensure a connected response on the part of suppliers, to potential and actual supply chain disruption, many supply-side integration measures can be undertaken. These are normally the same set of measures needed to ensure better supply network performance: frequent sharing of information with suppliers, greater transparency, sharing of inventory information, providing frequent, constructive feedback on quality and delivery performance, striving to establish long-term relationships with suppliers, working with suppliers to seamlessly integrate interfirm processes, joint development of new products/services, and joint operational planning. One of the potential benefits of providing quality improvement feedback and integration of interfirm processes is the identification and elimination of problems before they arise. Elimination of potential problems through process improvement is better than mitigating the impact of these problems (Van Mieghem, 2012).

It is also critical to have an extended view of the supply network and business intelligence pertaining to the upstream supply network. Many major supply disruptions and adverse incidents of safety or unfair labor practices have occurred due to suppliers who are two or three tiers upstream, and downstream firms do not have a sufficiently deep understanding of upstream supplier activities.

***External Integration with Downstream Customers.*** As for integration with upstream partners, integration with downstream partners also involves information sharing, and frequent inputs on demand trends and marketplace changes from downstream partners. A well-developed sensing mechanism, geared towards eliciting early market signals, serves to prepare upstream partners to anticipate and be prepared for changes. These measures also include the conventional demand-side integration tactics such as feedback elicited from customers on quality and delivery performance, frequent gathering of market signals, downstream partners being actively involved in new product development process, frequent sharing of demand information from customers, sharing of production plans and inventory levels with downstream partners, joint production planning with downstream partners as important elements in logistics planning, and information integration with downstream organizations.

***Cultivation of Flexibility.*** Many types of flexibility have been identified – such as machine, labor, process, routing, volume, and mix flexibilities – and they have been shown to be critical, competence elements of agility. Some of these are externally focused, like mix and volume flexibilities, and they affect agility performance of a firm and supply chain directly. These flexibilities involve capabilities such as the ability to operate efficiently at different levels of output, ability to operate profitably at different production volumes, ability to quickly change production quantities, and volumes of a process, the ability to produce a wide variety of products, and the ability to produce different product types with little or no changeover. Many of these flexibilities are created during the implementation of lean manufacturing systems. The bundle of lean practices includes reduction of setup times, single-minute exchange of dies (SMED), cross-training of the workforce, and designing versatile tools for a wider range of parts and machine operations.

In this context, even though lean manufacturing involves the cultivation of many flexibilities that contribute to agility, it also involves the systematic elimination of waste, especially reduction in inventory buffers, demand-driven (pull) systems, and tightly coupled systems that have rendered global supply chains more vulnerable to disruptions. Thus, going forward, lean implementation has to be judiciously pursued, without compromising resilience.

***Organizational Culture and People***. Finally, it is also important to address organizational cultures and individual behavioral attributes that are conducive to agile supply chains. Cultural traits such as market orientation and learning orientation have been shown to be indirect antecedents to agility (Braunscheidel & Suresh, 2009).

Firms with a high market orientation closely monitor the needs of customers and pay close attention to the competitive landscape in terms of the strengths and weaknesses of current and potential competitors. They provide strong sensing capabilities so that organizations can be alert and they swiftly seize opportunities which arise.

Likewise, a firm's learning orientation has a direct effect on internal integration, so that firms learn to work more effectively in a cross-functional manner. Another key advantage of possessing a learning orientation is the ability for organizations to learn from disruption events. Organizational culture types such as adhocracy – as opposed to clan and hierarchy – are desirable firm characteristics in terms of being agile. Firms that possess the attributes of an adhocracy culture may be better suited to sense and recover from disruption situations.

When highly uncertain, low probability events occur, employees may need to operate *on the fly* with real-time information of the particulars of the event. Such situations require employees to take some risks as they try to respond to disruption in real time. If an organization is highly structured, with too many formal rules, first responders to the disruption may defer to higher levels for guidance on to how to handle the disruption, thereby losing valuable time. Thus, many managerial implications of value can be drawn from the set of antecedents mentioned earlier in Sect. 2.4.

## 6 Conclusions

In this chapter, the critical issue of agility in the supply chain was addressed by summarizing the research literature along with managerial practices required for the systematic cultivation of agility in the supply chain. This chapter has attempted to provide an updated perspective on agility, synthesizing agility-related research from both operations management and information systems literature. Current and emerging managerial concerns were also addressed, along with major gaps in the literature and shortfalls in practices.

The topic of supply chain agility was directed towards a risk management initiative that enables a firm to anticipate as well as respond rapidly to marketplace changes and disruptions in the supply chain. Disruptions may have numerous impacts on supply chain performance. The scope and magnitude of the consequences of these disruptions require intra- and inter-functional, as well as interorganizational coordination and communication.

This chapter has provided an updated perspective of an emerging body of literature devoted to supply chain agility. Based on our own research stream on this topic, a set of supply chain initiatives were discussed as antecedents for the cultivation of agility. These included internal and external integration measures, cultivation of external flexibility, and lean practices. Following this, more fundamental, cultural antecedents towards the cultivation of agility were mentioned, which included the constructs of organizational culture type, market orientation, and learning orientation.

Since the validity of these models has been established through empirical research, these findings can be translated into a set of managerial practices for the cultivation of agility. Based on these practices, a systematic cultivation of agility in all segments of the supply chain is required, from both mitigation and response perspectives. Tactical issues coupled with the agility to reconfigure the supply chain (adaptability) are both important as business conditions become more volatile and unpredictable. Much work still remains to be completed on supply chain agility, and it is hoped that this chapter provides a broader and deeper understanding of agility in the supply chain.

# Lean Supply Chain 5.0 Management (LSCM 5.0): Lean and Value Reconceptualized

Soode Vaezinejad and Dara Schniederjans

## Contents

**Abstract**

Lean supply chain management (LSCM) has long been an approach to increase firm competitiveness. However, with rapidly changing, competitive markets, there is no guarantee on whether previously defined LSCM principles are enough to overcome today's challenges. The cyber-physical systems introduced by industry 4.0 have already transformed into talks of industry 5.0 with a focus on human centricity, sustainability, and resilience. In this chapter, we define LSCM through an industry 5.0 context via a two-dimensional matrix incorporating core values of industry 5.0 with LSCM pillars including stakeholder management, technologies, just-in-time (JIT) production, logistics management, and continuous improvement. Using this matrix, 15 lean supply chain management 5.0 (LSCM 5.0) principles and practices are defined in this chapter. We assert that a narrow focus on value in LSCM ought to be adjusted to reflect the broader nature

of value as it is defined through the emerging industry 5.0 context. In an industry 5.0 environment, all stakeholders such as workers, managers, shareholders, and customers should be considered in decisions and valued. In addition, a broader perspective of valuation through waste reduction ought to be reconsidered through a more inclusive stakeholder approach.

## 1 Introduction

It is arguable that in the past couple of years, supply chain as a field has seen an abundance of change in networks, practices, and processes more so than in the past couple of decades. Catalyzed by a global pandemic, causing massive shortages in material and human resources, risk management, regionalization, and agility were pushed to the top priority for most organizations across industries. Rapid adjustments forced by uncontrollable external events brought forth a renewed dedication toward lean practices for those companies who devote themselves to the lean philosophy, while at the same time led others to question these age-old practices.

The foundation of lean emerged in Japan during the 1950s when manufacturing companies were seeking to make the most use of confined resources (Schniederjans et al., 2018). It started in the automotive sector (Sinha & Matharu, 2019) and is now applied to both manufacturing and nonmanufacturing organizations alike (Samuel et al., 2015).

Lean management (LM) is a management system with the goal of waste reduction by simultaneously decreasing or minimizing internal and external variability (Núñez-Merino et al., 2020). Adopting LM and applying it to supply chain management (SCM) is considered as an approach to maintain company competitiveness by increasing organizational output given a respective level of input (Jasti & Kodali, 2015). LM has been linked to various operationalization of performance improvement – inventory-level reduction, customer satisfaction, and profitability (Kadarova & Demecko, 2016). In SCM, LM has been applied to almost all areas and is especially prevalent in studies focusing on product procurement, service level (Moyano-Fuentes et al., 2019), and systematic reduction of variability sources in supply network design (Núñez-Merino et al., 2020).

In a panel hosted by Decision Sciences Institute, Professors Tyson Browning, Richard Schonberger, Urban Wemmerlov, and Rachna Shah discussed the future of lean (Browning et al. 2021). They reiterated a need for a review of how LM ought to be framed. Previous research elucidates this notion suggesting a lack of agreement on defining lean. Specifically, value through lean can be defined in multiple ways, across different times and people (Samuel et al., 2015).

Schniederjans et al. (2018) define lean through four main principles: waste elimination, quality improvement, product flow maximization, and cost reduction. According to Cusumano et al. (2021), lean is defined as a way of thinking to create needed value with fewer resources and less waste. In another study, Samuel et al. (2015) define lean as an operations paradigm with the goal of variability reduction and time compression to improve flow. Tortorella et al. (2018) define lean through an aim to reduce waste, decrease variability, enhance operational performance, and add value to customers.

Shifting to lean with a focus on supply chains we arrive at lean supply chain management (LSCM). LSCM is defined through the mutual interaction between LM and supply chains (Moyano-Fuentes et al., 2019) but it is mostly defined as omitting any activity in supply chains which have no added value to customers (Jasti & Kodali, 2015). This definition – as well as others – take on a customer-centric approach to value creation in organizations.

Other LSCM definition examples include Núñez-Merino et al. (2020) who define interorganizational processes optimization from the end customer's point of view as the goal of applying lean principles into supply chains. Womack and Jones' (1997) five-stage process of lean thinking involves value being defined by customers in terms of their needs and expectations. However, some research has broadened this scope to include other concepts of LSCM value.

There have been suggestions that the goal of LSCM as customer satisfaction can be increased through a broader stakeholder approach by inefficiency reduction, establishing strong relationships with suppliers, and creating a balance between demand and capacity (Moyano-Fuentes et al., 2019).

When considering previous LSCM research, it can be concluded that the common element of the lean definition is to create a value stream with the final customer in mind. Hence, a customer-centric view of value has been considered and is often the focus in LSCM literature (Browning & de Treville, 2021). This customer-centric approach results from the critical role of customers in supply chains since the customer is the ultimate judge of supply chain performance (Jeong & Hong, 2007). However, with new and emerging concepts in automation, technology, and growing concerns in sustainability (from both social and environmental contexts), LSCM and its concept of value is adjusting due to questions of its legitimacy.

Industry 5.0 is defined through a shift from a technology-centric approach to a human and society-driven movement (Xu et al., 2021). Previous industrial revolutions mostly focused on the separation of manual labor with automated labor (Demir et al., 2019). Concerns of job displacement and ideation inefficiencies through highly automated tasks have since spurred the underpinning of collaborative efforts between human and machine.

Industry 5.0 complements the fourth industrial revolution (industry 4.0) – whose focus was primarily on automation integration and intelligent systems – by adding sustainability, resilience, and human centricity concerns. The rapid push toward automation has forced us to question the sustainability of the consistent change toward machinery versus manual labor. Additionally, supply chain scholars and practitioners are now rethinking traditional models for supply networks into new versions of digital capability models for supply networks (ASCM, 2022) in order to enhance performance via automation. Coupled with global pandemics that catalyze these changes, scholars and practitioners are rethinking fundamental concepts in value as they relate to LSCM. From a resilience perspective, LSCM was once primarily defined through the optimization of inventory levels. Yet in an environment wrought with global issues and crises, how can lean be leveraged and integrated within the boundaries of ever-evolving industrial changes?

This chapter identifies various lean principles and practices, their implementation, and applicability to the emerging industry 5.0 context. Industry 5.0 core values are reviewed to examine if defined lean principles and practices are aligned or redefined. To achieve the proposed objectives, this chapter first identifies LSCM history and definitions. This section is followed by an explanation of the revolution of industry 4.0 into industry 5.0. Next, the approach to redefining lean supply chain management 5.0 (LSCM 5.0) principles and practices is presented. Additionally, we provide both managerial and research implications in regard to calls for actions in: (1) stakeholder management, (2) implementation and adoption of technologies, (3) JIT production, (4) logistics management, and (5) continuous improvement as well as future research questions for empirical work in these areas. Finally, this is followed by a summary and conclusion and the last section includes future direction.

## 2 Background

### 2.1 Lean Supply Chain Management (LSCM)

With globalization, companies have encountered the demand for higher quality products, at lower prices (Prado-Prado et al., 2020), and shorter lead times (Tortorella et al., 2017). To survive within increasingly globalized markets, companies compete through supply networks as competition will inevitably surpass geographic boundaries (Moyano-Fuentes et al., 2019).

Applying lean principles and practices to SCM can provide the needed global competitiveness that organizations seek. The concept of LSCM was first introduced by Womack and Jones in 1994 (Jasti & Kodali, 2015) and remains active in research. The number of LSCM articles between 1996 and 2018 have grown significantly (Garcia-Buendia et al., 2021) – this growth in studies continues.

LSCM can be further defined as “a set of organizations directly linked by upstream and downstream flows of products, services, information and funds that collaboratively work to reduce cost and waste by efficiently pulling what is needed to meet the needs of individual customers” (Vitasek et al., 2005).

LSCM has been adopted from lean manufacturing and extended, which is not a simple process due to many reasons. It is easier to determine and quantify waste in manufacturing in comparison to supply chains since the manufacturing processes are managed by top management while collaboration from suppliers to customers is needed for supply chains (Tortorella et al., 2018). Since the main cause of waste in SCM systems is information (Jasti & Kodali, 2015), LSCM allows a clear flow of products and information among supply chain partners without waste (Nimeh et al., 2018).

Through LSCM, organizations can establish closer relationships with their main suppliers (Jasti & Kodali, 2015) and build and manage long-term relationships with customers. This situation results in achieving the long-held goal of LSCM focusing on customer satisfaction (Kumar Singh & Modgil, 2020). Hence, lean implementation in supply chains provides integrity among suppliers and customers – an important factor to boost organizational competitiveness (Tortorella et al., 2018). LSCM moves away from defining short-term profit goals and negotiating strongly with suppliers and customers to building and maintaining long-term trusting relationships with partners with a focus on waste reduction along supply chains (Tortorella et al., 2018).

Lean is governed by principles that include legal aspects and ideal situations (Kumar Singh & Modgil, 2020). These can be conceptualized in varied ways. For example, Nimeh et al. (2018) define LSCM practices as just-in-time (JIT) systems, the flow of information, supplier relationships, customer relationships, and waste reduction. In another study, Moyano-Fuentes et al. (2019) determine LSCM practices mostly focus on suppliers and chain agents. In terms of suppliers, LSCM practices are defined by having a limited number of suppliers, selecting and evaluating suppliers based on their added value, defining supplier development programs, and involving suppliers in the product design.

Considering chain agents, building trustable relationships, sharing information, and frequently exchanging feedback with them to solve problems through collaboration are LSCM practices. The conceptual complexity of LSCM has been core to the scholarly debate. For example, Jasti and Kodali (2015) investigate 30 LSCM frameworks to find out the standard elements referring to lean production procedures, techniques, practices, and tools which are adopted by organizations to implement in supply chains. A total of 129 LSCM elements are recognized in their study – a characteristics of the many dimensions and complexity of LSCM. In another study, 27 main practices adopted in LSCM are identified and the relationships among them are investigated furthering the complexity of LSCM (Tortorella et al., 2018).

Although LSCM can increase responsiveness to demand variations, reduce operating costs (Jasti & Kodali, 2015), eliminate waste, improve quality (Garcia-Buendia et al., 2021), minimize the production lead time, increase competitiveness and success, improve performance outcomes (Nimeh et al., 2018), and enhance flexibility and efficiency (Moyano-Fuentes et al., 2019), the complexity of lean continues to pervade its orientation surrounding value for an organization. This predicament is only propagated through emerging industrial changes. Successful implementation of lean principles and practices largely depends on varied technology, as well as organizational and environmental factors (Tornatzky et al., 1990), showing that not all organizations have to accept a defined set of principles and practices (Tortorella et al., 2018) but yet an ever-fluid orientation.

## 3 On the Route to Industry 5.0

In an evolving world, industry is always seeking to increase production and manufacture objects more efficiently and effectively using new machinery, technology, energy sources, or a mixture of them. Historically, to address this concern, three industrial revolutions are already behind us, while the fourth is being experienced. The onset of the first industrial revolution (industry 1.0) took place in the late eighteenth century over the mechanization and use of steam power (Vinitha et al., 2020). The late nineteenth century marked the start of the second industrial revolution (industry 2.0) focusing on manufacturing mass production (Vinitha et al., 2020). The development of machines running on electrical energy distinguished the second industrial revolution from the previous one. In the age of the third industrial revolution (industry 3.0), which began in the 1970s in the twentieth century, industries entered automation through electronics and computer-controlled devices (Vinitha et al., 2020).

On the back of the first three industrial revolutions the fourth industrial revolution was first publicly announced at the Hannover Fair in 2011 by a working group from a project in the high-tech strategy of the German government (Xu et al., 2021). Industry 4.0 is defined as "a group of rapid transformations in the design, manufacture, operation, and service of manufacturing systems and products" (Davies, 2015).

Although industry 4.0 originated in Germany, it was widely adopted by other industrialized or industrializing regions such as the European Union, China, and India (Gilchrist, 2016). Different terms have also defined it including smart factories, smart industry, and advanced manufacturing (Davies, 2015). Industry 4.0 is considered a technology-driven revolution that results in higher efficiency and productivity (Xu et al., 2021), better quality, increased speed, and mass customization (Davies, 2015).

The concept of industry 4.0 centers around the use of technologies – for example, artificial intelligence, cloud computing, and sensors – to enact greater automated and integrated efficiency (Demir et al., 2019). While currently in the midst of industry 4.0, practitioners and academics are seeking to fill the problems associated with rapid pushes toward automation including the disintegrating use of human capital (Frederico, 2021). Threats involving job displacement, ideation, and creativity reduction continue to pervade the current industry 4.0 environment.

In addition to the social concerns, environmental concerns are another reason researchers and practitioners are continually adjusting and looking for new opportunities. Sarkis et al. (2020) points to the various paradoxes emerging among industry 4.0 – via the Internet of Things, blockchain, and quantum computing – and green supply chains including the promise for efficiencies enhancing greater unit usage over time.

Industry 5.0 utilizes the efficiencies of industry 4.0 but does so through a human-centric approach concentrating on resilience, sustainability, purpose, values, ethics, diversity, and the circular economy. Industry 5.0 is a more stakeholder-centric approach to industry 4.0's focus on automation for the purpose of creating value.

Similar to the concept of lean, academics and practitioners are questioning how value is conceptualized from both an industrial revolution and philosophical context.

From an industry 4.0 context, lean has been conceptualized and reconceptualized through a more efficiency-driven focus. Supply chains for decades have experienced challenges related to accuracy, integrity, and timely information flow. Lean concepts have only become more important in the current global crises and the crisis impacts on supply networks. There is no argument that industry 4.0 technologies, with the ability to use intelligent processes, collect and analyze autonomous data, and provide interaction between suppliers and customers (Rosin et al., 2020), can help networks integrate information and physical flows to supply chain processes (Núñez-Merino et al., 2020). In this regard, many researchers have considered lean thinking as a foundation for industry 4.0 and industry 4.0 as an enabler of lean effectiveness (Rosin et al., 2020).

However, with a focus on automation, and with either a narrow or contingent scope of value defined by scholars and practitioners, societal obligations – including economic, social, and environmental dimensions – are at risk. As a response, in January 2021, the European Commission formally released the document titled "*Industry 5.0: Towards a Sustainable, Human-centric, and Resilient European Industry*" (Xu et al., 2021).

This document details industry 5.0 as a systematic approach to integrating social and environmental concerns while focusing on human resources at the center of the production process, with an effort to reconcile the automation paradoxes presented by industry 4.0 (Nahavandi, 2019). Industry 5.0 provides a symbiosis of humans and machines in the workplace leading to effective collaboration between automation and human resources, with a goal of imposing waste and cost reduction through more efficient production processes (Nahavandi, 2019).

If we continue toward the path of globalization, a sole focus on profit maximization and process efficiency through automation may not equate to long-run optimal value for organizations. Instead a focus on prosperity through social, environmental, and economical considerations and a balance among all three (Yun et al., 2019) ought to be considered from a broader stakeholder perspective (Breque et al., 2015).

Industry 5.0 goes beyond profits and focuses on three main elements: human centricity, sustainability, and resilience (Breque et al., 2015). The human-centric approach considers humans as the main focus of the production process and aligns technologies with human needs and expectations (Breque et al., 2015). In this approach, workers are valued as investments not cost and technology is in the service of humans and societies (Xu et al., 2021).

Using new technologies should guarantee no violations of human resource rights, privacy, and dignity (Breque et al., 2015). New technologies should support worker well-being. The second industry 5.0 core value is sustainability which means to reduce energy consumption and greenhouse emissions and not to threaten future generational resources to address today's needs. Resilience which is the last core value of industry 5.0 refers to having a high level of robustness in production systems to be able to act efficiently and effectively against disruptions and natural crises (Breque et al., 2015).

LSCM plays a critical role in society by providing and exchanging goods and services between businesses and consumers in the most efficient way possible. Industry 5.0 can be leveraged to create value given its ability to connect highly automated and intelligent digital ecosystems with human resources. However, a clearer understanding of industry 5.0 as well as its associations with value as defined by LSCM is necessary to understand how a more human-centric approach to the automation focus of industry 4.0 can be realized (Frederico, 2021).

## 4 Difference Among SCM, LSCM, and LSCM 5.0

To better illustrate the difference between SCM, LSCM, and LSCM 5.0, we adopt comparisons proposed by Martínez-Jurado and Moyano-Fuentes (2014), and Myerson (2012) focused on the differences between SCM and LSCM. Then, we add LSCM 5.0 to their comparison as presented in Table 1.

LSCM 5.0 takes a middle approach to the inventory management problem identifying the paradox among high levels of inventory while maintaining optimal levels for purposes of building resiliency in supply (Fig. 1).

## 5 Emergent Concerns, Outstanding Research, and Future Directions

### 5.1 A Conceptualization of LSCM Through Industry 5.0: A Two-Dimensional Matrix

So far, different views on LSCM have been developed which have resulted in a wide variety of LSCM principles that may at times conflict (Jasti & Kodali, 2015). Further, there is no guarantee if the defined LSCM principles and practices are still robust enough to help firms to gain competitive advantage now and into the future. The conceptualization of industry 5.0 provides an opportunity for researchers and practitioners to revisit the lens of lean methods, principles, practices, and solutions and redefine them in a more applicable way to current issues.

We leverage the understanding of LSCM 5.0 further by enacting a two-dimensional matrix (Fig. 2) combining LSCM pillars with industry 5.0 core values to conceptualize an understanding of the evolution of LSCM through industry 5.0 concepts. Using this matrix, 15 LSCM principles and practices in the industry 5.0 environment are defined (Table 2).

The rows of the matrix show LSCM pillars including stakeholder management, technologies, JIT production, logistics management, and continuous improvement. To define the LSCM pillars, this chapter relies on the extensive literature review paper conducted by Jasti and Kodali (2015). According to their research, related LSCM principles and practices in terms of goals and target groups are classified into different groups named LSCM pillars.

**Table 1** Comparison among SCM, LSCM, and LSCM 5.0

Adapted from: Martínez-Jurado & Moyano-Fuentes, 2014; Myerson, 2012

Since LSCM 5.0 exceeds only focusing on customers and values a wide variety of stakeholders, the first LSCM pillar of the matrix is devoted to stakeholder management including customer management, human resource management, supplier management, and shareholder management. Considering the intersection of this pillar with industry 5.0 core values, six LSCM 5.0 principles and practices are introduced including seeking a strategic stakeholder value focus, seeking leadership, seeking lean supporting teams, seeking sustainable partner selection, seeking to have a small

number of reliable suppliers, and seeking to build and maintain ethical and trust-based alliances with partners.

Bridging aspects from industry 4.0 within an emerging industry 5.0 context, we identify the second LSCM pillar: technologies. To define LSCM principles and practices aiming to advance industry 5.0 core values, particularly sustainability and resiliency, there is a need to focus on industry 4.0 technologies such as blockchain, cloud computing, Internet of Things (IoT), etc. In addition, to leverage the human-centric aspect of industry 5.0, collaborative robot technologies (cobots) which put machines very close to human life is required. The concept of cobots means working intelligently by employing disruptive technologies hand in hand with employees to improve productivity, minimize waste, and achieve sustainable goals (Frederico, 2021).

Lean development resulted in emerging a set of waste removal guidelines named Just in Time (JIT) principles. The concept behind the term JIT is to effectively and

**Table 2** LSCM conceptualized through industry 5.0 (principles and practices)

| | Industry 5.0 core values | | |
|---|---|---|---|
| LSCM pillar | Human centricity | Sustainability | Resilience |
| Stakeholder management | Seek a strategic stakeholder value focus: In industry 5.0 environment, which is a full integration of human and intelligent systems, firms should shift from customer-centric value to stakeholder-centric value which is itself a step forward to increase customer satisfaction. Nowadays, customers seek products marked by human care and design, they are also willing to even pay more for these products. In an industry 5.0 environment, workers are as important as customers and their health, welfare, job security, and job satisfaction are firms' concerns. Other stakeholders such as shareholders, suppliers, etc. play critical roles in the success of firms. Hence, firms should go beyond the customer-centric value and create a balance of value for all their stakeholders. Value is not only about value-adding actions, and it constitutes the interactions of those actions as well (Browning & de Treville, 2021), focusing on stakeholders help organizations to better manage the whole value stream<br>Seek leadership | Seek sustainable partner selection: There is an increasing demand for sustainable products and services from customers and stakeholders. To meet this expectation, firms' strategic partners should adopt the sustainability concept and apply it to their products/services. Since logistics services can significantly affect the green and sustainable supply chain, evaluation and selection of third-party logistics providers from a sustainability perspective are vital (Raut et al., 2018). In addition to third-party logistics providers, suppliers also significantly affect the success or failure of supply chains and play a critical role in producing/offering sustainable products/services. Environmental, economic, and social factors in suppliers' selection should be considered not to produce waste (Hoseini et al., 2020) | Seek to have a small number of reliable suppliers (Schniederjans et al., 2018; Jasti & Kodali, 2015): Having a limited number of reliable suppliers reduces administrative costs and increases response speed due to the familiarity between the firm and its suppliers as a result of frequent contacts between them (Schniederjans et al., 2018). On the other hand, a limited number of suppliers may decrease supply chain resiliency since any failure to deliver products from suppliers to the firm may create critical problems for customers. To meet resiliency, different levels of suppliers should be defined. During a shift in demands period, short-term contracts with noncritical suppliers should be considered to keep the system responsive (Schniederjans et al., 2018)<br>Seek to build and maintain ethical and trust-based alliances with partners (Schniederjans et al., 2018): To achieve this principle, there are two approaches. First, to create and maintain |

| | (Schniederjans et al., 2018; Jasti & Kodali, 2015):<br>For LSCM, high-level management support as a driving force is necessary. Successful leaders can provide accurate and sufficient information which avoids wasteful decisions (Schniederjans et al., 2018)<br>Seek lean supporting teams (Schniederjans et al., 2018):<br>Lean supporting teams such as lean training teams and lean problem-solving teams are necessary to help the implementation lean within supply chains (Schniederjans et al., 2018) | | ethical standards between the firm and its partners. This helps to reduce waste since low-quality products are not produced by suppliers as an example and as a result, no time will waste to return the unqualified products. Another approach is to build long-term contracts which help to create trust between the firm and its partners (Schniederjans et al., 2018). Defining ethical standards and building long-term contracts can decrease agility, so in order not to reduce the agility of supply chains, ethical standards should be defined and executed for main products. Also, long-term contracts should be built between firms and strategic partners not all |
| Technologies | Seek to use collaborative robots (cobots):<br>In industry 5.0 environment, the value focus is on human resources besides customers. Cobots are used to enhance the work atmosphere for human resources while they help firms to increase their efficiency and productivity. | | and creativity sides. The cooperation results in creating more efficiency without minimizing job opportunities. In addition, this rapidly changing environment intensifies the need to use cobots to keep supply chains responsive to market needs and being lean. During the covid-19 pandemic, issues like social distancing or unexpected time off come to attention. In these circumstances, cobots can be managed remotely. Thus, supply chains bear the least damage | decrease energy and resource consumption because of their ability to analyze data across supply chain processes. In addition, they play an important role in waste and $CO_2$ emission reduction, for example, due to traceable carbon footprint analyses<br>Considering the social dimension, they help employee health and safety by doing dangerous and harmful jobs for humans | allows supply chains to predict demands correctly which leads to a reduction in overproduction and inventory waste, and (2) accurate information provides visibility into every stage of supply chains. This visibility allows firms to continually monitor each stage such as production, warehousing, transportation, retailing to identify waste, and plan to eliminate it. Also, precise information increases the ability to analyze supply chain problems, bottlenecks, and detects to be well prepared to mitigate potential disruptions |
| JIT production | Seek JIT training for employees:<br>All human resources in different positions and roles do not need to learn the same skills and knowledge at the same time. JIT training refers to learning new skills and knowledge only when human resources need them. On-demand training helps human resources to enhance their knowledge and skills most efficiently. No financial costs are wasted using JIT training. In addition, JIT training can improve human resources performance since employees can apply | Seek a push-pull system:<br>Demand-pull systems reduce waste since whatever is produced will be consumed. Using this system, first, customers must place an order, then the request will be sent back upstream from the final customer (Schniederjans et al., 2018). While JIT inventory management reduces inventory, it increases transportation activity which leads to an increase in greenhouse gas emissions (Ugarte et al., 2016). A push-pull system can reduce waste | Seek standardizing work procedures for a few products or services within the firm (Schniederjans et al., 2018):<br>One of the lessons of JIT principles is to establish trust in supply chains (Schniederjans et al., 2018). Standardization of work procedures increases trust while decreasing agility in supply chains. Since, under industry 5.0 environment, firms need to be flexible to address change in customers' demands, standardization should be only adopted for a few products or |

A trade-off between responsiveness and trust should be considered.<br>Seek production leveling and scheduling (Tortorella et al., 2018; Jasti & Kodali, 2015):<br>One of the main sources of waste is variation in production which causes wasted cost, time, and effort. Production leveling is used to decrease the unevenness of the production process and, as a result, reduce waste. Production scheduling may decrease quick responsiveness to the market. Once resources such as materials and staff are scheduled to work, it would be difficult to change the process to align with new demand. Thus, a trade-off between responsiveness and uneven production flow is needed<br>Seek a push-pull system:<br>A pull system may lead a company to run into ordering dilemmas that make the firm unable to be quickly responsive enough to fulfill customers' orders. On the other hand, push systems lead to too many products left in inventory and waste creation. A push-pull system can reduce waste enhancing speed |

| Logistics management | | Seek to shortening lead time for only some products/services: Short lead time can reduce inventory level and as a result waste. At the same time, short lead time leads to more transportation which means more greenhouse gas emissions. Thus, short lead time may negatively affect sustainability. In LSCM 5.0, providing short lead time should be only for high-priority products/ services not all | Seek to eliminate supply chain flow constraints (Schniederjans et al., 2018): Flow constraints and bottlenecks within supply chains can result in system inefficiencies and poor supply chain performance. So, they should be identified and appropriate solutions to overcome them should be adopted (Schniederjans et al., 2018). Removing flow constraints and bottlenecks leads to a stable flow of products in which waste is eliminated and responsiveness to markets is improved |
| Continuous improvement | | Seek to create a sustainable supply chain value stream mapping (Gargalo et al., 2021): Mapping current flows of materials and information help to identify three groups of activities: value added, nonvalue added but necessary, and wastes (Boonsthonsatit & Jungthawan, 2015). Sustainable value stream mapping extends value stream mapping to include environmental, social, and sustainable manufacturing aspects (Gargalo et al., 2021) and can be obtained by omitting the identified wastes in current flows. | |

efficiently utilize resources just in time for their use. When all resources arrive just in time for their consumption, no unnecessary movement of materials, equipment, and products occur, and subsequently, no waste is produced (Schniederjans et al., 2018). Within the third pillar, the JIT production, five LSCM 5.0 principles and practices including seeking JIT training for employees, seeking a push-pull system, seeking standardizing work procedures for a few products or services within the firm, seeking production leveling and scheduling, and seeking a push-pull system are defined.

Considering the impact of inbound logistics on timely manufacturing products and outbound logistics on customer satisfaction (Edirisuriya et al. 2018), eliminating nonadded values activities in transportation, storage and warehousing, packaging and unitization, etc. leads to advancement in entire supply chains. Given the fourth pillar, two LSCM 5.0 principles and practices such as seeking to shorten the lead time for only some products/services and seeking to eliminate supply chain flow constraints are presented.

Continuous improvement, the fifth pillar, is a key element to achieving excellence in LSCM practices (Jasti & Kodali, 2015). In the context of LSCM 5.0, continuous improvement seeks to advance processes in SCM by focusing on enhancing principles and practices that create the most value for varied stakeholders, boost sustainability, and strengthen resiliency while minimizing waste in supply chains. The intersection between the continuous improvement pillar and industry 5.0 core values defines seeking sustainable supply chain value stream mapping as the last LSCM 5.0 principles and practices.

The columns of the matrix show three core values of industry 5.0 – human centricity, sustainability, and resilience. As discussed in this chapter, human centricity value targets to create a collaborative working environment between humans and machines in which human creativity and machine intelligence are combined. Focusing on this value takes away dirty and repetitive tasks from humans and empower them through collaborative learning. Sustainability, the second column of the matrix, is defined as "the balanced and systemic integration of intra and intergenerational economic, social, and environmental performance" (Geissdoerfer et al. 2017). It focuses on creating circular processes to reuse and recycle natural resources to eliminate waste and decrease environmental impact (Breque et al., 2015).

Lastly, resilience acts as guidance for LSCM as well as the development of the matrix. While various definitions of supply chain resilience exist, we borrow from

Ponomarov and Holcomb's (2009) definition: "the adaptive capability of the supply chain to prepare for unexpected events, respond to disruptions and recover by maintaining continuity of operations at the desired level of connectedness and control over structure and function." Building on this definition, we can be informed by the identification of four principles (Christopher & Peck, 2004): (1) supply chain reengineering, (2) collaboration, (3) agility, and (4) supply chain risk management culture.

Since agility is one of the most essential aspects of resiliency (Kamalahmadi & Parast, 2016), redefining LSCM 5.0 principles and practices requires an understanding of the alignment between lean and agility in supply chains. Lean and agility are strategies targeted at two different goals to improve SCM. Lean, as discussed, aims to omit nonadded value activities and can be applicable for predictable demand with limited variety. However, agility is "the ability of a supply chain to rapidly respond to change by adapting its initial stable configuration" (Wieland & Wallenburg, 2013) and is suitable for volatile environments (Nayak & Choudhary, 2022).

Despite varied goals of lean and agility, they have a complementary relationship (Fadaki et al., 2020) leading to the emergence of a paradigm, leagility. It is defined as "integrating the lean and agile manufacturing paradigms in the total supply chain"' (Naylor et al., 1999) where leanness can be decoupled from downstream and employed upstream while agility can be applied in the remaining downstream (Bhamra et al., 2021). According to a survey conducted by Fadaki et al. (2019), 90.3% of Australian firms adopted leagile supply chains rather than purely lean or purely agile supply chains. Their preference may root in the fact that lean and agility combination allows for achieving "the best of both worlds" (Naim & Gosling, 2011).

In the rapidly changing world, lean may need to be evolving over time to address today's needs and be aligned with future expectations. With emerge of industry 4.0, researchers started to view LSCM from a technological perspective (El Jaouhari et al., 2022; Rossini et al., 2022). However, besides the technological aspect, there is a need to expand LSCM principles and practices from other curtail aspects such as human centricity, sustainability, and resilience. These new perspectives may cause a shift in LSCM value creation from mainly focusing on waste minimization to a broader nature of value. In this regard, Table 2 creates an understanding of industry 5.0 and its association with the value defined by LSCM.

## 6 Managerial Implications

With significant increases in automation brought about by the rapid advances in technologies (i.e., artificial intelligence, machine learning, 5G, augmented reality, drones, etc.) companies that strategically deploy these technologies have been provided never-before-seen levels of visibility as well as the ability to streamline almost every transaction and movement of material. Examples of this range from NielsenIQ (a customer relationship management data organization) leveraging image recognition, deep learning, and robotics as well a creation of best-in-class cloud (PaaS) technologies for the purpose of data lake storage allowing for accelerated coverage expansion as well as integrated measurement of various channels for clients (Dol, 2021).

While these and other examples exist, ultimately, supply chains are more than just key performance indicators. They are more than numbers in cash-to-cash cycle time, fill rates, on-time deliveries, customer order cycle time, and inventory turnover. Supply chains, in the end, are about people. At the very start and in the end of each network is a buyer and supply chains exist to serve their needs. Doing so requires a network of collaborators and intelligence involving thousands upon millions of individuals that provide a basis for enhancing customization, customer satisfaction, reducing risk and waste, enabling logistics functions to optimize time of strategic experimentation, improving integration of strategic partnerships and gaining more value through retaining, and transferring knowledge across various characteristics.

This chapter provides a framework for practitioners detailing industry 5.0 values and action guides for organization when it comes to: (1) stakeholder management, (2) implementation and adoption of technologies, (3) JIT production, (4) logistics management, and (5) continuous improvement. While this book chapter advocates taking a long-term approach in these initiatives, understandably, companies will continue to have to balance both the short-term and long-term pressures from investors.

As one example, the Securities Exchange Commission issues a rule that requires publicly traded companies to disclose climate financial risks to all investors. Organizations now assess and mitigate climate-related transition and physical risk as well as strategies on enhancing resilience and shifting to a reduced carbon future. This includes both short-term and long-term actions. Over 40 companies have already supported the net-zero infrastructure package with targets set to 2050 and with most G20 countries pledging carbon neutrality by 2050 or 2070 (Financial Times, 2021). While infrastructure is strong and has the power to transition to net zero, the knowledge and pathways are under pressure to “build neutral now” in order to meet emissions targets (Financial Times, 2021). Unfortunately, these pressures can lead to issues related to companies pursuing green washing. This in turn creates distrust among stakeholders and end consumers leading to a loss of value in the beginning and end of the network. Technologies can be leveraged to mitigate these issues while at the same time providing integration mechanisms across boundaries that allow for greater trust and assurance leading to enhanced value among the individuals that make up the entirety of the value chain. The values provided in this chapter serve as a starting point for these organizations that face both short-term and long-term pressures in order to optimize value.

However, change is both difficult and inevitable. When the future is uncertain, it can lead to various stresses and impacts on systems, governance, and individuals. LSCM has – and we believe will continue – to provide useful guidelines in reducing the number of issues that arise from rapid change. Yet, it is the obligation of the individual to rethink and reevaluate the efficacy of these methods based on the context in which it is presented.

## 7 Research Implications

There is still much work needed to accurately conceptualize LSCM 5.0 given that the call to rethink LSCM (and its definition of value) is still questioned as well as the infancy of industry 4.0 and its potential successor industry 5.0 is still only a concept. Future research can enhance the 15 LSCM 5.0 principles and practices defined in this research through addressing and refining our understanding of the following:

First, lean is no more limited to the manufacturing industry where it first emerged from. Varied flavors of lean exist for different industries in supply chains such as transportation (Parajuli et al., 2022), warehousing (Shaikh et al., 2020), and retailing (Lukic, 2012). Although adopting lean is a universal approach in different industries, the most relevant, necessary, and applicable LSCM 5.0 principles and practices may differ depending on financial, temporal, and managerial limitations and a wide variety of needs and concerns of organizations. For example, an organization focusing on sustainability as its main goal may put a higher priority on seeking sustainable partner selection than an organization focusing on profitability. Another example is an organization with a lack of financial resources may not be willing to adopt industry 4.0 technologies as a LSCM 5.0 practice to improve its resiliency due to the high adoption cost (Sarkis et al., 2020). Hence, more research is needed to identify and prioritize the required applicable LSCM 5.0 for organizations in different industries.

Second, considering the sustainability value of industry 5.0, most LSCM 5.0 principles and practices are defined focusing on the environmental dimension. Hence, what are LSCM 5.0 principles and practices aiming to improve the economic and social dimensions of sustainability? Another question can be how to integrate sustainability dimensions, especially when trade-offs exist. For example, using industry 4.0 technologies can boost the social sustainability dimension by taking away dangerous work from employees to retain their health and safety. However, it can also negatively affect environmental sustainability due to air pollution and exhaustive use of raw materials and energy (Oláh et al., 2020).

Examples of tools leveraging games and system dynamics have enhanced optimization of donations and social good from a humanitarian perspective in times of uncertainty (see Ozpolat et al., 2015). What other tools might be available to enhance social considerations during rapid technological change?

During times of disruptive innovation, the use of analytics and machine learning will likely play a larger role in various decisions including product positioning and pricing (see Chen & Ni, 2020). How might discrete choice modeling be used to further optimize organizational decisions while maintaining values?

Future research might also consider the role (or lack thereof) of policy in enhancing the benefits achieved by LSCM 5.0.

More important than perhaps policy (or related to) might be the role of investment in education and workforce development in promoting the benefits of automation while doing so within a humanistic perspective. What is the role of higher education in training the workforce in this rapidly changing environment? How must policies adjust to the ever-changing infrastructure and environment. As just some examples: How might legal frameworks be adapted to advance transformation of economic systems? How might public funding schemes be redesigned or made more flexible? (EU, 2022).

## 8 Summary and Conclusion

Nearly 30 years have passed since LSCM was introduced. During these 30 years, supply chains have undergone many changes. International relations, policy-driven cooperation among firms, the emergence of new technologies, and unpredictable and fast-changing markets each has added more complexity to supply chain performance.

Issues outside supply chains scope can also affect supply chains severely and augment more complexity. Global pandemics have posed immense challenges for supply chains due to disruption in the flow of materials, fluctuations in demand, lack of resources, etc. According to a survey conducted by McKinsey & Company in 2020, 93% of senior supply chain executives expressed that they intended to make their supply chains more flexible, agile, and resilient. With new industrial revolutions on the horizon with a potential focus on humans, sustainability, and resilience lean scholars and practitioners need to reimagine concepts of LSCM in future dynamic environments. We thus review the values, goals, principles, and activities of LSCM 5.0.

In this chapter, we conceptualized LSCM through an industry 5.0 concept via a matrix presentation specifically focusing on human centricity, sustainability, and resilience. We hope that researchers and practitioners can leverage this information as well as the questions presented above to detail how we might rethink and reevaluate LSCM through new and emerging concepts during times of rapid change to create value from a larger stakeholder context now and into the future.

supplier relations are key factors in managing healthcare quality, hospitals are at the center of our research. Proceeding with a conceptual representation of a typical US hospital supply chain in mind, we offer a conceptual framework depicting hospital quality management practices and quality performance. Finally, we discuss two major emergent concerns and research areas in healthcare – population health management and managing stressful environments in healthcare – and offer our insights drawn from quality management in the context of the US healthcare supply chain.

## 1 Introduction

The persistence of medical errors is a major issue in healthcare delivery (Heath, 2019) despite the rapid growth in healthcare quality assurance and performance improvement efforts by healthcare systems in recent years. According to the report *To Err is Human: Building a Safer Health System* by the Institute of Medicine (IOM), as many as 98,000 hospital deaths due to medical errors occur per year (Donaldson, 2008). The Fifth Annual HealthGrades Patient Safety in American Hospitals Study (2008) estimated that from 2004 through 2006 more than 220,000 incidents and over 37,000 deaths among hospitalized Medicare patients might have been preventable (p. 6). The following year, HealthGrades, also focusing on Medicare patients during the same period, released a report that estimated as many as 171,424 lives might have been saved and 9,671 major complications might have been avoided if these patients were treated at hospitals performing at the level of Distinguished Hospitals for Clinical Excellence (HealthGrades, 2008 p. 2).

Research findings show that based on patient safety measures, patient care has significantly improved in recent years. According to data collected by the Agency for Healthcare Research and Quality (AHRQ), hospital-acquired conditions (HACs) have consistently decreased over time. Findings show that between 2014 and 2017, HACs dropped 13%, cut $7.7 billion in costs, and saved an estimated 20,500 lives. These improvements in performance built on earlier advances. Between 2010 and 2014, the healthcare industry recorded 2.1 million fewer HACs than in previous years. However, many problems still affect the safe and effective delivery of healthcare services. A Johns Hopkins report notes that "patient safety mistakes accounted for nearly 250,000 patient deaths," greater than the death toll from respiratory disease by nearly 100,000 incidents (Heath, 2019). It may be noted that even though patient safety has emerged as a key aspect of healthcare quality (Pronovost et al., 2006), many detailed quality metrics based on specific health conditions (e.g., stroke, pneumonia, and cardiac arrest), length of hospital stay, and hospital readmission rates have become popular as standardized metrics to measure healthcare quality.

While increasing quality improvement efforts is an important goal in healthcare, decreasing healthcare costs is also critical to have sustainable and equitable healthcare delivery systems. US healthcare is the most expensive per capita among the Organization for Economic Co-operation and Development (OECD) countries (Statista, 2022). In 2019, the *Journal of Operations Management* published a special issue on "delivering effective healthcare at lower cost." Supply chain management (SCM) in healthcare has been considered one area in which cost can be reduced by synchronizing the flow of information and goods throughout the entities in a chain (Chakraborty & Gonzalez, 2018). The critical effect of SCM on healthcare operations has become more apparent during the COVID-19 pandemic. Improving the quality of services available to patients and effectively managing supply chains while reducing costs are currently three pressing needs of the US healthcare system.

In this chapter, we explore quality management and the supply chain of US community hospitals to better understand quality challenges in the US healthcare delivery system. The American Hospital Association defines community hospitals as "all nonfederal, short-term general, and other special hospitals. Other special hospitals include obstetrics and gynecology; eye, ear, nose, and throat; long term acute care; rehabilitation; orthopedic; and other individually described specialty services. Community hospitals include academic medical centers or other teaching hospitals if they are nonfederal short-term hospitals" (AHA, 2022a). The chapter provides an overview of the extended healthcare supply chain of hospitals, care processes, relationships among hospital quality management practices and quality performance, a discussion about population health management and lean systems, and some insights on stressful environments and healthcare quality.

## 2 Background: An Overview of a Hospital's Extended Healthcare Supply Chain

Healthcare is a complex activity that is dependent on the medical treatment processes followed to cure a patient's health condition. During diagnosis and medical treatment, knowledge that physicians rely on depends to a large extent on the philosophy of their medical school education and the specific objectives of a given hospital (i.e., whether the hospital is a teaching, physician-owned, or nonprofit hospital) (Bohmer, 2009). These considerations pose additional challenges to delivering high-quality patient care (Bohmer, 2009).

Many healthcare experts and other stakeholders now agree that hospital SCM is crucial to improving the performance of US healthcare systems (Buttigieg et al., 2020). Although the cost of facilities, clinical support, and their administration still form the major components of total healthcare costs, 20.6% for the cost of supplies is a significant amount, and it is rising every year (AHA, 2022b). Managing supply chains effectively (and therein quality management of the healthcare supply chain as well) is critical to controlling and maintaining the quality and cost of medical supplies. In the context of healthcare, SCM includes both the internal chain (e.g.,

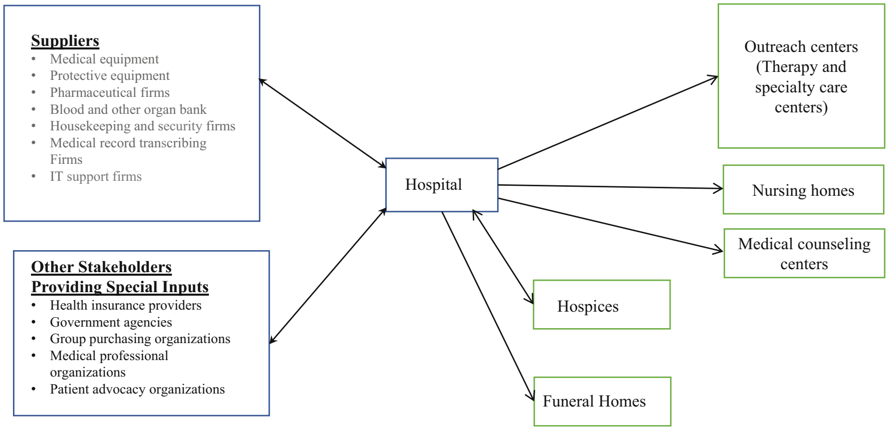

**Fig. 1** A schematic diagram of a typical U.S. hospital's extended healthcare supply chain. (Adapted from Chakraborty and Gonzalez (2018))

patient care unit, hospital storage, and patient) and the external chain (e.g., vendors, manufacturers, and distributors) (Denton, 2013).

Keeping patient flows in mind, a conceptual depiction of the current US healthcare supply chain is presented in Fig. 1. The upstream of a typical US hospital supply chain consists of two entities: (1) suppliers and (2) other stakeholders providing special inputs (Chakraborty & Gonzalez, 2018). Medical equipment firms provide medical and other related types of equipment (e.g., beds) required by hospitals, doctors, and nurses for treating patients. These are broadly classified into the following seven categories: storage and transport medical equipment, durable medical equipment, diagnostic medical equipment, electronic medical equipment, surgical medical equipment, acute care equipment, and procedural medical equipment. Also included in the supply chain are firms that provide furnishings and supporting materials for patients such as curtains and bed sheets and personal protective equipment (PPE) for healthcare team members. Hospital staff wear PPE to reduce the potential for injuries resulting from being exposed to workplace hazards, medical and mechanical, commonly found in hospitals. This protective equipment includes items such as shoes, safety glasses, respirators, and gloves, among other equipment. A pharmaceutical firm could be involved in developing, producing, and marketing drugs licensed for use as medications. Pharmaceutical companies are permitted to sell and distribute generic and/or brand medications and medical devices. Dosage forms include tablets and capsules, injectables, creams, ointments, inhalants, and solutions.

Blood bank refers to the division of a hospital laboratory where blood products are stored, and compatibility testing is performed before transfusion and may also process blood donations, depending on the capabilities of the facility. The term also includes other organ banks such as eye banks, which retrieve and store eyes for corneal transplants and research, and amniotic stem cell banks, which store stem cells derived from amniotic fluid for future use. Housekeeping and security firms provide environmental services such as security services and housekeeping services that include cleaning rooms, medical equipment, and laundry. These firms also stock and keeps track of basic hospital amenities in hospital rooms, especially in the emergency rooms and intensive care units. Medical transcription is the process of converting voice-recorded reports as dictated by transcribing firms, physicians, and other healthcare professionals into text. A few specialized firms provide such transcription services to their clients. Information technology (IT) support firms typically provide some or all IT services, from computer support, IT consulting, IT outsourcing, helpdesk services, data backup, disaster recovery, application hosting, and email hosting to chief information officer–level consulting, managed services, and call centers.

Health insurance providers are firms that provide health insurance services. Health insurance protects a patient from the prohibitive cost of medical care by providing coverage for providers of specific healthcare services. The three broad types of health insurance are: consumer directed, fee-for-service (often known as "indemnity" plans), and managed care. These plans cover medical, surgical, and hospital expenses. Some cover prescription drugs and offer dental and behavioral and mental health coverage as well. Government agencies that monitor and test product safety include the Food and Drug Administration (FDA), the Centers for Disease Control and Prevention (CDC), and the Department of Defense's Office of the Surgeon General. Agencies that monitor the operation of healthcare programs such as Medicare and Medicaid are authorized to audit, investigate, and inspect any facility.

A group purchasing organization (GPO) is an entity that helps healthcare providers such as hospitals, nursing homes, and other health agencies realize efficiencies by aggregating purchasing volume into bulk and using that leverage to negotiate discounts with suppliers. As measured by the total number of member hospital beds, Premier Inc., MedAssets, Vizient, Intalere, Cardinal Health, McKesson Pharmaceutical, AmerisourceBergen, HealthTrust Purchasing Group (HPG), the Department of Veterans Affairs, and Provista are some of the large GPOs. Professional associations such as the American Medical Association (AMA) help doctors by uniting physicians and medical students to work on the most important professional and public health issues. Professional fraternities are organizations whose primary purpose is to promote the interests of a particular profession and whose membership is restricted to students in that particular field of professional education or study. Common medical fraternities are Phi Beta Pi, Theta Kappa Psi, Phi Delta Epsilon, Phi Rho Sigma, and Phi Chi. Patient advocacy organizations are nonprofit organizations that provide patients a voice in improving access to and reimbursement for high-quality healthcare through regulatory and legislative reform at the state and federal levels. Examples are National Patient Advocate Foundation, HealthHIV, and the National Association for Hearing and Speech Action.

At the center of a typical US healthcare supply chain is the hospital, which is generally the primary facility for most healthcare services that any person receives, ranging from diagnostic services to surgery to continuous nursing care and advanced disease and other medical treatments. Hospitals vary from small, free-standing rural facilities to a vast, multifacility, geographically dispersed but integrated system. Some hospitals specialize in the treatment of a particular disease such as HIV/AIDS, cancer, or for particular types of procedures such as cardiology and heart surgery. Others are full-service hospitals that prioritize medical treatment for most ailments.

Next, moving to the downstream side of a typical US hospital supply chain, discharged patients who are not fully cured may need such specialized services as outreach or medical counseling centers, or they may be candidates for a nursing home. Patients that die in the hospital are sent to funeral homes. Hospices provide medical care for people with an anticipated life expectancy of 6 months or less, when a cure is no longer possible, and the focus of care shifts to symptom management and quality of life.

Outreach centers can provide both therapy and specialty care. Therapy centers provide developmental and rehabilitation services such as speech-language therapy, pediatric occupational therapy, and pediatric physical therapy services. Specialty care centers provide high-quality medical services such as radiation treatment, stem cell care centers, transplantation, and cellular therapy. A nursing home is a residence for people who require constant nursing care and have deficiencies that render them incapable of performing the activities of daily living. Residents generally are elderly and younger adults with physical or mental disabilities. Patients in a nursing facility could also receive physical, occupational, and other rehabilitative therapies following an accident or illness. Medical counseling centers generally take a team approach to patient care in which psychiatrists and other therapists regularly collaborate on a patient's care to determine the best treatment option. Patients in medical counseling centers are primarily those who suffer from such disorders as depression, bipolar anxiety, panic attacks, obsessive-compulsive disorder (OCD), or from life-threatening diseases such as HIV or cancer. These centers typically offer a variety of services, from medication management to counseling on how to cope with a patient's affliction.

## 3 Care Processes in Patient-Centric Hospitals

As in all service processes (Jacobs & Chase, 2020), the customer (patient in healthcare) is the focal point of hospital operations. Doctors, nurses, and all other infrastructure support systems are designed to serve the patient in the most effective and efficient manner. The infrastructure support system includes all departments and units in a hospital. Other care processes include internal stakeholders that receive the services – patients and their friends/relatives as well as those who provide the services such as physicians, nurses, and support staff.

As we will discuss in the next section, to provide high-quality patient care, all these processes need to be designed keeping quality management (QM) principles in mind. In other words, QM must be the foundation of care hospital processes.

## 4 Quality Measurement in Hospitals

QM is defined as a holistic management philosophy that guides continuous improvement in all functions of an organization (Kaynak, 2003). In healthcare settings, in order to implement QM, hospitals need to strive for continuous improvement, beginning with the acquisition of resources to the care of patients and other stakeholders. The Malcolm Baldridge National Quality Award (currently known as the Baldrige Excellence Award) was established in 1987 (Kaynak, 1997) to encourage quality improvements in firms**,** and it was followed by the European Foundation Quality Award in 1988 (Nabitz et al., 2000), which also encourages quality improvements in firms. In 1998, the scope of the Malcolm Baldridge National Quality Award was expanded by the US Congress to include the healthcare industry (Baldrige, 2022). Since then, many healthcare organizations in the USA, Europe, and around the globe apply the quality improvement efforts introduced in these frameworks, even during the COVID-19 pandemic (Shah et al., 2021). The results of a study by Shah et al. (2021) show that the use of quality improvement approaches by healthcare organizations increased during the COVID-19 pandemic in England.

In this chapter, we discuss the relationships among QM practices implemented in a hospital and quality performance measures drawing from the extant literature in healthcare, particularly from the arguments in Chakraborty and Kaynak (2018), Chakraborty et al. (2021), and Kaynak and Hartley (2008). Suggested practices also have been documented in numerous studies that have investigated the implementation of QM in healthcare organizations (see Table 1 for major studies). We identify eight QM practices in the context of hospitals – hospital quality leadership, healthcare training, healthcare teamwork, hospital quality data and reporting, patient focus, supplier quality management, hospital services design, and hospital process management. These healthcare-applicable QM practices, along with the major studies that discuss these practices, are indicated in Table 1. Although there are similarities between the practices in our framework and those shown in Malcolm Baldridge, some differences are also evident. For example, the Malcolm Baldrige healthcare criteria for 2021–2022 does not identify supplier quality management as a distinct practice of QM, although some related questions are included under strategy development. Furthermore, patient care and patient satisfaction are not clearly differentiated. Thus, we believe that the QM practices we offer are more detailed and informative than those in the Malcolm Baldridge framework.

One of the most important antecedent variables is hospital quality leadership. The structure that leaders impose on an organization and the care they take to provide daily encouragement to all levels of staff are crucial to the successful implementation of quality in an organization. Different resources are necessary for training people in the use of new principles and tools and creating a work environment in which employees are engaged with changes in the organization and its work culture (Kaynak, 2003). Stable processes are essential to maximizing patient satisfaction and success in the marketplace, a principle a quality leader recognizes (Smith, 2018). It is the hospital leadership’s responsibility to implement practices that will improve the quality of patient care.

**Table 1** Quality management (QM) practices implemented in healthcare organizations

| QM Practices | Definition | Recent healthcare studies |
|---|---|---|
| Hospital quality leadership | Hospital leaders' acceptance of quality responsibility. It refers to the participation in quality improvement efforts and direction to workers and managers by senior management, having specificity of quality goals, with importance attached to quality in relation to cost and schedule and comprehensive patient care quality planning | Chakraborty et al. (2021) |
| Healthcare training | Quality-related training and statistical training for hospital management and all healthcare (HC) employees | Zaka et al. (2020) |
| Healthcare teamwork | Implementation of employee involvement and teamwork, open employee participation in quality decisions; continuous quality awareness of all HC employees; responsibility of HC employees for quality; recognition of HC employees for superior quality performance | Rosen et al. (2018) |
| Hospital quality data and reporting | Timely and reliable quality measurement; availability and timeliness of quality data to HC employees and managers for problem solving; use of poor-quality cost data to manage healthcare quality | Geraedts et al. (2018) |
| Patient focus | Continuous assessment of patients' needs; use of patient feedback surveys, focusing on achieving greater patient satisfaction | Greene et al. (2012) |
| Hospital supplier quality management | Timely and accurate delivery of supplies; reliance on supplier quality system; coordination and cooperation between internal and external suppliers and hospitals and HC employees (internal customers) | Priestman et al. (2019) |
| Hospital services design | Patient hospital services design based on patient preferences; involvement of all affected departments in hospital services design and reviews; review and test of new hospital services prior to their introduction to patients | Zepeda and Sinha (2016) |
| Hospital process management | Hospital service process management for continuous service quality improvement; use of statistical process control; fail-safe process design; use of preventive quality controls to provide quality hospital services | Smith (2018) |

Hospital leaders' awareness of all risks associated with improper patient care procedures and ensuring that staff at all levels understand these risks and how to mitigate them is essential to the creation of an environment in which patient safety initiatives can take hold (Saint et al., 2010). A critical practice of both QM and SCM is the interaction with customers (Robinson & Malhotra, 2005), and the development of strong relationships with patients or customers, and customer (patient) focus is a function of quality leadership. Creating policies and designing structures that create a work environment in which the attention of employees – physicians, nurses, and healthcare teams – is focused on serving the customer is a crucial function of hospital leadership.

Patient feedback surveys could be used to promote patient involvement thereby improving quality of care. Patient satisfaction can be improved if quality leaders make consistent effort to focus on and assess patient needs (Asif et al. 2019). Effective management of relationships with key suppliers is essential to SCM, especially in life-threatening situations such as those encountered often in hospitals. It is hospital leaders' responsibility to ensure an elevated level of integration when designing healthcare services not only within the hospital but also across the hospital supply chain. Hospital administrators manage a wide range of suppliers serving all functions in a hospital, and effective leadership can promote mutually beneficial relations with these suppliers by emphasizing quality and delivery performance over price when developing, selecting, and certifying them for quality of supplied materials or items. Moreover, both hospitals and their suppliers can benefit from facilitating the exchange of proprietary and competitive information.

Training increases staff engagement with the attention to quality-related issues. Healthcare staff need to be trained on the collection and use of quality data, but training alone will not sustain an improvement effort. Staff must receive quality data in a timely manner and use it effectively. Training in quality-related issues that emphasizes problem-solving in teams, effective communication, and statistical process control transform healthcare employees into creative problem solvers (Moore et al., 2018), which, in turn, enables staff members at every level to understand patients' needs, identify their requirements, and communicate effectively with them (Moore et al., 2018).

A team may be defined as a collection of three or more people in an organization whose members take pride in their collective identity and collaborate on one or more common tasks. Teamwork is defined as the action of a group working together with a common, well-defined objective. In hospitals that have implemented electronic health record (EHR) system, high-quality data on patients that is timely and accurate is available to the healthcare team members, which in turn will improve the teamwork and the effectiveness of the team as a whole (Graetz et al., 2015; O'Malley et al., 2015).

Whether it is in manufacturing or in services, the collection and analysis of quality information is important for successful implementation of QM practices. Also key to SCM is the sharing of information among supply chain members (Kaynak & Hartley, 2008). The use of quality data and reporting in hospitals is necessary for improving supplier quality management, as it allows buyers to monitor and assess the performance of suppliers, which is also improved by measuring their performance and providing feedback (Gonete et al., 2021). Quality data disseminated throughout a hospital in a timely manner is also a crucial factor when designing hospital services, for it facilitates the feedback from healthcare teams during the service design stage. Timely and effective use of quality data impacts a hospital's process management. Healthcare staff members are alerted quickly to process changes so they can fix problems before undesirable and inferior services become a problem.

Kaynak's (Kaynak, 2003) study suggests that supplier quality management is effective because of its direct relationship with service design and process management. Successful relationships could emerge whereby, for example, suppliers become engaged early in the design services of a new electronic data interchange (EDI) program at a hospital's pharmacy encouraging them to offer suggestions regarding the type, quantity, and frequency of the medical supplies that the hospital could order from the supplier, which would ultimately enhance the quality of patient care (Priestman et al., 2019). Under SCM, suppliers are integrated (Robinson & Malhotra, 2005) because improved quality of supplies positively affects process management by eliminating or reducing variation in healthcare services (Hughes, 2008).

Effective supplier management shrinks inventory and reduces waste in the supply chain (cf. Kaynak & Hartley, 2008), which reduces inventory costs, a goal of SCM. Improving quality by collaborating with suppliers also reduces the need for safety stock inventory. If the number of suppliers can be reduced, organizations can work more closely with those retained. As Chakraborty and Gonzalez (2018) explain, supplier quality management plays a critical role in a hospital's continuous quality improvement effort (McLaughlin et al., 2004). Successful and sustained quality improvement initiatives require that hospitals develop long-term and mutually beneficial partnerships with key suppliers to reduce inventory while still meeting service quality standards for patient care (Dahlgaard et al., 2011).

It is during service design that the processes employed in a firm and within its supply chain are established. Kaynak and Hartley (2008) empirically validated the proposition that effective product design is related to efficient process management, and this relationship applies to hospitals as well.

If hospitals are to realize the full benefits, hospital leaders must recognize that QM practices are interdependent and need to be implemented as a system. The ultimate objective of implementing QM is to improve outcomes for at all three major stakeholders**:** the patients, who need care; the healthcare team, which provides the treatment most likely to make the patients better; and the hospital, which needs to enhance its reputation so that it will attract new patients and enable its healthcare teams to thrive (Chakraborty & Gonzalez, 2018). Next, we describe these outcomes in detail.

## 5 Quality Outcomes in Hospitals

Nerenz and Neil (2001) suggest that scholars should integrate a range of aspects of healthcare performance: quality of care, utilization, cost, efficiency of hospital resources, patient satisfaction, and reports of care and financial performance. We offer a conceptual framework for quality measurement in hospitals (Fig. 2) that

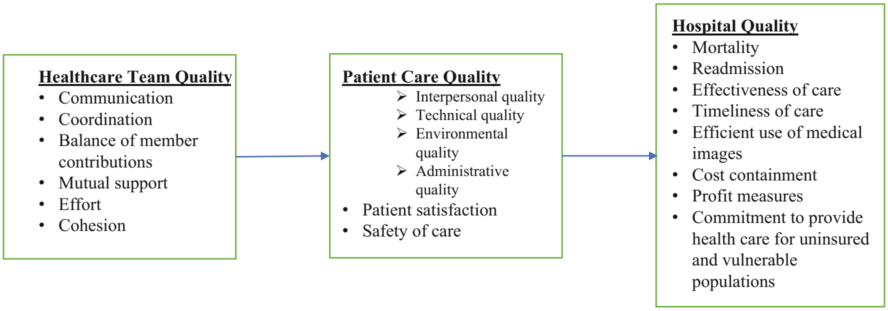

**Fig. 2** A framework for quality measurement in hospitals. (Adapted from Chakraborty and Kaynak (2018)). Copyright © American Society for Quality, reprinted by permission of Taylor & Francis Ltd, http://www.tandfonline.com on behalf of American Society for Quality

unifies three dimensions of the healthcare system: the team, the patient, and the hospital. Our framework emphasizes the fact that quality healthcare teamwork is positively related to patient care quality (PCQ), and PCQ is positively related to hospital quality performance. In the rest of this section, we discuss each dimension of quality measures in hospitals.

### 5.1 Healthcare Teamwork Quality

In healthcare, a patient's medical treatment and cure generally involves work of a resolute healthcare team. *Healthcare teamwork quality* is defined as the ability of the members of a healthcare team to collaborate well with each other to achieve their team objective(s).

Care teams are the norm in all areas of healthcare delivery. For example, members of small surgical teams are able to quickly learn from each other due to workload sharing and team helping, especially when task complexity is very high (Vashdi et al., 2013). Healthcare teams generally use physician empathy and nurse emotional involvement to positively influence the interpersonal relationships that they are able to establish with their patients. They typically take an active interest in their patients' medical condition, empathize with their suffering, communicate clearly to the patient and kin about their medical condition, and work together to rapidly improve health outcomes. Members of a healthcare team try to avoid medical errors, check schedules and room/equipment availability in advance of patients' medical procedures, take steps to prevent infections in hospitals, and keep the patients' care at the forefront of their decision-making. In addition, they generally follow hospital procedures or established workarounds, take all necessary precautions related to hygiene, and ensure that all physical elements of the hospital including the beds and other medical and surgical equipment are thoroughly cleaned and disinfected before use on any patient (Carling et al., 2008).

Overall, there are three major advantages of working in integrated healthcare teams – increased task effectiveness, which improves the patients' health and thereby their satisfaction with care; improved morale and mental well-being of the healthcare team members; and team viability which indicates the degree to which a team will function effectively over time. Based on the above discussion, we suggest that the measurement of the quality of teamwork is essential, not only to improve the quality of patient care, but also to help maintain healthcare team viability and keep them going on to serve patients. In summary, healthcare teams play a pivotal role in providing patient care and in continuously improving PCQ. Teamwork is one of the QM practices (Kaynak & Hartley, 2008) and its relation to healthcare team quality.

## 5.2 Patient Care Quality

PCQ may be defined as the excellence of medical care received by admitted patients in hospitals (Nelson & Niederberger, 1990). In extant literature, many studies have focused on identifying the determinants of PCQ both in hospital and clinical settings. Based on a synthesis of the multidimensional nature of patient care quality discussed in extant literature, Chakraborty and Kaynak (2018) identify the following four facets – *interpersonal, technical, environmental,* and *administrative quality.*

*Interpersonal quality* refers to the relationship developed and the dyadic interplay that occurs between the patient and the healthcare team (Sweeney et al., 2015) that comprise doctors, nurses, and support staff working together as a group to care for admitted patients in most hospitals. It includes issues such as whether healthcare teams treat their patients with respect, healthcare team members listen to what patients have to say, members give personalized attention to patients, and whether team members are willing to answer questions that the patient or their kin may have.

*Technical quality* identifies with the expertise, professionalism, and competency of the healthcare team in delivering treatment. It takes into account whether patients are administered the correct medical treatment that is required to cure their ailment, tests (e.g., X-rays and lab tests) are ordered on patients only when required, healthcare team members are qualified, and whether they carry out their tasks competently.

*Environmental quality* includes hospital atmosphere such as cleanliness and order and tangibles like hospital bed and required equipment for patient health needs. Whether the design of the hospital is patient friendly, the lighting at the hospital is appropriate, the temperature at the hospital is pleasant, and whether the furniture at the hospital is comfortable are issues considered in this PCQ facet.

*Administrative quality* alludes to the support provided by the administrative and support staff that facilitates the medical treatment while adding value to the patient. Considerations such as whether the internal hospital services (e.g., pathology) work well, waiting time at the hospital is minimal, the hospital provides patients with a range of patient support services, and whether the hospital records and documentation (e.g., billing) are error free are in the domain of this PCQ facet.

### 5.3 Hospital Quality Performance

*Hospital quality performance* is defined as a comprehensive reflection of how well the hospital is performing on a wide variety of quality-related parameters. Many scholars have already investigated the impact of QM practices on a firm's quality performance (Fynes & Voss, 2001). Hospital quality performance intends to capture all aspects of quality of the medical treatment processes and other products and services that are used in providing patient care which affect the hospital's overall quality performance.

Hospital quality performance measurement has been a continuing concern for quite a few years now, albeit it may be known by different names such as overall hospital star rating and may be calculated differently by many organizations. On one hand, it could be fairly sophisticated as using ten Hospital Quality Alliance (HQA) performance indicators to calculate a summary performance score for each of the three clinical conditions – acute mesenteric ischemia acute myocardial infarction (AMI) or heart attack, congestive heart failure (CHF), and pneumonia (Jha et al., 2007). On the other, it could be as simple as averaging all hospital star ratings given by patients or their kin on websites like Healthgrades, RateMDs, Vitals, and Yelp. As a third example, the overall hospital star ratings introduced by the Centers for Medicare and Medicaid Services (CMS) could be considered. The current (2016) CMS overall hospital rating follows a detailed methodology using 57 items from the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey grouped into seven subcategories. HCAHPS is the patient satisfaction survey required by CMS for all hospitals in the USA (Cahill & Wang, 2012).

In Table 2, we offer a detailed research design for quality measurement. For each dimension, we also identify a few existing and enhanced instruments that can be used in hospitals that involved in quality measurement. One of the pillars of our quality measurement framework is the patient (either admitted into the hospital or visiting the outpatient clinic). Along with the patient(s), the other key stakeholder is the patient's relatives and friends, who stays with the patient/visits the hospital during the period of admission or accompanies the patient to the outpatient clinics. PCQ can be measured by tapping the patient's health record(s) from the EHR system (Middleton et al., 2013) and their perceptions of the quality of care that he/she experienced in the hospital using the HCAHPS survey questionnaire. EHR is the software platform extensively used in US hospitals by the nurses, staff, and physicians to electronically record all patient information beginning with their name and demographics to their body temperature, medication history, medical procedures, allergies, and several other relevant medical information. The HCAHPS survey, administered mostly by independent survey contractors and sometimes by hospital staff to patients in the hospital, is currently used by CMS to collect patient data on PCQ and several other aspects of hospital operations for its own annual reporting to

*CMS Centers for Medicare and Medicaid Services* is the nodal body tasked with tracking hospital quality improvements. *The Joint Commission* is an independent, not-for-profit body to which patients can complain about their hospital issues. *QIO Quality Improvement Organization* is the organization to complain to if the patient is receiving Medicare; there are separate bodies for each state. *HCAHPS* the *Hospital Consumer Assessment of Healthcare Providers and Systems* is the (survey) method of data collection currently used by CMS. Table is adapted from Chakraborty and Kaynak (2018) the US Congress. Systemic analyses of patient complaints could help healthcare researchers find recurring themes among patients' complaints for each hospital, and the recurring themes among similar hospitals across the USA, which could be considered as areas of enhancement of the HCAHPS survey. These gaps or areas of improvement could also prove to be directly helpful for the hospitals in their effort to improve PCQ.

Most hospitals have three primary responsible stakeholders who work in teams and interact very closely with the patient – the physician, the nurse, and the healthcare staff – who could be playing one or more of the following roles: physician assistant, dietician, pharmacist, therapist/rehabilitation specialist, or hospital administrative/support personnel. We refer to these three stakeholders collectively as the healthcare team.

Measuring teamwork quality is important because it not only affects PCQ on one hand but is important for the healthcare team members' viability and mental well-being on the other. All hospitals need to routinely measure how effectively their team members interact and work on providing patient care (Poulton & West, 1993, 1999). In addition, human resource utilization should also be checked using the hourly work schedule for all team members to ensure that all team members are optimally utilized. For the in-house team surveys, hospitals could randomly select one or more of their healthcare teams who come into direct contact with patients. Further, data on the number of patients handled by the healthcare team in a month and the number of hours worked each day by every team member could be used from hospital records to gauge team success.

We suggest that the focus of a quality measurement framework should be to measure all aspects of PCQ including its four dimensions – interpersonal, technical, environmental, and administrative quality. Patient satisfaction with the medical treatment is also important because ultimately the patient must not only recover fully from the disease/ailment but must also be satisfied with the treatment and its associated costs. Patient perception and satisfaction data for every hospital could be mined from four common websites (e.g., Healthgrades, RateMDs, Vitals, and Yelp) to obtain customer complaint themes and all the individual data for the hospital collected in a month to be grouped to ultimately enhance/augment the HCHAPS survey domains.

Finally, we advocate that the focus of measuring hospital quality performance should be based on the care provided in the hospital. In this context, a lot of existing detailed hospital-level averaged data already tracked by CMS and published in the *Hospital Compare* website could be used. A few examples of detailed metrics currently used in hospitals include the following: (1) the 30-day risk-standardized mortality rates for each of the three ailments – acute myocardial infarction (heart attack), heart failure, and pneumonia, and (2) the 30-day risk-standardized readmission rates after each of the four medical procedures – acute myocardial infarction (heart attack), heart failure, pneumonia, and hip/knee surgery.

There are five other key stakeholders that routinely interact and collaborate with CMS and a few others that occasionally interact with CMS in quality measurement and management efforts as and when required. The Joint Commission and the state quality improvement organizations (QIO) are two important stakeholders. The Office of the National Coordinator (ONC) for Health Information Technology (IT), the federal body responsible for coordinating nationwide efforts to implement electronic exchange of health information using the national healthIT.gov network, is a third stakeholder. Similarly, the American Medical Association (AMA) which helps physicians help patients by uniting doctors and medical students nationwide to work on the most important issues and medical universities that teach/train all budding physicians, nurses, and other healthcare staff are two other important stakeholders in quality measurement because together they guide all physicians, nurses, and medical research teams with the care issues and help determine the evolving medical standards. For a broader discussion of the different systems that help a hospital measure its overall quality, see Chakraborty and Kaynak (2018).

## 6 Emerging Concerns, Existing Research, and Future Directions

### 6.1 Population Health Management (PHM) and Lean Systems

Population health management (PHM) has emerged as an important strategy to address the triple aim of enhancing the individual care experience, reducing healthcare costs per capita, and improving health. Although PHM initiatives are being adopted widely, the term is used somewhat loosely – population health, population medicine, community health, public health, and disease management – and the components of PHM vary across different healthcare organizations (Kaynak et al., 2017). As commented upon by Vic Zuccarello (2015) in this 2015 *Health Affairs Forefront* blog by David Kindig, "population health" is "the health outcomes of a group of individuals, including the distribution of such outcomes within the group." It is an approach to health that aims to improve the health of an entire human population (Kindig & Stoddart, 2003) whereas PHM is "the technical field of endeavor which utilizes a variety of individual, organizational and cultural interventions to help improve the morbidity patterns (i.e., the illness and injury burden) and the healthcare use behavior of defined populations" (Coughlin et al., 2006). Hospitals utilize PHM tools (e.g., data dashboards, registries, and care coordination) to not only manage their patient population but also to meet healthcare quality targets and participate in value-based care initiatives.

Effective implementation of PHM requires continuous improvement, leadership, and teamwork – the topics we have addressed in this chapter – as well as lean systems. Implementing lean systems has its own challenges. Even before the COVID-19 pandemic hit, lean or just-in-time (JIT) system was not overwhelmingly popular among healthcare providers and hospital leaders. The reason for practitioner reluctance is simple: becoming and continuing to be lean is not easy and many do not end up as successful and some give up midway once their leadership changes. A quick search showed that lean is not widely implemented in either US (Po et al., 2019) or in European hospitals (Marsilio et al., 2022).

Among the 288 public hospitals that responded to the survey, 54.2% reported that they had adopted lean. The average length of time of lean implementation was 4.58 years. The mean number of units in which lean was implemented was 11.9 out of 29 possible hospital units, with the emergency department (ED) being the unit in which lean was most frequently implemented (Po et al., 2019).

However, there are also successful implementation accounts of lean systems. For example, Washington Hospital looks at the value added and waste from the patient's perspective to focus on the patient experience. Their lean management system is based on two concepts: continuous improvement and respect for people (Washington Hospital, 2016).

Needless to say, further research is essential to better understand PHM and its implementation in hospital settings. Currently, the focus seems to be on the clinical management of subgroups of patients by health systems and payers. Future research can focus on performance measures at each level (e.g., geographic population, an entire community) and for every stakeholder, in a way that it can support the strategies of hospitals or groups of hospitals to improve population health in their service area. Directly addressing social determinants of health and paying for these strategies can be other fruitful research topics as only 20% of health is determined by healthcare utilization, the rest is due to income, housing, social isolation, and the environment (Gottlieb et al., 2019).

### 6.2 Managing Stressful Environments in Healthcare

As we discussed in the beginning of this chapter, although the jury is out about the specific number of deaths due to medical errors, everyone agrees that patient safety and healthcare quality must be improved to reduce preventable deaths. One reason for medical errors is the occupational stress that "U.S health care clinicians, clinical students and trainees" (p. 1) are experiencing, with burnout rates at approximately 50% (Marchalik et al., 2020). The recent COVID-19 crisis and shootings in hospitals have certainly been adding to the healthcare workers' stress level. Increased burnout rates among healthcare workers have three major implications: (1) a healthcare workforce shortage due to stressful working conditions; (2) low job satisfaction, high absenteeism, and high turnover; and (3) a decline in patient care and hospital quality performance (National Academies, 2019).

A review of the extant literature indicates that healthcare organizations can create an environment in which healthcare staff can feel their jobs are meaningful. "Meaningful work refers to work that is experienced as worthwhile, significant, purposeful, important, and valuable to oneself or others" (Cf. Kimakwa et al., 2021; Allan, 2017; Pratt and Ashforth 2003), which can reduce occupational stress. A study of meaningful work in healthcare can be conceptualized as antecedents of meaningful work as inputs, meaningful work as process, improved employee well-being as output, and patient care quality as outcome. Antecedents of meaningful work include leadership (e.g., Arnold et al., 2007), information technology (to reduce administration work) (e.g., National Academies, 2019), worker empowerment, worker development/learning environment (e.g., Albuquerque et al., 2014), and safe work environment (e.g., Linzer et al., 2009). In other words, the antecedents are the facilitators of meaningfulness. We posit that the outputs of meaningful work are reduced burnout reflected on increased job satisfaction, reduced turnover, and increased work effort, leading to the outcomes – patient care quality and hospital quality performance.

The experience of NYC Health + Hospitals during the COVID-19 pandemic makes it clear that there is a need for further research to fully understand the antecedents of meaningful work and the factors that influence employee well-being given its potential impact on healthcare quality. The leadership at NYC Health + Hospitals was able to use information technology, worker development, and learning tools to create a supportive staff environment during the most stressful part of the COVID-19 pandemic (Salway et al., 2020). Efficient staff redeployment and onboarding processes together with distinct types of support certainly helped the public healthcare delivery system of NYC to manage workforce burnout as well as possible.

## 7 Summary and Conclusion

The COVID-19 pandemic has made it more evident than ever that healthcare systems should continuously improve to be able to provide excellent, equitable care to everyone at reasonable cost (Chakraborty et al., 2021). Hospitals play a critical role in the healthcare ecosystem and – as our discussion in this chapter reveals – continuous improvement, quality leadership, teamwork, and supplier relations are key factors in managing healthcare quality. The supply chain of a hospital is extensive and complex, and the patient is the focal point of its operations. Physicians, nurses, and all other infrastructure support systems are designed to serve the patient in the most effective and efficient manner.

The provision of high-quality patient care requires a supply chain that keeps quality management principles at the front and center of all hospital processes. Quality management practices that are essential in the context of hospitals include hospital quality leadership, healthcare training, healthcare teamwork, hospital quality data and reporting, patient focus, supplier quality management, hospital services design, and hospital process management. Hospital quality leadership is the crucial factor for the successful implementation of quality initiatives and efforts in these organizations. Effective leaders can leverage resources, increase staff engagement, and stabilize processes to move a hospital through its own quality improvement journey. Quality healthcare teamwork is positively related to patient care quality which, in turn, is positively related to hospital quality performance.

An emerging area of work is how population health management can be used as a strategy to enhance the patient care experience, reduce healthcare costs, and improve health. Hospitals can use population health management tools such as data dashboards, registries, and care coordination to manage patient populations more effectively, achieve healthcare quality targets, and participate in value-based care initiatives. The effective implementation of these ideas requires a continuous improvement mindset, leadership, teamwork, and lean systems. Being lean is not easy to accomplish and maintain, but successful lean management systems incorporate continuous improvement at their core.

Lastly, occupational stress and burnout should not be ignored. Burnout in healthcare leads to workforce shortages, low job satisfaction, high absenteeism, increased turnover, and declines in hospital quality performance. Healthcare organizations need to create environments where healthcare staff members feel safe and that their jobs are meaningful to reduce occupational stress and improve healthcare quality.

**Abstract**

An efficient supply chain management system is the key to running product- and service-oriented businesses. In a perfect world, an efficient supply chain provides accurate information to all supply chain players from the downstream (retailers) to the upstream (supplier's suppliers). This helps in ensuring an uninterrupted flow of products and services to the customer. The supply chain is usually a complex network of companies that work together to meet customer demand for a product or service by allowing each company to focus on its specific process to maximize supply chain profit. Uncertainties threaten this coexistence of organizations in a supply chain. Uncertainties such as changes in market conditions and customer demand can lead to inaccurate forecasts and supply chain inefficiencies that may strongly affect a supply chain. The bullwhip effect (BWE) is one such inefficiency. This chapter focuses on the BWE in supply chains. To give the reader an understanding of the BWE, a brief review of some critical perspectives on the BWE in supply chains as well as some proposals discussed in the literature in the recent years has been carried out. The chapter also describes the context within which the BWE has emerged and its characteristics. It also reflects on its relationship with the current trends of sustainability, nonlinear supply chain networks, intangible products (services), monetary and financial issues, competition in supply chains, and the BWE during the COVID-19 pandemic, among other trends, to reveal new research interests on the topic.

## 1 Introduction

The bullwhip effect (BWE) is one of the oldest and most studied topics in supply chain management. A random search in Google Scholar of the words "bullwhip effect" can result in more than 30,000 results in less than 5 s. The topic is old, spanning from the age of production and inventory control (before 1958), through the stages of the *beer game* (1989–1997), to the age of avoiding the BWE (after 2000). The history of the BWE has been documented by authors such as Jia, Wang, and Luo (2011) and Holweg and Disney (2005), among others.

However – as old as the topic is – it is still one of the main concerns in supply chain management with new research emerging with each passing year. In an argument as to why it is still necessary to study the BWE, Fransoo and Wouters (2000) mentioned how existing studies analyze BWE in a simple supply chain, consider different business environments, and have limited assumptions made regarding practical supply chains which are more complex. This situation happens because adjusting even one parameter in the system would significantly affect other parameters and influence the supply chain behavior.

More recently, the BWE received additional attention after extreme disruption situations such as the COVID-19 pandemic (Moraes & Yuan, 2021). The COVID-19 pandemic has raised the importance of studying both the operational and behavioral causes of the BWE due to frequent stockouts in supermarkets for basic products and the scarcity of lifesaving drugs, ventilators, and personal protective equipment (PPE). These stockouts are some of the consequences of having unexpected fluctuations in demand, and these justify the study of the BWE even after all the years of studying the topic (Moraes & Yuan, 2021). Besides the pandemic, BWE has been shown to be a consistent and present concern as shown by two recent independent empirical studies from the USA and China that demonstrated the existence of the BWE within almost two thirds of the analyzed cases (Wiedenmann & Größler, 2019). This pernicious existence of BWE in supply chains after 60 years of study justifies the need to further study the topic.

The BWE has been defined as an *almost ubiquitous problem* occurring in supply chains (Lee et al., 1997). This *almost ubiquitous problem* was the BWE referred to by Dominguez, Cannella, and Framinan (2014) as a "phenomenon by which even small variations in customer demand may generate high alterations in upstream production of suppliers" (p. 2).

"The bullwhip effect is a supply chain phenomenon comprising two information distortion mechanisms, the demand distortion and the variance amplification" (Fransoo, 2021, p. 130). In BWE, the demand distortion occurs for a given firm; the orders it places to its suppliers tend to be more variable than the demand it observes from its customers. This demand distortion increases the further a firm moves upstream and away from the final consumerm causing variance amplification. The combined effects of demand distortion and variance amplification generates a demand shock downstream that creates demands that oscillate with increasing amplitude at each successive stage of the supply chain (Fransoo, 2021).

The BWE is usually characterized by:

- Amplification of demand variation across the supply chain (Lee et al., 1997)
- Lack of coordination between companies in the chain (Bhattacharya & Bandyopadhyay, 2011)
- Lack of transparency in information (Lee et al., 1997)
- Formation of excess inventories in the supply chain aimed at preventing demand variation (Sucky, 2009)
- Product unavailability (Sun & Ren, 2005)

When managing inventories and operations, the BWE is an interesting and important topic to study. The reasons, as we introduced above, are manifold. It is because of the costs associated with the phenomenon such as "setup and shutdown of machines, idling and overtime in the workload, hiring and firing of the workforce, excessive upstream inventory, difficulty in forecasting and scheduling, systems' nervousness and poor supplier or customer relationships among other consequences" (Wang & Disney, 2016, p. 691).

This chapter aims to explore emerging trends and issues in BWE research and practice brought about by emerging supply chain developments such as digitization, sustainability, and e-commerce. The chapter will also explore topics on the BWE that arose because of supply chain disruptions caused by natural disasters and pandemics such as the COVID-19. Section 2 of the chapter will give a brief background on the BWE in supply chains and explore other definitions of the BWE outside of manufacturing and operations management. Section 3 will look at current trends in BWE research, and Sect. 4 will explore emerging research topics on the BWE because of the COVID-19 pandemic. Section 5 will explain some future research directions worth exploring on the BWE. Section 6 will explain the managerial implications of the BWE, and Sect. 7 will conclude the chapter.

## 2 Background

The study of the BWE has evolved over the years, and the topic continues to be interesting and study worthy to both industry and academia. Studies on the topic started before 1958 in the period of production and inventory control as documented by Holweg and Disney (2005).

In this early period, production and inventory control models were built based on control theory, and the dynamic characteristics of production and inventory control systems were discussed. Authors such as Simon (1952) and Vassian (1955) introduced the servomechanism theory and its use in production and inventory control problems. The authors clearly stated the dependence of the inventory level on the sales forecast error and system constants. In the same period, there existed books by Magee (1958) and Brown (1963) that formally described the use of z transforms in production and inventory problems.

This earlier period paved way for the stage of smoothing production between 1958 and 1969. An important discovery in this stage was by Forrester (1961) who built original system dynamics models of the supply chain using DYNAMO revealing the counterintuitive phenomenon of fluctuations in the supply chain. This approach formed the basis of system dynamics modeling. Contributions have included a focus on demand signal amplification in supply chains with more than one echelon. In this stage, authors recognized the importance in how production and inventory control systems influence the stationary variance of inventory levels. Seasonal fluctuations in inventory and demand amplification were gaining attention, but the terms BWE and stability of supply chains were not formally proposed. The emphasis of research in this period was traditional production management.

An important stage in the history of the BWE research was the stage when the *beer game* was introduced between 1989 and 1997. This is the stage when system dynamics became popular as a method of modeling supply chains to study the behavioral effects in supply chains. Sterman (1989) suggested a general stock management model after doing some experimental studies on the *beer game* at the Massachusetts Institute of Technology (MIT).

Many studies emerged because of this beer distribution game. The term *bullwhip effect* was defined in the period from 1997 to 2000 (Lee et al., 1997) with exploratory research on the main causes of BWE. Four factors were identified: (1) demand signal processing, (2) rationing game, (3) order batching, and (4) pricing variations (Lee et al., 1997). This early work formed the basis of research on BWE as most research was centered on either some or all of these factors. A key focus of this stage was investigating relationships and causes of BWE.

The period from 1997 to 2000 identified the causes of the BWE, classifying them as either behavioral or operational causes. Operational causes of the BWE are usually a result of supply chain structures and processes, material and information lead times, and supply variability, among other reasons.

Behavioral causes of the BWE happen because "both in real-life and in experiments, humans operate in ways that deviate from theoretical predictions. We make mistakes. We exhibit psychological biases that affect our decisions" (Udenio et al., 2017, p. 980). The operational and behavioral causes of the BWE have been summarized in Table 1.

Table 1 shows how the BWE cannot just be eliminated by just eliminating the four causes first identified by Lee et al. (1997). It is interesting to note that simple things like personality differences can cause the BWE in a supply chain. The table demonstrates how the existence of the BWE in various supply chains is because of a combination of both behavioral and operational causes. This makes it more complex to study and eliminate the BWE. These multiple relationships are another reason why the topic has evolved over decades, and it is still evolving. Many causes of the BWE have been investigated in isolation.

There have been attempts to mitigate and eliminate the BWE. This reduction of BWE was and still is the focus of most research after the year 2000. Methods have been suggested in literature to mitigate and eliminate the BWE. These include information sharing, integrated supply chain information systems, joint planning, vendor managed inventory, shorter lead times, and synchronized deliveries. However, Yang et al. (2021) mentioned that in spite of such preventive measures, the BWE still exists in supply chains. In their research, the authors demonstrated that human and behavioral factors cannot be ignored when examining the BWE. Such human and behavioral factors include individual cognitive limitations, social interactions with others, and cultural evolution and transmission.

## 3 Other Forms of BWE

Although the demand and information variance (defined by Lee et al. (1997)) in product manufacturing supply chains is the most common form of BWE explored in literature, other forms of bullwhip have also been identified. This section explores other forms of BWE mentioned BWE the literature including the reverse BWE, cash flow BWE, green BWE, service BWE and data quality BWE.

**Table 1** Operational and behavioral causes of the BWE

| BWE cause | Type | Associated with | Explanation | Authors |
|---|---|---|---|---|
| Demand forecast updating | Operational | Supply chain structure and processes | Reliance on past demand information for present demand situation | Lee et al. (1997) |
| Order batching | Operational | Supply chain structure and processes | Batching of orders to minimize unit ordering cost and production cost. Causes distortion of demand information | Lee et al. (1997) |
| Rationing and shortage gaming | Operational | Supply chain structure and processes | In an environment where there is a shortage, buyers tend to over-order to secure resources, and suppliers tend to correct this by rationing to smaller quantities | Lee et al. (1997) |
| Price variations | Operational | Supply chain structure and processes | Promotions and discounts disrupt regular buying patterns buyers will want to capitalize on the discount offered during a short period, while the manufacturer suffers an uneven production schedule, unnecessary inventory costs, and distorted demand information | Lee et al. (1997) |
| Material and information lead times | Operational | Material and information lead times | An order placed by one business unit reaches an upstream supplier after an information lead time, and as the product is made, the order is completed and delivered and there is a material lead time. As demand for materials may change from the time the order is placed to the time the material is received, difficulties arise in effective management of a supply chain | Paik and Bagchi (2007) |
| Machine breakdown | Operational | Supply variability | Potential to exaggerate demand due to over-ordering in times of breakdowns and shortage is perceived by downstream players in the supply chain | Paik and Bagchi (2007) and Forrester (1958) |

(continued)

**Table 1** (continued)

| BWE cause | Type | Associated with | Explanation | Authors |
|---|---|---|---|---|
| Capacity limit | Operational | Other | Decreases in capacity levels cause excessive swings in the supply chain once production problems are detected down the chain. This causes erratic ordering by downstream members and causes a BWE | Paik and Bagchi (2007) and Forrester (1958) |
| Number of echelons | Operational | Others | Removal of one echelon removes the amplification caused by the pipeline and inventory accumulation in that echelon | Paik and Bagchi (2007) |
| Lead time variability | Operational | Others | The level of lead time changes and increases does not initiate the BWE, but the quality of information does | Chatfield et al. (2004) |
| Workloads | Operational | Others | As higher workloads deteriorate process quality, more rework is required, which in turns results in higher workloads | Akkermans and Vos (2003) |
| Communication and coordination | Behavioral | Social interaction | Social interactions that can provide additional information feedback about the dynamic system in supply chains to decision-makers | Sterman (2000) |
| Information sharing and exchange | Behavioral | Social interaction | Sharing point of sale information in the downstream of the supply chain and reducing delays in information delay | Croson and Donohue (2006) |
| Trust | Behavioral | Social interaction | If participants believe in their partners and their abilities, it improves supply chain performance | Croson et al. (2014) |
| Perception | Behavioral | Information feedback | The way information is organized, selected, and interpreted so that the environment can be represented and understood | Haines et al. (2017) |
| Ambiguity | Behavioral | Information feedback | Results because of limited information and decision-makers tend to make decisions based on known information and causality | Yang et al. (2021) |

**Table 1** (continued)

| BWE cause | Type | Associated with | Explanation | Authors |
|---|---|---|---|---|
| Debiasing | Behavioral | Information feedback | An intervention and a method to improve decision-making in supply chains, e.g., training | Tokar et al. (2012) |
| Rationality | Behavioral | Mental models | Reasoning to achieve goals within mental models | Cantor and Macdonald (2009) |
| Judgment | Behavioral | Mental models | Human judgmental interventions strongly influence adjustments in forecasting and ordering | Syntetos et al. (2011) |
| Decision patterns | Behavioral | Decision strategy | How players make decisions in both the presence and absence of demand information | Delhoum and Scholz-Reiter (2009) |
| Risk aversion | Behavioral | Decision strategy | A strategy or decision rule that decision-makers apply under risk | Cannella et al. (2019) |
| Decisions | Behavioral | Others | The behavioral implementation after the decision-making process | Sterman and Dogan (2015) |
| Personality | Behavioral | Individual traits | Influential factor in decision-making and it varies from person to person | Bloomfield and Kulp (2013) |
| Age and experience | Behavioral | Individual traits | Comparing decision-making based on age and professional experience | Turner et al. (2020) |

### 3.1 The Reverse BWE

The reverse BWE is caused by "the variability in delivery from the supplier to customers, through retailers, as opposed to the straight BWE caused by the variability in customer's demand from the customer to the suppliers, through the retailers" (Shukla, 2014, p. 7).

The reverse BWE is the opposite of the BWE defined by Lee et al. (1997). This BWE characterization has not been explored by many studies. There could be investigation into conditions that lead to reverse BWE in supply chains where decisions on pricing and order replenishment are jointly made.

Ozelkan, Lim, and Adnan (2018) defined the reverse BWE as, "amplified price variability as one moves downstream the supply chain due to the impact of upstream supply chain price variability on the downstream retail prices and supply chain mechanisms" (p. 2). The authors provided empirical evidence of the reverse BWE in the natural gas, currency exchange, and food product pricing. They argued that this reverse BWE is increased by procurement practices that use auctions and reverse auctions where decision-makers compete on price. This situation creates fluctuations in procurement price.

The reverse BWE may not only occur in pricing but also in product flow (Rong et al., 2017). A reverse BWE is characterized by a growing variability in the demands downstream from the suppliers caused mainly by interruptions in delivery. The reverse BWE in product flow may also be caused by either a delivery interruption or the product shutdown in an upstream supply chain echelon (Dias Brito et al., 2020).

Although multiple forms of reverse BWE are mentioned in the literature, the topic has not seen as much investigations and requires significantly more research to understand the phenomenon.

## 3.2 The Cash Flow Bullwhip (CFB)

The “cash flow bullwhip (CFB)” – a term introduced by Goodarzi, Makvandi, Saen, and Sagheb (2017) – is “a phenomenon which is derived from the oscillation of the Cash Conversion Cycle (CCC) that takes place throughout the cash flow of the supply chain” (p. 640).

In addition to information, cash also flows in a supply chain, and this flow of cash within the supply chain can be affected by other activities of the supply chain. The presence of the BWE in a supply chain brings about the CFB (Tangsucheeva & Prabhu, 2013). Lead time is a main factor for CFB control. Factors that have a large effect on the BWE will have a great impact on the CFB (Goodarzi et al., 2017). In addition, Lamzaouek, Drissi, and El Haoud (2021) explained that the amplification of stocks caused by the BWE extends the time needed to transform them into cash, leading to cash flow problems. Companies suffering from the CFB can be held hostage by their inability to finance their activities even though they are profitable. To mitigate the CFB, Goodarzi et al. (2017) advise managers to pay more attention to work in progress (WIP) to decrease cash-to-cash cycle fluctuations and the CFB.

A variation of the CFB was introduced by Vousinas (2019) who defined the “supply chain financial BWE” as a phenomenon on the financial flow level of the supply chain that involves the amplification of financial distortion along it. This type of BWE is said to occur when there exists an oscillation in the financial flows from the financing institutions, due to both internal and external factors causing cash flow fluctuations and financial distress at the firm and economic level. This phenomenon can also be studied across global supply chains.

Although there are a number of publications on CFB, this is another form of BWE that is still underexplored and provides a gap for further research. Wang and Disney (2016) mentioned the CFB, as an extended concept of the BWE that is among the current trends and issues in BWE research.

### 3.3 The Green BWE

While the ordinary BWE considers inventory flow, there is another form of bullwhip that looks at environmental regulations applied to products. This form of BWE is termed the green BWE. Lee, Klassen, Furlan, and Vinelli (2014) explained that the green BWE is a "dynamic phenomenon whereby environmental obligations flow back upstream in the supply chain with significant variation" (p. 40).

The authors also defined the green BWE as an "event motivated by changes in environmental requirements such as new regulations and the industry needs to respond to environmental incidents, practicing urgency when it comes to meeting new environmental pressures from customers and moving them upstream in the supply chain" (p. 40). These changes can create risks and uncertainties, complicating the response to them and managerial planning in the supply chain. The following characteristics of the green BWE are as follows (Lee et al., 2014):

- Rigor of demands on products and materials based on environmental characteristics tend to increase as one moves upstream of the supply chains.
- Deadline of meeting the requirements based on environmental issues tends to get shorter at each upstream level of the supply chain.
- The responses to the green BWE may vary in accordance with the characteristics of the relationships between customers and suppliers.

In the green BWE, the position in the supply chain can play a role in intensifying green BWE outcomes (Pais Seles et al., 2016). The argument is that the further the organization is from the end customer, the more delayed the environmental pressures will be, leading to the organization to compensate intensely to respond to the environmental pressures. While the BWE is a negative phenomenon, the green BWE can have positive results if focal companies provide shared environmental training and shared development of technologies with their suppliers.

The green BWE needs greater exploration.

### 3.4 The Service BWE

The service BWE is not exactly a new phenomenon as it was first explored decades ago (e.g., Akkermans & Vos, 2003). By then, many authors had mixed feelings as to the differences between manufacturing supply chains and service supply chains. The service BWE has the same definition as defined by Lee et al. (1997); however, the BWE is being experienced in service industries such as hotels and airlines rather than manufacturing organizations.

There are both similarities and substantial differences to product supply chains in terms of the nature and cause of amplifications (Akkermans & Vos, 2003). Service supply chains tend to focus on backlogs on orders rather than inventory buildup like product supply chains do. Other triggers for amplification in service supply chains have been identified and include interactions between workload and quality, sales campaigns, overloads, and errors (Akkermans & Voss, 2013).

An extension to the service BWE is when manufacturing and services are integrated to form what are termed *integrated manufacturing and service networks (IMSN)*. An IMSN is "a group of companies working together to offer a bundle of products and product-related services that deliver value to customers over the entire useful life of the product, from purchase to disposal" (Viswanadham et al., 2005, p. 3005).

On investigating the BWE in an IMSN, Viswanadham, Desai, and Gaonkar (2005) observed that the service system exhibits oscillatory behavior in resource levels for repair crews, spare parts, etc. The authors used system dynamics modeling to demonstrate that integration and collaboration between the manufacturing and service operations with two-way information flow between them enhances profitability and minimizes the BWE within repair centers.

The BWE in service supply chains is also one of the topics mentioned by Wang and Disney (2016) as a trending and interesting topic to look into as far as the BWE in supply chains is concerned.

### 3.5 The Data Quality BWE (DQBE)

Information sharing has been mentioned as one strategy for reducing the BWE in supply chains. However, new research has emerged as to the impact of the quality of data shared in supply chains. Ge, O'Brien, and Helfert (2017) defined a new form of BWE which they claimed to be almost similar to the ordinary BWE. They termed this the *data quality BWE* (DQBE) and defined it as an "increase in the variability of data quality success over time" (p. 158). The DQBE is said to be affected by delays and reluctance to react to data quality problems on the part of the supply chain players. There is an argument that if variability in data quality can be predicted, then the DQBE can be reduced.

There is only one article on this form of BWE. This means that DQBE needs to be explored further with other studies to see what conforms or does not conform to basic BWE.

## 4 Trending Topics on the BWE

In an invited review, Wang and Disney (2016) explained the evolution of BWE research and what is still being expected in the coming years. In their narrative literature review, the authors identified main topics of interest that are emerging under BWE research and which serve as a reminder that the BWE is still an interesting topic of research; this section explores some extensions and trending topics on the BWE. Some of these topics have already been discussed as other forms of the BWE, for example, the BWE in service supply chains and the CFB. This section explores some of the trending topics on the BWE mentioned by Wang and Disney (2016).

## 4.1 BWE in Complex Systems

There is an argument that supply chains are complex systems, and a representation of supply chains with just cascading echelons is not enough. The decomposition assumption was accused of underestimating bullwhip measures by Chatfield (2013). The consideration of arborescent supply chains by Beamon and Chen (2001) helped to explain that sometimes there is more than one player at each echelon of a supply chain. "Future research on complex systems will investigate other kinds of non-linear mechanisms in more realistic supply chain models such as capacity constraints, lost sales, bargaining, competition and transhipment" (Wang & Disney, 2016, p. 697).

The concept of complex supply chains was also introduced by Ma, Wang, He, Lu, and Liang (2015) when they presented an argument that the BWE in supply chains cannot be investigated without considering the interactions among supply chains. They investigated parallel supply chains with interacting price-sensitive demand and concluded that managers who ignore interactions between supply chains are likely to overstate or underestimate the BWE in the supply chain. Ma and Ma (2017) claimed that market competition monotonously impacts the BWE, but it is a simple factor. Lee et al. (1997) did not list these factors, but they are factors worth investigating.

Different supply chain network structures were also investigated by Tombido, Louw, and van Eeden (2020) who compared series and divergent supply chain networks for both forward and closed-loop supply chains. The authors concluded that in closed-loop supply chains, increasing the number of collectors in the reverse chain increased the BWE in all supply chain configurations. Therefore, it seems to be more beneficial for a closed-loop supply chain to have one reliable collector supplying used products than more than one collector with uncertainties in the quantity of products returned. Tombido et al. (2020) also revealed that a serial network is more sensitive to changes in the reverse chain in terms of the number of parties involved compared to a divergent supply chain. A similar study was carried out by Osadchiy, Schmidt, and Wu (2021), who studied the BWE from a supply network perspective. Although they did not focus on closed-loop supply chains, Osadchiy et al. (2021) argued that variance amplification can be lowered when suppliers serve multiple customers, and this offsets the impact of individual customer's demand distortion. The authors presented another argument that firms may mitigate the BWE and its impact through their choice of customers and suppliers that change their customer base on average experience subsequent reduction in demand variability.

Studying the BWE in complex supply chains has become a new norm and an interesting topic; however, there is still need to explore different supply chain network structures. The supply chain has also been complicated by the introduction of e-commerce. Supply chains have started using dual channels (online and offline) not just for selling products but also for reverse logistics. In their review on dual and multichannel closed-loop supply chains, Tombido and Baihaqi (2022) mentioned that there is a need for more studies on the impact of having dual and multichannels on supply chain dynamics and the BWE in supply chain dynamics as a way of studying the BWE in complex supply chains.

### 4.2 Bullwhip in Make-to-Order Supply Chains

Most research assumes tangible products in a make-to-stock environment where inventories can be stored as a cushion for variations in demand. There is barely consideration for the make-to-order supply chains where production and consumption occur simultaneously. A search in the web of Science and Google Scholar shows no record of any research on the BWE in make-to-order supply chains. This means that this topic on its own presents a new area for investigation.

### 4.3 BWE Models Incorporating Price and Negotiation Processes

Wang and Disney (2016) mentioned, “Research on the influence of process on the BWE requires models that incorporate price setting and negotiation processes, dramatically increasing the complexity of the model” (p. 697).

Drift (2012) argued that present research toward solutions on the BWE has focused mainly on the systemic and operational causes of the BWE, resulting in solutions that require high levels of organizational integration, central coordination, and information sharing. They argued that such solutions are not always feasible within actual complex supply chains and are not acceptable toward the strategic perception of sensitivity of operational information, nor suitable within the authority and responsibility structures of organizations. In their research, the authors developed and proposed forecast accuracy discount agreements as decentralized solutions. These solutions incentivize customers to smoothen their purchase orders by rewarding predictable ordering according to previously shared forecasts of their own expected future orders. Qu and Raff (2020) also agreed that decentralized supply chains where upstream players use linear wholesale prices may be less susceptible to the BWE than vertically integrated supply chains as they may experience lower upstream production and downstream sales volatility.

Unique research by Ma, Lou, and Wang (2021) combined two trends mentioned by Wang and Disney (2016), that of competing supply chains and price considerations. The authors studied the BWE influenced by a pricing strategy in two parallel supply chains distributing price-sensitive and price-substitutable products. They discovered that the BWE in two parallel supply chains is affected by lead time, product substitution rate, and the pricing coefficient. Their main conclusion was that the BWE in two supply chains with alternate products could be lowered by having a higher degree of substitution between the products.

Recent research by Moghadham and Fazel Zarandi (2022) focused on the management of the BWE in a four-echelon supply chain through information sharing and cooperation. In their research, the authors proposed a fuzzy reverse ultimatum automated negotiation model based on game theory to determine the ordering policy of the supply chain as a way of lowering the BWE.

Although the idea of incorporating price and negotiations in BWE research seems to have more recent publications, also another evolving topic without solid conclusions leaves a considerable gap for research.

## 4.4 Bullwhip with Resource Competition

Resource competition is a phenomenon that was investigated by Lee et al. (1997) in the form of rationing and shortage gaming. This occurs when retailers perceive a shortage in a commodity and they buy more than necessary to cover for the period when there is a shortage. However, competition may also arise in the form of retailers competing to sell their products. Yuan, Zhang, and Zhang (2020) analyzed the impact of different forecasting techniques on the BWE in two parallel supply chains with competition.

In their research, market demand was affected by self-price sensitivity coefficient, the cross-price sensitivity coefficient, market share, and demand shock of two supply chains with one manufacturer and one retailer. Similar research was carried out by Yin (2021) and Ma and Ma (2017) who measured the BWE in supply chains with one supplier and more than one retailer competing. Yin (2021) captured the degree of market competition using copula and concluded that market competition does have a significant impact on the BWE. Ma and Ma (2017) measured the BWE under moving average forecasting technique and investigated the effects of lead time, span of forecast, market competition, and the consistency of demand volatility on the BWE.

## 4.5 Bullwhip and Sustainability

Environmental laws and regulations have been addressed in what is termed the "green BWE." However, the majority of research that has studied the BWE and sustainability has focused on the BWE in closed-loop supply chains.

Studies such as those by Tang and Naim (2004), Zhou, Disney, Lalwani, and Wu (2004), Turrisi, Bruccoleri, and Cannella (2013), Das and Dutta (2013), Zhang and Yuan (2016), Tombido and Baihaqi (2020), Tombido, Louw, and van Eeden (2020), Tombido, Louw, van Eeden, and Zailani (2021), and Zhou, Naim, and Disney (2017) studied the BWE effect in closed-loop supply chains. Overall, they concluded that an increase in the return rate decreased the BWE in a supply chain.

The main factors of interest in this research included return rate, lead times, and remanufacturing rate. Additional factors investigated were capacity limitations

(Tombido et al., 2021), product substitution (Tombido & Baihaqi, 2020), supply chain structure (Tombido et al., 2020), impact of different recovery options (Sy, 2017), inventory holding rates (Corum et al., 2014), return policy, and number of echelons (Cannella et al., 2016).

There are studies who did not agree that increasing product returns reduces the BWE. These include Ding and Gan (2009), and Adenso-Díaz, Moreno, Gutiérrez, and Lozano (2012) argued that when remanufacturing is introduced in a supply chain, BWE increases in the closed-loop supply chain, and it increases with an increase in product returns. This is one topic with a growing number of publications; however, there are still disagreements as to the impact of product returns on the BWE. This issue arises because studies differ in modeling assumptions and methods. This means that the BWE in closed-loop supply chains will continue evolving over time.

### 4.6 BWE as an Extended Topic

Although most of what Wang and Disney (2016) considered as BWE as an extended concept has been covered in most of the sections, a special BWE was introduced by Asgary and Li (2014) caused by unethical operations. In this type of BWE, risk amplification moves from the supply side to the demand side due to unethical operations conducted along the supply chain. Asgary and Li (2014) argued that this form of BWE originates from a minor unethical operational decision in the supply chain and results in a significant economic loss of a company's reputation and bottom line on the demand side.

It is interesting to note that since the introduction of the trends observed by Wang and Disney (2016), there has been an increase in the number of articles on the proposed trending issues on the BWE. However, there is still a need to explore all these trending issues.

## 5 BWE and the COVID-19 Pandemic

In this section, some research topics on the BWE introduced by the COVID-19 pandemic are explored. The COVID-19 pandemic started in early 2020 and is still in existence to date. This means that research needs to address this pandemic and future pandemic supply chain issues, and research on the BWE is no different.

The BWE during the COVID-19 pandemic has been known to be caused by changes in "customers' purchasing behaviour during the pandemic and businesses anticipating the situation inaccurately" (Zighan, 2022). In an exploratory research based on online interviews with 41 firms, Zighan (2022) investigated how firms can deal with the BWE caused by the COVID-19. Additional causes of the BWE during COVID-19 were identified by Zlotskaya (2021) who focused their investigation on information and technology and firms. They argued that there was an increase in demand in information and technology firms, and this led to fluctuation in prices, order delays, deviations from supply, and poor communication across channels, which are the main causes of the BWE during COVID-19.

Zighan (2022) identified situational analysis, localization of supply chains, and supply chain digitalization as the best ways of mitigating the BWE during the COVID-19 pandemic. Hsu, Yang, Zhang, and Chang (2021) also proposed a multi-criteria decision management framework for identifying key data enablers to enhance supply chain agility and mitigate the BWE, and Ran, Wang, Yang, and Liu (2020) also argued that the application of higher digital technologies can improve the BWE in a broader range, but it increases the production cost.

Research on the BWE during the COVID-19 pandemic did not just focus on the causes and mitigation – new research topics emerged on the BWE as a result of the COVID-19 pandemic. Since the pandemic started in China, Zhang (2021) investigated the BWE of Chinese exports. They discovered that the outbreak of COVID-19 in foreign countries caused a lagged import substitution toward Chinese products that initially reduced negative demand shocks that were prevalent during the initial stages of the COVID-19 pandemic. The author also concluded that the BWE is stronger in regional supply chains, among geographically close countries that are closely connected in terms of trade volume.

With the COVID-19 pandemic came the introduction of the COVID-19 vaccine supply chain that is expected to be strongly affected by the BWE as companies struggle to predict demand for the vaccine. Focusing on the BWE in the COVID-19 vaccine supply chain, Hosseini Bamakan, Malekinejad, Ziaeian, and Motavali (2021) designed a cognitive map based on influential factors for reducing the BWE. They argued that by improving inventory management and reliability, it is possible to control lead time and therefore overcome the BWE in the COVID-19 vaccine supply chain.

The COVID-19 pandemic also led to most companies focusing on supply chain resilience as an important goal. However, this did not eliminate the importance of studying the BWE. As a result, it became necessary to establish interrelationships between supply chain resilience and the BWE. Thomas and Mahanty (2020) examined interrelationships between resilience, robustness, and the BWE in an inventory- and order-based production system being subjected to operational disruption in the customer demand process. Their main conclusion was that resilience and robustness are two conflicting performance characteristics that exist in trade-off relationships and that the improvement in both supply chain resilience and the BWE can be achieved simultaneously if there is a proper selection of control parameters.

Lastly, the COVID-19 pandemic increased the use of online delivery apps as people avoided contact during lockdowns. Online delivery apps were used for the delivery of food and medicines among other products. Online delivery apps have an impact on the demand in a supply chain as the "e-supply chain causes price variations and result in poor forecasts and hence enhance the BWE" (Jain et al., 2020, p. 2).

In their research, Jain et al. (2020) investigated the impact of food delivery apps on the BWE in a food supply chain. Their argument was that the availability of many eateries at a single online platform with large price variations and different fame has increased competition and has imposed a threat on quantifying the demand of food on the online food industry. Online food delivery apps have shifted the demand of food from push to pull. They quantified the BWE differently and concluded that e-supply chain generated by food delivery apps reduces the BWE by increasing efficiency and effectiveness and increases value in the supply chain.

## 6 Emergent Concerns and Future Research Directions

The BWE is one topic that has evolved over decades, yet new topics and trends have emerged. This supply chain issue and topic that is not going away any time soon given that the structure and behavior in supply chains will make it a continuing issue. In this section, the chapter will identify some research gaps for future research on the BWE. These gaps are explained in the following sections and include gaps in BWE mitigation, other forms of BWE, and behavioral aspects of the BWE.

### 6.1 BWE Mitigation

It is evident that the majority of study and investigations have focused on the BWE as defined by Lee et al. (1997). In carrying out research on mitigating the BWE in supply chains, studies have mostly targeted causes of the BWE. Most research focuses on the operational causes on their own or the behavioral causes on their own. However, operational and behavioral causes of the BWE do not exist in isolation. Future study investigations should consider both operational and behavioral causes of the BWE together as a way of mitigating its outcomes and not just isolate the causes. In addition, more empirical evidence is needed on the study of the BWE, especially when trying to mitigate the BWE. Most studies have resorted to mathematical modeling and simulation with limited empirical evidence. It is necessary to have more of empirical evidence where mitigation is successful – detailed case studies will also be helpful from both a research and practical perspective.

In terms of the behavioral causes of the BWE, it should be interesting to investigate the impact of different technological developments such as Industry 4.0 and supply chain digitalization on the behavioral causes of the BWE. Currently, most supply chain players make decisions in groups, and it is also necessary to investigate the impact of group decisions on the behavioral causes of the BWE.

### 6.2 Other Forms of the BWE

A search for the BWE on Google Scholar results in more than 10,000 articles; however, a search for the other forms of the BWE such as the service BWE, CFB, reverse BWE, and green BWE results in less than 10 publications for each, respectively. There is a need for more investigation on other forms of BWE, from their causes, ways of modeling and measuring them, and their mitigation. This emergent concern needs to be addressed.

The service BWE was first mentioned in 2003, yet there are less than ten publications that exist on the topic to date. Another interesting research topic is that of the BWE in IMSN. Organizations are now integrating manufacturing and services as customer needs change. It becomes necessary to study such networks by defining the BWE, finding ways of measuring it, and providing empirical evidence of the BWE in such networks.

Companies are now focusing on maintaining their social responsibility by incorporating environmental issues in their supply chains. This focus has made green BWE study more important. Although there are publications on the green BWE, there are not enough to make consensus conclusions on the topic. The response to the green BWE in a supply chain depends on the characteristics of relationships between supply chain players. On this topic, it is necessary to explore relationships between supply chain players that can mitigate green BWE in supply chains. It is also necessary to study conditions that can make green BWE a positive phenomenon in the supply chain. It is quite evident that no one has studied the behavioral causes of the green BWE in a supply chain. That is also an interesting gap as relationships between supply chain players are sometimes a result of behavioral issues such as trust among other issues.

The reverse BWE can be caused by a delivery interruption or a production shutdown in an upstream supply chain echelon. Both these causes were experienced during the COVID-19 pandemic as industry shut down, and there were lockdowns that led to delays in delivery. However, it was also interesting to note that there were no studies specifically focusing on the impact of the COVID-19 pandemic on the reverse BWE in supply chains. This research gap can be explored with empirical evidence. The reverse BWE has also been studied more from a pricing point of view rather than from a product flow point of view. This also an emerging gap especially with the COVID-19 pandemic.

Although the CFB has been well defined in literature, much of the topic still remains a mystery, for example, the impact of the CFB on the profitability of a company and its investment capacity. The CFB has also not been studied from the COVID-19 perspective. There is also a need to study CFB control mechanisms and the dynamics associated with the CFB from the perspective of the omni-channel commerce.

Data quality BWE also represents an area in dire need of study as there is only one publication on the topic. Data quality BWE still needs further investigation in terms of its existence, causes, and mitigation. These investigations need to be backed by empirical evidence.

It is quite possible that a supply chain can have more than one form of BWE existing concurrently. This concurrency of multiple BWE types requires investigating the existence of different forms of BWE in one supply chain and establishes interrelationships between these forms of BWE. Another related type of investigation would be how mitigating one form of BWE might affect BWE types existing in that supply chain.

As supply chains introduce digital technologies, it is necessary to investigate the role of digital technologies in reducing each BWE type. It is also important to study these forms of BWE using different supply chain structures and not just the simplified one echelon supply chain. Supply chains rarely contain one manufacturer and one retailer, so it is necessary to consider other supply chain structures. Usually, supply chains exist in competition; it is also necessary to study these forms of BWE under conditions of competition between supply chains.

## 7 Managerial Implications

The analysis of BWE assists managers in evaluating their supply chains. By understanding the forms of BWE in their supply chain, managers can avoid costly losses and maintain a competitive edge in their supply chains.

The demand shocks, shortages of products, and economic decline that came about because of the COVID-19 highlighted the necessity of studying the BWE in all types of supply chains, be it manufacturing, processing, or service supply chains. The BWE moves in all directions of the supply chains and not just from downstream to upstream. As a phenomenon, the BWE is no longer associated with just demand variability but also data quality, environmental regulations, transportation disruptions, refers logistics, remanufacturing and cash flow among other things. This makes it more complicated, and managers need to understand the forms of BWE associated with their supply chain operations and continuously find the best strategy to mitigate the BWE. Companies need to assess how every decision they make might cause the BWE.

In a situation where every organization is trying to recover from the blows of COVID-19, studying the BWE at every angle and in every form becomes necessary because of the waste associated with BWE – such as overstocking, among others. Most organizations are focusing on recovery, and they cannot avoid such waste.

In addition, while most organizations are focusing on recovery and supply chain resilience in the face of future pandemics, it becomes necessary to investigate the impact of recovery and resilience strategies on the BWE as an organization might solve one problem by creating another. The implications of BWE in a global setting also arose; whether local or regional BWE impacts differ would be interesting for practitioners in terms of where to source from BWE and resilience perspectives.

The pandemic COVID-19 has reminded supply chain managers the importance of supply chain risk management. Disruptions caused by the pandemic are propagated in many directions. Managers must take into account the various forms of the BWE in their supply chain risk management.

## 8 Summary and Conclusion

This chapter introduced the concept of the BWE, its evolution, causes, characteristics, mitigation, and different forms. Current trends in BWE research and some trending research gaps were offered in the chapter. The chapter also explored research on the BWE introduced by the COVID-19 pandemic. By explaining some managerial implications, the chapter highlighted why studying the BWE has become more necessary now than ever, even though the topic has been studied for decades.

The BWE is a topic that has been studied for decades, yet it still evolves and new research gaps keep on emerging. Investigations on the operational causes of the BWE have mostly focused on make-to-stock environments; however, nowadays customers have gained the upper hand as they can demand customized products through online channels. This makes research on the BWE in make-to-order environments and interesting concept.

The COVID-19 saw the growth of online delivery apps. Online delivery apps are being used in different industries, including food, clothes, and medicines, among other industries. It is necessary to compare the impact of these online delivery apps on the various forms of the BWE for different industries as their impact may differ with industry and also the form of BWE.

In addition to introducing the vaccine supply chain, the COVID-19 pandemic also made some existing supply chains popular, for example, PPE, medical devices, and some pharmaceuticals. Since the COVID-19 pandemic is still in existence, there is a need for research investigating both the BWE in such supply chains.

Lastly, there is a need to expand research on the trends on BWE topics mentioned by Wang and Disney (2016). There has been research on the trending topics; however, there is a need to expand on each and every one of the topics.

To conclude, the BWE is a concept that has bothered supply chain managers and has been studied for decades. After studying the topic for decades, however, the BWE still exists in supply chains, and it is still a cause for concern. The COVID-19 pandemic has also revealed weaknesses in various supply chains, thereby highlighting the importance of studying the BWE. This chapter has shown that there is a need for more research on the BWE and that the topic is still evolving even after decades of study.

# Supply Chain Performance Measurement: Current Challenges and Opportunities

Sharfuddin Ahmed Khan and Syed Imran Zaman

## Contents

**Abstract**

This chapter considers factors associated with supply chain performance (SCP) and investigates linkages between SCP and a variety of issues, which include enterprise resource planning systems, blockchain technology (BCT), data analytics, and supply chain sustainability. The chapter also provides an illustration of how these issues relate to (SCP). A holistic model to enhance SCP is presented. The chapter can help enhance supply chain operation efficiency.

## 1 Introduction

COVID-19 and the rising degree of competition in the global economy mean supply chains need to have effective supply chain performance measurement (SCP) (Kumar et al., 2017). Traditional supply chains have difficulty satisfying customer demands for high-quality goods at affordable prices. The current tendency is to incorporate new components while simultaneously making the present system more intelligent, automated, and environmentally friendly (Yadav & Singh, 2020). Issues businesses face, such as wasting time on the analysis of inaccurate and irrelevant data and dealing with difficulties like how to store and access massive amounts of data, lead to a decline in supply chain overall performance, efficiency, and organizational profits (Gopal et al., 2022). In this chapter, we introduce potential solutions to these problems. Solutions include boosting resilience, embracing blockchain technology (BCT), improving sustainability, deploying enterprise resource planning (ERP) systems, and integrating supply chains more effectively.

Performance measurement and management have emerged as crucial components for continued viability of businesses. Appropriate performance measurements help managers take a long-term view and devote organizational resources to improve operations. These performance systems ensure that managers adopt appropriate performance metrics (Elgazzar et al., 2019). Supply chain managers regularly compare their operational performance against benchmarks – an important performance measurement activity (Zhao et al., 2023). Nevertheless, modern supply chains are vulnerable to ever-changing business contexts leading to uncertainty and unpredictability.

In this uncertain environment, businesses are shifting their attention away from the development of resources and toward the growth of dynamic skills in order to reduce risks – such as a loss of reputation – and establish competitive advantages (Bag et al., 2020). Managers and researchers place high value on improving SCP, an important factor for fulfilling customer expectations and establishing competitive advantage. Businesses are strongly reliant on their supply networks to help in meeting competitive goals (Rahimi & Alemtabriz, 2022).

## 2 Background

SCP is defined as the degree to which a supply chain fulfills the needs of the end consumer (Carvalho et al., 2012; Hausman, 2005). According to Daneshvar, Hajiagha, Tupėnaitė, and Khoshkheslat (2020), the implementation of a successful strategy for the supply chain has a positive influence on the performance of the supply chain. Through supply chain management (SCM), organizations can support their competitive strategy and maintain competitive advantage (Sutanto & Japutra, 2021).

Companies may collaborate with another to monitor their SCP by using a measurement system with measuring instruments (Fernando et al., 2023). This measurement system measures SCP. Overall firm performance requires performance improvement of each function across the company's supply chain.

SCP refers to extended supply chain actions that fulfill the customer criteria. These activities consist of product availability, on-time delivery, inventories, and the capability of the supply chain to achieve the desired performance in a reactive way (Almatarneh et al., 2022). As part of SCP, organizations devote resources to new technology developments. These technologies support effective channels of communication and cooperative frameworks. This development ensures that information be effectively exchanged (Govindan et al., 2017). Competition across supply chains and maintaining organizational competitive advantage requires achievement and maintenance of SCP.

SCM performance can be separated into financial and nonfinancial indicators. Strategic financial performance measures are required for senior management decisions. Operational measures are required for decisions made by junior management and employees (Saleheen et al., 2018).

SCP should emphasize three distinct kinds of performance measurements: *resource measures*, which include costs, inventory levels, and manpower needs; *output measures* such as responsiveness to customers, and quality; and flexibility measures, which represent a system's adaptability to varying demand levels (Mazzawi & Alawamleh, 2013).

The supply chain operation reference (SCOR) model can be utilized to conduct an evaluation of SCM system performance in relation to customers, companies, and suppliers (Putri et al., 2019). The high-quality value of strong connections between members of the supplier network is directly tied to the successful performance of the supply chain as a whole (Mukhsin et al., 2022).

Since SCP encompasses raw materials, components, and final goods, as well as distribution to customers through a variety of channels, it cuts beyond the boundaries that separate individual companies. In addition, SCP crosses conventional organizational functional boundaries, such as those separating production, distribution, marketing, sales, and research and development (Almatarneh et al., 2022).

## 3 Supply Chain Performance and Resilience

The capacity of supply networks to address unforeseen disruptions is one definition of their resilience. The traditional focus for supply chain design has been to reduce cost or improving service. Recent focus has shifted to emphasize supply chain resilience (SCR) (Carvalho et al., 2012; Christopher & Cristopher, 2011; Hosseini et al., 2019). Resilient supply chain networks make it easier to deal with interruptions – resilience also makes it easier for supply chains to recover quickly. Resilience effects supply chain performance (Piprani et al., 2020).

Building resilience deters disruptive events from happening and contributes to establishing and sustaining acceptable levels of performance. Resilience is currently a critical SCP facilitator (Chowdhury et al., 2019).

When information-processing capability is aligned with the extent of supply chain interruptions, SCR may be favorably correlated with SCP (Belhadi et al., 2021). In order to improve the efficiency and robustness of the supply chain, studies have focused on identifying SCR indicators. Some of these indicators include redundancy and the flexibility of the transport system (Singh et al., 2019a). The effective supply chain resilience benchmark, as outlined by Guoping and Xinqiu (2010), includes the following: a rapid response to unexpected shifts in demand and supply; the ability to adapt to changing market structures and strategies; and the formation of unions among members of the supply chain in order to maximize both their individual benefits and the overall performance of the supply chain as a whole.

## 4 Supply Chain Performance and Sustainability

According to Seuring and Müller (2008), sustainable SCM (SSCM) is defined as: "*the management of material, information, and capital flows as well as cooperation among companies along the supply chain while taking goals from all three dimensions of sustainable development, i.e., economic, environmental, and social, into account*."

Organizational sustainability is now a strategic endeavor (Gong et al., 2019). Both small and large organizations view environmentally friendly business practice adoption to have positive financial impact, lead to the creation of new income streams, and ultimately boost both consumer and staff satisfaction (Mincer, 2008; Narimissa et al., 2020).

Green supply chain management (GSCM) and SSCM include integrating environmental considerations into SCM activities – including product and design service, procurement, manufacturing processes, distribution, and end-of-life management of the product (Hapsari et al., 2021; Olugu et al., 2011). SSCM helps companies improve their environmental, economic, and operational performance; it is necessary to consider environmental factors when evaluating the past, present, and future performance of companies and their supply chains. This necessity occurs because SSCM contributes to improved company performance in all three of these areas.

As a consequence of this, studies argue that SSCM indicates increases in efficiency that result in cost reductions (Gold et al., 2010). Stakeholder involvement in SSCM helps determine the extent to which it may have an impact (Jermsittiparsert et al., 2019).

The features and practices of SSCM have a significant influence, both positively and adversely, on the performance of the supply chain in terms of environmental sustainability. Social responsibility practices have a significant correlation with environmental performance, and social responsibility activities, such as the design and development of environmentally friendly products, have a positive impact not only on environmental performance but also on social performance and financial performance.

Other social responsibility activities include the design and development of environmentally friendly products (Le, 2020). In a similar vein, a number of studies indicated that interactions with customers, processes and equipment, product design, and connections with suppliers all have a significant influence, both positively and negatively, on sustainable performance (Iranmanesh et al., 2019). Lean culture was found to have a positive relationship to sustainability (Bandehnezhad et al., 2012; Jum'a et al., 2021). The adoption of environmentally friendly methods also comes with a number of important financial advantages (Dubey et al., 2015). These benefits provide a "win-win" scenario for both businesses and the environment (Beckmann et al., 2014).

Green and sustainable activities can save materials and manufacturing costs, transportation and logistics costs, increased product quality, reduced costs for warehousing, and even increased inventiveness (Pagell & Gobeli, 2009). SSCM improves resource efficiency which is directly related to economic success (Cherrafi et al., 2018; Zhang et al., 2012).

Social sustainability indicators and supply chain performance measures include health and safety, as well as expenditure, social policy, workforce, job satisfaction, and ethical behavior on the job. Positive and negative societal repercussions may be determined by looking at factors such as accident rates and the number of employment possibilities available in the service sector (Sreedevi & Saranga, 2017).

In addition to these sustainability measures, ecologically responsible policies foster greater economic and environmental performance across areas (Colicchia et al., 2017; Khan et al., 2020). The improvement of both economic performance and environmental performance through the establishment of long-term buyer–supplier relationships is one of the most important components of SSCM. The provision that suppliers satisfy sustainability performance standards is another important aspect of SSCM (Trivellas et al., 2020).

## 5 Supply Chain Performance and Blockchain Technology

The blockchain (BCT) is a distributed ledger technology that employs features to guarantee the safety, openness, and transparency of a network (Liu et al., 2023). A decentralized structure, a distributed notes and storing system, a consensus method, smart contracts, and asymmetric encryption are some of the elements that are included in this technology.

BCT enables distributed data and storage (Dutta et al., 2020). Since the introduction of industry 4.0, several technologies, such as artificial intelligence, the Internet of Things (IoT), and blockchain, have been implemented more frequently. This implementation has led to an improvement in SCP assessment (Bamakan et al., 2021).

A BCT-enabled supply chain can support building closed supply chain partnerships and improving SCP (Kamble et al., 2021). BCT can provide new and desired directions for supply chains and boost SCP (Hald & Kinra, 2019). The BCT-SCP linkage includes the vertical restructuring of supply chain transactions as well as changes in the resources and capabilities of the businesses (Stranieri et al., 2021). Privacy, auditability, and overall operational efficiency in supply chains can be improved with BCT (Wang et al., 2018).

Manufacturing companies have recently applied blockchain for the purpose of improving SCP (Korpela et al., 2017). BCT has an effect on the resources of organizations and the performance of supply chains (Kamble et al., 2021). BCT is able to improve the level of collaboration that exists between supply chain participants in SCM and can positively influence supply chain costs and efficiencies (Aste et al., 2017).

BCT has to be supplemented by additional activities and procedures to contribute to the improvement of SCP that are more narrowly focused (Kim & Shin, 2019). The degree of openness of the supply chain as well as the degree of transparency offered by the blockchain both have a significant bearing on SCP (Wamba et al., 2020).

Kshetri (2018) provided an explanation of the function of blockchain in relation to the various SCP aspects – speed, dependability, cost flexibility, risk reduction, and sustainability. This structure had the intention of achieving strategic supply chain objectives with appropriate monitoring and increased responsiveness and operational efficiency (Kumar & Pundir, 2020).

BCT importance is growing partially due to it being a facilitator of SCP and for other aspects including trade partner preparation and pressure, information sharing, diffusion, and transparency (Wamba et al., 2020). BCT can help companies achieve improved performance on sales expenses, and ultimately relate to SCP (Figorilli et al., 2018; Wamba et al., 2020).

Businesses and the performance of their supply chains can benefit from BCT, and each benefit may have an effect on the overall economic performance of the organizations (Kamble et al., 2021). According to J. Wang, Wu, Wang, and Shou (2017), a blockchain-enabled application has the potential to improve the procedures that are currently used in SCM by improving data and product flow transparency and traceability. To best achieve these beneficial results, the number of participants should be larger (Abeyratne & Monfared, 2016). BCT has the ability to alter practically all SCM business models, improve supply chain business processes from beginning to finish, and, as a result, provide greater support for SCP (Aste et al., 2017).

## 6 Supply Chain Performance Measurement and ERP

Enterprise resource planning (ERP) systems refer to integrated and adaptable (modular) information systems (Kumar & Van Hillegersberg, 2000). ERP integrates cross-functional business processes and facilitates the communication of information across several divisions and stages both inside and outside the organization (Ghosh & Biswas, 2016).

ERP systems typically have a modularized suite of business software packages that are seamlessly integrated to allow automatic interactions and a common source of data for the performance of a company's supply chain (Jonsson et al., 2007). An ERP system is sometimes referred to as a business information system (BIS) (Forslund, 2010).

Stratman and Roth (2002) define ERP competency as a portfolio of competences that encompasses not just management but also organizational and technical abilities. In order to put these capabilities to use and enhance not just the performance of the company but also the performance of the supply chain, the ERP system has to be reliable from a functional standpoint and able to execute its intended functions (Koh et al., 2014).

ERP systems and SCM offer potential to improve SCP (Su & Yang, 2010). ERP can meet SCM requirements integrating all aspects of the organization and can confer a variety of benefits. ERP can support improved decision-making founded on accurate and updated information. The cumulative impact of all of these factors will result in an improved SCM efficiency (Klaus et al., 2000; Shatat, 2015).

ERP benefits are improved if appropriate partners are part of the SCM performance system especially in complex business environments (Chang et al., 2008). Appropriate partnerships allow organizations to better manage their SCM (Ghosh & Biswas, 2016). ERP can support supply chain operations and analyze its influence on supply chain outputs (Aziz et al., 2018).

Effective ERP deployment can support data alignment and constantly improves the systems. It results in improving supply chain performance (Madapusi & D'Souza, 2012; Santoso et al., 2022). It has been shown that the successful deployment and efficient utilization of ERP systems may assist toward increasing SCM measurement and performance (Shatat & Udin, 2012). ERP software programs throughout a company's supply chain function without any hiccups, allow for the smooth and real-time exchange of data across the supply chain, and facilitate a strong relationship with the company's suppliers and consumers, including SCP (Alazab et al., 2021).

## 7 Supply Chain Performance and Integration

According to Samaranayake (2005), supply chain integration is defined as a "*circumstance in which members of the supply chain interact and work together with the purpose of improving the supply chain's performance and profitability*" (Kumar et al., 2017). When businesses can use each other's resources through an integrated supply chain, the supply chain's performance in meeting consumer needs improves (Som et al., 2019). According to Stank, Keller, and Closs (2001), supply chain integration is the process by which a company aligns its internal business functions with its supply chain partners, with the goal of improving the value provided to customers and the overall performance of the supply chain as a whole for all partners involved (Kumar et al., 2017). Integration of a company's supply chain is one of the strategies that can be used to improve a company's competitiveness and its delivery of performance. These kinds of activities may enhance the supply chain performance measures (Sundram et al., 2016). It is generally accepted that companies pursue integration to obtain advantages such as enhanced quality, reduced manufacturing costs, enhanced SCP, and a competitive edge over other enterprises (Mofokeng & Chinomona, 2019). According to da Silveira and Arkader (2007), the integration of supply chains facilitates the reduction of lead times between processes, the improvement of product availability, and the enhancement of SCP (Sundram et al., 2016). One of the goals of businesses to develop a supply chain integration is to improve the performance measures of their supply chains and to meet industry standards (Youn et al., 2013).

Integration in the supply chain has been shown to improve its performance measures; hence, it is vital to lay out clear cut indications on what they aim to assess in order to accurately evaluate the supply chain. There are various detailed indications such as increased quality, stock-out rates, and improved lead time (Crandall et al., 2009; Kang & Moon, 2016). Integration of supply chains is connected to the business performance and the operational performance of supply networks (Qrunfleh & Tarafdar, 2014). The supply chain integration strategy has a substantial influence on the performance of supply chains, but this influence is exerted only in the capacity of an enhancer of the connection between information integration and SCP (Yawar & Seuring, 2017). Given that supply chain integration has been highlighted as an essential competitive strategy, it is possible to think of SCP as a proper antecedent of supply chain integration (Li & Chen, 2018). Long-term connections have the potential to boost a company's success, and a substantial correlation exists between the integration of logistics and SCP (Prajogo & Olhager, 2012).

## 8 Supply Chain Performance and Data Analytics

Data analytics may be defined as "*the gathering of data, analytical tools, computer algorithms, and procedures in order to draw meaningful insights and patterns from the massive data sets that have been gathered*" (Jeble et al., 2018). The integration of data science with other disciplines, including statistics and computer science, enables the extraction, refinement, storage, and monitoring of valuable data from vast quantities of raw data, with the aim of facilitating informed decision-making (Kamble & Gunasekaran, 2020). According to Janssen, van der Voort, and Wahyudi (2017), adopting and implementing data management systems are imperative for companies to attain optimal supply chain sustainability performance. This scenario arises when there is a notable ambiguity level in the surrounding environment (Bag et al., 2020). Supply Chain Data Analytics is becoming an increasingly important tool for executives working in the supply chain (SC) to use for the management, processing, and analysis of their data. Data analytics has traditionally been portrayed as the primary driving force behind both organizational and supply chain success (Bahrami et al., 2022; Jha et al., 2020). Companies have utilized data analytics to enhance supply chain efficiency and leverage company performance to achieve business optimization via innovation. Industries are under a great deal of pressure to improve the overall performance of the SC in order to get a competitive advantage over their rivals, and this pressure is increasing with time. In a world that is driven by data, businesses may be able to live, breathe, strive, and keep their competitive advantage by inventing and producing innovations that are data-driven (DDI). This is the method that businesses use in order to build and develop data-driven innovations (Gopal et al., 2022).

The incorporation of data analytics into corporate processes and supply chains helps firms to more effectively realize their customers, lower service costs, more effectively regulate risks, and generate new revenue streams that were not previously envisaged (Bahrami et al., 2022; Mishra et al., 2018). Data analytics helps companies improve SCP components. Improvements can be made in areas such as increased flexibility, responsiveness, customer service, and dependability (Cho et al., 2012; Fernando et al., 2018). The strategic value of the DA phenomenon is a significant reason why organizations recognize its substantial contribution toward their goals. Nevertheless, it is necessary to emphasize the significance of strategic planning to the operational effectiveness of businesses, given that this factor contributes to and improves supply chain sustainability performance (Singh et al., 2019b). According to I. J. Chen and Paulraj (2004), SCM focuses on improving the flow of products and materials through a company by exchanging and evaluating data on the activities that take place throughout the supply chain during both internal and external business dealings. This is accomplished by exchanging and evaluating data on the activities that take place throughout the supply chain during both internal and external business dealings (Hallikas et al., 2021).

## 9 Current Concerns

Even though there are many methods and models for measuring SC performance, there are still many obstacles to overcome. These include the need to evaluate vast amounts of data that must first be analyzed, a lack of alignment between tactical, strategic, and operational measures, an absence of clearly defined metrics, and the absence of a balanced approach (El-Baz, 2011; Panayides et al., 2018). Due to increased complexity, we need more powerful tools of performance measurement and evaluation processes (Ramezankhani et al., 2018).

Datta (2017) and Dubey et al. (2020) noted that the research on how supply networks create resilience is still in its infancy and needs to be updated to keep up with the rapid advancements in technology and supply chain dynamics, because the research has not yet matured. This shortcoming has an effect on the performance of the supply chain, which is one of the most essential goals of supply chain management (Belhadi et al., 2021).

Evaluating the success of SCs in terms of sustainability among their multiple members, such as suppliers, manufacturers, distributors, and consumers, is a challenging and demanding task. The extensive array of existing sustainability metrics should be combed through by SC management to select, combine, and form key performance indicators (KPIs). This would make the decision-making process simpler across the board for management (Qorri et al., 2018).

Blockchain is dealing with a lot of severe problems. As a result of the immaturity of the technology, it has some technological challenges. The challenge of ensuring that inter linkages between BC shards are both efficient and consistent may be a demanding one. Furthermore, mining BC transactions may require a significant amount of computer power, and the addition of even a single block to an existing BC may result in a tremendous amount of energy usage. In addition, there is a dearth of human resources that possess the appropriate knowledge and abilities (Jabbar et al., 2021; Rad et al., 2022). When the blockchain is enabling, when it is created with usability and when it is developed with an upgrade logic, only then will it support and increase the capabilities of the supply chain and use the supply chain's talents and intelligence. This shifts organizational processes in new and desirable directions, and it also has the potential to improve SCP over time (Hald & Kinra, 2019).

The supply chain integration literature suggests that integration may influence performance results various ways. Integration, on the other hand, is believed to heighten the level of rivalry between the two companies, and it boosts the competitive advantage of supply chain partners (Li & Chen, 2018; Mofokeng & Chinomona, 2019). Similarly, the quantity of information and data that is available is fast expanding. Retail companies are facing issues such as wasting time in analyzing irrelevant and inaccurate data, as well as challenges such as how to store and access massive amounts of data, etc., which, in turn, decreases the overall performance and efficiency of the SC as well as the profits of the organizations. Retail companies are also facing challenges such as how to access massive amounts of data. This is because the SC has a wealth of information in its storage space (Gopal et al., 2022).

## 10 Emergent Concerns, Outstanding Research, and Future Directions

In today's world, supply chains are implementing innovative ideas, policies, and strategies in an effort to eliminate the insurmountable obstacles associated with their supply chains. In other words, they are looking for a way to find a solution to the problems that cannot be solved. They achieve this goal by making it a priority to identify and implement solutions to the problems that are linked with the various links in their supply chains. Consequently, there is a significant need for a performance assessment system that is both effective and accurate to assist businesses in accomplishing their financial goals by monitoring the implementation of new strategies, because such a system is needed to assist businesses in accomplishing their financial objectives (Jayaram et al., 2014; Ramezankhani et al., 2018).

When businesses work toward environmental sustainability, managers have a responsibility to strengthen environmental practices throughout the entire supply chain. The amount of published material describing environmental management inside the supply chain has been steadily increasing, although it is still relatively limited. Consequently, there is a need to expand the SCP evaluation utilizing a fuzzy logic method to a close loop chain, which is an environmentally friendly supply chain that combines suppliers, manufacturers, distributors, consumers, and reverse logistics (Olugu et al., 2011).

A low data quality would have a severe influence on the overall performance measures of supply chains because of the rising significance of data-driven decision-making in the management of supply networks. It is essential to perform duties such as monitoring, measuring, and controlling the data quality to ensure its accuracy (Arunachalam et al., 2018). Businesses need to construct resilient RSCs through their capabilities in operational and information management to improve their current business performance and achieve sustainability in the postpandemic environment. This will allow the businesses to improve their performance going forward. They will be able to react more quickly to shifts in customer preferences and developments in technical capability as a result of this. This will help businesses improve their corporate performance (Sharma et al., 2021).

## 11 Managerial Implications

This chapter allows policymakers, industry professionals, consumers, and practitioners to identify and assess drivers connected to the adoption of SCP. The research of this chapter may help managers develop strategic policies to progress SCP decision efforts in SCs. The following are implications:

Backing and encouragement from the government in SCP-focused initiatives: It is essential to have governmental support in terms of finances for the implementation of sustainability-focused activities. It may boost the SCP efforts and raise the SCP trends when seen within an SC framework.

Understand the behavior of organizations and markets, as well as create high standards and goals: From the standpoint of SCP, understanding market and organizational behavior and building sustainability into strategic policies are both crucial. This makes setting sustainable development criteria and goals easier for organizations.

The chapter educates customers and people about adopting SCP trends in business. To improve their capacity to embrace sustainable modes of production and consumption, workshops and public awareness campaigns may be organized.

Conduct research on external elements and align the sustainable goals of members of the supply chain: This work enables a better knowledge of external aspects concerning sustainability in business, such as the behavior of the market, the attitude of suppliers, and the preferences of customers.

This effort also assists managers in aligning and streamlining the operations of members and partners of the supply chain in order to achieve SCP trends throughout the SC. Building an SCP-centric system from within an existing SC framework in an organization requires careful synchronization and coordination among all involved parties.

The identified opportunities for both managerial decision-makers and government policymakers play a significant role in making the most of the opportunities in a way that improves SCP and mitigates the impact of the challenges experienced by supply chain. Sustainable SCP requires supply chain managers to adopt reliance, enterprise resource planning (ERP), data analytics, and supply chain integration; and improve the blockchain's enabling powers while minimizing its constraining powers.

## 12 Summary and Conclusion

During the investigation for this chapter, we came across a number of recent developments that are still in the process of gaining momentum. It is anticipated that these trends would provide both theoretical and practical challenges in terms of the performance evaluation process. During the performance management literature review, many research objectives were found, but most addressed current issues. Although each of these problems deserves consideration on its own, taken together they do not provide a perspective of the difficulties involved with performance assessment that is exhaustive, unified, or prospective. This chapter anticipates and draws attention to future performance assessment challenges. Consequently, we have made it possible for the community to develop preventative research projects in order to prepare for the difficulties that lie ahead. The primary shortcoming of the research is that the chapter covers a broad range of topics, analyzing and debating literature from several different aspects of performance assessment, but without delving deeply enough into any one of them. This is so because the chapter touches on so many different topics. On the other hand, we believe that this piece of writing contains an error which also serves as one of its merits. After doing such a comprehensive review of the relevant literature and having a discussion about the findings, we have identified several obstacles to further research which have come to our attention. Henceforth, there is a need to rethink our approach to how we do research in the field of performance evaluation. This came to our attention recently. Indeed, there is a need for research that takes a systems-based, all-encompassing approach to the issue at hand, acknowledging the intertwined nature of the challenges that the industry faces while focusing on a specific issue. The existence of a gap in the existing body of knowledge necessitates this research. As researchers, we may feel driven to concentrate on a certain occurrence and try to get an understanding of it within the context of this complex system. However, practitioners have to live and deal with all of this complexity and the phenomena concurrently; as a direct consequence of this, we have the opportunity to rethink and restructure how we do research on performance evaluation in the future.

# Performance Measurement: Value Creation

Nathalie Fabbe-Costes

## Contents

**Abstract**

Performance measurement–value creation is a core competence of supply chain management (SCM). It is an important topic for researchers, a key competence for supply chain managers, and an important subject for students. This chapter is

aimed at both SCM novices and professionals, working in research, teaching or involved in practice, and its purpose is to provide valuable knowledge as well as to motivate readers to think and ask questions about this complex topic. This chapter provides an in-depth analysis of the "performance measurement–value creation" topic in supply chain management (SCM) from the 1970s until now, highlighting the successive issues and key points discussed over time. A general review of this evolution shows the increasing importance of supply chain (SC) performance measurement and value creation, but also points out its complexity in practice. This analysis pinpoints strategic issues as well as difficulties, in particular with regard to SC performance management systems (SCPMSs). The current questions identified by the overall analysis reveal the need for renewed approaches to designing SCPMSs from both the research and practice perspectives. This chapter offers a conceptual basis to address the performance measurement–value creation topic and to think about how to design relevant, useful, and impactful SCPMSs that help SCM to create more value. This chapter looks at under-researched questions and raises important issues for future research. It includes a comprehensive framework that provides guidelines for practice.

## 1 Introduction

Supply chains (SCs) and supply chain management (SCM) are recognized as strategic elements of organizations in all economic activities. SCM is meant to improve SC performance and create value. However, this well-acknowledged assumption results in a difficult and endless journey for SC managers and top management of organizations. The assessment of SC performance measurement–value creation is a core, but complex SCM activity and a competence that helps bridge business strategy and operations through tactical and operational strategy (Cavinato, 1992). But, many companies find it hard to develop a clear operational strategy to fit within the broader corporate strategy – making execution difficult (Forbes, 2021; McKinsey, 2019) with this challenge being even more crucial for their supply chains.

Performance measurement and value creation assessment is an essential but challenging interactive process between SC strategy (with expected and effective value creation) and SC operations (with evidence of SC performance). These items and relationships provide evidence of SCM contribution to the organizational success – or failure. Performance measurement and value creation assessment is also a source of learning through the analysis of SC performance and SC outcomes. Implementing refined performance measurement systems and diving into the data to better understand how to improve the management of SCs and their contribution to value creation can be worth the investment. However, building and maintaining a relevant SC performance management system (SCPMS) is more complex than generally acknowledged.

> Performance management is a key ingredient of successful strategy execution. If done ineffectively, this leads to problems such as unclear or missing objectives and targets, wrong use of measures and performance indicators (KPIs), failing resource allocation, or counterproductive incentives. (Forbes, 2021)

SC performance measurement and value assessment is also a time-consuming activity, leading to bureaucratic excess and intrusive monitoring, which exacerbates sensemaking problems both at the strategic and operational levels. It is important not to fall into the "tyranny of metrics" (Muller, 2018). We need a clear understanding of what SCM performance measurement and value creation means, of the difficulties that arise in designing and implementing beneficial SCM performance management systems, and of ways to overcome them. The goal is to benefit from efforts of measuring things that really "count."

This topic, of great importance for practitioners, is a critical area for researchers in SCM. Since the 1970s, logistics and SCM have focused on improving performance, in particular cost-effectiveness and productivity. However, with a better understanding of the strategic power of SCM in companies, the nature of SC performance targets has evolved in connection with value creation. Today, more SCM academics consider that SCs have to fulfil evolving and paradoxical objectives – for example, to be profitable and sustainable. These paradoxical objectives make SC performance measurement and value assessment complex and challenging. It is all the more challenging since SCs themselves have become more complex because of globalization and outsourced activities, made possible by and encouraging specialization, leading to worldwide fragmentation. In the 1990s, SC performance measurement and value creation was a hot topic for researchers. With current challenges – such as climate change and emergent risks and uncertainties – and current SC digitalization efforts it has once again become a critical research topic raising new ontological, epistemological, methodological, and ethical questions.

Therefore, it is of strategic importance to better understand how SCs and SCM can create value – what kind of value and for what kind of stakeholder. It is also important to define and implement a comprehensive SCPMS with useful SC performance measures that make sense for everyone, and to improve the understanding and assessment of the SC performance–value link. These key issues exist for researchers and practitioners facing the need to develop and adapt their SCPMS to address SC strategic sustainability issues and adoption of digital technologies. Students should acquire the conceptual bases to address this topic and to learn to think about how to design and implement relevant, useful, and impactful SCPMSs supporting SCM value creation.

The purpose of this chapter is to explain the importance of measuring SC performance and linking it with SCM value creation. The chapter also describes the current state-of-the-art regarding performance measurement and value creation in SCM and raises important issues for future research. Approaches to overcome difficulties, limitations, pitfalls of performance measurement in SCM, and criticism regarding the phenomenon of "metrics fixation" are also presented.

The chapter offers a solid conceptual basis regarding SCM, SCs, performance, measurement, and value. It also traces the evolution of performance measures related to the evolution of the strategic value that SCs must deliver in line with business strategies – a never-ending story. The paradoxical nature of SC performance and the complexity of measuring it require renewed approaches to designing SCPMS both from the research and practice perspectives. Accordingly, the chapter provides guidelines for designing performance management systems dedicated to SCM aligned with strategy.

The **Background** section provides discussion on origins and evolution of the topic; it is important to understand the beginning in order to assess where it stands now. The **Current concerns** section provides an analysis of the evolution, pointing out the most important aspects to consider today, as a novice or an experienced SC manager or researcher. The **Emergent Concerns, Outstanding Research, and Future Directions** section raises issues, questions, and directions for future research. Finally, the **Managerial implications** section proposes a comprehensive set of guidelines for practice.

## 2 Background: Performance Measurement and Value Creation – Overview of the Evolution of This Topic in the SCM Academic Literature

Performance measurement has always been considered a core logistics and SCM activity and competence. The study of the relationship between SC performance and value creation is a critical research question. An analysis of the academic literature on this topic – which has always been connected to practice – reveals an important evolution that is worth retracing. Table 1 at the end of the section summarizes this evolution.

### 2.1 The Roots of SC Performance and Value Creation: The 1970s and 1980s

An analysis of the academic literature shows that this topic has significant roots in the logistics management literature (e.g., Persson, 1991; Chow et al., 1994). In the 1970s, the management of materials and material flows became a concern. "Logistics tend to become an unavoidable cost factor that at best should be minimized" (Persson, 1991, p. 2). Performance measurement was focused on the cost of stocks, of material flows, and of in-house logistics activities in companies. The link between business strategy and logistics was not studied though, since logistics was considered to be determined by business strategy. Moreover, since logistics activities were

scattered under the responsibility of multiple departments, there was no logistics strategy as such. The objective during that period was to better understand how to control costs and improve the productivity of logistics, presumed to contribute to profitability.

In the 1980s, the nature of competition changed. Cost remained an important issue, and cost reduction was a cornerstone of logistics management. However, quick delivery and reliable quality of products and services were becoming weapons to differentiate from competitors. It became clear that logistics activities could contribute to creating a competitive advantage and that logistics should be linked more systematically to business strategy (Persson, 1991). It was therefore important to measure the performance of the service delivered to customers and to better understand how to improve it.

Although some logistics activities were progressively outsourced, performance metrics were mostly internal in the 1980s and early 1990s (Lambert & Pohlen, 2001). To balance service quality and costs, material flow processes needed to be better integrated and logistics management more consistent, leading to the creation of dedicated departments in charge of the overall management of flows. This formalization paved the way to greater recognition of the strategic significance of logistics and its capacity to create value. The rather negative cost-center view of logistics progressively gave way to a more positive profit-center orientation. Improving the effectiveness and efficiency of logistics and SC processes led companies to recognize the importance of working more closely with direct customers and suppliers, acknowledging that their logistics and SC performance was interwoven with that of their partners.

## 2.2 Toward Excellent Extended SCs: The 1990s – The Rise of SC Performance Metrics Fixation

The end of the 1980s and early 1990s marked a paradigm shift. Logistics became recognized as a core activity in value chains (Porter, 1995) and logistics and SC departments entered into the conversation to formulate business strategy (Fabbe-Costes & Colin, 1994). Logistics performance measurement therefore played a central role in achieving functional excellence and guaranteeing the success of "world-class firms." A study by Fawcett and Cooper (1998) proved that firms were improving their overall measurement capability, which was "one part of their effort to develop world-class logistical capability" (p. 342).

> Four dimensions encompass effective measurement practice at world-class companies: an improved functional measurement capability; a process orientation that facilitates internal integration and external alignment; benchmarking that provides the impetus for continued learning and improvement; the use of partner and supply chain scorecards to evaluate the role and performance of supply chain members and the overall supply chain. (Fawcett & Cooper, 1998, p. 352)

Measurement, which “reflects a firm’s adoption and regular use of internal and external performance metrics” (Goldsby & Stank, 2000, p. 193), is one of the four competencies identified in the “world-class logistics competency model.” Measurement includes three dimensions: Functional Assessment (the development of comprehensive functional performance measurement capability), Process Assessment (the extension of performance measurement systems across internal and external logistical processes), and Benchmarking (the comparison of metrics and processes with best practice performance).

In the early 1990s, the notions of supply chain and SC management (SCM) competed with logistics. Behind the “relabeling or new reality” debate was the need to promote an integrated vision of SCs (Cooper et al., 1997). The competition was increasingly between entire SCs rather than between individual companies. As stated by Lambert and Cooper (2000), “individual organizations can no longer compete as solely autonomous entities, but rather as supply chains.” According to Chow et al. (1994, p. 26), “consideration should be given to assessing the performance of the supply chain, not just that of individual participants.” It was therefore necessary to “move beyond the dyadic relationships to measure the performance of the entire supply chain” (Fawcett & Cooper, 1998, p. 356).

Defining SC metrics to evaluate and align performance across multiple companies in the SC became an issue both for practitioners and researchers (Lambert & Pohlen, 2001). Owing to the development of outsourcing, both for manufacturing and logistics activities, most SC managers considered SC metrics “as a means to increase their ‘line of sight’ over areas they do not directly control, but have a direct impact on their company’s performance” (Lambert & Pohlen, 2001, p. 1). This was even more important because of globalization and the international deployment of SCs.

The 1990s revealed that the competition was not only to deliver the best product or service at the most attractive price, but that companies should develop new products and services, be more responsive to customer demand and work in a more flexible way. Improving the behavior of SCs to produce more customized products and services in a timely manner became a strategic issue that called for new SC performance measures – such as responsiveness and flexibility. To give greater voice to SC departments in the company strategy conversation and justify investments in developing SCM, it was also necessary to clearly demonstrate the contribution of SCM to financial value creation. This justified the introduction of financial measures such as Economic Value Added (EVA) as detailed in Lambert and Pohlen (2001).

Intensified SC competition also led practitioners and researchers to undertake SC performance benchmarking studies. The objective was to compare performance metrics – such as hard, quantitative, if possible, fact-based, key performance indicators or KPIs – and search for best practices in terms of SC performance management systems (SCPMS). In the mid-1990s, the quest for SC excellence (Stewart, 1995) boosted research about SC performance measures and metrics that could help performance assessment and benchmarking in order to identify so-called “best SC practices” (Cohen & Roussel, 2005).

Efforts were directed at defining performance standards to facilitate comparisons, in particular standardized SC benchmarking metrics – such as cash-to-cash cycle time and supply chain response time – with hard indicators that could be linked together in a chain from the supplier of the supplier to the customer of the customer, the SC being inter-organizational. These efforts were supported by the implementation of enterprise resource planning (ERP) systems, promoting the integration of systems and databases in companies, and easing inter-organizational electronic data interchanges (EDI).

Various characteristics evolved during this time, including: geographical extension of SCs; their development in terms of the number of actors involved and the variety of activities; and the multiplicity of different types of performance and value to measure. All these characteristics required more structured SCPMSs that could help to identify trades-off and provide elements for decision-making. Companies developed or adopted balanced metrics frameworks (e.g., in Stewart, 1995) associated with benchmarking initiatives. Consultancies such as PRTM (a subsidiary of Price-Waterhouse Coopers) promoted such combined practices – see Cohen & Roussel, 2005. Adopting the balanced scorecard (Kaplan & Norton, 1992), most SCPMSs used performance metrics to assess the performance of SC processes from three perspectives: customers, shareholders, and internal stakeholders. The popularity of these initiatives led to the formulation and widespread adoption of the supply chain operations reference (SCOR) model (Sürie & Wagner, 2008).

By the end of the 1990s, the development of reverse SCs, the beginning of environmental concerns, and the implementation of more environmentally responsible logistics practices (Goldsby & Stank, 2000), were the impetus for addressing SC green performance. These green performance metrics linked to more general strategic issues related to sustainable development. This evolution led to significant impacts since: “A proactive or ‘value-seeking’ environmental approach calls for major revisions in planning, training, and systems” (Goldsby & Stank, 2000, p. 200).

Measurement systems were revealed to be critical in the incentive programs that reward employees and managers for their involvement in more sustainable logistics and SC activities, and consistent evaluation of environmental performance and environmental auditing were needed to obtain world-class certifications (Goldsby & Stank, 2000). More generally, competence in performance measurement was expected to be conducive to the implementation of any new SC practice.

The 1990s laid the foundations of measurement best practices with normative guidelines for companies. For example, Stewart (1995) suggests establishing and communicating a clear set of regularly measured goals for the company. These goals should include accountability throughout the organization for achieving them. This communication also allows information to be readily accessible and shared throughout the organization – allowing everyone to understand the key metrics and their respective drivers. It also allows for making broad fact-based decisions quickly and consistently. All these characteristics made it was necessary to develop SC performance management capabilities, which entailed collaboration with management accounting (Seal et al., 1999; Dekker & van Goor, 2000).

## 2.3 New Technologies, Increased Digitalization and SCM Innovations: The 2000s

The 2000s marked an important turning point linked to the development and diffusion of information technologies (IT) and information systems (IS) in companies. Alongside IT/IS, the Internet played a key role, opening the door to virtualization and wider digitalization of SCs and SCM. New technologies also offered opportunities to improve the SCPMS and its role in SC control and governance. As a consequence, a significant amount of work has been done in the area of SCPMSs starting in the 2000s (as reported by Balfaqih et al., 2016; Maestrini et al., 2017).

From a strategic point of view, the Internet opened new SCM horizons. It inspired the reengineering of processes: sourcing, manufacturing, retailing, and product returns (end-of-life or returned to repair or resell). The Internet boosted the development of e-commerce: online selling (sometimes combined with physical stores and/or drive-throughs), virtualizing some products and services (doing away with physical flows, e.g., music, books), developing vertical and/or horizontal marketplaces (with suppliers, customers and/or competitors) with new partnership management, and inventing new services based on virtual channels.

Multi- or omni-channel distribution led to more complex distribution networks, with new challenges in terms of stock, asset and flow management, and logistics with last-mile issues. Industry 4.0 technologies also introduced changes in designing, manufacturing, assembling, maintaining, and recycling products and services. The servitization of industries – such as the automotive industry – with new business models also had major impacts on SCs and SCM. These changes expanded the role of end-customers in SCs. They pull on supply chains with online orders specifying the desired characteristics of products or services, last-mile delivery puts them in direct contact with logistics, and they participate directly in the evaluation of products and services. Crowdsourcing strategies call on them to participate in more operations – even logistics ones with crowd logistics. The use of web-based platforms has even led to the development of consumer-to-consumer supply chains.

New technologies and systems combined with SC digitalization has resulted in many intertwined strategic and SCM innovations that had to be translated in the SCPMS, leading companies to include new SC cost and performance measures, as well as new valuable outcomes. The agility and adaptability of SCs became key areas of SC behavioral performance to develop; with SCs increasingly being considered as complex adaptive systems (Choi et al., 2001).

IT/IS, the Internet and other technologies (such as radio-frequency identification – RFID) offered many opportunities to develop SC measurement abilities. New technologies helped to develop close real-time monitoring of activities – such as track-and-trace systems – and automatic data collection. This tracing and data collection included remote actors in the chain, such as the end-consumer. It became easier to share data at a wide inter-organizational level – the extended SC – and to feed data into the SCPMS automatically.

SC managers could dream of extending their SC visible horizon (Carter et al., 2015) and their control over SCs. SC visibility became a desirable performance goal for SCs. But to offer end-to-end SC visibility and to achieve reliable SC performance and value assessment, it was necessary to express cost and performance data in similar terms. The result was a call for harmonization, if not standardization, of measures and systems.

The 2000s were a challenging decade for SCM departments. During this period, more activities were outsourced, giving greater power to purchasing as well as to third-party logistics and emerging fourth party logistics providers. The greater reliance on information systems increased SCM dependence on IT departments and providers.

The strategic contribution of SCM was to design and control the SC, viewed as a complex adaptive system (Choi et al., 2001), to dynamically align business strategy, SC strategy, and their environment. The constant monitoring of remote SC operations and the assessment of SC performance and value creation became a strategic competence and an SCM dynamic capability.

This context resulted in renewed attention to and research on SCPMSs in the mid-2000s. SCPMSs represented a way of improving SC performance and governance. Literature reviews (Gunasekaran et al., 2001; Shepherd & Günter, 2006; Gunasekaran & Kobu, 2007) collected and compiled existing SC performance measures into structured lists or taxonomies. They also levelled certain criticisms at SCPMSs, including: “lack of connection with strategy; focus on cost to the detriment of non-cost indicators; lack of a balanced approach; insufficient focus on customers and competitors; loss of supply chain context, thus encouraging local optimization; and lack of system thinking” (Shepherd & Günter, 2006, p. 247).

The new technologies encouraged companies to introduce additional measures to address new activities or challenges. These new measures’ introduction was the case in the mid-2000s with the development of e-commerce and virtual enterprise environments (Gunasekaran & Kobu, 2007). It was also observed in the need to demonstrate SC compliance with environmental and social responsibility, leading them to develop green performance measures (Shaw et al., 2010).

## 2.4 Toward Complex and Paradoxical Demands with a Wider Scope: From the 2010s Until Now

The 2010s further introduced complexity and uncertainty for SCs with new pressures for SCM and SC managers. A number of crises – natural disasters, economic crises, terrorist attacks, military conflicts, and pandemics – revealed SCs vulnerabilities with greater disruption, but also the need for greater resilience.

In hostile environments and in crisis periods – such as the Covid-19 pandemic – companies and researchers focused on new behaviors and characteristics such as vulnerability, robustness, and resilience. This new focus led to focus on new SC performance measures such as time to respond and to recover. It was becoming necessary to make better use of data with SCPMSs to assess performance with *ex-post* observations and to dynamically monitor supply chains with real-time, fine-tuned monitoring. The additional important dimension was the need for measures to also become predictive to help foresee changes.

The development of risk-sensing tools related to SC measurement was identified as a new strategic necessity. Again, new technologies – such as artificial intelligence with big data, deep learning, or digital twins – were viewed as solutions to improve SCPMSs and increase their usefulness in SCM decision-making. Dynamic dashboarding to anticipate changes and simulations to better forecast risks and estimate their probability of occurrence with potential impacts helped to understand and manage SC resilience and transformation. The successive crises revealed that SCs were embedded in a complex ecosystem. The ecosystem focus supported investigating many understudied stakeholders. It became clear that the behavior of SCs was dependent on many other SCs with inter-SC lock-in effects – which pointed to potential synergies that could be developed.

The 2010s also questioned some hidden assumptions behind the development of contemporary SCs. Globalization, productivism (efficiency and productivity), governance of global value chains such as questioning the role of "voiceless" people (Glover & Touboulic, 2020), and the negative externalities of global SCs.

The need to fulfil sustainable development commitments put new pressures on SC managers and called for new changes in SCM. New performance indicators were also further introduced, including CO2 emissions related to transport and logistics activities. Global warming issues (see GIEC report, 2022), combined with a perceived change in consumer preferences and concerns, led companies to adopt a "purpose-driven orientation" for their business and SC strategies (Gartner, 2021a). The SCPMSs had to support assessment of companies and SCs capacity to meet their sustainability commitments. The SCPMS had to help companies progress toward better SC compliance with environmental and social responsibility and deliver more value to stakeholders.

Since the end of the Cold War, geopolitical issues had regained importance. The era of open globalization and easy international trading, with relatively free positioning of SC assets to seize emerging markets and benefit from low-cost opportunities, has recently been challenged. So-called emerging markets are maturing and want to get the value from the SCs that have been using their resources without compensating them properly. Powerful nations (US, China, and Russia) are using SCs as political and economic weapons – for example China's new Silk Road logistical strategy. Some countries have left trade agreements – such as the UK with Brexit and leaving the EU – to reaffirm their sovereignty, leading to unexpected impacts.

In such a complex and uncertain environment, there is a need to manage multiple and sometimes paradoxical types of SC performance and value. Advanced SCPMSs are expected to contribute to ecosystem sensemaking and improve decision-making in SCs. By assessing performance and value creation throughout the SC and between SCs, they are expected to avoid mismatches in the perception and behaviors of SC actors. These systems are expected to improve collaboration and commitment of organizations while coping with changes, dangers, and disruptions.

# 3 Current Concerns About SC Performance Measurement and Value Creation

Based on the big picture drawn in the previous section, the objective of this section is to identify the current concerns that are important to practitioners, researchers, instructors, and students. It highlights the state-of-the-art in SC performance measurement and value creation. We identify points of consensus, debates, and questions. Some answers to pragmatic questions about performance measurement and value creation assessment in practice are answered. Specifically, questions such as – How should SC managers proceed? What are the key questions to answer? – are addressed in this section.

The evolution of the topic over five decades shows that performance measurement and value creation is both complex and challenging, but that it is necessary to develop this strategic SCM capability. Our overview of the evolution from the 1970s onward shows that each decade has increased the number of performance and value measures, changed the vision of the link between performance and value, and revealed the multiple relevant units of analysis used to study how to improve SC performance and outcomes. Each decade has also revealed the usefulness of SC measurement and SCPMSs, as well as the difficulties in putting them into practice. Table 2 at the end of the section summarizes the evolution on these key points. The key points are of strategic importance for research and practice.

## 3.1 The Need for SC Performance Measurement Capability

Performance measurement is the process of quantifying the effectiveness and efficiency of action (Neely et al., 1995). In the management sciences, there are some well-known maxims: “If you can’t measure it, you can’t manage it.” “No measures, no improvement.” Although critical studies challenge these assumptions, performance measurement has always been considered a vital task in logistics and SCM because it can help to identify problems (e.g., poor quality), monitor progress (e.g., tracking performance improvement), enhance employee motivation (by rewarding progress), and strengthen SC accountability (assessing performance and value).

Performance measurement – or obtaining the performance data from others – has been considered in SCM as a means for gaining control over the entire SC and spotting areas for improvement (Lambert & Pohlen, 2001). Considering that the ultimate objective of improving SC performance is value creation, effective SC measurement has to link value with performance.

There is a clear consensus on the need to develop and improve general measurement capability in SCM. However, it is not easy to determine the types of value to create, the performance measures and metrics, and data acquisition methods. The development and management of SCPMS call on many management competencies and functions – SCM, accounting, IS, purchasing, marketing, and human resources – across many SC partners. The increasing role of IS and IT in SCPMSs, with new information technologies and systems constantly appearing, is a key issue. There is a

**Table 2** Overview of the evolution of SC performance and value measurement: key points

goal for improved competence but this goal faces big challenges. The development of this capability is a key point that must be addressed in every firm as well as at the SC level.

### 3.2 Defining Relevant SC Performance Measures and Metrics

As reported in Table 1 (**column 1**), every decade has introduced new SC performance measures, building on previous ones. The relevance of existing (traditional) measures and the need to develop new (modern) ones is an important question (Gunasekaran & Kobu, 2007).

After an initial focus on cost measures – to better control and, if possible, reduce costs – many non-cost measures have been introduced. For example, time, quality, and flexibility were introduced to reflect the SC's ability to deliver better customer service. Efforts to better understand SC behavior also resulted in new measures to reflect the overall SC ability to perform better. These measures include improved integration, responsiveness, and visibility. Additional measures to effectively manage change in demand, supply or in the context of deployment or implementation were also included such as: flexibility, adaptability, agility, robustness, and resilience. Every decade has identified new strategic drivers for future supply chain development, such as sustainability and responsibility.

The most problematic SC performance measures are those concerning SC behaviors that have to be clearly defined before trying to decide how to measure them. New concepts are difficult to measure, especially if these concepts have not been clearly defined (Yao & Fabbe-Costes, 2018). Literature reviews (e.g., Fabbe-Costes & Jahre, 2007, 2008 on SC integration) show that there are many different competing measures that have to be carefully studied before selecting one and that different measures may produce contradictory results.

Another important general question is whether to adopt "hard" measures – such as net income or accounting values that are meant to be objective, or whether there needs to be inclusion of "soft" measures such as customer satisfaction ratings. Usually, soft measures are based on the subjective perception or interpretations of individual actors. These categories of measure have strengths and weaknesses associated with them. Those who promote purely quantitative measures acknowledge the usefulness of qualitative analysis to make sense of them. For example, while benchmarking encourages "quantifying performance improvement opportunities across the entire supply chain," it also calls for "qualitative analysis of best-in-class performance" (Stewart, 1995, p. 40).

The cumulative development of SC performance measures has led to a very large number of individual measures (Shepherd & Günter, 2006; Balfaqih et al., 2016). Measures include quantitative, qualitative, single indicators, or composite measures. Early on in the evolution of SC and SCM, the lists of SC performance measures were rather unstructured (Chow et al., 1994). Categorization efforts from the mid-1990s onwards (Stewart, 1995; Fawcett & Cooper, 1998) resulted in structured lists with many different categories (see Gunasekaran & Kobu, 2007). The content and structure of these lists vary depending on the underlying model – for example some use the SCOR model – or logic used to classify measures and metrics.

From the 2000s, some new or modern categories were developed, broken down into sub-categories with numerous detailed measures – for example green SC performance (Shaw et al., 2010). The result is that there are many SC performance categories; for each performance category several SC performance measures are generally recommended to monitor and manage a variety of SC activities. Each measure has a variety of operational definitions and indicators.

This profusion of measures is challenging for SC managers who have to select suitable SC performance measures and structure them in their SCPMS. There is no consensus about the most appropriate technique for selecting SC performance measures. It is not an easy task since there are different levels of performance. Some measures are operational such as on-time delivery, others are tactical such as service quality, while others are strategic such as SC responsiveness. These multiple levels of measures lead to embedded measures (Cavinato, 1992). The consistency of the overall selection is problematic since some performance measures are interrelated, for example SC collaboration and SC transparency. Other dimensions are independent forming a more global (multi-facets) performance measure. Despite attempts to design standardized measures and SCPMS models in the 1990s, the choice remains open and directly linked to the expected strategic SC outcomes: the type of value to create and for whom (Fabbe-Costes, 2002).

While any single measure or metric may be of interest, no single measure or indicator is sufficient to assess SC performance (Chow et al., 1994). The challenge is to develop a useful set of performance measures, viewed as a system. Challenging managerial questions include: How can we find a balance between exhaustiveness and parsimony? How to choose KPIs that make sense?

The priority is to identify the stakeholders and the types of value to create before deciding on a tactical and operational strategy and a set of SC performance measures and metrics.

## 3.3 Clarifying Value Measures

Compared to SC performance, value measures (Table 1**, column 2**) are far less developed. These measures are described in more general terms such as profit, development, competitivity, and compliance, usually with less precise formulas. The value expected by the company, which is directly linked to its strategy, has also cumulatively increased in its diversity. Value measures have been evolving in keeping with the perception of the strategic value produced by SCs and SCM, as well as with each new strategic issue facing companies and their SC.

In earlier historical time periods of SC, the focus was on financial value creation with quantitative financial measures such as profit, turnover, added value, and EVA. The quest for profitability prioritized shareholder satisfaction. However, to succeed in fierce competitive environments, creating value for the customer rose in priority.

The customer (and customer's customers) satisfaction rapidly became the focus of SCM efforts to build customer loyalty and commitment.

In line with Porter's analysis, an SC could win the competition through cost leadership or through differentiation, leading to new financial value measures related to costs combined with perceived outstanding quality. A consensus emerged on mixing financial and non-financial measures in the SCPMS (Gunasekaran et al., 2001).

In the 1990s, the search for best SC practices revealed the role of strategic processes and strategic resources in creating value, which included human resources. The balanced scorecard (Kaplan & Norton, 1992) introduced inward value related to personnel satisfaction – related to safety, well-being, and rewarding work. There was also development of intangible assets and resources with competence, knowledge, and social network measures. The loyalty, commitment, and efforts of employees working in SC operations were key success factors in competition and proved to be even more strategic in the 2000s for innovation, which included individual creativity. Survival since the 2010s included individual adaptability, robustness, and resilience.

With the recognition of risks and responsibilities, value is not only about intra-SC corporate social responsibility (CSR) value, but also broader societal outcomes. Changes in laws and regulations at the national or international level are a powerful impetus to include new types of value and new measures to prove SC compliance – such as no counterfeiting, no conflict minerals, and no use of illicit products. Seeking credibility, reputation, and trust, companies try to obtain certifications and labels, which guide their selection of value measures. Some international initiatives also provide inspiring frameworks such as the Global Reporting Initiative (GRI) standards, and the UN sustainable development goals (SDGs) to target the most impactful strategic values.

Shareholders are not the only beneficiaries to consider, and financial value is no longer the unique objective. SCM value creation is multi-dimensional, targets multiple stakeholders, and calls for a multi-level assessment (Fabbe-Costes, 2002). SC value creation co-evolves with business strategy, resulting in a system containing both financial and non-financial values to satisfy an increasing number of shareholders and stakeholders. The resulting variety of value creation measures reveals paradoxical issues. A balanced approach is needed and has to evolve dynamically with strategic changes in the SC environment.

## 3.4 Questions Related to the Performance–Value Link

The link between performance and value is key for SCM. As recalled from the introduction of this chapter, there is no success without the coupling of business strategy, SC tactical and operational strategy, and the day-to-day execution of SC operations. However, the evolution of the topic (Table 1**, column 3 and column 5**) explains why it is a complex link to study.

In the early years of SC performance measurement, the link was an expected one, although not studied greatly, it was more a conceptual postulate rather than a demonstrable hypothesis. With the emergence of logistics and SC departments and their participation in the formulation of strategy, it became necessary to provide evidence of the contribution of SC performance to value creation, especially with respect to financial value contribution. The first frameworks for developing supply chain metrics that translated the performance of core SC processes into shareholder value showed the relevance of the approach and its difficulty (see, for example, Lambert & Pohlen, 2001).

Aside from financial value, each new business strategy considered new types of value, generating a distinct analysis of the performance–value link. For example, in the 1980s, cost (C) reduction was related to cost leadership strategies, quality (Q) and time (T) with service differentiation strategies. The links were considered to be mutually conflicting trade-offs.

In the 1990s, integrated views were promoted. An SC that mastered the famous CQT triangle was supposed to win the competition. Balanced scorecards combining four performance perspectives became a best way for capturing the SC performance–value relationship. However, from the 2000s onward, the multiplication of different types of SC performance and value made this picture complex. In-depth studies of the new/modern measures, in particular behavioral performance measures, produced separate evaluations.

However, an in-depth analysis of studies that sought to prove the contribution of specific types of SC behavioral performance to value creation (see Fabbe-Costes & Jahre, 2007, 2008 about SC integration) showed the lack of clear empirical proof of the performance–value link. These studies unveiled some critical issues to consider in research and practice, including: the problem of the conceptual definition of SC performance which contained very diverse definitions; the selection of metrics to measure it that were sometimes inconsistent with the definition; the choice of data source and data type to calculate; and the values impacted.

Considering the many types of value emerging in the 2010s and the challenges facing SCs today, a holistic understanding of the SC performance–value link is necessary. Some types of value are related to short-term objectives, others to longer-term ones. Some types of value are interrelated, others conflicting. The paradoxical nature of some types of performance and value, the difficulty and sometimes futility of identifying clear causal links, the recursive nature of some effects, and the time horizon to observe some of the expected impacts make the SC performance–value link complex.

The systemic and dynamic nature of the interactions in practice calls for specific methodologies and methods. The complexity also varies depending on the SC scope and units of analysis.

## 3.5 Specifying the Units of Analysis

The scope of the performance–value analysis (Table 1**, column 4**) evolved in parallel with the vision and definition of SCM, SC, and the place of SC/SCM in the company structure (Table 1**, column 6**). Studies show that there are many potential units of analysis – corresponding to different scopes. The evolution shows a widening scope, but also a more complex situation. Many questions arise around the definition of SC, its scope, the unit of analysis, and perspective (Cooper et al., 1997). The decision to adopt and at what level and with what lenses along with the scope of measurement such as internal SC or inter-organizational represent some of the multitude of concerns.

The initial focus of these measures was on individual operations that were separately optimized. As the SC department emerged, the unit of analysis rapidly became the firm or the organizational level – which remains the most frequent scope for SC analysis. In the 1980s, inter-organizational units of analysis emerged in order to encompass direct SC partners such as customers and suppliers. Dyads, such as firm-supplier or firm-customer, and triads, a focal firm with a supplier and a customer, also became frequent inter-organizational units of analysis.

The end of the 1990s marked an important turning point regarding efforts to define SC and SCM (Mentzer et al., 2001). This time period led SC managers and researchers to go beyond internal logistics metrics and to demonstrate the strategic role of SCM (Mentzer et al., 2004). They also set to demonstrate SC and SCM value creation. Definitions of SCM always emphasize the importance of key SC processes. Processes are important SCM units of analysis because their execution entails the coordination of multiple actors behaving as if they belonged to a single organization – an SC. Seamless intra- and inter-organizational processes are supposed to deliver better value. The combined analysis of SC process performance and of its perceived value, adopting multiple viewpoints, is a powerful source of improvement. See, for example, the case of the purchasing process in Nollet et al., 2017, 2019.

Since the 2000s, the attempt in both academia and industry to adopt a wider SC scope – such as end-to-end SC, extended SC or the SC ecosystem – revealed additional complexity. The evolving definition of what an SC is or should be has produced a variety of pictures. The measure of SC performance also varied, depending on how companies define their SC. It may be an internal inter-functional chain or process, a dyadic or linear triadic chain, a network centered around a pivotal firm, or a more complex network combining multiple SCs including closed-loops.

Performance can also be measured by considering the output of an organizational SC department or function. It can be measured at the company level, in line with the control it wants to have over its SC. The organization can also try to measure the overall impact of an extended supply chain on its ecosystem.

It is necessary to define the SC, its scope, and the scope of SCM action. It is also necessary to decide if the focus is a single optimization criterion or if the objective is to adopt a systemic approach to performance measurement. The SC scope, units of analysis used to measure SC performance and value, and measurement choices are important to determine for the SCPMS. But before diving into building the SCPMS, it is useful to question its expected usefulness.

### 3.6 Understanding the Usefulness of Measurement and the Supply Chain Performance Measurement System

The history of the SC performance–value topic shows an evolution in the perceived usefulness of performance measurement and value creation assessment in SCM. The overall evolution appears to be a learning process, since every decade has increased SCM knowledge thanks to a better understanding of how to increase the performance of SCs and SCM value creation.

In the early decades of SC evolution, cost-based performance measures offered a view of neglected logistics activities. Production was what added value, not logistics. Therefore, few people cared about this field and it was not really managed. The discovery of logistics costs and of ways to improve productivity opened the door to logistics management.

Lean management and total quality management contributed to continuous improvement based on performance monitoring and empowering employees, so they might find better ways of operating. In a broader perspective, it was acknowledged that "measuring supply chain performance can facilitate a greater understanding of the supply chain, positively influence actors' behavior, and improve its overall performance" (Shepherd & Günter, 2006, p. 243).

The 1980s helped SC managers understand the question of trade-offs between conflicting measures (such as costs and services). One consequence was widespread recognition of the importance of adopting a balanced multicriteria approach to designing the SCPMS, which would better support SCM decision-making than a single SC performance objective.

In the 1990s, the intensity of competition was combined with the underlying assumption that there were indeed SC best practices – a positivist vision of SC practices. There was also a perspective that benchmarking was the most important use of SC performance measurement. The benchmarking literature argues in favor of one-size-fits-all measures that allow for comparisons and identification of best in class SCs. Best in class seeks to identify best practices to dominate the competition or at least survive. This remains a popular approach and an important source of learning for SCM researchers and consulting firms, related to the quest for SC excellence obtained by climbing from one maturity stage to the next, with recognition for the levels achieved (Estampe et al., 2013).

In the 2000s and 2010s, SCM innovation and environmental uncertainties showed that creativity and disruptive models were needed. SCPMS could still be useful to compare value and performance – if the comparison was still relevant – but could be more useful as sensemaking tools to fully understand the overall SC behavior. SCPMS could also be used as sensing tools to detect unexpected evolution or paradigm shifts in the SC ecosystem.

Expanding the "visible horizon" of SC agents (Carter et al., 2015), which has always been a central goal of SCM and of SC performance measurement for various reasons – to get better control, identify risks, perform due diligence – became easier with IS and IT support.

Starting in the 1990s, great hope was placed in new technologies. Information technology supported logistical performance measurement which had been difficult to assess (Fawcett & Cooper, 1998). Data-capturing capability – with real-time tracking systems – coupled with better database technology, provides managers with better decision-making capability in diverse areas (Fawcett & Cooper, 1998). What was more of a dream than a reality in the 1990s is becoming possible not only in companies but on a broad scale for SCs, at many decision levels and on different scales of analysis.

This overview of this section concludes by affirming that useful SCPMSs should balance financial and non-financial measures, adopt a multi-level approach combining strategic, tactical and operational measures, and tries to provide multiple SC views – not limited to internal measures. Despite being rather optimistic, the literature does mention various difficulties and risks to overcome.

## 3.7 Being Aware of Difficulties and Risks

In the 1970s, difficulties were related to the lack of available data and there was no performance–value reference to assess progress. Owing to the infancy of computer systems, automated SC measurement was limited. Inter-organizational SC performance was difficult to measure because of the reluctance to share data. The 1990s marked the development of SCPMSs. Most studies have a positive view of SCPMSs and emphasize their usefulness and contribution to SCM.

Some studies identify the limitations of existing measurement systems:

> They encourage short termism; they lack strategic focus (the measurement system is not aligned correctly with strategic goals, organization culture or reward systems); they encourage local optimization by forcing managers to minimize the variances from standard, rather than seek to improve continually; and, they fail to provide adequate information on what competitors are doing through benchmarking. (Shepherd & Günter, 2006, p. 243)

One of the challenges is to define the type of measure, the type of data, and the sources of reliable data to obtain a reliable measure. The SCPMS needs many types of data, from many sources. Because of the focus on costs, accounting measures – such as cost-based performance measures – are often preferred. As stated by Dekker and Van Goor (2000, p. 52), “accounting measures can be important in supporting SCM decisions, but... they are not sufficient for the success of SCM.”

The SCPMS needs to combine multiple measures coming from SC members or use their data to measure the overall SC performance. How can they select the right source of data to measure an SC performance dimension or source of the measure? Is this source trustworthy, transparent? The measurement base of the SCPMS is an important question.

It is often difficult to obtain an overall SC performance evaluation, especially if a wide scope is selected. The many SCPMSs in the SC and the heterogeneity of the measures and metrics make overall performance evaluation difficult. Standardization efforts are needed.

Some industries such as the automotive industry have tried to develop international standards to facilitate data consolidation and common SC measurement practices. Car manufacturers use such standards to compare supplier performance and audit their SCs (Estampe et al., 2013). Since the 1990s, most SC managers and researchers have considered it important to continually improve supply chain performance using agreed upon metrics (Stewart, 1995). But who decides what metrics to agree upon, or who imposes the SC performance metrics? Who governs these answers has a significant source of power in SCs.

A measurement system that is imposed on one of the partners can conflict with shared destiny principles and thus weakens the long-term health of the relationship. It can influence SC governance and equity in sharing the value created, such as measuring cost reductions and allocating the benefits among the parties.

It is difficult to measure inter-organizational performance. Seal et al. (1999, p. 308) report: "Not only were internal costs measured in an unsatisfactory way, there was also a failure to understand the 'all-in cost' of bought-in supplies." An SCPMS should support SC relationships that deliver tangible and measurable benefits to parties over a long period and allow the sharing of ideas and information.

Another risk in SC performance measurement is to become obsessed with performance improvement and develop what is known as metrics fixation (Mueller, 2018). SC performance needs to be aligned with what matters for SC members, in particular for end-customers, and for SC stakeholders. Metrics fixation is a well-known problem, in particular when adopting ready-made key performance indicators (KPIs). There are more ready-made models with standardized KPIs, such as the SCOR model (Estampe et al., 2013). Sometimes, it can be easier to simply adopt them than to find one's own way of measuring SC performance and value creation with dedicated KPIs. These KPIs can be developed through a participatory approach to better fit what is at stake for the personnel, managers, and decision makers.

Another risk is to design the wrong SCPMS. It is necessary to question the assumptions underlying the way of improving SC performance and value creation – either by creatively seeking one's own way or by adopting existing best practices. It is necessary to choose between a ready-made top-down approach or an ad-hoc dialogic approach to define SC performance measures and metrics. In this field, the technologies and the companies that provide them are not neutral and the IS are so sophisticated that it is difficult to criticize some ready-made tools. How can one be sure that the SCPSM is aligned with what is needed and what counts?

Another difficulty is to maintain SCPMSs over time to remain aligned with dynamic environments and changing strategies. A critical aspect of many SCPMS is that they tend to be static and little attention is paid to their management, resulting in their limited evolution over time (Shepherd & Günter, 2006).

Considering the dynamic nature of SC performance and value creation and the need to keep measures aligned with strategy, the question of how often the SCPMS should be re-evaluated is important. And it is a never-ending complex process that must consider the factors influencing the successful implementation of SCPMSs, the forces shaping their evolution over time, and the problem of their ongoing maintenance. It is important to consider SCPMSs as dynamic entities that must dynamically co-evolve with environmental and strategic changes.

Table 2 summarizes the main points of the evolution.

## 4 Emergent Concerns and Future Research Directions

The performance measurement–value creation topic has remained on top of the organizational research agenda since the 1970s because of changes in companies' business strategy, changes in the SCs themselves and their strategy, and changes in their environment. This situation has led to new business and SC strategies – as well as the adoption of new technologies in SCs, also changing performance measurement management.

Performance measurement and value creation is still an open area of research. Studying the evolution of the topic and identifying key points that need consideration has also revealed under-investigated questions as well as emergent concerns related to digitalization. Moreover, the Covid pandemic experience, combined with sustainable development issues and climate change urgency – made more complex by geopolitical uncertainties – are powerful triggers for further research. This section raises issues, questions, and directions for future research.

The first questions are ontological and epistemological. What is an SC? Does it exist? How does a company (or a researcher) define or view its SC(s)? Is there a best way to manage SCs? Do we need objective ways of measuring SC performance and value? Are there best measures? What are the legitimate points of view to discuss SC performance and value creation?

Depending on the answers, the study of SC performance measurement and value creation (and management) will differ significantly. An analysis of the literature shows a mainly positivist orientation, with few ontological questions. More pluralistic research could improve our understanding of the complexity and offer new answers.

Many underlying hypotheses need to be questioned. Does more SC performance measurement always create value? Do we target the right "beneficiaries" with the right types of value? Are all stakeholders included in the SC scope? Have any relevant stakeholders been omitted? More research is needed to address voiceless stakeholder issues and detect "silent" beneficiaries' needs and values. SC performance and value creation raises ethical questions and issues that have not been sufficiently addressed.

Considering the variety of viewpoints, more research is needed on the capacity of SCPMSs to embrace different perspectives and provide multiple views of SC performance and value creation. This could help us to recognize the diversity of shareholders and stakeholders' expectations and their need to dialogue to navigate the paradoxical nature of SC performance and value creation. The SCPMS could be viewed as a boundary object which could combine different viewpoints that do not have the same objective or culture. How might we design an SCPMS that could operate as a boundary object? In building the SCPMS, KPIs could also be selected using a boundary object perspective.

The SCM literature adopts a very technical approach to the topic, focusing on the rationality of decision-making and viewing SC measurement and value creation assessment as neutral. This vision needs to be balanced with a more sociological approach. There is power in choosing measures and metrics as well as in setting objectives. An SCPMS is not a neutral tool. It says a lot about influence, the "tyranny of metrics" and metrics fixation, which may lead to extremism, particularly in human resources management (e.g., with intrusive monitoring).

There is a need to better connect SC performance with value creation. The literature often studies SC performance alone, disconnected from value creation. Are we measuring what really "counts"? Are we correctly measuring the SC and SCM contribution? Does measuring lead to SCM and SC improvement? Does measuring lead to the improvement of what really matters concerning SC and SCM?

The risk is to create an SCPMS that results in unproductive decisions because of metrics fixation, leading to a loss of meaning and even suffering at work. More generally, studies on SC performance and value creation do not really take humans into account, and the impact of SCPMS on people is insufficiently investigated. There is a need to study the alignment of SCPMSs – which often favor the expectations of the company – with people's expectations and values.

Companies need to improve understanding of the SC performance–value creation link. Most studies assume a causal relationship between SC performance and value creation. This relationship is a simplistic vision, since most relationships are recursive. Studies and practice also often neglect the time horizon for value creation, sometimes focusing on short-term value creation and neglecting the longer term. Sustainability issues and climate change call for a more balanced approach to value creation.

The question of improving SC visibility and transparency thanks to SCPMSs and accountability mechanisms in SCs has been a hot topic in performance measurement and SCM for decades. While there is consensus on the need for more SC accountability and to develop performance assessment in SCs, there is also consensus to acknowledge the complexity of the task and the need to focus on what is worth measuring. Thanks to new technologies and the development of increasingly sophisticated IS, it is possible to gather data to measure more and more types of SC performance and value. Is it possible or necessary to measure everything? Are we sure the measures are relevant? What is best – exhaustiveness or parsimony? How can effective and useful monitoring of the SC be done? There is a risk of relying on precise but out-of-scope metrics, which miss problems.

More research is needed to study how to determine the appropriate scanning scope and how to align this with business and SC strategies. This calls for a dynamic approach to SCPMSs, while most research views them as static.

There is little research on the effective use of SCPMSs and the effect of using SCPMSs. How can the results of the SCPMS be used? Understand? Incentivize? Control? Reward? Monitor activity? Contribute to the implementation of any new SC practice? Develop dialogue, collaboration and SC governance? Foresee changes, risks, or disruptions?

No matter what the intended use of the SCPMS is, it must also contribute to sensemaking and help SCM managers develop and refine their professional judgment. The systemic and dynamic nature of the different interactions at play in the SC calls for specific methodologies such as action research or in-depth case studies.

In the quest for good SC performance and value measures, researchers (and consulting firms) try to define general measures and KPIs. The objective is to

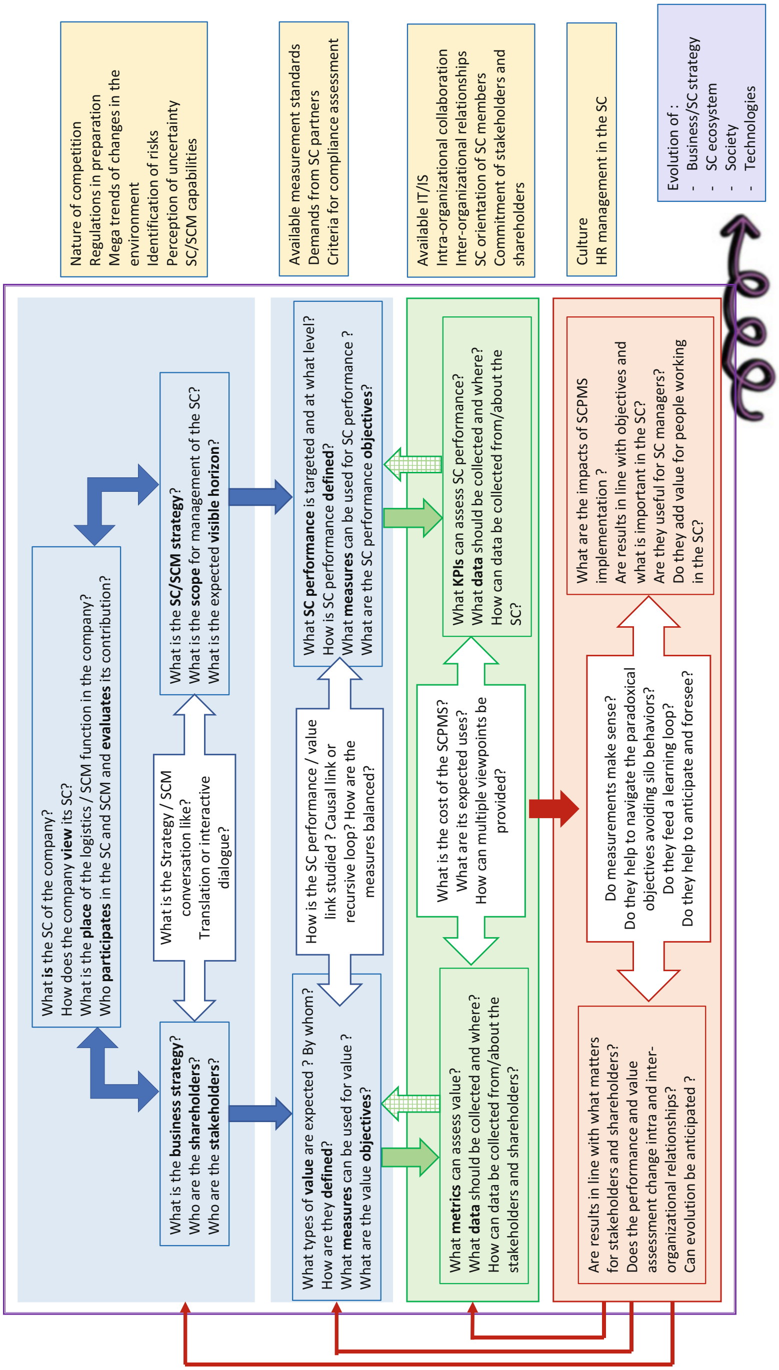

**Fig. 1** The holistic framework of performance measurement – value creation "in practice"

produce comparable and transferrable results that increase the general understanding of the question. Despite this search for standardization, the variety of SC performance measures makes it difficult to draw broad inferences from the literature (e.g., with meta-analysis or aggregating the findings of several studies). Researchers should take care in doing this type of study, making an in-depth analysis of conceptual definitions of measures and the calculation of metrics.

## 5 Managerial Implications

The importance of being recognized as excellent in SCM emerged in the 1990s. It is still important today (see Gartner, 2021b, 2022) even though the criteria for assessing this excellence have changed and will change over time. It is therefore important for SC managers to assess SC performance and value creation. Based on the background to this topic, current key points and in view of the questions raised for further research, this section proposes (see Fig. 1) a comprehensive framework providing guidelines for practice.

The overall approach is dynamic and combines four interrelated groups of questions and decisions. It is not a linear and causal process, but a recursive and endless journey that requires ongoing auditing. It deliberately emphasizes questions more than ready-made solutions and suggests being critical vis-à-vis some mainstream practices (e.g., benchmarking).

## 6 Summary and Conclusion

This chapter provided a detailed analysis of the performance measurement–value creation topic in SCM from the 1970s until now. It highlighted the successive issues and key points discussed over time, showing that – although complex and challenging – performance measurement and value creation is a core competence of SCM. Each decade has increased the number of performance and value measures, changed the vision of the link between performance and value, and revealed the multiple relevant units of analysis used to study how to improve SC performance and outcomes.

Each decade has also demonstrated the usefulness of SC measurement and SCPMSs, as well as the difficulties in putting them into practice. Building and maintaining a relevant and effective SCPMS is more complex than generally acknowledged. The chapter tried to answer pragmatic questions about performance measurement and value creation assessment in practice: How should SC managers proceed? What are the key questions to answer?

Accordingly, the chapter provides a comprehensive set of guidelines for practice. The goal is to benefit from the efforts of measuring things that really "count." Owing to the paradoxical nature of SC performance and the complexity of measuring it, renewed approaches are needed both from the research and practice perspectives.

# The Inter-play Between Performance and Risk in Supply Chain Management

Sadaf Aman

## Contents

**Abstract**

Risk and performance are inseparable terms, yet how these two influence each other within sustainable supply chain management (SSCM) is still an evolving question. In this chapter, we explore various factors that influence decisions of supply chains considering risk and performance dimensions. We specifically discuss performance measurement (PM) and its characteristics and what role it plays in supply chain risk management (SCRM). The chapter includes an introduction and background of SCRM and how it links to PM. Further, it identifies dimensions of PM and options to integrate it in SCRM. The link will encourage managers to consider PM characteristics in risk management to improve overall sustainability. Emergent concerns and future directions are also presented.

## 1 Introduction

Risk and performance are old concepts coining its history from the strategic management literature (Miller & Bromiley, 1990). Financial risk was the primary strategic focus and measured through research and development (R&D) intensity, standard deviation of return on asset (ROA), return on equity (ROE), and variance from stock analyst earnings forecasts (Miller & Bromiley, 1990). Negative deviation and variance in performance objectives indicate the presence or absence of certain risks. Early literature tries to identify the causality between the two by implying performance as a driver of risk (Bowman, 1982) and discusses the influence of performance on risk and vice versa (Miller & Bromiley, 1990). This literature suggests an inter-play between performance and risk exists from the beginning of the risk management debate which somewhat builds on the narrative "what is not measured is not managed" (Manuj & Mentzer, 2008, p. 216).

Performance is widely studied as performance measurement (PM) while risk is studied under risk management (RM). Building on this, the following arguments explain how this interplay has evolved with the evolution of the respective domains.

In the literature of risk measurement or assessment has been treated as a subsequent process after risk identification to check the magnitude and probability of the identified risk (Tummala & Schoenherr, 2011). Similarly, RM literature cultivates two broad types of risk management strategies – preventive and reactive (Thun et al., 2011). Gouda and Saranga (2018) contend that "both preventive and reactive risk mitigation strategies are devised before a risk event occurs" (p. 3). The former reduces the effects of risk before its occurrence while latter mitigates the effects after a risk has been occurred.

For preventive strategies, the perceptions regarding risk are formed on the basis of various parameters for example, past experiences, risk preferences, and infrastructural robustness. The conclusion is that the firms need to "track" the actual risk highlighting the need for proper control and monitoring (Gouda & Saranga, 2018). To ensure that the risk management strategies cascade down and lead to concrete actions, a conscious effort in linking PM with risk management strategies is a prerequisite.

A recent shift in current research endeavors to establish a link between performance and risk management by characterizing the former as an antecedent to the latter (Munir et al., 2020). It highlights that less attention has been given to how a company can identify these potential risks or what drives risk management, that is, determining the antecedents of risk management (Fan et al., 2017; Manuj & Mentzer, 2008). PM can support risk control and monitoring allowing managers to detect risk. Therefore, companies with PM can improve their risk visibility by detecting early diversions from the set targets. PM can be viewed as a determinant of risk management. The chapter aims to define the role of PM as both the antecedent and the consequence of risk management in the risk management process.

Furthermore, PM philosophies are convoluted by incorporation of management activities beyond the organizational boundaries. Business today functions as interlinked firms forming networks facilitating the efficient flows of products, capital, and information across the globe. These chains or networks of interconnected firms are referred to as supply chains (SC) in the management related literature (Mentzer et al., 2001). The changing paradigms of today's business necessitates researchers and practitioners to focus on supply chain performance measurement (SCPM). However, the narrative of boundaryless management of associated actors and activities increases complexity and exposes firms to supply chain risks. Therefore, measuring performance for supply chain risk management (SCRM) has become the crucial criteria for firms to become successful.

Moreover, recent studies on financial, environmental, and social performance sustainability into the perspective – also referred to as triple bottom line. Therefore, SCM has also evolved to sustainable supply chain management (SSCM). The concerned literature also suggests that "sustainability performance management is not often due to direct demand enforced by the legal act but because the companies aim to reduce the related risks" (Seuring & Müller, 2008, p. 1703). Example, a focal firm implementing an environment certificate implies that the firm wants to avoid the associated risk of reputational loss, which links PM to risk management. Therefore, understanding that risk is an obscure reality in SSCM and an inseparable concept from performance, where exploring and linking the two is a precursor in minimizing SC problems, hence, the chapter addresses the question:

How can the concepts SCRM and SCPM can be linked under SSCM?

The subsequent sections of the chapter discuss the historical view and practices in SCRM and links it to the SCPM by reviewing studies considering it as an antecedent as well as consequence of RM. Next, SCPM characteristics are presented considering its evolution under (sustainable) supply chain management. Current concerns are highlighted along with emergent concerns, outstanding research, and future directions. Lastly, managerial implications are presented along with the conclusion.

## 2 Background

There are numerous definitions of risk proposed in the literature of supply chain risk management. Most definitions inevitably link performance to risk management. For example, Manuj and Mentzer (2008) define risk as "the distribution of outcomes related to adverse events" (p. 197). Similarly, Tummala and Schoenherr (2011) conceptualize supply chain risk in more detail as "an event that adversely affects supply chain operations and hence its desired performance measures, such as chain-wide service levels and responsiveness, as well as cost" (p. 474). The former definition argues the effect of risk on strategic performance whereas the latter argues its effect on strategic performance through short-term performance measures.

These short-term performance measures are derived based on the managerial strategic choices and decisions for reducing and mitigating risks. For example, disruption risk and proposed measures for two disruption management strategies – flexibility and redundancy – have been linked (Rogerson et al., 2022). In RM, collaboration is a risk reducing strategy (Simangunsong et al., 2012) where trust and trust worthiness are intangible relational performance measures (Aman & Seuring, 2021; Choi et al., 2018; Maestrini et al., 2017). These short-term performance measures are a part of PM initiative, also known as PM metrics, indicators, or measures.

For many years, it has been recognized that PM can affect the successful implementation of company strategy (Laihonen & Pekkola, 2016). It ensures that the company strategies are competently and wholly implemented to sustain organizational growth (Rompho, 2011). A PM must be designed and implemented in accordance with a company's business strategy and must link the strategy to the objectives of functions, groups of people, and individuals (Kaplan & Norton, 1996; Nanni et al., 1992; Neely, 1999; Schneiderman, 1999), as well as to operations (Greatbanks & Boaden, 1998; Lynch & Cross, 1991; Neely et al., 2002). PM further includes tools, systems, instruments, and indicators which are regarded by managers in implementing the risk management strategies. For example, lean operations are a risk reducing strategy incorporating lean six sigma tools devoted to control and measuring quality under two perspectives, either linked to total quality management (i.e., a PM system) or as a continuous improvement approach (Aboelmaged, 2010).

Similarly, lead time management through just-in-time (JIT) modeling usually focuses on the link between changes in different production factors and the corresponding production performance measures (Banker et al., 1993). This perspective discusses the influence of risk on the performance and specifically entails that PM is important in the implementation of SCRM strategies.

PM can enhance SC visibility (Lauras et al., 2010). Visibility is deemed desirable since it increases SC efficiency and decreases SC risk (Nooraie & Parast, 2015). Visibility has been found to be positively related to disruption risk (Brandon-Jones et al., 2014). This finding has also been observed with SC visibility as an antecedent to SCRM capabilities (Yang et al., 2021). Moreover, integration, can be viewed as a performance measure that improves SC visibility and an antecedent to SCRM (Munir et al., 2020). This perspective implies influence of performance on risk and specifically discusses PM as a perspective that improves visibility of the SCs. Therefore, the role of PM in SCRM is twofold. On the one hand, studies consider it a consequence (Tummala & Schoenherr, 2011), and alternatively, it is viewed as an antecedent to SCRM (Munir et al., 2020).

The former conceptualization has been long considered in the SCRM literature (Gouda & Saranga, 2018; Ritchie & Brindley, 2007; Simangunsong et al., 2012); however, less attention has been given to performance as an antecedent of SCRM (Fan & Stevenson, 2018; Fan et al., 2017; Manuj & Mentzer, 2008). This latter conceptualization can further be viewed in the light of chaos theory, which defines systems as complex as opposed to deterministic, in which if the equations describe its behaviors as nonlinear, then the slightest change in the initial conditions can lead to cataclysmic and unpredictable results (Levy, 1994). Chaos theory supports the

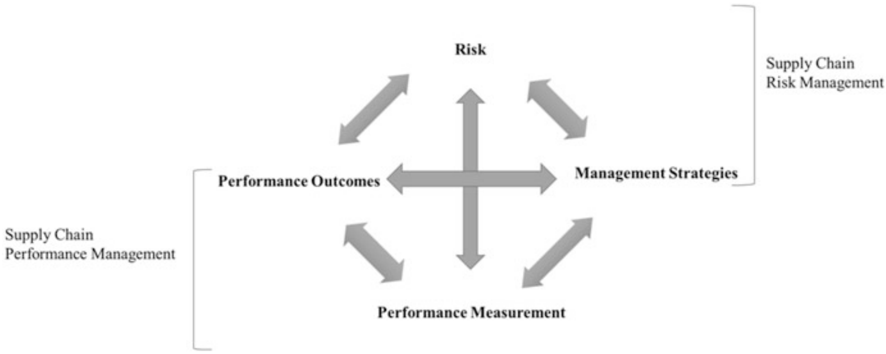

**Fig. 1** Conceptualizing SCPM in risk management

argument of short-term PM to observe change in the initial conditions to timely understand the risks prior to their occurrence (Levy, 1994).

PM facilitates short-term visibility that is necessary for risk management and strategic performance outcomes. It also offers operational or tactical measures for risk management strategies to successfully implement managerial RM strategies. Both former and later explanations are presented in Fig. 1, where the relationship between risk and performance is presented in a loop rather than a linear one. Further, multiple organizational managerial levels are presented in a coherent manner to facilitate the conceptual argumentation of interplay between performance and risk as explained in the previous paragraphs. Figure 1 is further elaborated in Sects. 2.1 and 2.2 which describe SCRM and SCPM, respectively.

## 2.1 Supply Chain Risk Management

Today's market environment is considered fragile and requires swift actions for risk management to control its effects on performance. Risk management involves identifying and assessing risk and devising the strategies accordingly. Once the strategies are devised, concrete actions are required to ensure limiting deviation from the intended outcomes. These considerations demand concrete monitoring of the risk to achieve strategical performance outcomes. One way of managing these considerations is by linking PM with the risk management.

### Sustainability Performance Measurement in Supply Chain Risk Management

SC risk management is broadly divided into three broad steps – identification, assessment, and evaluation, planning and mitigation, and control and monitoring. The identification, assessment, and evaluation of the risks is step one and can identify the probability and magnitude of their occurrence. Once identified and evaluated, related risk management strategies (step two) are devised, which then lead to control and monitoring (step three). To understand the SCRM, all these things need to be explored.

### Step One

The identification, assessment, and evaluation of risk is operationalized into number of potential risks that a firm encounters, including assessing the probability and impact of the risks. Most common and widely discussed risk factors include demand risk, supply risk, distribution risk, transportation risk, delay risk, supplier risk, manufacturing risk, capacity risk, sovereign risk, system risk, and, most recently, disruption risk. Disruption risk is a relative term which has often been discussed with the resilience concept.

### Step Two

Risk planning and mitigation require a set of strategy deployment to mitigate related risks. Risk management is managed at strategic and tactical levels. The strategic level risk is often directed towards the probability of occurrence of a certain event, for which preventive risk strategies could lead to positive outcomes. Practices include product design, shorter planning periods, good decision support systems, collaboration decision policy and procedures, use of information communication and technological (ICT) systems, pricing strategy, and redesign of chain configuration and infrastructure.

These practices can reap long-term strategic benefits as well as protection against risks. The tactical level is linked to the operational level risk and often needs reactive mitigation strategies to reduce their effects on performance. Risk mitigation literature identified reactive mitigation strategies such as postponement, volume and delivery flexibility, process flexibility, customer flexibility, multiple suppliers, strategic stocks, lead time management, financial risk management, and quantitative techniques.

### Step Three

Once top management determines the strategy for risk prevention or mitigation, related action plans need development. This step combines two phases of SCRM: (a) implement and execute and (b) review and adapt (Ha & Tang, 2017). Institutionalizing PM approaches help in addressing the most critical risks, while measuring the amount and need of resources such as information, material, finance, or products. PM facilitates the implementation and execution of risk management strategies by tracking and evaluating the performance measures linked to them (e.g., Blos et al., 2009; Chenhall & Langfield-Smith, 2007; Laihonen & Pekkola, 2016). The risk response actions can be reviewed and adapted according to the priority and the available resources which become visible with performance metrics or indicators measuring them (Lauras et al., 2010).

For example, a strategy such as “postponement” is introduced for managing “capacity risk” and related performance measures such as “cost” linked to postponement can be analyzed. Measuring cost and information throughout the chain can identify the decoupling point to avoid capacity risks. Accordingly, these performance measures or indicators can be proffered by different functional units of an organization (Chenhall & Langfield-Smith, 2007; Laihonen & Pekkola, 2016).

Upstream and downstream suppliers and buyers can also be incorporated to develop the indicators for the entire chain. PM tools can also be incorporated in identifying defects in a firm's operations through continuous auditing and reporting of changes once the risk management strategy has been implemented (Arzu & Erman, 2010). Incorporating sustainability PM efforts as control and monitoring can initially check that the risk management strategies have been cascaded down the organization and reap strategical performance outcomes as intended and further improve visibility to detect early threats of risks and adapt accordingly to ensure that the maximum risk can be avoided. Section 2.2 explains most commonly used PM systems, tools, instruments, and indicators in performance management literature that can be incorporated into the SCRM. It ranges from deciding the measurement tools and instruments to specific indicators.

## 2.2 Supply Chain Performance Measurement

SCPM can be defined as a set of metrics used to assess the efficiency and effectiveness of supply chain processes and relationships, spanning multiple organizational levels and multiple firms. The focus here is on the "metrics" that are used to access efficiency and effectiveness. These PM metrics can be derived from various measurement systems, tools, and instruments (Fig. 2). The literature

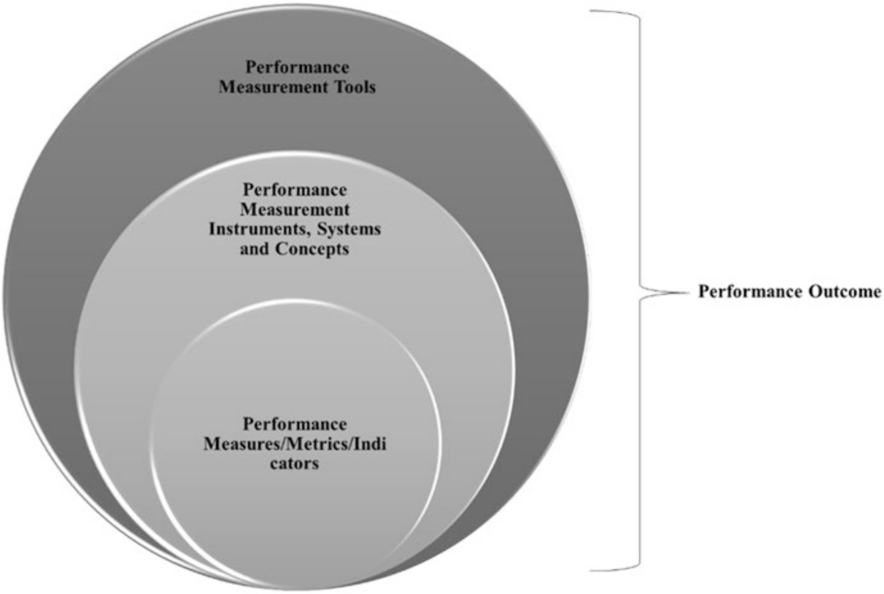

**Fig. 2** Performance measurement attributes

further distinguishes between these tools, systems, and instruments based on their focus. The PM tools can be categorized as instruments, system, or concepts (Beske-Janssen et al., 2015).

Whereas the PM instruments have a narrow focus and can be categorized as indicators, labeling, and reporting (Aman & Seuring, 2021; Beske-Janssen et al., 2015; Schaltegger & Burritt, 2014). Other examples of instruments include benchmarking, auditing, and lead-time reduction etc. These PM instruments are further analyzed through specific performance indicators (PIs) at organizational, operational, and supply chain levels. Therefore, a visual representation is made in Fig. 2 which distinguishes between the terms used in the PM literature and what they entail. Figure 2 explains that these PM terms differ in their scope, where PM tools have a broader scope which includes PM instruments, systems, and concepts as well as PM metrics. Furthermore, what constitutes these terms is explained in upcoming sections.

### Performance Measurement Tools

PM literature comprises various PM tools. Some of the frequently used tools will be defined below:

**Quality Standards (ISO 9001)** International Organization for Standardization (ISO) 9000 is about quality systems and consistency. It aims to give customers confidence in their suppliers by assuring them that the suppliers have the management processes that deliver consistency. It includes a set of standards that encourage organizations to assure product quality (Terziovski et al., 1997).

**Environmental Standards and Certificates** These standards and certificates help companies reach the environmental goals of their business operations using policies and standards for environmental protection (Huber & Bassen, 2018).

**Social Certification** Social certificates are a coordinated and systematic approach to managing health and safety risks by maintaining social standards such as Occupational health and safety (OHS), social accountability (SA) 8000, and Occupational Health and Safety Assessment Series (OHSAS) 18001 (Gold et al., 2010).

**Sustainability Standards** These refer to the standards or rules, procedures, and methods used to systematically assess, measure, audit, and/or communicate the social and environmental behavior and/or performance of firms (Gilbert et al., 2011).

### Performance Measurement Systems

**Quality Management System** A management system which uses the ISO quality certificates for managing the quality of the products (Beske-Janssen et al., 2015).

**Environmental Management System (EMS)** "ISO defines an EMS as 'that part of the overall management system which includes organisational structure, planning, activities, responsibilities, practices, procedures, processes and resources for developing, implementing, achieving, reviewing, and maintaining [the organisation's] environment policy" (ISO, 1996).

**Social Management System** A management system which includes the social ISO certificates for managing the social impact and also includes the occupational health and safety system (OHS) (Beske-Janssen et al., 2015).

**Integrated Management System** A management system which uses integrated managing tools such as Global reporting initiative (GRI) and United Nation (UN) global impact (Beske-Janssen et al., 2015).

## Performance Measurement Concepts

**Corporate Citizenship** "At a minimum, corporate citizenship means the conduct of business in ways that reflect proactive, responsible behaviour in business and dealings with all constituents and with respect to communities, society, and the natural environment more generally" (adapted from Logan et al., 1997, p. 7).

**Stakeholder Dialogue** "In the dialogue with stakeholders (both primary and secondary) opinions are exchanged, (future) interests and expectations are discussed, and standards are developed with respect to business practice" (Kaptein & Van Tulder, 2003, p. 208).

**Sustainability Balanced Scorecard** The well-known four dimensions of the BSC developed by Kaplan and Norton (1992) (i.e., finance, customer, internal business process, learning and growth) are shaped according to the SCM scope, by considering: SCM goals, end-customer benefit, financial benefit, SCM improvement. The idea behind the supply chain balanced score card (SCBSC) is to design a SC strategy coherent with the business strategy, including critical success factors within the four performance dimensions above (Maestrini et al., 2017).

**Supply Chain Operations Reference Model** Set of metrics grouped according to the five distinctive management processes, namely plan, source, make, deliver, and return. These metrics are also classified according to their strategic, tactical, or operational nature (adapted Maestrini et al., 2017).

**Resource, Output, Flexibility (R-O-F) Model** Resources: various dimensions of cost are monitored (e.g., distribution cost, manufacturing cost) with the purpose of fostering efficiency, Output: various dimensions of customer service are reported, Flexibility: it measures the ability to respond to a changing environment. This framework is thought to assess the SCM capabilities of a specific firm and keeps a mainly internal perspective (Maestrini et al., 2017).

## Performance Measurement Instruments

**Life Cycle Assessment** Life cycle assessment is a "cradle-to-grave" approach for assessing industrial systems. LCA evaluates all stages of a product's life from the perspective that they are interdependent, meaning that one operation leads to the next (Scientific Applications International Corporation, 2006).

**Eco-audit** Eco-auditing is a method of describing the state of the environment. It also includes environmental analysis as an approach by the management evaluating to what extent the organization complies with the internal and/or external environmental requirements (Aall, 1999).

**Environmental Benchmarking** Environmental benchmarking is a PM instrument through which companies are given a mark for their actions and achievements.

This enables stakeholders to judge how responsible a specific company is (Graafland et al., 2004).

**Environmental Reporting** "[This is the] process of communicating the environmental effects of organisations' economic actions to particular interest groups within society and society at large" (Nitkin & Brooks, 1998, p. 1499).

**Financial Report** This is an annual report published by companies that tells society at large about the companies' financial situation, including profit or loss for particular periods (Nitkin & Brooks, 1998).

**Social Audit** A social audit attempts to provide a mechanism for decision-makers to evaluate economic and social planning, facilitate popular involvement in economic decisions, and identify the social need as a primary criterion for resource allocation. (Owen et al., 2000). It also assures that the organization is meeting the social requirements.

**Social Benchmarking** It is a set given mark for the companies are for their actions and achievements. It enables stakeholders to judge how socially responsible a specific company is (Graafland et al., 2004, p. 139).

**Social Reporting** This is the process of communicating the social effects of organizations' economic actions to particular interest groups within society and society at large by publishing reports (Nitkin & Brooks, 1998).

**Sustainability Audit and Monitoring** Sustainability auditing refers to characteristics such as suppliers' compliance with the measurable standards that are employed to assess environmental management, the use of a trained audit team, and the organization's release of progress reports.

**Sustainability Monitoring** includes the evaluation of suppliers by auditors vis-à-vis ability to meet measurable standards and improving the flaws by training them (Seuring et al., 2019).

**Sustainability Benchmarking** "Through benchmarking, companies are given a mark for their actions and achievements, which enables stakeholders to judge how responsible a specific company is" (Graafland et al., 2004, p. 139).

**Sustainability Reporting** Sustainability reporting is a process of communicating the companies' initiatives towards environmental and social requirements. One trend that is also apparent in many parts of the world is the tendency of companies to produce separate social and environmental reports. In this context, such reports are generally termed as CSR reports or sustainability reports, depending upon the development of the corporation concerned (Aras & Crowther, 2009).

## Performance Metrics

### Performance Metrics Levels

The performance metrics can be devised for two organizational levels, i.e., strategic and process (Fig. 3). Figure 3 also explains that the process level measures are further divided into output measures and efficiency measures. These subcategories of the process performance measures are explained in further sub sections.

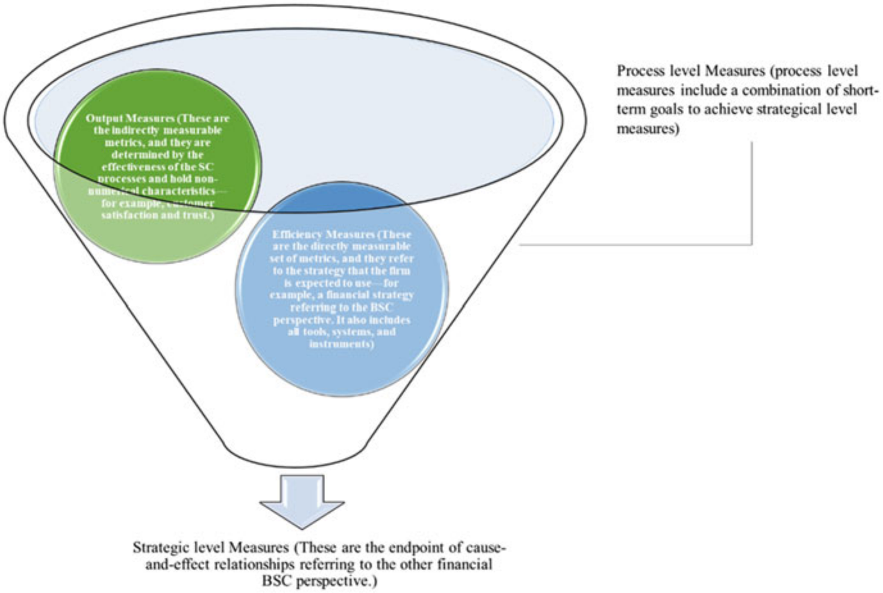

**Fig. 3** Performance metrics

### Strategic Level

A firm's strategic level measures include its final objectives, long-term goals, or outcomes. These strategical level performance measures often considered separately from the PM and are the strategic consequence of management strategies (Aman & Seuring, 2021). Therefore, this level represents the vision of an organization and thus includes long-term goals, for example, sustainability.

**Economics/Business Performance** Financial gains yielded from a business activity – that is, profitability, revenue, and economic growth. The endpoint of the cause-and-effect relationship.

**Sustainable Competitive Advantage** It is achieving and maintaining a competitive advantage as a result of business activity.

**Operational Performance** Cost reduction, speed, time, flexibility, dependability, output quality achieved, new quality product developed.

**Social Performance** Social benefits achieved as a result of a business activity – poverty alleviation, empowerment, inclusiveness, and so on.

**Environmental Performance** Environmental benefit achieved as a result of business activity – that is, energy consumed, waste produced, improved air quality, and so on.

**Sustainability Development** of all three dimensions of sustainability: social, economic, and environment, i.e., not focusing on performance outcome of a single dimension.

### Process Level

A firm's process level measures include a combination of short-term goals which are deployed to achieve strategical level goals. Process level measures further hold tangible or intangible characteristics (Hervani et al., 2005). The tangible measures include greenhouse gas (GHG) emissions and waste production, which are used to observe growth or decline patterns in SC processes. These tangible measures are measured directly (i.e., numerically) and the literature suggests that they should be used to assess the efficiency of SC processes (Beske-Janssen et al., 2015).

The intangible measures are also present in the performance measurement. These performance measures are determined by the effectiveness of SC processes, such as customer satisfaction, trust, and commitment. For example, trust is a non-numerical measure that can determine the reliability of the relationship between two SC actors. Because this relationship cannot be directly assessed, the actors assume trust in each other if they adhere to the standards that they set mutually, such as those required for ISO certification. Therefore, these measures are labeled as output measures, and they hold intangible characteristics. In sum, the efficiency measures have tangible characteristics while output measures hold intangible characteristics.

### Efficiency Measures

These are the directly measurable set of metrics, and they refer to the strategy that the firm is expected to use – for example, a financial strategy referring to the BSC perspective. It also includes all tools, systems, and instruments.

**Financial** The financial perspective indicates whether the transformation of a strategy leads to improved economic success. Financial performance here is defined as a process rather than an end point of the cause-and-effect relationship (Figge et al., 2002).

**Customer** "The customer perspective defines the customer/market segments in which the business competes. By means of appropriate strategic objectives, measures, targets and initiatives the customer value proposition is represented in the customer perspective through which the firm/business unit wants to achieve a competitive advantage in the envisaged market segments" (Figge et al., 2002, p. 271).

**Cycle time** "Cycle time refers to the time it takes from initiation to completion of the purchasing process" (Hult et al., 2002, p. 580).

**Cost** is usually a monetary estimation of effort, material, resources, time and utilities consumed, risks incurred, and opportunity forgone in the production and delivery of a good or service – that is, cost-efficiency (Adegbile & Sarpong, 2018).

**Quality** Quality includes a tangible dimension, i.e., it deals with procedures and specific systems which are established to provide the goods or service.

**Asset** Asset attribute refers to the effectiveness of asset utilization measured in terms of cash-to-cash cycle time, return on fixed assets, and return on working capital (Heuër, 2017).

**Resources** Resource measures include tangible resources, such as capital requirement, inventory levels, and equipment utilization.

**Flexibility** Flexibility refers to how easy it is for an SC to change based on its range of options (Ahrens et al., 2019).

**Gender Diversity** This refers to the consideration of gender diversity in the life cycle of a product. "It is the proportion of males to females in an organisation that can affect the way in which they interact and behave with one another at the workplace, and thereby impact the social and cultural environment" (IGI Global, 2020).

**Human Rights** This refers to the consideration of human rights in the life cycle of a product. Human rights include the right to life and liberty, freedom from slavery and torture, freedom of opinion and expression, the right to work and education, and many more. Everyone is entitled to these rights without discrimination (United Nations, 2020).

**Fair Trade** This is the consideration of fair trade in the life cycle of a product. Fairtrade means that the producers receive prices that cover their average costs of sustainable production, the premium which can be invested in projects that enhance social, economic, and environmental development (Fairtrade International, 2019).

**Fair Labor** This is the consideration of fair labor in the life cycle of a product. "This includes paying less than the minimum wage, employing young children, and working employees for long hours without premium overtime pay" (Goldstein, 1999, p. 1003).

**Child Labor** This is the consideration of child labor in the life cycle of a product. "A child (5–14 years) is defined as economically active if he or she works for wages (cash or in-kind); works on the family farm in the production and processing of primary products; works in family enterprises that are making primary products for the market, barter or own consumption; or is unemployed and looking for these types of work" (Edmonds & Pavcnik, 2005, p. 201).

**Waste Production** This is the consideration of waste production in the life cycle of a product: the production of unwanted materials as a by-product of economic processes (Sustainable Development Indicator Group, 1996).

**Greenhouse Gas (GHG) Emission** This is the consideration of GHG emission in the life cycle of a product for example, $CO_2$, SOx, and NOx. The emission of harmful gases into the air is called air pollution because they alter the chemical composition of the natural atmosphere (adapted from Daly & Zannetti, 2007).

**Noise Pollution** This refers to the consideration of noise pollution in the life cycle of a product. Noise pollution is generally defined as regular exposure to elevated sound levels that may lead to adverse effects in humans or other living organisms (Environmental Pollution Centers, 2019).

**Recycling** This is the consideration of recycling in the life cycle of a product. Recycling means the processing of waste (i.e., unwanted or useless materials) and its (re)introduction back into the material cycle so that contamination of the environment is minimized (Tanskanen, 2013).

**Pollution** This is the consideration of pollution in the life cycle of a product. Pollution is the introduction of harmful materials into the environment which further damage the quality of air, water, and/or land (adapted from Daly & Zannetti, 2007).

**Innovation** Innovation is the setting up of a new production function. This covers the cases of a new commodity and new ventures – that is, an organization or a merger – or the opening of new markets, new relationships, new products, or new marketing infrastructure (Hall et al., 2014).

### Output Measures

These are the indirectly measurable metrics, and they are determined by the effectiveness of the SC processes and hold non-numerical characteristics – for example, customer satisfaction and trust.

**Resources** Resource measures also include intangible resources, such as personnel requirements, relations, and information.

**Quality** Quality also includes an intangible dimension which deals with the interactions among workers and their attitudes and behaviors with customers.

**Customer Satisfaction/Expectation** Various dimensions of customer service are reported. Output measures include customer satisfaction measured through return on the quantity and quality of the products being produced and customer expectation through being more considerate and responsive to customer demand (Viswanathan et al., 2012).

**Local Community Commitment (LCC)** This is the consideration of the local community in the life cycle of a product. LCC means taking the long-term views and embeddedness of firms in local communities into account to deal with the local contestations for survival that filter into the everyday lives of the poor (Ansari et al., 2012) – for example, social inclusion.

**Social Capital** Social capital refers to three broad forms of capital further measure through structural capital, relational capital, and cognitive capital (Nahapiet & Ghoshal, 1998).

**Trust** The degree of reliability enjoyed between the SC partners which also facilitates SC processes (Al-Saa'da et al., 2013).

**Commitment** Commitment may be defined as the relative strength of an individual's identification with and involvement in a particular organization (Steers, 1977).

**Integration** Integrating suppliers, buyer, and intra-firm functional units into the SC processes (Schrader et al., 2012).

**Learning and Growth** The learning and growth output performance measures describes the infrastructure necessary for the achievement of the objectives. It includes information required for new products developed, new markets entered, Research and Development (R&D) spending/sales, training/sales, and investment/total assets/capability development (Figge et al., 2002).

## 3 Current Concerns

PM and SCRM have been separate within the SSCM literature, which highlights a need for exploring the interplay between the two topics. Within the literature, the most commonly used conceptualization includes the strategic level performance measures, that views performance as an ultimate or long-term consequence of SCRM (Simangunsong et al., 2012). This work neglects the role of short-term PM.

Process level measures are also viewed as SCRM antecedents (Munir et al., 2020). PM tools, concepts, and instruments play facilitator or enabler roles. The presence of performance in SCRM has been discussed but the idea of conceptually linking the multiple levels of analysis is relatively new. For example, a container of 500 lithium-ion batteries ordered from company A situated in China by company B in Germany through marine ports. Since the temperature is one of the crucial measures to check the likelihood of getting fire during shipment, company B strives to monitor the temperature during shipment using their PM system. While reaching B, the measurement system showed the company B that the temperature of the container is close to exceeding the set measure thereby indicating a likelihood of disruption risk. Without a proper measurement system or the set PIs, in this case, temperature, how would a company be able to detect a fault?

Taking the same example, suppose the container caught fire, the next step is how to mitigate the risk that has been occurred. The company can check for internal capacity, i.e., use either the social capital, such as alternative suppliers or ad hoc partners, or check the warehouse stock to fulfill the customer demand. Having a measurement system indicating warehouse stock and nearest alternative suppliers can then determine the effectiveness of the company's response to the risk occurred. Therefore, embedding PMs into the risk management – as shown in this example – plays a vital role in reducing and mitigating risk effects. This requires exploring the two concepts in detail and then linking them in such a way that is beneficial for mangers, in particular, and supply chains, in general.

### 3.1 Performance Measurement for Risk Management in Developing Countries

Globalization has caused a greater need for integrating developing regions into supply chains. With the changing paradigms of today's world, measuring performance of supply chain processes and actors in these regions have become important for various reasons. First, increasing focus on sustainability measures put pressure on the companies to ensure sustainability of the entire chain. Upstream performance in developing regions can use related indicators that can curb the sustainability risks. For example, most developing regions are crucial for primary resource-based global supply chains (Silvestre & Neto, 2015). Making sure the practices in these upstream supply chain actors conform to the mission of the company to avoid reputational losses thereby posing financial risks.

Second, offshoring poses a threat of opportunistic behavior which is difficult to determine. Having PMs based on the indicators such as "quality" and "trust" can ensure the integrity of the first and second tier suppliers thereby reducing the probability of risk occurrence. For example, suppose a company is under pressure to quickly start offshoring, primarily due to short-term focus of bonus incentives, can lead to inadequate quality check of second tier suppliers. If not checked, the likelihood of such supplier for suppling defective wires, or other poor practices, is high. These wires are then used by manufacturer and get integrated into a range of appliances. The defective wire then causes the appliances to malfunction. The cost to fix this quality lapse includes replacement of defective appliances, including installation costs, reworking the existing appliances stocked at different levels in the supply chain, and reworking the goods in the three-week long pipeline as they arrived. Therefore, PM for SCRM is an important consideration when organizations devise plans for emerging economies regions.

Considering the "consumer-oriented" and "inclusive business-practices" arguments of the emerging economies literature (Tate et al., 2019), it is evident that measurement of quality and trust play a crucial role in overcoming the risks associated with the two, respectively. Highly uncertain environments of these markets further stress the need for short-term PM which should be well aligned with the risk management strategies of the firms. If considered, it can help in successful implementation of strategies and improve visibility which are two critical components for risk management. Nevertheless, developing countries are important in this context as their market environment is considered highly uncertain and riskier also because of the presence of institutional voids (Parmigiani & Rivera-Santos, 2015). Therefore, it is crucial to devise and incorporate PM for risk management throughout the supply chain.

## 3.2 Sustainable Performance Measurement Through Digitization

Another current concern lies in the enhanced usage of digital platforms, tools, and technologies. The transition towards a digital era brings various performance related concerns such as environmental, social, and financial wellbeing of the organizations. For example, the high-tech firms are highly prone to downsizing the workforce considering them as incompatible for the digital transition. Besides, the environmental hazards embedded in the manufacturing of digital equipment rises the concerns of long-term environmental degradation, unless circular economy concept has been integrated into the system. Here PM improves the visibility and makes organizations more sustainable. For example, using digital scorecards elaborates on the organization's standing on the three dimensions of sustainability.

With advance digital tools one can improve the resource consumption within planetary boundaries, and therefore strive to reduce its consumption footprint and double its circular material use rate. However, it is easier said than done. Using correct PM instrument together with advanced digital tools can circumvent various concerns of today's scholars and organizations. The idea of using digital tool as overall process improvement is further mentioned in the Sect. 4.

## 4 Emergent Concerns, Outstanding Research, and Future Directions

Striving for better performance while successfully managing risks is important for a firm's existence, in particular, and their supply chain, in general. The inter-play between the two topics demands more understanding of the conceptual linkage. It is crucial to explore the literature on PM and SCRM. PM comprises PM tools, systems, concepts, instruments, and indicators which are further categorized based on their focus (Aman & Seuring, 2021; Beske-Janssen et al., 2015; Schaltegger & Burritt, 2014). Within risk management, conceptualization requires details on the risk factors, management practices, and control and monitoring. Furthering the risk management debate is on how PM can influence and be influenced by SCRM is still needed – we have only started the discussion in the chapter, much more is still required.

Various factors have been suggested that can influence decisions that are particular to supply chain risk. The conceptual definition of the performance characteristics has been presented and most common risk and related strategies have been identified. Consideration of their inter-play can affect the strategic outcomes of a firm, and this outcome, through various empirical and case studies, can provide additional insights for future developments.

PM both before and after devising risk management strategies is found critical for risk management. Therefore, understanding this role and its successful implementation can help managers in detecting early diversion from the set performance targets – but can also lay the foundation for long-term strategic competitiveness of firms and their supply chains. How these issues interact needs further study.

There are other directions for discussion and development of the topic especially from scientific, theoretical, and/or research investigation perspective. First, which PM tools, concept, systems and instruments, and indicators are linked to which risk and which risk management strategy? This linkage highly depends on the company's values, competitive priorities, and broadly their vision. Linking the two topics better in such a context require company's managers to consider long-term aims of the company. Consequent strategies and accurately linking them with short-term performance measures ensure that the maximum risk can be avoided. Nevertheless, these PIs for risk management can further be devised for internal, upstream, downstream, and reverse logistic activities as well as actors using the measurement instruments, tools suggested.

Second, the PIs vary from company to company and should be the focus of focal firms. For example, the PIs for food supply chains would be different from the automotive supply chains and that of the apparel supply chains. However, some of the PIs mentioned in the chapter can be applied to all these supply chains and adding more specific indicators based on the company strategic objectives need to be discussed further by the researchers. This industry and contextual difference also mean that the linkage between SCRM and PM may also vary (Negri et al., 2021). These nuances need careful investigation.

Third, there is a question on what behavioral aspects can cause risk and PM problems. There is always a risk of opportunistic behaviors; however, incorporating collaboration as a strategy and relative incorporation of collaboration themed balance scorecard can ensure that the risk can be avoided – or at least studied to determine if this mitigation is likely to occur. Researchers can test this proposition in real world setting. It would be insightful to understand how behavioral aspects relate to various type of risks and how measurement of these indicators minimizes the risk of subsequent negative outcomes. Similarly, what other contingency factors do a company need to consider while linking risk and performance measures? Exploring further contingency factors would help both the practitioners and researchers in understanding the interplay between the two.

Lastly, identifying how digitization facilitates linking risk and PM is a serious and open question. Recent disruption risk faced from COVID-19 enforced the supply chains to incorporate digitization of the existing supply chain activities. Digitization can ease the PM and help in swiftly managing the associated risks. Taking the example of lithium-ion batteries, suppose the company was using sensors in container to check the temperature and a digital assistant to check PIs and upon any diversion, an alarm was set to alert the managers for potential risk of fire in the container. The mangers would quickly try to resolve the related risk such as delay of order by checking the internal capacity of the company through digital assistant.

With the evolution of digitization and digital components such as big data and Internet of Things (IoT), a company can harness web analytics for more informed performance measures to exploit in reaching the performance outcome (Järvinen & Karjaluoto, 2015) as it provides the real-time visibility (Ivanov & Dolgui, 2020). Therefore, digital PM or selection of performance measures from the use of digital components holds several ideas for future studies.

## 5 Managerial Implications

The managers and policy makers can consider these performance and risk factors in strategic decision-making regarding risk management. These factors are also extracted from sustainability perspective, so as to incorporate financial, environmental, and social factors together into their PM. The strategic performance outcomes reflect on the company's vision statement and the process level measures reflect on the mission statement, where PM tools, systems, instruments facilitate the measurement of the latter to monitor and control the risk for the achievement of former. The managerial implications are further elaborated concerning the (1) organizational, (2) technological, and (3) external relationship perspective.

Organizational risk management and PMs not only need to be linked to each other, but also linked to external systems across the supply chain partners. Here the managers need to include SC partners in the early design of the PMs by incorporating suggestions for necessary risk management. Off course this is not an easy thing to do. Considering different SC partners have diverse risks and devising the PMs for each partner can tremendously help the managers for timely risk management.

Besides, schedules of the necessary evaluation based on PM metrics should be included in the initial contract between the parties. This will help the managers to understand which SC partners are prone to more risk and to devise the strategies timely.

Further, managers can use the digital platforms for updating the SC partner's data on the devised PM metrics. A user-friendly interface can even allow for daily visibility of partner's performance making the risk management easy. However, the digital platforms may raise the concerns of reliability when the SC partners are dispersed worldwide, i.e., developing countries. Therefore, strong external relations based on trust are required to work more effectively towards overall risk management.

The managers can use "trust" metrics to measure external relationship with the SC partner, as discussed in section "Performance Metrics", which further can resolve the issue of reliability in measuring the PM metrics digitally. The external relationship can also be built on mutually agreed upon sharing the performance data between managers of two or more SC entities.

## 6 Summary and Conclusion

Building on the notion that there is a dearth of understanding on the interplay between performance and risk, the chapter introduced the current state of performance in SCRM. It further elaborates on this by presenting a comprehensive understanding of the performance considering the PM literature. In doing so, the chapter addresses the previously sought comprehensive view on the antecedent and consequences of SCRM. The role of SCPM within SCRM is presented as a loop which can be explored further by taking individual performance instruments, tools, concepts, or indicators and their role in SCRM. One such example includes role of social capital in SCRM. The chapter concludes that there are many PM constructs that can serve as antecedents and consequence in SCRM which still require future research in its own right.

**Abstract**

Successful supply chain management involves balancing multiple objectives, such as cost, responsiveness, sustainability, and flexibility. These objectives are dependent upon a secure and functioning information system, especially with the integration of information technology (IT) platforms to perform multiple supply chain management functions. Securing the materials, information, and finances

transmitted along the supply chain is paramount, as supply chains have become the target of malicious supply chain attacks which can result in costly data breaches, physical impacts, and other compromises. Even the most secure information systems are vulnerable due to information exchanges with third parties, thereby incentivizing malicious parties to often target the weakest links in information-sharing partnerships. In this chapter, we will review the theoretical and methodological approaches to supply chain security, identify emerging challenges across a variety of technological use cases, and provide managerial recommendations for managing risk and ensuring a secure supply chain.

## 1 Introduction

Several high-profile security attacks have plagued supply chain information systems in recent years. For example, the recent JBL ransomware attack disrupted one-fifth of the US meat supply. Another recent ransomware attack resulted in disrupted operations for hundreds of businesses, disrupting abilities to conduct transactions (McMillan, 2021). The SolarWinds attack is particularly notable for its potential to impact the functionality of critical infrastructures (CISA, 2020). The city of Oldsmar, Florida, suffered an attack on their water treatment system in which an attacker remotely increased sodium hydroxide levels in the water to deadly levels (Greenberg, 2021). A casino was attacked through an Internet of things (IoT)-enabled thermometer in a fish tank, enabling access to a database of high rollers (Marks, 2021). *Bloomberg Businessweek* reported on a state-sponsored attack dubbed "the big hack" in which tiny chips, the size of a sharpened pencil tip, were inserted into motherboards during manufacturing by subcontractors in the supply chain. This tiny chip allowed attackers to create a stealth doorway into the networks of the compromised systems (Robertson & Riley, 2018). The global nature of the 5G telecommunications supply chain has raised national security concerns within the federal government (Donahue, 2019).

Societies and economies depend critically upon functional and secure supply chains, particularly within manufacturing, critical infrastructures, and cyber systems. For example, we rely upon secure supply chains for food, ensuring that the food is kept at safe temperatures and free from harmful contaminants (Conrad et al., 2012; Alvarez et al., 2010). Similarly, the supply chain for pharmaceuticals must be free from potentially harmful counterfeit drugs (Outterson & Smith, 2006). As global supply chains grow more complex, coupled with a lack of visibility and an increasing reliance on information technology (IT), supply chains are appealing targets for malicious actors. One such concern is that supply chains may be the target of "supply chain attacks," which according to NIST are defined as "attacks that allow the adversary to utilize implants or other vulnerabilities inserted prior to installation in order to infiltrate data, or manipulate IT hardware, software, operating systems, peripherals (IT products) or services at any point during the life cycle" (NIST, 2021). These attacks are often executed indirectly by exploiting a target's upstream suppliers. According to one study, 56% of companies have experienced a breach caused by one of their vendors (Korolov, 2019).

With the advanced rate of technological progress, supply chain security is becoming a critical component of organizational management. In particular, operations are becoming increasingly automated and interconnected, creating avenues for attacks to impact systems that historically have been managed by humans. These types of attacks have the potential to not only disrupt the movement of goods and services but can also impact physical systems, including the health and well-being of populations. However, an effectively secure supply chain that leverages these new technologies has potential to benefit societies in a variety of ways. Most notably, the increased reliance on artificial intelligence (AI) and automation can drastically improve efficiencies (Manyika & Sneader, 2018; Nunez, 2019) and improve aspects such as health and safety, food security, operational efficiencies, and economic prosperity of nations.

In this chapter, we review the topic of supply chain security. In Sect. 2, we describe the historical and theoretical background of security and risk. In Sect. 3, we summarize current concerns and research efforts, followed by emerging concerns and future research directions in Sect. 4. In Sect. 5, we highlight managerial concerns and implications for supply chain managers. Finally, we offer a summary and concluding discussion in Sect. 6.

## 2 Background

This section will discuss main principles and definitions related to supply chain security and risk.

### 2.1 Supply Chain Security

Closs and McGarrell (2004) defined supply chain security as: "The application of policies, procedures, and technology to protect supply chain assets (product, facilities, equipment, information, and personnel) from theft, damage, or terrorism and to prevent the introduction or unauthorized contraband, people or weapons of mass destruction into the supply chain."

Security-related risks may arise throughout the supply chain, impacting the goods being transported, the factories belonging to the firm and those of outsourced firms, other third-party supply chain vendors, the facilities where supply chain activities are carried out such as warehouses and ports, freight carriers (truck, air, rail, ships), people who have access to the goods and facilities, and information that is transmitted along the supply chain (Sarathy, 2006).

Supply chain security involves the activities of cargo management, facility management, information management, and human resource management (Hintsa et al., 2009). Traditional security measures focus on implementing effective methods, prevention, detection, and reporting of security threats, as well as practices such as background checks on employees and monitoring of facilities via security guards and camera systems (Hintsa et al., 2009). Related to transportation, one example is the routing of hazardous materials along highway systems. Abkowitz et al. (1992) devised five different objective functions for route selection: minimize distance traveled, minimize travel time, minimize accident likelihood, minimize population exposure, and minimize risk (as the product of accident likelihood and population exposure) (Abkowitz et al., 1992).

While security within the context of supply chain management has always been an important topic, it increased in importance in the wake of the September 11th terrorist attacks (Williams et al., 2008). Sheffi (2001) noted that it was not the attacks themselves but rather the government's responses that were disruptive to the supply chain such as border closures and grounding of air traffic. In the post-9/11 world, companies are increasingly focused on managing risk associated with other potential attacks, managing supply chains under increased levels of uncertainty surrounding other types of risk events, managing relationships with the government, and protecting employees, physical assets, and intellectual property (Sheffi, 2001).

Another trend which has accelerated rapidly in recent years is the integration of IT systems supporting supply chain activities. IT systems enable information sharing, communication, and collaboration between supply chain partners, as well as automation of processes like ordering (Subramani, 2004). The use of IT in supply chains typically seeks reduced costs, reduced lead times and cycle times, increased operational capabilities, improved partner relationships, and better decision-making (Nath & Standing, 2010).

Sahay and Gupta (2003) discussed various supply chain software platforms, including enterprise resource planning (ERP) systems with supply chain-related models, as well as more specialized packages for supply chain planning (SCP), order management systems (OMS), warehouse management systems (WMS), manufacturing execution systems (MES), and transportation management systems (TMS). While IT has yielded benefits for supply chains, Spekman and Davis (2016) identified IT systems as a source of risk. Not only do disruptions to IT systems disable and disrupt the firm's operations – in terms of flows of goods, information, and money – but IT systems may inadvertently grant access to proprietary information by an unauthorized party (Spekman & Davis, 2016).

Ransomware is an example of a relevant supply chain disruption. Typically, ransomware is accidentally downloaded onto a computer and encrypts files on the computer and network, requiring a key to unlock the files in exchange for a ransom payment. Within the healthcare field, for example, ransomware has been prevalent, and hospitals incur risks due to medical malpractice which may occur if a patient is affected as a result of the ransomware attack. There are also data privacy concerns, reputational risks, and other costs and expenses associated with ransomware (Spence et al., 2018).

The US National Institute of Standards and Technology (NIST) Special Publication 1500-201 defines a cyber-physical system as follows: "Cyber-physical systems (CPS) are smart systems that include engineered interacting networks of physical and computational components" (NIST, 2017). The IoT, industrial Internet, and "smart" systems such as cities, grids, vehicles, etc., fall into this category. Such systems increasingly play a dual role – they have their own supply chains, which must be secure, and they also support and facilitate the supply chains of other products and services as well. As an example, the supply chain for microelectronics supports the digitally enabled economy. Issues related to counterfeit parts entering into the supply chain and malicious functions inserted into the circuitry result in security issues from degraded functionality to unauthorized remote access to the system and sensitive data (DiMase et al., 2016). Other trends accelerating these concerns within the microelectronics industry include the shift away from in-house manufacturing toward contract manufacturing, increased globalization, and the reuse of intellectual property licensed from third parties (Guin et al., 2016; Polczynski, 2004; Mason et al., 2002). The result is a lack of traceability across the supply chain and opportunities for adversaries to insert malicious code and/or hardware into the final product or system (DiMase et al., 2016).

Therefore, supply chain risk management is an important area of concern for cyber-physical security (DiMase et al., 2015), while the security of the supply chain itself is also important as it represents an entry point for supply chain attacks on downstream partners (Collier & Sarkis, 2021).

## 2.2 Defining Risk

The Society for Risk Analysis (SRA) provides several definitions of risk. Many of these definitions involve uncertainty as it relates to the severity of consequences, involving some aspect that humans value (SRA, 2021). The ISO 31000 standards agree, as it defines risk as the effect of uncertainty on objectives. Kaplan and Garrick (1981) defined risk in terms of the answer to the following questions: "What can happen?" "How likely is it?" "What are the consequences?"

Threats that can impact the functionality of supply chains can take many forms. Natural disasters are often the most visible, taking the form of floods, tornados, hurricanes, earthquakes, wildfires, and others (DHS, 2021). Human-induced threats could include the release of hazardous materials and infrastructure accidents, such as the Deepwater Horizon oil spill. Threats may also be in the form of terrorism, state-based attacks, and cybercrime groups who seek financial gain (e.g., ransomware), information (e.g., trade secrets, intellectual property, information for subsequent attacks), sabotage (e.g., acts of war), and attention (e.g., hacktivism).

The vulnerability of a supply chain can be assessed as the "degree to which a system is affected by a risk source or agent" (SRA, 2021). Modern supply chains are increasingly interconnected, such that the functionality of one firm can have cascading effects on interrelated firms within the supply chain system. Thus, incidents occurring in small or less secure firms can have impacts on larger and more secure partner firms. These types of cyber incidents often result from cyber-vulnerabilities, which can be unknown by the firm – such as *zero-day* threats with previously unknown methods – and attacks can often go undetected.

To manage vulnerability requires active risk management practices that are supported by firm stakeholders. For example, consider the Equifax data breach, which was caused by employees neglecting to install a patch for a known vulnerability (Newman, 2017). This situation can be particularly challenging in times of employee dispersion, as in during the COVID-19 pandemic where workers were required to work remotely using nonsecure connections that bypass physical security controls. Additionally, technologies evolve rapidly, with new devices and software emerging, making it even more difficult to manage vulnerabilities. In times of increasing automation, it is unclear how increased reliance on AI will impact system vulnerabilities, as AI could potentially perform insufficiently in new or surprise situations – where learning typically occurs iteratively.

Cyberattack consequences related to supply chain security can vary. Maintaining *confidentiality*, *integrity*, and *availability* is often the main objective for information security (CISA, 2019). In cases of cyber-physical systems, the consequences can have direct impacts on the health and safety of systems. For example, consider the use of vehicles that are increasingly managed by computer systems – to the extent of being fully autonomous. Attacks on the information systems of those vehicles can cause physical consequences, even for non-autonomous vehicles (Greenberg, 2015).

Once risks have been assessed, the question remains as to how the risks should be managed. This process is often referred to as risk treatment, risk response, or risk control and involves decision-making about what actions to take, which generally fall into four categories – avoidance, transfer, mitigation, and acceptance (Hillson, 1999). Risk *avoidance* activities involve eliminating uncertainty and may include refraining from the activity altogether. Risk *transfer* involves shifting ownership of the risk or liability to a third party. The classic risk transfer mechanism is insurance. The third strategy is risk *mitigation*, in which countermeasures and controls are implemented which bring the residual risk down to an acceptable level. Finally, risk *acceptance* involves moving forward with the activity and devising responses to control and monitor the activity (Hillson, 1999).

Haimes (1991) proposed a series of guiding questions for risk management: "What can be done and what options are available?" "What are the associated trade-offs in terms of all relevant costs, benefits, and risks?" "What are the impacts of current management decisions on future options?"

## 3 Current Concerns in Supply Chain Security

This section discusses current concerns in supply chain security, including legal/regulatory issues, physical safety, and management.

### 3.1 Requirements About Data and Privacy

Data privacy is highly regulated. Organizations that accept or process payment cards are subject to the payment card industry security standards. These standards require organizations to invest heavily in information security, with activities that include maintaining a secure network, managing vulnerabilities, monitoring their networks, and maintaining information security policies (PCI, 2021).

In cases of healthcare-related data, organizations also need to invest heavily in meeting the requirements of the Health Insurance Portability and Accountability Act of 1996. These rules apply to protected health information, which includes medical test results, diagnoses, and treatment information (HIPAA Journal, 2021). The regulation also requires that organizations ensure confidentiality, integrity, and availability of protected data, maintain information security, and certify compliance.

The European Union General Data Protection Regulation (GDPR) of 2018 made a global impact on the practice of data protection. While this regulation applies to the data privacy of people in the EU, the impact is more widespread in cases of multinational outreach efforts. This regulation calls on organizations to minimize the collection and processing of data, limiting the length of time data is stored, and again ensuring security, integrity, and confidentiality of data (GDPR, 2021).

### 3.2 Physical Safety for Supply Chains

IT is increasingly used for critical tasks related to physical systems. For example, consider automation related to infrastructure management, manufacturing, and IoT technologies (IBM, 2021b). Because algorithms and real-time data inform a wide variety of tasks, there is overwhelming potential for increased efficiencies. However, there is also increased potential for risk events that can impact the functionality of these systems. Consider again the example of a cyberattack on a water treatment plant in Oldsmar, Florida, in which an attacker attempted to increase the level of sodium hydroxide in the water to dangerous levels, noting that poisoning from this chemical, known as lye, can cause serious physical health consequences (PEW, 2021).

Similarly, attacks can have serious physical consequences in cases of autonomous vehicles. In the context of infrastructure management, automation of the energy grid may pose serious consequences, for example, recognizing that a functioning energy grid is critical for the operation of essential services, such as security systems, the operations of hospital functionalities such as ICUs, operation of critical traffic signals, and even operation of electric vehicles. Healthcare organizations are frequently targeted by cyberattackers, and these attacks can be serious and deadly (Skahill & West, 2021).

These technology systems can be vulnerable to many types of attacks. The National Security Commission on Artificial Intelligence identifies several AI-related threats, including the presence of automated and stealthy cyberattacks, data poisoning, theft, and bias of AI systems (NSCAI, 2021).

### 3.3 Managing Disruptions to Operations

A current and ongoing concern is managing disruptions to supply chain and other business operations. With the variety of potential disruptions facing firms – such as terrorism, natural disasters, cybercrime, and ransomware – planning and management for business continuity is critical.

ISO 22301:2019 defines business continuity as the "capability of an organization to continue the delivery of products and services within acceptable time frames at predefined capacity during a disruption," while the British Standards Institution defines business continuity management as "A holistic management process that identifies potential threats to an organisation and the impacts to business operations that those threats, if realised, might cause, and which provides a framework for building organisational resilience with the capability for an effective response that safeguards the interests of its key stakeholders, reputation, brand and value-creating activities."

Business continuity management is often associated with other activities such as business continuity planning, crisis response, crisis management, and disaster recovery planning. While there is overlap between these concepts, some have put forward definitions and taxonomies to differentiate between them (e.g., Herbane et al., 2004; Krell, 2006). The use of the term "management" rather than "planning" indicates that there is no start or end to the activity but rather that it is a continuous, dynamic, and proactive process (Smith, 2003).

The strategic contribution of business continuity management is value preservation – the capability of the organization to resist and recover from disruptions and minimize their impacts and losses (Herbane et al., 2004). One of the key activities of business continuity management is business impact analysis (BIA). In BIA, the organization identifies critical business functions, determines the impacts associated with disruptions of those functions, and identifies the resources needed to reestablish critical functions after a disruption (Torabi et al., 2016).

BIA is often compared with risk analysis because they are both associated with identification, analysis, and treatment of risks. But risk analysis typically considers impacts and probabilities of occurrence, while business continuity management typically focuses on impacts and time (Krell, 2006; Torabi et al., 2016). As BIA relates to supply chain management, Suresh et al. (2020) proposed a six-step framework for business continuity management for supply chain resilience, linked to the plan-do-check-act (PDCA) cycle:

1. Examine the organizational context of the supply chain
2. Leadership commitment
3. Prevention (mitigation tactics)
4. Recovery (response tactics)
5. Assessment of plans
6. Continuous improvement

Zsidisin et al. (2005) identified 12 principles for effective supply chain continuity planning:

1. Create internal awareness.
2. Drive awareness into the supply base.
3. Prioritize suppliers and commodities to focus attention.
4. Understand both probability and impact of supply chain disruptions.
5. Eliminate/reduce exposure where feasible; buffer or mitigate where elimination is not feasible.
6. Use multiple information sources to monitor risk.
7. Revisit these issues on a regular basis.
8. Plan for disruptions.
9. Manage the impact of disruptions.
10. Take a continuous improvement view of supply chain continuity planning.
11. Make a post-event audit of supply chain disruptions standard operating procedure.
12. Share knowledge of supply chain continuity planning throughout the organization.

### 3.4 Vendor Risk Management

Another concern within the supply chain is how to effectively manage the risks posed by third parties. In an ongoing effort to enhance competitiveness, companies continue to outsource their noncore business processes to other manufacturers, suppliers, and service providers, creating mutual dependencies within an "extended enterprise" (Spekman & Davis, 2016). The sharing of information and knowledge across supply chain partners builds trust, but the rapid adoption of IT to facilitate information transfer results in an increased attack surface for the firm (Keskin et al., 2021). Target's data breach in 2013 is an example of a supply chain attack in which a third party – a heating, ventilation, and air-conditioning (HVAC) vendor – was the point of entry into Target's systems, ultimately costing the Target company $290 million (Stevens, 2018).

Companies with extended and complex supply chains must implement rigorous third-party risk management practices to mitigate their risk exposure. Much of the guidance on third-party risk management originates from the banking industry – but easily applies to other industries.

The US Office of the Comptroller of the Currency (US OCC, 2013) defines a third-party relationship as "any business arrangement between a bank and another entity, by contract or otherwise" that includes activities like "outsourced products and services, use of independent consultants, networking arrangements, merchant payment processing services, services provided by affiliates and subsidiaries, joint ventures."

Importantly, even though an attack might originate from a third party, the primarily impacted firm tends to hold the responsibility and pay the price of such an attack (Vitunskaite et al., 2019).

The US OCC (2013) summarizes: "A bank's use of third parties does not diminish the responsibility of its board of directors and senior management to ensure that the activity is performed in a safe and sound manner and in compliance with applicable laws." The US Federal Deposit Insurance Corporation (US FDIC, 2008) identified six major categories of risks incurred as a function of third parties: strategic, reputational, operational, transaction, credit, and compliance risk.

The US OCC (2013) introduces a multistep process for third-party risk management, including aspects such as planning, due diligence and third-party selection, contract negotiation, ongoing monitoring, and termination. Specifically, it is suggested that companies engaged with third parties clearly define expectations and responsibilities to limit liability, as well as develop contingency plans to transition outsourced activities in-house (US OCC, 2013). Part of due diligence and vendor selection should include an assessment of the third party's information security program – such as infrastructure and application security, software development practices, vulnerability, and penetration testing – and their management of information systems (US OCC, 2013).

Other risk management practices include the addition of a *right-to-audit* clause to enable monitoring and risk mitigation of third parties (Jackson, 2010). Supplier selection measures should be risk-informed, including consideration of whether the supplier is a sole/single-source, the criticality of the information to which they have access, and whether they are a high-value strategic partner (Wolff et al., 2021).

Firms can partner with third-party suppliers to mitigate risks through cybersecurity education training, maintain oversight of the third party's compliance program, restrict the use of data to hard copies or read-only access, or simply terminate the relationship (Wolff et al., 2021). Following the principle of *least privilege* is another security measure, in which the minimum amount of access privileges is granted to third parties necessary to complete a task (Saltzer & Schroeder, 1975). Finally, organizations must contend with the risks associated with so-called fourth parties, i.e., the outsourced firms contracted by third parties (Bwanya, 2018).

### 3.5 Anti-counterfeiting and Protection of Product Integrity

Another threat to supply chain security is not found in the form of disruptions but through the introduction of counterfeit goods into the supply chain. Many counterfeit products exist, ranging from luxury goods to pharmaceuticals (Outterson & Smith, 2006). Even counterfeit foods exist, which either may be food that has falsified markings on the packaging indicating a misleading brand or origin – such as incorrectly claiming a product was "Made in Italy" – or may be adulterated with different substances not normally found in that type of food (Ministry for Economic Development, 2021). Examples of the latter include documented instances of counterfeit eggs made of various resins and pigments (Boehler, 2012) and cooking oil collected from the sewer, refined, and sold to small restaurants and street vendors (Riggs, 2013).

Another area of concern for counterfeiting is in the semiconductor industry, where electrical, electronic, and electromechanical (EEE) parts are relabeled, refurbished, or repackaged to misrepresent the authenticity of the component (Sood et al., 2011). Guin et al. (2014) developed a taxonomy of counterfeit type, identifying seven main forms of counterfeit electronics – recycled, remarked, over-produced, out of specification/defective, cloned, forged documentation/part substitution, and tampered.

The source of counterfeit electronics is often from collected and recycled electronic waste (e-waste) and resold as new. Consequences of counterfeit electronics include lost revenue, damaged brand reputation, and potential legal liabilities for the firm whose intellectual property has been infringed (Pecht & Tiku, 2006; DiMase & Zulueta, 2009). Moreover, counterfeit electronics are a threat to security, as they may include viruses and malware (sometimes referred to as hardware Trojans) (US Department of Homeland Security, 2020).

Combating counterfeiting within the supply chain is a difficult challenge. When possible, the safest way to procure authentic goods is to purchase directly from the original manufacturer or from an authorized distributor (Livingston, 2007).

Within the defense microelectronics sector, the “Trusted Supplier Program” was created to accredit trusted suppliers of microelectronics for defense applications. In this context, trust is defined as “the confidence in one’s ability to secure national security systems by assessing the integrity of the people and processes used to design, generate, manufacture, and distribute national security critical components” (US Department of Defense, 2004). Specifically, trusted suppliers follow supply chain security practices such as maintaining a chain of custody, mitigating the risks of supply disruptions, preventing modification and tampering, and protecting against reverse engineering (US Department of Defense, 2004).

DiMase et al. (2016) discussed the importance of traceability across the supply chain for ensuring security. Other mitigations include traceability documentation, compliance verification, following good supplier selection practices, and obsolescence management (Livingston, 2007). Additionally, the US government tracks and maintains watch lists of nations and companies suspected of engaging in nefarious trade practices and intellectual property infringement (e.g., Office of the US Trade Representative, 2021; US Department of Commerce, 2020).

## 4 Emergent Concerns, Outstanding Research, and Future Directions

This section will discuss emergent concerns in supply chain security, including developments in AI and technologies. We will also discuss needs for future research and development.

### 4.1 AI

AI is defined by the ability to analyze data and act in ways that mimic the abilities of humans. The data used in AI models can be in the form of text, numbers, or imagery. IBM distinguishes between weak and strong AI. Weak AI involves narrow or specific tasks, as exemplified by personal assistants, robots, and autonomous vehicles. Strong AI involves an intelligence equivalent to humans, in which the system is self-aware and can learn (IBM, 2021a).

Technology including AI has large potential to promote efficiencies in supply chain management. Consider abilities for data sharing that would allow for transparency in information among suppliers. Also, consider vehicle routing using information technologies, which have the potential to reduce costs, emissions, and labor requirements in the transportation sector. For example, Google Maps, which leverages AI, historical data, and real-time data from users (Lau, 2020), identifies the most efficient routes based on user-inputted parameters. AI can also be used to address risk. For example, AI can be used for threat detection in cyber-security applications (Lee et al., 2019).

The movement of goods and services also benefits from the development of smart cities that leverage technology to aid in safety, security, and information sharing. Most notably, these applications can be used for physical security for property throughout the supply chain. For example, AI-based surveillance technologies can be used to not only monitor crime but also to make predictions, allowing supply chain organizations to proactively secure their systems. AI is also used for tasks such as regional traffic monitoring using remote sensing, disaster assessment, and optimization of performance on multimodal transportation infrastructure (Vasudevan et al., 2020).

AI methodologies are used widely in the modern, algorithm-driven economy for applications such as consumer behavior prediction, fraud detection, and making credit decisions (Ozbayoglu et al., 2020). These algorithms often rely upon personally identifiable information. While deidentification methods are often used, this information is still at risk of being reidentified with public information (De Montjoye et al., 2015). Models trained on datasets which have not been deidentified, or only weakly deidentified, can be compromised by various types of algorithmic inference attacks (Gong & Liu, 2018; Shokri et al., 2017).

There are also risks that can emerge from the use of AI. There is unchartered territory from the perspective of addressing biases in activities such as image analysis (Glusac, 2016). These biases have been explored from the perspective of facial recognition software, suggesting that the model accuracy is only as good as the data used for training. As AI-based image detection can be used for managing inventories (Verma et al., 2016), remote sensing and management for infrastructure, and other critical supply chain decision-making activities, biases remain a concern.

Additionally, while AI shows accuracy in typical or as-planned situations, it may not be as accurate in cases of surprises or unforeseen events. Thus, there remains concern about the use of AI from a risk perspective, as these algorithms may lose accuracy during unexpected risk events, times at which the algorithms would be needed the most.

## 4.2 Automation

While self-driving cars have received much attention, it is self-driving trucks that are projected to be revolutionary for supply chains and economies as a whole. Due to their large size, these trucks are able to make more effective use of sensors, leveraging a larger field of view. As these trucks may use more familiar roads, they can operate in less variable environments, making them amenable to automation. Using automated driving, these trucks are more fuel efficient and reduce wear on the truck (Ackerman, 2021).

Drones can be used for monitoring and delivery of goods. The use of drones could potentially decrease congestion on roadways. Of course, there are regulatory issues with implementing drone service, comparable to those faced around autonomous vehicles. Additionally, the use of drones may not result in improved environmental impact, in terms of increased need for warehousing and impact on wildlife (Austin, 2021).

There is also large potential for autonomous robots. The use of these robots can increase productivity and efficiency, reduce error, and improve safety (Fitzgerald & Quasney, 2017) with minimal rest. For example, industrial robots have the capacity to perform redundant and unsafe tasks such as welding, assembly, polishing, and grinding. In cases of food manufacturing, there is potential for robots to detect defects in the production process, which can result in improved food safety and cost. In the case of agriculture, robots and automated systems can perform tasks such as spraying fertilizers and pest control and other laborious and potentially unsafe operations (CMTC, 2021).

Security for these technologies remains a large concern. If these technologies remain reliant on the power grid, their operation would be vulnerable to infrastructure attacks, such as state-sponsored terrorist attacks. These technologies could also be subject to ransomware attacks, which can disrupt operations for extended periods of time. In cases of cyber-intrusions, remote attackers can take control of the technology and use that technology for physical attacks on people and property or reroute those technologies to aid in larger-scale attacks. Attacks could also alter data used by those technologies, which could result in communication loss or inability to perform related business functions. Attacks could also steal data and use that stolen data for activities such as identity theft or sharing of trade secrets. Because these technologies are often connected to other devices, they may also serve as an entry point to other technologies, such as computers and other IoT devices.

There also remain many questions surrounding legal liabilities when automated systems are used, for example, involving industrial robots damaging people or property or accidents involving autonomous vehicles. Consider the case of an autonomous vehicle developed by Uber, which killed a pedestrian in 2018. While Uber did not face criminal liability, the safety driver was charged on grounds of negligent homicide (Conger, 2020).

### 4.3 Zero Trust

One emerging area of research is in the application of "zero trust" principles to the supply chain. The concept of zero trust originated in a series of reports from the IT security field (Kindervag, 2010a, b, 2011). In these reports, it was observed that traditional perimeter-based security approaches were inadequate to deal with modern IT systems, which had porous and amorphous boundaries, with a number of users such as customers, suppliers, and end users accessing the network from within and remotely from cloud platforms. With a large and dynamic attack surface, Kindervag concluded that the paradigm of trusted and untrusted networks no longer applied and that all network traffic should be considered untrusted (Kindervag, 2010a). In a perimeter-based security posture, the goal is to keep attackers out, while in a zero trust security posture, it is assumed that the attacker is already present on the network. Therefore, instead of granting implicit trust, in a zero trust network, access is granted on a per-request, least-privilege basis, ensuring that all network resources are secure and that all network traffic is inspected and logged (Kindervag, 2010a). NIST (2020) published a special publication on zero trust architecture, which summarized the zero trust principles as follows:

> Zero trust security models assume that an attacker is present in the environment and that an enterprise-owned environment is no different—or no more trustworthy—than any nonenterprise-owned environment. In this new paradigm, an enterprise must assume no implicit trust and continually analyze and evaluate the risks to its assets and business functions and then enact protections to mitigate these risks. In zero trust, these protections usually involve minimizing access to resources (such as data and compute resources and applications/services) to only those subjects and assets identified as needing access as well as continually authenticating and authorizing the identity and security posture of each access request. (NIST, 2020)

Recently, there has been interest in applying zero trust principles, originally developed for IT systems, to supply chains. For example, Collier and Sarkis (2021) attempted to draw parallels between zero trust assumptions for IT systems, which are intended to protect information flows, with proposed assumptions for supply chains, which are intended to protect flows of information, materials, and finances.

DiMase et al. (2021) discussed the difficulties of applying zero trust principles to the microelectronics supply chain, noting that IT networks are very different than supply chains, in that the former are highly distributed and redundant, while the latter may have small numbers of suppliers leading to bottlenecks and supply disruptions. In both cases, the application of zero trust to supply chains is an exercise in analogical reasoning. An analogy is when an assertion is made that the relational structure of one domain can be applied in a different domain (Gentner, 1983). In this case, there is not a direct one-to-one mapping of concepts between IT networks and supply chains, meaning that thoughtful translation and application of zero trust principles to supply chains must be conducted and adapted for this new use case. An incomplete or incorrect mapping on concepts could be worse than no mapping at all (DiMase et al., 2021) and therefore requires future research.

### 4.4 Blockchain

Another area of emerging research and application is the role of blockchain technology for supply chains. Blockchains are distributed ledgers which enable decentralized, autonomous, immutable, and trustless record keeping (Chohan, 2019). While there has been much hype about the application of blockchain to supply chains, exactly how they will be implemented is still open to interpretation and development (Saberi, Kouhizadeh, Sarkis, & Shen, 2019b).

Among the drivers for blockchain technology adoption include increases in the need of companies to strengthen their information security and the increased need for information traceability (Saberi, Kouhizadeh, & Sarkis, 2019a). Additional benefits include transparency and component traceability, supply chain visibility, and monitoring of critical assets for auditing, compliance, and security purposes (Mylrea & Gourisetti, 2018). Nandi et al. (2021) speculated that blockchain technology can enhance supply chain redesign efforts around localization, agility, and digitization. Supply chain applications such as asset tracking and paperless order fulfillment have also been proposed (Min, 2019).

As it relates to supply chain security, blockchains can be used to create an immutable record of transactions to provide assurance of a product's authenticity (Hassija et al., 2020). Blockchain technology can facilitate tracking and documentation of product origin, manufacture, raw materials and components, and the intermediaries along the supply chain who handled, transformed, or transported the product (Oliver Wyman, 2017). The tracking of transactions of goods with radio frequency identification (RFID) technology can be integrated with blockchain to provide a record of the chain of custody (Dutta et al., 2020). This provenance can aid in the detection of counterfeit goods, and such transparency in sourcing and distribution can be used to ensure that partners are implementing responsible sourcing practices (Hassija et al., 2020).

However, questions remain about the adoption of blockchain technology within the supply chain (Francisco & Swanson, 2018). Some factors potentially inhibiting adoption include issues with scalability, future legal and regulatory requirements, large amounts of computing power needed, organizational resistance, the need to select the correct technology platform, and lack of organizational expertise (Min, 2019). Saberi, Kouhizadeh, and Sarkis (2019a) further identified barriers such as lack of benchmarking data for technology implementation, lack of supply chain cooperation and coordination, technological immaturity, and market and industry uncertainty about adoption. Further, interoperability of blockchain technology with legacy technologies is a challenge (Linkov et al., 2018). Within organizations and across supply chains, governance structures must be developed to ensure that the use of the technology is consistent with the organization's mission (Linkov et al., 2018).

## 5 Managerial Implications

A managerial implication of supply chain security is organizations needing the ability to effectively assess and manage risk across the supply chain. However, measuring risk for security is particularly difficult. Unlike other fields with plentiful historical data, emerging security threats are difficult to quantify in terms of likelihood and impact. Moreover, these risks are dynamic, especially in the cyber domain, where adaptive adversaries are continuously developing novel attacks (Linkov et al., 2014). Additionally, measuring security is difficult because we cannot test all of the security requirements for complex systems, systems often interact with other systems in unpredictable ways, and cognitive biases about risk skew our perceptions of system security (Pfleeger & Cunningham, 2010).

Managers may focus on a cyber resilience posture. Cyber resilience has been defined as "the ability to anticipate, withstand, recover from, and adapt to adverse conditions, stresses, attacks, or compromises on cyber resources" (Graubart & Bodeau, 2016). Resilience is a system property which describes the ability of a system to plan/prepare for, absorb, recover, and adapt to disruptions in one or more critical system functions across physical, information, cognitive, and social domains (Linkov et al., 2013).

Whereas risk assessment involves the identification of known threats to the system, resilience applies both to known and unknown threats (Linkov et al., 2013). Instead of developing frameworks from scratch, standard work exists to support managers interested in security, risk, and resilience. Managers may leverage industry and government standards to support security- and resilience-based practices, such as NIST Special Publication 800-160 Vol. 2 (NIST, 2019), NIST Cybersecurity Framework (2018), and SAE International's suite of standards from the G-32 Committee on hardware assurance, software assurance, and development of a Cyber-Physical Systems Security Engineering Plan (DiMase et al., 2020).

Given the serious risk concerns, it is imperative for organizations and their supply chain partners to collaboratively invest in risk assessment and management practices. Consider ISO 31000 (ISO, 2021) or Enterprise Risk Management (Moeller, 2007) practices to supplement risk training. However, it is not sufficient to only have a single or few individuals responsible for these risk-based practices. It is important that an effective ERM program include the entire organization in terms of accountability, workforce training, engagement, culture, staying up to date to with new innovations/technologies, and managing legacy systems. Moreover, effective risk management should include one's supply chain partners, since many risks affect the entire network of interrelationships rather than an individual firm in isolation. The impacts experienced by a company can be mitigated (or amplified) by actions taken (or not taken) by others within their supply chain (Ritchie & Brindley, 2007). Noncooperative behavior can be costly and fail to exploit synergistic benefits across supply chain partners, while collaboratively engaging in information sharing and risk management practices can aid in identification of vulnerabilities and managing crises (Kleindorfer & Saad, 2005).

A risk-based strategy is a significant investment for an organization. This strategy needs to consider a variety of stakeholders, including employees, suppliers, shareholders, partners, customers, the environment, and communities. This strategy should also involve the development of a risk culture, in which all employees and key stakeholders are engaged in the risk-based mission. This type of culture can be fostered using communication and transparency. However, communication and transparency are not simple efforts. There is a large literature base for understanding the most effective methods for communicating with various stakeholders (Bier, 2001). The effectiveness of a risk-based strategy is also contingent upon the risk perceptions of those stakeholders which can in turn influence behavior (Sjöberg, 2000). Supplier relationship management is also critical as these practices call for firms to segment suppliers based on criticality to the operation, develop governance policies with those critical suppliers, and actively manage performance and supplier development (Deloitte, 2022).

Two critical managerial questions revolve around how much to spend on security investments and how to justify such spending to management (Rosenquist, 2012). The field of security economics seeks to answer these questions by applying economic theory and tools to the problem of securing the organization (Anderson & Moore, 2006). Spending too little on security can leave the organization exposed to unacceptable levels of risk, while spending too much means that resources are not being allocated optimally (Su, 2006). While technological solutions and business practices are important for cybersecurity, "economics – not technology – determines what security technologies get used" (Schneier, 2003).

One of the prominent models in the field of security economics is the Gordon-Loeb model (Gordon & Loeb, 2012), which seeks to maximize the net benefits of reducing security risk through investments in vulnerability reduction. The model defines an expected loss function which is a function of the monetary consequences of a security breach, the probability of a threat, the baseline vulnerability of the asset or system being protected, and the reduction of vulnerability due to implemented countermeasures (Gordon & Loeb, 2012). Similarly, researchers have attempted to define return on investment metrics for security countermeasures to justify security investment. The return on security investment (ROSI) metric defines returns as costs avoided due to the implementation of security countermeasures, rather than profits (European Network and Information Security Agency, 2012). Additionally, research has been growing in the field of cybersecurity insurance (Romanosky et al., 2019; Eling & Schnell, 2016). Finally, innovative market-based solutions have been proposed such as cyber-vulnerability trading markets and exploit derivatives (Böhme, 2006). More research is needed in this developing field to apply the concepts to the domain of supply chain security.

## 6 Summary and Conclusion

Supply chains are critical to the functioning of modern society, and their security helps to ensure that materials, information, services, and finances flow effectively, efficiently, and safely amidst the complex web of global trade. Physical and cyber threats can disrupt supply chain operations and may be targeted at the organization itself or one of its many third-party vendors. The impacts of supply chain security breaches and disruptions can impact physical safety, cost organizations millions of dollars, and damage their reputation.

Best practices for supply chain security include security strategy assessments, vulnerability scanning and penetration testing, modernization of business practices and technologies, data protection and encryption processes, establishing permissioned controls for access to sensitive information, implementation of blockchain technology, third-party risk management practices, and incident response planning (Ramos, 2020).

Supply chain security investments in areas such as asset visibility and tracking, personnel security, physical security, standards development, supplier selection and investment, transportation and conveyance security, organizational infrastructure awareness and capabilities, collaboration among supply chain partners, proactive technology investments, total quality management (TQM) investments, and voluntary security compliance are all areas impacting supply chain security (Williams et al., 2008).

Supply chain security is a multifaceted and interdisciplinary issue which requires collaboration between multiple functional roles within the organization as well as with supply chain partners. Good supply chain security practices require sound risk management to identify risks and direct resources to those risks which are the highest for the organization. Moreover, ongoing training and education is needed as threats continue to evolve to prepare the next generation of supply chain security professionals.

## Contents

**Abstract**

Supply chain visibility and resilience – cotermed as *visilience* – have emerged as major areas requiring significant improvement. Practitioners have put forward supply chain mapping as one of the effective strategies for supporting supply chain *visilience*. Since supply chain mapping is a complex process, involving various entities, it is essential to determine how supply chain mapping could be achieved. In this chapter, we put forward blockchain-based supply chain management as a major enabler of supply chain mapping. We also argue that blockchain-based supply chain management will help a firm to attain effective supply chain mapping, which will improve its overall *visilience*. A few of the issues related to blockchain adoption have also been highlighted. This chapter offers some background and insights to researchers, students, and practitioners.

## 1 Introduction

Current supply chains are complex and extended, consisting of multiple geographically dispersed organizations collaborating to serve customers globally (Choi et al., 2020; Mubarik et al., 2021, 2022). The extended nature of supply chains characterized by diverse cultures, customer pressures, and varying human behaviors make sharing of the right information to the right entity at the right time – *information sharing and evaluation* – highly challenging (Ivanov et al., 2019).

The need for information-sharing evaluation is increasing as the failure to do so may raise the transaction cost, pilferage, and fraud, further leading to trust deficit. Often incidences of altering information about the provenance of high-value products or their losses have been reported by supply chain (SC) partners (Maurer, 2017). In this context, traceability, verifiability, and transparent information sharing appear as the cornerstone supply chain capabilities in any industry (Maurer, 2017).

Lower transparency of any product flow impedes organizations from evaluating and validating the actual value of that product. Further, the cost of intermediaries, their dependability, and their clarity make traceability even complicated. These risks, coupled with poor transparency, may cause supply chain disruption and reputational risks. Such risks are high in conventional supply chains since they heavily rely upon centralized, in some cases heterogeneous and stand-alone, information management systems. In such a situation, supply chain partners need a higher level of trust to rely upon a single firm or agent to store their valuable, strategic, and sensitive information.

Similarly, a conventional centralized system may be exposed to the "single point failure," putting the whole system at the mercy of hackers, errors, and attacks (Dong et al., 2017). There is a serious question on existing supply chain information management systems' ability to provide the required relevant information in a basic, robust, secured, transparent, and trustworthy manner. This situation demands a system of the supply chain where information visualization, traceability, and verifiability of information.

A number of studies (e.g., Fabbe-Costes et al., 2020; Khan et al., 2021; Kusi-Sarpong et al., 2022; Mubarik et al., 2023) consider SC mapping as a major source to improve the traceability and visualization of the value chain processes. SC mapping can play a breakthrough role in improving a firm's supply chain visibility, traceability, and verifiability (Mubarik et al., 2023). It also offers companies flexibility by monitoring threats and avoiding or minimizing the effects of possible disruption (Fragapane et al., 2022).

According to Choi et al. (2020), *"[companies] have better visibility into the structure of their supply chains. Instead of scrambling at the last minute, they have a* *lot of information at their fingertips within minutes of potential disruption. They know exactly which suppliers, sites, parts, and products are at risk, which allows them to put themselves first in line to secure constrained inventory and capacity at alternate sites*."

Ironically, conventional supply chains have limited ability to map supply chain processes to deal with traceability, verifiability, and visualization (Saveen & Radmehr, 2016). It is critical to know how SC mapping can be put into practice to improve the SC visibility, traceability, and verifiability. Blockchain-based supply chain management (BCSCM) can be a solution to this issue. We argue that blockchain-driven supply chains have ability to drastically improve supply chain mapping.

Blockchain provides better economically and technologically viable solutions as this technology has a decentralized "trustless" database (Abeyratne & Monfared, 2016). This characteristic allows the execution of large-scale transactions globally and permits decentralization and process disintermediation among multiple supply chain entities (Crosby et al., 2016). Anecdotal evidence on the use of blockchain technologies in managing various aspects of supply chains demonstrates its ability to support traceability, verifiability, and mapping of supply chains.

Literature on BCSCM has increased in the past few years; however, concrete studies are missing concerning whether BCSCM is improving supply chain mapping (Mubarik et al., 2021, 2023; Yli-Huumo et al., 2016). This chapter is devoted to exploring the role of BCSCM in improving the supply chain mapping of a firm which can be instrumental in channeling the effect of BCSCM toward supply chain performance.

The remainder of this chapter begins with Sect. 2, where the background covering supply chain mapping and BCSCM are presented. Discussion on how supply chain mapping can be improved through BCSCM is presented in Sect. 3. In Sect. 4, the managerial implications of the literature are presented. A chapter summary and conclusion with relevant recommendations and future directions are presented in Sect. 5.

## 2 Background

### 2.1 Supply Chain Mapping

Supply chain mapping could be traced back to the early 1980s, when a few studies emphasized supply chain maps to better understand the nature and processes of a supply chain (Mubarik et al., 2021). These earlier studies on the supply chain focused on physical mapping of the processes, using conventional map-building techniques. These maps were expected to work as the stand-in of the actual supply chain and were used to understand the overall design of the supply chain (Farris, 2010; Gardner & Cooper, 2003). However, these supply chain maps had a major flaw: lack of dynamism.

The maps were able to illustrate the supply chain positions at a certain point in time. Any changes taking place after those maps would not be addressed. Hence, the reliability in using these initial supply chain maps for decision-making was limited.

Supply chain mapping includes documenting a company's supply chain from the very initial stage till the last stage (Fabbe-Costes et al., 2020; Mubarik et al., 2023). This concept resurfaced in 2020, during COVID-19, when a lack of supply chain mapping made the supply chains response poor and unorganized (Ali et al., 2021; Choi et al., 2020; Khan et al., 2022; Kusi-Sarpong et al., 2022; Mubarik et al., 2021, 2023, 2022).

The empirical evidence supporting the need for supply chain mapping appeared from various parts of the world. They also provided a brand-new definition of supply chain mapping, which was an extension of the earlier concept. They defined SC mapping as the process of recording information from suppliers to manufacturers to consumers and everyone in between, so that it creates an overall map of the supply network compiled in a single data platform for easy analysis (Mubarik et al., 2023). This information includes, but is not limited to, the sources of suppliers, routes of shipments, manufacturing facilities, warehouse networks, and other useful information that might help stakeholders involved to better understand the supply network and make well-informed decisions accordingly (Mubarik et al., 2021).

Since the concept of SC mapping is in its nascent phase, we have only the study of Mubarik et al. (2023) that offers a measure of supply chain mapping. Mubarik et al. (2023) stipulate that SC mapping has three subdimensions (upstream mapping, midstream mapping, and downstream mapping) and 25 items.

The next section sheds light on as to why supply chain mapping could be a strategic weapon to combat disruptions.

## 2.2 Why Supply Chain Mapping?

Some of the many benefits of supply chain mapping include the following:

- Distinguishing where in the supply chain network value is added or lost. For example, whether the means of transportation to carry raw materials to production facility might be slowing down the manufacturing speed.
- Moderating and identifying risks earlier than their occurrence. For example, how might the company's supply chain be affected by a natural disaster such as flooding?
- Reinforcing the whole supply chain. By supporting connections through clear correspondence between organizations linked to your company, you assist them to better understand their position in the supply chain network, along with your expectations and objectives.
- Aligning processes and increasing speed. In reviewing a supply chain map, companies can identify processes that are slowed or bottlenecks and take necessary corrective action. For example, a company has a supplier who provides raw material 10 days later than the agreed upon delivery date which in turn slows

down production and distribution. Organizational decision makers can identify this delay with the help of a supply chain map – they can request the supplier to fix delivery durations or opt for a more reliable supplier.

- Identifying the main points affecting a company's cash flow. For example, a supplier might want cash in advance before materials delivery. In this case, the company's decision makers can either agree on alternate payment terms with the supplier or find another supplier that agrees to work on credit.

Supply chain mapping helps a company avoid risks in general. For example, if a company has the entire supply network mapped, it is easy for them to track a lost shipment or find an alternate supplier if any issue arises. If there is a sudden increase in demand or even if something like a pandemic occurs, a focal company can put strategies in place thanks to supply chain mapping to counter such situations. A company can also assess situations like climate change, global shortage of certain raw materials, or any other natural occurrences to determine supply chain and business process impacts and can address concerns in a timely manner.

Supply chain professionals and companies have significant interest in supply chain mapping as the current pandemic suddenly disrupted global supply chain processes and left companies and individuals in hazardous situations. More studies are taking place to better understand the supply chain mapping dynamics, approaches, and solutions to the problems arising while mapping the supply chain. Some of these studies are reviewed below to understand some of these aspects.

## 2.3 Blockchain-Driven Supply Chains

Blockchain technology (BC) has emerged as a disruptive digital technology that can transform conventional ways of doing business. Equipped features such as decentralized databases, immutability of data, and higher traceability provide an agile and secure way of executing business transactions.

BCSCM can also help improve supply chain transparency at multiple stages from producers to consumers. These sets of relationships and their governance can be completed through smart contracts. Further, digitally signed messages ensure that the message received by the receiver is from the claimed sender and there is no alteration being done during the transit. This process does not allow for modification in message due to technical reasons as limits or stops malicious modifications, that is, data is immutable. Digital signatures depend on hashing functions, cryptography, and public key. Interconnection between lower and higher blockchain could be established through serial number (Kawaguchi, 2019). Due to these benefits, blockchain technology is being implemented in supply chains. A number of firms are in the pursuit of blockchain-driven supply chains across various sectors.

One of the key sectors in developing countries is agriculture. In the agriculture sector, information shared is not symmetric, the price of crops is altered at every step as each and every supply chain stage takes additional profit resulting in a smaller share for farmers. BC can resolve these issues by uniting – and disintermediating some – parties having trust issues on a single platform while keeping security and verifiability. The main entities involved in implementation of blockchain in the agriculture sector are *data, process,* and *stakeholders*.

Blockchain data may comprise various forms of information such as climate and environmental data, farmers, soil moisture content, seed quality, harvest yield, and sale price of crops as well as demand of crops. BC-driven agro-supply chains, utilizing the features of traceability and smart contracts, help execute these transactions in a secure, agile, and efficient manner. BCSCM integrates all the agro supply chain stakeholders including users (wholesalers, farmers, retailers, and customers), regulators (assessors, surveyors), and agencies (insurance companies, banks).

Within the agricultural industry, AgriOnBlock is a specific blockchain example. With this blockchain system, retailer submits their requirements on AgriOnBlock and credential details to bank. Once the bank verifies credentials on AgriOnBlock, then the BC instructs warehouse to process shipments. Warehouse determines the validity of transactions on AgriOnBlock after which the transaction is considered to be complete. Further, insurance claims raised by farmers are communicated to AgriOnBlock, which is further communicated to an insurance company and surveyor for verification of a claim. After due verification of a claim by surveyor, the insurance company intimates bank to make the payment. After payment, transaction is committed once it has been communicated to AgriOnBlock.

Farmers may request pickup of crops to a shipping company and further submits invoices to retailers. Once, the retailer confirms the invoice, the shipping company picks up the crop from the farmer's site and delivers it to the retailer, the transaction is updated on AgriOnBlock, and BC system then makes payment to farmers. The retailer further transfers the crops to a distributor or wholesaler through a shipping company. Once the crops are shipped to a distributor or wholesaler, the bank makes payment to the retailer from the wholesaler or distributor account and the transaction is committed. The entire chain of transaction is recorded on a block present in a blockchain network (Patel & Shrimali, 2021). Many times, this type of approach will shorten the supply chain as some levels may not be needed as more direct communication has likely occurred among upstream and downstream supply chain partners.

Besides the agriculture sector, implementation of BCSCM has occurred across many other sectors. The World Trade Forum estimated that effectively managing key supply chain aspects (e.g., transportation management, procurement, global trade logistics, track & trace, and customs collaboration) could help increase global trade by 15%. The aspects of these issues could be well managed by using blockchain-driven supply chain. The following discussion provides a few examples, illustrating the use of BC in managing supply chain processes of various industries.

(a) ***Blockchain in the textile industry***: An industry facing volatile demand from customers, rising competition, and product counterfeits is the textile and clothing industry. The textile industry has been subjected to severe criticism due to lack of transparency and unfair practices in supply chain processes. Since the textile supply chain network can be spread broadly across various geographical regions, it is often difficult for companies to keep track on all the suppliers, subsuppliers, and contractors. This situation reduces transparency in supply chain processes – a situation that can be addressed to help stakeholders get a chance of maximizing profits while reducing costs from difficult to manageable situations such as an unethical practices. These issues can be solved by establishing traceability through blockchain technology.

Traceability in textiles is necessary for identification, history tracking, and distribution as well as identification of product location. All the desired features of traceability could be achieved through BCSCM implementation – further establishing an information trail. Information could be shared in a secured manner supporting improved product quality, operational monitoring control, data-acquisition, in addition to visibility throughout the supply chain.

In the textile supply chain, it is the retailer who is responsible for maintaining and initiating the blockchain network. The retailer has to interact with upstream suppliers forming a cluster. Each cluster can be connected with one or more channels. Each cluster includes the subsupplier network from a fiber manufacturer to apparel manufacturing unit. There may exist a separate blockchain for each channel which stores a set of transactions. One or a set of channels can be connected to a cluster of upstream suppliers – dealing in a specific product – depending on the type of transactions. This process divides the main network into subnetworks having its own smart contract, shared ledger, and common rules over the network, defining access rights of partners involved as well as the interaction they could make over the network (Agrawal et al., 2021).

(b) ***Blockchain in the Retail Sector***: As an example of a successful retail chain, WALMART worked with IBM on a blockchain food safety solution to make the decentralized food supply ecosystem more transparent by digitizing the food supply chain process. They created a food traceability system based on Hyperledger Fabric, the open-source accounting technology. Blockchain makes it possible to make the process more transparent and traceable to a specific location. They worked with the Barcode and Labeling Standards Authority to define the attributes of the data to be uploaded to the blockchain. IBM then wrote the code for the chain.

The providers used new tags and uploaded their data via a web-based interface. To test the system, IBM partnered with WALMART used two proof-of-concepts one in the USA and other in China, and the system is proven effective in both the cases. In the USA, it took a week to trace an origin of an item. The new system helped reduce the time to 2.2 Seconds. The good news is that suppliers do not have to be blockchain experts to benefit from the system; they just need to know how to upload data to the blockchain application. After the successful implementation of phase 1 in 2016, WALMART later shifted over 25 of its products and its stock keeping units (SKUs) on the hyperledger system (Network, 2020).

(c) ***Blockchain in the Manufacturing Sector***: Mitsubishi Heavy Industry (MHI) partnered with IBM to develop a blockchain solution to control carbon emissions through tracking and making captured carbon dioxide more reusable. The system is called CO2NEX. Mitsubishi provided all the necessary infrastructural support to capture carbon emissions in its manufacturing, and IBM was responsible for providing the digitalized platform. According to Nikkei, MHI planned to create a buyer-seller market to test in 2022.

Capturing carbon dioxide emissions at the emissions point of electricity or cement production is significantly cheaper than removing carbon dioxide from the atmosphere. The United Nations estimates the cost of capture to be between $ 10 and $ 100 per ton of carbon dioxide, but that does not include transportation and storage. By 2050, 1030 gigatons of carbon dioxide could be removed annually, although the capacity for this is currently not available. With the use of blockchain, CO2NEX follows the collection and distribution of carbon dioxide, which provides transparency. The test of IBM product had been conducted earlier in May, and now trading market platforms are developed parallel to Mitsubishi equipment. Now the use of blockchain is becoming the new normal, and many organizations are in plan to accelerate the projects in carbon marketplaces globally (Insights, 2021).

(d) ***Blockchain in the shipping industry***: MAERSK and IBM collaborated to establish a blockchain technology for transparency and cost-effective procedures with paperless system. The platform will provide benefits not only to MAERSK but also to all its partners as it provides the platform to all partners to access the data and extract the values out of it. It aims to bring the industry together at an open blockchain platform that offers digital products and services integration.

The shipping industry's cost of global trade is around 1.8 trillion dollars; the blockchain network will help to enhance the process and will support to save up to 10% of the costs – representing billions of dollars in savings. The shipping industry consist of a global network of interconnected shipping corridors connecting ports and terminals, customs authorities, shipping companies, third-party logistics (3PL), land transport, freight forwarders, and other concerned authorities, all together. The two most important functions at launch address transparency and documentation challenges. The end-to-end process transparency will be increased which enables all the stakeholders in global transactions to exchange the shipments more efficiently. Digitized and automatically filled documents stamped and approved for trade by enabling end user to submit it securely globally (White, 2018).

(e) ***Blockchain in the healthcare industry***: Blockchain in healthcare can aid the field of medical sciences. BC can help to ensure transparency in recordkeeping, while maintaining privacy, of individuals and broader populations via smart contracts through an Ethereum blockchain. The Medrec Model is an example system that helps to restore the comprehensive patient directory on healthcare information.

MedRec's smart contract structure serves as a model for a "Directory of Healthcare and Resource Location" that is protected with public key cryptography and equipped with crucial data integrity and provenance properties. It provides a proof-of-concept system demonstrating how the principles of decentralization and blockchain architectures could contribute to secure and interoperable systems by using Ethereum smart contracts to establish a content access system on separate storage and orchestrate provider sites.

MedRec's authentication register regulates access to medical records and at the same time offers patients a comprehensive review of records, verifiability of care, and data exchange. These systems can be integrated with existing provider systems, prioritizing open APIs and transparency of the network structure (Azaria et al., 2016).

In this section, we illustrated how and why firms across the various sectors are adopting blockchain technologies to improve their supply chain processes. The adoption of blockchain is especially expected to improve the end-to-end traceability of supply chains, improve integration (from suppliers to customers), and make processes more transparent, secure, and visible. Thus, key benefits expected from blockchain are improved traceability and visibility of supply chains. Anecdotal evidence supports this supposition – that blockchain improves a firm's visibility, traceability, verifiability, and security through supply chain mapping. It implies that blockchain can greatly benefit a firm's supply chain mapping, which provides its visibility, transparency, integration, and security. In the following section, we explain this association in the light of various published literature.

## 3 Improving Supply Chain Mapping Through Blockchain

Supply chain mapping supports effective delivering of goods or services in a supply chain. Actors and relationships are mapped to enable traceability, visibility, and verifiability of activities and transactions along the supply chain (Mubarik et al., 2022, 2023). It improves the visibility of the processes by providing real-time data from across various interfaces and helps to ensure trust exists among the supply chain partners since information shared are verifiable (Ivanov & Dolgui, 2020; Kusi-Sarpong et al., 2022; Mubarik et al., 2021).

To operationalize supply chain mapping, there is the need to integrate the mapped processes using technologies (Kusi-Sarpong et al., 2022). BCSCM – the integration of blockchain technology within the supply chain – can enable and improve supply chain mapping of organizations. BCSCM will enable organizations to accurately map their supply chains helping them to visualize their suppliers, their locations, and their contributions to the supply base, materials flows, finance, and information (Soto-Viruet et al., 2013).

Supply chain partners can have decentralized and mutual records, where every validated transaction made by SC partner is placed into a block. These transactional blocks from individual SC partners are connected and collectively blocked to generate an irreversible record in the SC. Any modification effected by any of the

SC partners will be notified to all SC participants, thereby providing a map for every transaction (Khan et al., 2022).

The integration of radio-frequency identification (RFID) and Internet of Things (IoT), as a part of a BCSCM, do offer the opportunity for mapping process for entering real-time data such as stock issuances or purchases into blocks. This system does provide a very important means to improve SC traceability, visibility, and verifiability which leads to transparency and enhances SCM and aid a positive effect in digitally mapping the supply chain (Ali et al., 2021; Ivanov & Dolgui, 2021; Khan et al., 2022).

As an example, organizations that can transition their traditional supply chain to a digital supply chain (Khan et al., 2021) using a blockchain system are able to trace their operational raw materials or components from their origins or suppliers through to their production and the finished products to their customers. This structure will enable these organizations to be able to map their processes that are involved in moving the raw materials from the source or origin through to the focal firms and to their customers, creating visibility and becoming resilient – such as organizations' preparedness, flexibility, and responsiveness, to deal with any demand fluctuations or supply disruptions (Mubarik et al., 2021).

However, should organizations fail to connect their SC partners via digital technologies, they can significantly reduce the level of information shared by and with their SC partners impeding visibility which can result in difficulties in managing and predicting SC disruptions. Thus, should they identify any issues with any raw materials or components along their supply chains, it may be extremely challenging for them to identify the origins or sources of the problems and eradicate them. An example framework is shown in Fig. 1.

Figure 1 exhibits the role of BCSCM in improving supply chain mapping, visibility, and resilience. It shows how BCSCM directly contributes to SC mapping. It helps see the overall structure of an end-to-end map supply chain of a firm, resulting a seamless integration and flow of information from tier 2 suppliers to tier 2 customers. Effective supply chain mapping uplifts a firm's supply chain visibility. Likewise, it also improves a firm's supply chain readiness, response, and recovery, in a combined way affecting its supply chain resilience. The framework

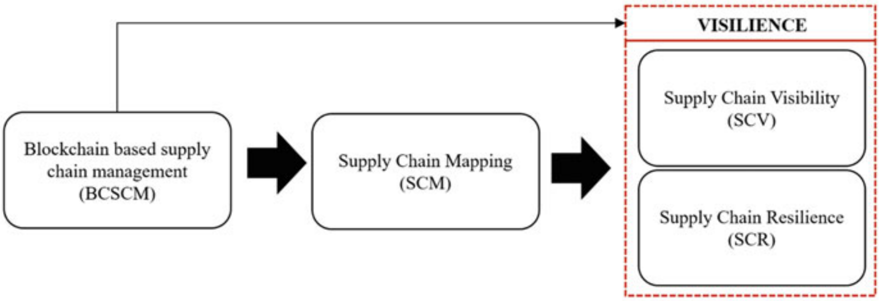

**Fig. 1** BCSCM-led mapping and "visilience"

depicted in Fig. 1 also highlights a direct impact of BCSCM on supply chain visibility and resilience of a firm. Putting together, a firm can yield threefold benefits by adopting BCSCM: Supply chain mapping, visibility, and resilience. Based on the above discussion, we present a few managerial implications to offer in the next section.

## 4 Managerial Implications

There are a number of implications regarding the improvement of supply chain visibility and resilience ("visilience"). COVID-19 unveiled two essential supply chain capabilities when encountering supply chain disruptions. These capacities are supply chain visibility and supply chain resilience. Supply chain visibility represents the ability of a supply chain to visualize the changes at various supply chain stages – upstream, downstream, and midstream. This visualization helps firms proactively plan to address any unforeseen abnormal situations. For example, during COVID-19, a number of firms in China were not able to keep their supply chains afloat and serve their customers. These firms happened to be tier 3 or tier 4 suppliers of a number of firms located outside China. Since these firms were not aware of what was happening in their upstream supply chain, they were caught off guard once those effects occurred in downstream supply chains. This lack of visibility resulted into a subtle, unorganized, and weak response of the firms to SC disruptions further resulting into massive supply chain losses.

Likewise, supply chain resilience – *characterized by a firm's ability to prepare, respond, and bounce back supply chain disruption* – has appeared as the other important supply chain capability essential for firm survival. Supply chain visibility and resilience go hand-in-hand. Visibility helps a firm to be more resilient, hence the term "visilience," an essential capability for survival and growth of any firm and their supply chains.

Supply chain mapping strategies can effectively improve these twin supply chain capabilities. Based on the framework derived in this chapter (see Fig. 1), supply chain mapping – defined as the extent to which a firm has mapped its upstream, downstream, and midstream supply chain processes so that these provide real-time information about the supply chain entities – appears to be instrumental for "visilience."

Supply chain mapping allows a firm to look beyond the immediate supplier through mapping the processes of suppliers and subsuppliers across multiple tiers. Likewise, mapping allows a firm to have real-time information about its downstream supply chain, reaching down the line to multiple tiers down to the ultimate customers. In other words, mapping not only provides the real-time information about the various players in supply chain – such as physical location, financial stability, and process sustainability – but also allows for real-time flow of goods and funds visibility across the supply chain. This ability of a supply chain not only improves its visibility but also builds its resilience. Our findings suggest that managers need to address supply chain mapping-led visilience.

The proposed framework reflects that blockchain-based supply chain can be a single important strategy, which can simultaneously cater the issues of mapping, visibility, and resilience. Our framework suggests that BCSCM not only helps firms to significantly map their supply chain processes across the three streams (upstream, midstream, and downstream) but it also directly improves the "visilience" of a firm.

One of the prominent features of BCSCM is its ability to trace the products to its point of origin with immutable records. It allows managers to not only visualize the various SC processes but also see the source of any transaction. BCSCM allows to not only map the supply chain processes but also to thoroughly look into the supply chain processes to identify any waste. BCSCM-led supply chain mapping can also allow firms to control supply chain issues like the horsemeat scandal in Europe.

BCSCM can provide multidimensional information about the various facets of supply chain, thus making supply chain planning process – and the necessary performance management of these systems – more robust, and resilient. For example, as noted by Gaur and Gaiha (2020, p.1), "Execution errors—such as mistakes in inventory data, missing shipments, and duplicate payments—are often impossible to detect in real time. Even when a problem is discovered after the fact, it is difficult and expensive to pinpoint its source or fix it by tracing the sequence of activities recorded in available ledger entries and documents."

Such execution errors greatly compromise the "visilience" of a supply chain. BCSCM has the ability to effectively cater for such errors by clearly exposing the origin of the transactions.

Although organizations and managers can benefit from BCSCM, some concerns do arise; these issues include the following:

(a) Blockchain platform selection: There are various blockchain platforms available, having varying degrees of conformance to various blockchain features. It is tricky for firms to choose the appropriate platform as wrong selection of platform can cause harm to the whole business and supply chain partners.
(b) The linkage of blockchain with upstream and downstream supply chain partners requires care and is challenging. Adoption of blockchain requires building relationships with other entities in supply chain (suppliers, customers, regulators, etc.), which may be challenging if the SC partners have heterogonous technologies and goals.
(c) The cost of blockchain adoption can be significant. Since blockchain is required to be implemented across the organization and linked to other stakeholders in the supply chain, it may be capital intensive.
(d) Regulations related to blockchain are currently in the nascent stage. Hence, in case of any legal issue, firm may face some serious challenges. As noted by Eliacik (2022), "Many businesses today operate under the constraints of legislation. Their customers put their trust in them with important information. However, if all of this data is kept on a public ledger, it will not be truly private."
(e) The use of consensus algorithms is highly energy intensive and may increase the average usage of energy of an organization. Sustainability considerations play an important role in blockchain operations.

(f) Cyberattacks can hurt multiple stakeholders and processes: Although blockchain is much more secured than other peer systems, open blockchain can have issues of security. According to Eliacik (2022), "Some are more secure than others. The decentralized blockchain, for example, are more vulnerable to 51% attacks than the centralized ones."

## 5 Summary and Conclusion

In this chapter, we identified factors that can improve the supply chain visibility and resilience, termed as "visilience" of a firm. A comprehensive review of the literature reveals that firms faced challenging situation due to lack of "visilience." Many firms could not survive due to poor "visilience," and many were struggling to keep their supply chain afloat – especially from the aftereffects of the COVID-19 crisis.

In order to build these twin supply chain capabilities, we put forward supply chain mapping and blockchain-based supply chain as the major precursors. Execution of BCSCM significantly minimizes traceability, verifiability, and coordination issues, thus improving the resilience of a firm. The framework offered in this chapter depicts that BCSCM is a viable way of pursuing supply chain mapping and "visilience" simultaneously. It shows that organizations with an end-to-end mapping of the supply chain can not only have a much better visibility and capability to respond to any disruptions or unpredictable occurrences but also bounce back much quickly and stronger. The blockchain-based supply chain can help the organizations to be prepared by creating visibility and enabling them to be able to manage this situation with ease.

Conclusively, there exists a significant gap to improve SCs in context of visibility, and resilience. BCSCM appears to be a powerful strategy to address these deficiencies. This is the right time for supply chain managers and other relevant stakeholders to come forward and plan as to how BCSCM can be executed to uplift the performance of their supply chains.

# Resilience in the Supply Chain

E. Revilla, B. Acero, and M. J. Sáenz

## Contents

**Abstract**

Supply chain resilience is vital to long-term viability of firms. Supply chain design and operation conditions will influence their survival during major crises. While most firms have focused on how to quickly recover from disruptions, resilience is more than quickly overcoming a natural disaster that destroyed part of their facilities. Resilient firms are also capable of adapting to new operating contexts as a result of unexpected changes or disruptions. Supply chain resilience

is better defined by the integration of two main historical approaches: engineering resilience and social-ecological resilience. Traditional resilience practices with a focus on mitigating disruption impact seem insufficient in the current landscape. This chapter presents a comprehensive understanding of supply chain resilience. We introduce supply chain disruption definitions and discuss why these unexpected events are central to the current operating environment. The understanding of resilience in the current context leads to the development of a framework that integrates the necessity of both proactive designs and reactive deployments of supply chain elements. The chapter categorizes and details a set of practices that companies should holistically implement to deal with unexpected events. The concepts presented are reinforced with numerous practical examples, so they are easy to understand for professionals and students with different backgrounds.

## 1 Supply Chain Disruptions

Early in 2020, shortages of masks, ventilators, and adequate protective gear to respond to the COVID-19 pandemic triggered unprecedented shifts in demand of diverse products such as toilet paper, printers, exercise equipment, or baking-related gadgets such as stand mixers. This situation put incredible pressure on *well-oiled* supply chains that had accustomed us to get whatever we desired at our doorstep within days and, in some cases, within hours. Suddenly, consumers had to wait weeks, if not months, to buy furniture or electronic gadgets for the newly installed home offices, and companies had to compromise their selections because goods were stranded in ports for an unknown period of time.

After this crisis – with several developed countries functionally declaring an end to the pandemic – virtually every single industry is still affected to some extent by shortages and delays. Skyrocketing energy and fuel prices, inflation, new pandemic-related shutdowns in China, and the invasion of Ukraine, with subsequent economic sanctions on Russia, mean more chaos to an already fragile supply chain situation.

Construction and chemical industries are suffering from limited availability of raw materials and shipping containers; technological and automotive companies are struggling to meet the demand due to a serious microchip shortage; China's energy crisis occurring since 2021 is restricting factory production; and the list just keeps growing. It does not seem that the problem will end soon. In particular, for the chip shortage will only get worse as conflicts continue, Ukraine for example is a major exporter in neon, a crucial component in chips manufacturing. Additionally, automakers, cosmetics, or food manufacturers have started to suffer the shortages of raw material imported from Russia and Ukraine. Predictions on food and energy disruptions are such that Egypt devalued its currency in an attempt to contain the impact (Dodd, 2022).

These geo-political disruptions, in addition to longer term concerns such as climate change, are likely to continue this situation for global supply chains.

Disruptions, which are defined as an unexpected breakdown in the production or distribution of goods of the supply chain (Ivanov, 2021), have become so important in our daily lives that even the popular media has given it a name, *the Great Supply Chain Disruption* (Goodman & Bradsher, 2021). The US White House has designated a dedicated special task force team to address the existing supply chain discontinuities (TheWhiteHouse, 2022).

Although disruptions have always been present in supply chains, we have reached a point in which the previous scenario of smoothly run supply chains suffering isolated interruptions has now transformed into a continuous struggle to cope with disruptions that are stretched in time. But today's disruptions are not just Covid-related. Companies are facing more recurrent cyberattacks to access storage data or to create an interruption in the operations – a more integrated system from Industry 4.0 efforts becomes more common (ENISA, 2021). Public pressure on sustainability and human rights are disrupting the operations of companies whose manufacturing or suppliers are located in areas with relaxed or unethical environmental and labor regulations (Villena & Gioia, 2020). And overall, companies, whether operating in global or more local context, are suffering the consequences of geopolitical instability due to armed conflicts, border closures, or regional trade and tariff policies.

Disruptions in supply chains impact the stability of companies related to operational, financial, and reputational aspects (Katsaliaki et al., 2021). First, operational consequences impact day-to-day business and may include an increase in the lead times, poor asset utilization, increase in the production costs, or unbalances in the inventory levels (Chopra & Sodhi, 2014). We can find a recent example in the blockage of the Suez Canal in 2021 that during a week exacerbated the already existing congestion on ports and the container shortage caused by Covid-19 imbalances in demand predictions.

Second, disruptions also affect the financial stability of firms. Persisting disruptions can take a serious toll on the financial health of companies. They can lead to poor performance of supply chains, which in turn can translate into loss of revenue, sales, and even reduced market shares. In fact, regardless of the size of the company, disruptions have been linked to a reduction of stock returns of nearly 40% and an increase of equity risk of around 13.5%, both lasting up to a year after the disruption occurs (Hendricks & Singhal, 2005).

Third, depending on the type of disruption, companies can suffer significant losses in their reputation and credibility. Reputational damage relates to the loss of credibility due to damage in the perception that stakeholders and society have on firm image, status, and popularity (Alfarsi et al., 2019; Rhee & Haunschild, 2006). A loss in the goodwill of the company as well as corporate embarrassment can have severe damaging effects on its viability. Reputational consequences are specially challenging to manage and can escalate tremendously. That was the case of Samsung that saw its reputation among consumers plummet after the firm had to issue a global recall on over 2.5 million Galaxy Note 7 smartphone devices due to a high risk of their batteries exploding (Rahim, 2017).

### 1.1 Supply Chain Fragility and Its Search for Efficiency

The catastrophic consequences of disruptions have revealed the fragility of supply chains and how efficient systems can easily break external, unpredicted, and, in appearance, even unrelated – to the supply chain – events (Pettit et al., 2019). During the past few decades, we have witnessed how companies have searched for efficiency by means of globalization and adoption of lean practices, allowing firms to be more competitive while opening new markets (Reeves & Whitaker, 2020). Lean management's objective of minimizing costs and increasing profits caused companies to embrace practices that eliminate redundancies through just-in-time or lean inventory management approaches. Following those principles, companies mainly rely on one supplier for a critical component; workforce is optimized to minimum and relies on overtime if needed; processes are streamlined and highly standardized, and inventories and safety stocks are kept low.

In a well-oiled system, slight fluctuations, either from the demand or supply side, can be easily absorbed with minor adjustments on production while maintaining lean practices and limited inventory; however, as the pandemic has shown, major delays and shortages on components can severely impact production (Goodman & Chokshi, 2021). Many automotive and general appliance companies had to reduce and even temporarily halt production because their suppliers were not able to deliver their required parts on time. Their inventory levels could not make up for such delays and reduction on the quantities received. Globalization has amplified this scenario due to global interconnection of economies, firms, and suppliers (Sheffi, 2020).

Globalization has facilitated trade and increased efficiency. With the help of digital tools and flexible trade agreements, companies have opened to new and distant markets; what in the past was cheap and reliable sea transportation facilitated the location of manufacturing plants in distant countries with much lower labor cost. However, globalization has considerably increased the interdependence of supply chain activities. Even the smallest manufacturing or service firm will depend to some extent on components produced in distant parts of the world.

Supply chain risks are exponentially escalated as complexity increases (Pettit et al., 2019). Lead times are impacted by customs delays and lack of adequate transportation. Quality may not be up to the expected standards due to difficulties with distant (sub-)suppliers. Ensuring compliance with social and safety rules may not be easy to achieve in complex networks. Political instability may cause difficultly in sourcing a given product or commodity. Fluctuations in exchange rates may impact the economic outcomes. The disruption risk list is extensive. Each risk makes supply chains more vulnerable and more exposed to suffer unwanted, and sometimes catastrophic, consequences.

Globalization and lean management practices have historically given companies a competitive edge, but at the expense of creating vulnerable unbalanced supply chains that have to face multiple risks that arise from numerous sources (Purvis et al., 2016). As a consequence, when a disruption hits, this global and efficiency-oriented supply chain configuration has proven to be too rigid to adapt to the newly disruptive operating and environmental context. Therefore, there is a need for change and for developing supply chains that can resist during turmoil and transform adverse situations to their advantage. Companies need to be resilient and develop mechanisms that will keep them afloat during disruptions. Supply chain resilience is the key to navigate disruptions while maintaining and even increasing their competitive advantage (Pires Ribeiro & Barbosa-Povoa, 2018; Purvis et al., 2016).

## 2 Understanding Supply Chain Resilience

The discussion about resilient supply chains has been occurring for decades – examples include major natural disasters temporarily halting operations in well-known global companies. Disasters like Katrina in 2004, the volcanic eruption in Iceland in 2010, or the earthquake and tsunami in Japan in 2011 initially expounded the vulnerability of global supply chains (Pettit et al., 2013; Purvis et al., 2016).

However, as the impact of such disruptions were mostly contained to a limited number of companies, few firms seriously considered investing in supply chain resilience strategies to be prepared for the next disruption (Sáenz et al., 2018). This perception has changed with cascading disruptions generated by the Covid-19 pandemic, bringing to light the importance of being prepared for the worst through the development of resilient supply chains (Alicke et al., 2020). By furthering resilience in supply chains, leading companies are trying to neutralize the risks originated by globalization and the prioritization of efficiency (W. Shih, 2020a). To that end, firms are developing new approaches and strategies to create supply chains that are both capable of minimizing the impact of disruptions and recover their functionality once the disruption has occurred (Fig. 1).

Even though resilience is increasingly appearing on the agenda of supply chain executives as a key enabler of operations and business continuity, as success, and as

**Fig. 1** Balancing supply chain risks

a long-lasting competitiveness enabler, there is still no consensus on how to successfully develop resilient supply chains or what does it mean for a firm to be resilient (Sáenz et al., 2018; Wieland & Durach, 2021). For that reason, it is necessary to understand what being resilient means and its analysis across different fields beyond the traditional supply chain risk management-focused approach. Resilience has been widely researched in the engineering and socioecological fields, with former discipline exerting a wider influence resilience definition (Ponomarov & Holcomb, 2009; Wieland & Durach, 2021).

## 2.1 Resilience from an Engineering Perspective

The engineering approach to resilience is rooted in the original conception of supply chain which conceptualizes them as engineerable systems whose different parts (suppliers, warehouses, distribution centers, and production facilities) are to be designed, optimized, and controlled to maintain a stable status (Wieland & Durach, 2021). Although, this approach is outdated and no manager would doubt the complex interactions that global supply chains face beyond their own components, the engineering approach to resilience still prevails.

A widely accepted conception of resilience revolves around the optimization of two engineering concepts: the time-to-recovery (TTR) and the time-to-survive (TTS) (Simchi-Levi et al., 2014). These concepts measure the time the system would need to recover after a disruption and the maximum time that service levels could be guaranteed after such disruption and before recovering the previously defined equilibrium. These mechanisms aim to create a robust supply chain capable of both resisting disruptions and maintaining their stable and optimized functioning (Simchi-Levi et al., 2018).

Robust supply chains share two distinctive features: anticipation and preparedness for disruptions (Wieland & Wallenburg, 2013). Through investment in processes and capabilities, robust supply chains improve their capacity to anticipate disruptions that can later have a negative impact on the operations and profitability of the company (Brandon-Jones et al., 2014). To that end, it is important for firms to proactively revisit previously defined signals that can provide hints about upcoming disruptions (Sáenz et al., 2018). Robustness enables the deployment of a series of mitigating mechanisms that allow supply chains to continue their normal operations during turbulent times. By anticipating disruptions and being prepared to face their consequences, robust supply chains are capable of retaining the stable status that they had prior to a crisis without having to make any adjustments to their organizational or operational structures (Purvis et al., 2016).

Firms deploying an engineering approach to resilience design their operations through a careful analysis of what can go wrong. For this approach, firms initially seek to understand the supply chain vulnerabilities (Sáenz et al., 2018). However, global supply chains are so complex that controlling all the possible risks at any given point in the supply chain becomes unrealistic. Take, for example, the case of Boeing, the airplane manufacturer. In just 1 year the company procures 783 million parts in 5400 factories distributed globally. Listing the risks associated with these

783 million parts, the risks from each factory, their different suppliers, and sub-suppliers is virtually impossible (BOEING, 2013). Not all risks can be accounted for or controlled.

When the Rana Plaza garments factory complex collapsed in 2013 killing over 1100 people in Bangladesh, many companies ignored that they were affected. That was the case for Walmart that 1 year earlier had banned the only supplier the company had working in the Rana Plaza complex. However, that same supplier was later subcontracted by another – this time authorized – Walmart supplier. Well-known global retailers – such as Walmart – were affected by this incident, and each of them saw damage to their reputation (Sheffi, 2015).

Adopting a pure engineering approach to resilience may not return the desired results in every disruptive situation firms face (Wieland & Durach, 2021). Traditional engineering conception of resilience revolves around the principle of a recovery to the previous equilibrium or state. Such recovery stabilization may never occur. Multiple companies have been experiencing this situation since the pandemic outbreak. This situation has forced firms to adapt to a new equilibrium or "new normal" if they want to survive. Firms have been forced to adapt to new ways of consumption, shifts in demands, and struggles with shortages to keep afloat. In these cases, a pure engineering approach seems insufficient as the survival of the firm requires adaptation and reconfiguration to achieve a new stable status.

### 2.2 Resilience from a Social-Ecological Perspective

In the current global economies, supply chains have become complex entities with multiple echelons that do not operate in isolation but with a series of interdependencies and connections with their operating, economic, and social environment. This situation is more like an ecosystem where a network of organizations, resources, information, and social actors align their work to achieve a common goal (Ponomarov & Holcomb, 2009). In this context, it makes sense to delve into the origins of resilience from ecological and social studies.

Ecological resilience is defined as the ability of a system to absorb changes that will facilitate reaching an equilibrium (Pettit et al., 2013). The difference from the engineering approach is that it is not a preestablished predisruption equilibrium but one that the system has reached after reconfiguring itself so it can continue its operations via an adaptation to new circumstances. As such, the ecological approach to resilience highlights the system's adaptive capability by assuming changes due to disruptions are inevitable, and that resilience is reached via adaptation to new conditions (Wieland & Durach, 2021).

The system capacity to reconfigure itself to reach a new equilibrium requires a well-orchestrated combination of all the available resources, capabilities, and strengths of the organization, together with the different channel partners and stakeholders. Incorporating social and human factors to the equation activates a learning capacity (Ponomarov & Holcomb, 2009). In this way, the system can pick up from previous disasters and deploy adaptive and transformative strategies to better react to future undesirable events, highlighting supply chain agility.

Agility focuses on rapid system reconfiguration in the face of unforeseeable changes (Kamalahmadi & Parast, 2016). It is the ability to rapidly respond to undesirable events by adjusting to a new disrupted environment. The multiple definitions of agility highlight the reactive and transformative nature of supply chains in which they have developed the capability for a quick reaction, response, or reconfiguration of its resources in order to maintain productivity levels (Bakshi & Kleindorfer, 2009). However, a fast reaction to disruptions is only possible if the supply chain has the resources and capabilities to perceive crises happening not only inside the supply chain but also in its operating context, in its environment, and even in adjacent industries. This situation creates awareness and facilitates a fast reaction to changes or disruptions. Fast reaction is a crucial element in supply chain redesign. It is important for firms to anticipate disruptions in firms to successfully and rapidly reconfigure their resources to meet these disruptions (Kamalahmadi & Parast, 2016; Wieland & Wallenburg, 2013).

Adopting the socioecological perspective of resilience allows supply chains to embrace disruptions in two different ways. First, when a disruption threatens a given equilibrium, supply chains are capable to effectively reorganize themselves and adapt to the new conditions for continued operations (Wieland & Durach, 2021). Second, resilient supply chains can exploit adverse situations with a goal of converting them into opportunities. They learn from the past and adapt their organizations and operations to face similar disruptions in the future.

Resilient supply chains are better prepared to maintain a competitive advantage during disruptions. This response is what happened during the covid-19 pandemic. Multiple companies, driven by a mix of community responsibility and necessity to survive, adapted their operations to manufacture medical or protective-related material. Demcon, a Dutch manufacturer of high-technological products in aerospace, food, and health industry rapidly adapted their supply chain processes of traditional blowers to design and manufacture their first hospital respiratory ventilation systems (B. Acero & Revilla, 2021).

Transformation and adaptation are also about foreseeing upcoming disruptions. The electric car industry is a clear example. The boom in electric vehicles is expected to cause serious environmental problems regarding the disposal of lithium-ion based batteries as well as sourcing scarcity of some of the metals required to manufacture them (Domonoske, 2021). As such, leading automotive companies have foreseen such disruptions and are already investing in adapting recycling technology and research pilot projects to avoid them (Nicola, 2021) (Table 1).

## 2.3 The Concept of Supply Chain Resilience

An analysis of two different approaches to supply chain resilience suggests that not all disruptions can be dealt in the same way. *Engineering resilience* facilitates resistance to turbulent changes and speeds-up the return to the previously defined equilibrium. *Socioecological resilience* allows supply chains to rapidly react to undesirable events and adapt operations and organizational structures to the new disruption-created scenarios, whether temporary or permanent.

**Table 1** Features of the resilience approaches

| Resilience | |
|---|---|
| Engineering approach | Social-ecological approach |
| Resist to disruptions | Reacts to disruptions |
| Return to a predisruption equilibrium | Adapts to a “new normal” equilibrium |
| Anticipates disruptions | Senses disruptions through visibility |
| The supply chain is prepared to deal with disruptions | The supply chain deploys a speedup recovery process |

For companies to survive in existing global and disruptive scenarios, it requires that organizations remain unaffected by disruptions and to continuously adapt to new situations. Adopting a combination of social-ecological and engineering resilience perspectives facilitates a holistic approach to supply chain risks and vulnerabilities (Wieland & Durach, 2021) – whether these disruptions are anticipated or not.

As an example, the engineering approach hinges on the robustness dimension of resilience allowing the supply chain to anticipate something such as a winter storm that may temporarily affect the production and distribution of a given product. A social-ecological approach rests on the agility dimension of resilience and prepares firms to efficiently react and adapt to unexpected events that may affect the normal operations of the supply chain for an unknown period of time (Wieland & Durach, 2021). An example of this latter situation is a shortage of critical components such as microchips. Supply chains need to be simultaneously robust and agile (Wieland & Wallenburg, 2013). Robustness facilitates the supply chain to retain the same stable configuration prior the disruption, while agility prepares it to respond to disruptions by adapting to a new stable condition through a reconfiguration of resources (Purvis et al., 2016).

Capturing both dimensions – agility and robustness – of resilience implies the ability to anticipate and respond efficiently to disruptions and unforeseen, unknown, or unquantifiable risks. It also means the ability to restore equilibrium to a more desirable state of operations as soon as possible to ensure high operational performance. Resilient firms are less vulnerable and more capable of dealing with all types of disruptions. Based on the definition provided by Wieland and Durach (2021, p. 2), we understand supply chain resilience as the capacity to persist, adapt, or transform in the face of *unexpected* changes.

*Supply chain resilience is the capacity to persist, adapt, or transform in the face of unexpected changes*

## 3 Developing a Resilient Supply Chain

Supply chain leaders are becoming aware of the need to build more resilient enterprises. Firms have started to adopt a series of practices to ensure supply chain resilience in times of disruptions.

Resilience is not an easy endeavor. Traditionally, firms have developed a series of risk management approaches including deploying a series of mitigation strategies for identified risks (Sáenz et al., 2018). While this technique, if done in a diligent way, can help in the avoidance and mitigation of risks from known sources – risks that can be identified and measured – a global, interconnected, and complex environment in which today supply chains operate is packed with risks that are impossible or extremely difficult to foresee, unknown risks (W. Shih, 2020a).

Analyzing how leading global companies are dealing with disruptions highlights how supply chain resilience cannot be achieved just by developing a couple of isolated practices. It requires a holistic approach through a set of practices that can be categorized as proactive or reactive mechanisms (Sáenz et al., 2018). Proactiveness assumes that disruptions will eventually happen and prepare the firm to deal with them by working at the core of the supply chain itself: the design of the supply chain, its products, and its processes. Reactive practices are deployed once the disruption hits the supply chain to contain or mitigate its negative consequences. These two complementary mechanisms and how successful companies are implementing them are further explored in the following subsections (Fig. 2).

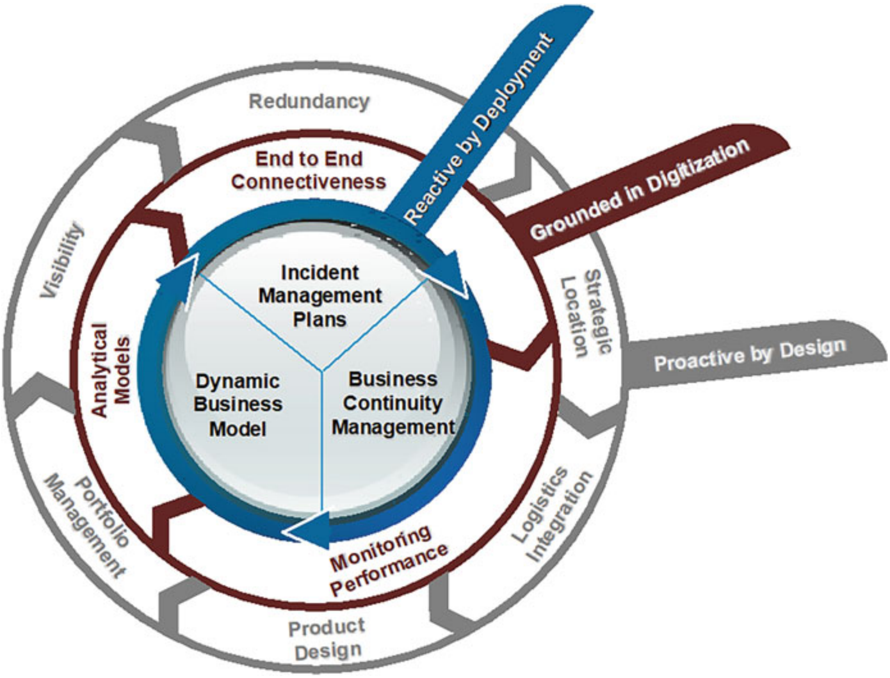

**Fig. 2** The resilience framework. (Adapted from Sáenz et al. (2018))

## 3.1 Proactive by Design

Companies anticipate disruptions by planning resilience based on the supply chain and product design. The design of supply chains has traditionally taken into consideration the idiosyncrasies of their operating industries and a series of efficiency and cost objectives (Sáenz et al., 2018). However, as it has been highlighted in previous sections, efficiency goals make supply chains fragile and operating around a unique equilibrium point that is difficult to maintain during tumultuous situations. For that reason, supply chains that are designed find a balanced trade-off between their operational procedures and resilient capabilities outperform their competitors in difficult times.

We summarize seven leading practices that companies should take into consideration when designing a resilient supply chain.

### Redundancy

Supply chain redundancy relates to the design of the supply chain using series of backup resources so that operations can continue during failures of critical parts. Such redundancies involve three main practices: holding extra inventory, securing alternative suppliers, or designing production lines to accommodate additional extra capacity (Reeves & Whitaker, 2020).

Traditionally, the most conservative way to secure operations continuity has been holding extra inventory and the safety stock in line with the company's "time-to-recovery" and "time-to-survive" strategy. This robustness practice may not suit every supply chain, like those with short-life span or highly perishable products, but it can be an advantage in times of disruption. For example, during the massive lockdowns of 2020 the demand for some type of foods drastically increased. Kellogg's, the giant food manufacturer, successfully dealt with the high demand rise of cereals, snack, and noodles thanks in part to their large inventory holding of grains and quick shift to a previously identified local provider of cardboard. Their robustness, through a redundant design, paid off during the pandemic disruption by buying them time to quickly reorganize their supply chain to the new situation (Silver, 2021).

But, holding extra inventory could be a costly practice as every dollar invested in extra stock beyond what is considered strictly necessary for normal operations is not a dollar spent in the company's R&D, investment on new assets, payment of dividends to shareholders, or bonuses to executives. In fact, a recent analysis highlights how in the past 40 years companies around the world have been reducing their inventories while rebuying their own stocks (Goodman & Chokshi, 2021). While this approach has largely benefited their shareholders during stable times, it has proven greatly damaging when demand suddenly becomes unpredictable or when shortages of key components are sustained in time. For that reason, it seems necessary to identify alternative redundancy practices that would increase the resilience of the supply chain without compromising the efficiency of operations or the commitment with shareholders and employees.

A different way to create redundancies is qualifying alternative suppliers or sourcing the same component from different suppliers. Through this policy, firms can enhance the resilience of their supply chain as if one of the suppliers becomes disrupted, the company can still secure the product (Lund et al., 2020). For example, Apple gradually shifted part of its primary contract manufacturer to alternative qualified firms (Rapoza, 2020). Other companies, motivated by geopolitical disputes like the US-China trade war or Brexit, have opted for a "plus one" strategy. They do this by moving part of their production to other countries, qualifying extra suppliers from other regional areas and nourishing the relationship with these alternative suppliers in order to adapt to the new context and minimize the consequences of the political instability. This type of practice may not be feasible for some supply chains, especially ones where companies rely on suppliers with sophisticated technology or "know-how." This situation is the case of a vast number of car manufacturers given that some of the required automotive parts imply high levels of investment that having second sources becomes extremely expensive (Geriant, 2014).

A third way of increasing supply chain redundancy is by diversifying what is manufactured in each production plant. In this way, if a plant is shut down or its production is halted due to, for example, inclement weather or labor strikes, other plants can absorb part of the missing production. Companies that are aware of the impact of a disrupted facility on their revenues and market share build redundant manufacturing lines for the most important products of their portfolio. This is how Procter & Gamble designs its supply chain to increase its resilience. This approach was successfully tested when a tornado badly damaged the only production facility of Pringles chips in the USA and the firm managed to mitigate its impact by diverting production to another plant in Belgium (Sheffi, 2005).

**Strategic Location**

The location of suppliers, distribution centers, and production plants conditions how the supply chain reacts during a disruption. Location is of critical importance, because it can affect the time it takes to notice that something is wrong. Location also dictates the reaction time once a disruption is identified. The farther apart different elements of the supply chain are, the longer it will take to react. Global location of manufacturing facilities and suppliers and the extreme dependency of global supply chains on Asia was a major issue during the recent global pandemic. Yet, there were already globalization concerns with trade protectionism sentiment of previous years already causing global supply chains to rethink their previous configurations (Rojas et al., 2022; Schwartz, 2022).

Searching for low-cost and optimized supply chains saw companies from all around the world move part or their entire production to Asia. Later, that work was simply overtaken by external suppliers located in these low-cost labor markets. Europe and the USA are now paying a high price as their economies and supply chains have become highly dependent on Asia. This issue has expanded beyond textiles, technology, or automobiles. Around 80% of the active pharmaceutical ingredients (API) used in the European Union come from India and China. Just these two countries account for 90% of the penicillin, 60% of the paracetamol, and 50% of the ibuprofen world production (EUParliament, 2022).

Dependency is global and has serious consequences. As of March 2022, the US Food and Drug Administration was listing shortages of over 100 basic drugs (FDA, 2022). To avoid future disruptions, the EU is providing economic incentives of API producers to locate in Europe, which will increase the robustness of their supply chains (EUParliament, 2022). Similarly, movements to reshore and regionalize strategic value chain activities are being developed globally to create supply chains that can reconfigure themselves to adapt to the new operating environment.

A drastic reshoring may not be a wise decision. With the risk of stagflation in some major economies, producing in higher-cost countries may not be feasible for firm survival, although the introduction of new technology such as automation and robotization can significantly lower production costs (Burke et al., 2021). Companies should reevaluate their production practices to balance profit and efficiency maximization with disruption minimization or avoidance due to overreliance on remote sourcing (Hartman et al., 2017; Lynch, 2021).

As an example, if a given company has some of their suppliers concentrated in one geographical area, it might be wise to think about moving part of the production closer. This becomes especially pertinent if political circumstances show signals of instability. Nearshoring certain manufacturing capabilities and critical suppliers contributes greater supply chain control, reduces lead times, and facilitates adaptation to demand fluctuations. When combined with the current practices of relying on low-cost locations, this locational diversification increases supply chain resilience by facilitating the procurement of materials and parts from different sources depending on the situation, and by setting the foundations to adapt to new operating contexts.

### Logistics Integration

Traditional supply chain design has, in many cases, left aside the role of transportation and logistics providers (Acero et al., 2022). A resilient supply chain should account for logistics diversification to ensure that goods can be delivered on time during disruptive times. Previous disruptions such as the Icelandic Volcano in 2010 or port strikes in 2012 highlighted the resilient role of supply chain transportation. However, these disruptions were temporary, and companies did not seem to pay much attention to transportation once the situation returned to normal. The interruption of ports' activities due to lockdowns, the global shortage of sea containers, and the lack of air freight capacity seem to have changed this idea, and it has irrevocably revealed the need to include logistics in the resilient design of supply chains.

More recently, sanctions on Russia are causing a nightmare to the already fragile global logistics system. Cargo that was shipped by rail between China and Europe can no longer transit Russian territory. There are not many alternatives as sea and airfreight capacity is limited with exorbitantly high fares.

The creation of a resilient supply chain will require collaboration between transportation and logistics providers when designing the supply chain (Revilla & Acero, 2021). A joint assessment of the vulnerabilities and "what-can-go-wrong" scenarios can contribute toward the robustness and agility of the supply chain. This collaboration can completely avoid disruptions or adapt to a new operating situation such as a long-term reduction of shipping capacity or inability to use the predefined transportation model.

It is important to develop agreements with strategic logistics partners that will secure capacity and service during periods of disruption. As new business models that prioritize e-commerce and omnichannels emerge, transportation partners that integrate real-time information and multimodal shifts become critical players. As a bonus, transportation and logistics may significantly contribute toward achieving the sustainability targets of supply chain through multimodal promotion and partial freight shifts toward railway and waterways (McKinnon, 2018).

### Product Design

Integrating a resilient product design can help companies to quickly adapt their operations in times of disruptions (Sáenz et al., 2018). Products should be designed for adaptation to different potential uses or configurations that arise from adverse events. Flexibility in product design includes modularity and postponement. By standardizing components and interfaces between components, modularity avoids the failure of one part affecting the entire system. A modular product design embeds coordination and loose coupling, while reducing cost and improving response time (Revilla & Acero, 2021). This approach is especially suitable for companies that rely on single sourcing for key components or whose main suppliers are concentrated in a particular geographical area. A flexible product design facilitates the adaptation to new requirements imposed by disruptions. Finally, understanding the design of the products creates awareness of the risks associated to each step, which promotes the development of mitigating strategies and may even lead to rethink some of the process' stages (Sáenz et al., 2018).

A second flexible product design practice, postponement, is based on designing a group or family of products with a core element that can later be easily customized to produce different products. This practice, successfully developed by leading companies such as DELL, allows companies to benefit from offshore outsourcing of the core component to reduce costs while the final stages of the manufacturing can be done in closer locations to the final consumer (Sheffi, 2005). This way, production is finalized once the customer orders are received, avoiding forecasting uncertainty associated with volatile markets and the overstocking of final goods. Therefore, flexibility through postponement can enhance the resilience of the supply chain as production of goods is mostly guaranteed by tailoring the offered products to sudden changes in the demand or supply side (Tukamuhabwa et al., 2015).

### Portfolio Management

Product portfolios refer to the number of products that a given organization manufactures. How this portfolio is designed will directly affect the extent to which certain occurring challenges impact the supply chain. Supply chain managers could believe that providing a large variety of product options (type and size) may increase their resiliency to disruptions. However, companies should be aware of the trade-offs between product variety and resilience (W. C. Shih, 2020b).

With companies offering multiple varieties of the same base product, it becomes harder to adjust to demand, and shifting among production lines may not always be possible. Furthermore, in times of disruption a large variety can work against firm operational efficiency. Limiting the options provided streamlines production facilities and reduces logistics downtime, and it ultimately helps to maintain a satisfied customer base.

Companies such as Coca-Cola, Mondelez, or Procter & Gamble have historically provided plenty of options to customers and are now reevaluating their product portfolio, so they can simplify their supply chain. Simultaneously they are investing in flexibility to increase their agility to adapt their products and processes during future disruptions (Cosgrove, 2020). However, product portfolio simplification should go beyond a mere reduction of the products offered or just keeping the "best-sellers." It requires of a careful review of the current product strategy and alignment with current and future potential trends through a flexible planning, so production can be adapted to foreseeable changes or existing disruptive events (Sheffi, 2020).

Flexible planning sets the stage for agile reactions during disruptions by taking into consideration the needs for manufacturing equipment with different production rates as well as the staff requirements to operate in such a flexible environment. That was the case of some automotive companies that in absence of microchips focused its constrained resources in producing those cars with the highest revenue margins, which help to maintain the firms' financial solvency in highly unpredictable and disruptive times (Yergin & Fini, 2021).

### Visibility

Introducing end-to-end visibility in supply chain designs creates awareness of vulnerabilities in both the supply chain and its operating context. It also facilitates continuous monitoring that triggers the signals of an imminent disruption (Sáenz et al., 2018). To this end, firms need to have access to accurate, timely, and useful information of what is happening in every node and link of the supply chain (Brandon-Jones et al., 2014).

Visibility in supply chains can help identify its actors through an exhaustive mapping of its suppliers. Mapping has proven to be a useful tool in the identification of risks and preparation of the company to face the consequences of the materialization of such risks. However, the traditional mapping exercise performed by companies is mostly limited to the identification of tier-one suppliers, underestimating how a disruption on tier-2 or tier-3 suppliers can impact the normal operations of their own supply chains. For example, the recent trade restrictions on Russia have revealed the existence of over 7.6 million tier-2 relationships with Russian entities all around the globe, which may have a tremendous impact for global supply chains (D & B, 2022).

Visibility is more than a deep knowledge of where each component required for the manufacturing process is being produced or sourced. Complementing the identification of subtier suppliers with a real-time evaluation of critical performance variables – such as supplier inventory status, production schedules, shipment information, or supplier disruptions – can improve supply chain performance and decision-making (Caridi et al., 2014).

For supply chain resilience, firms should also assess the origin and criticality of supplied components. This tracing requires recurrent monitoring of direct suppliers in terms of financial and operational viability. For example, corporate restructuring or lawsuits in suppliers may trigger new risks. By integrating supply chain monitoring with the supplier data, companies can have a comprehensive and holistic view of risks, which will increase the robustness of the supply chain.

Finally, a visible supply chain requires understanding of the operating context in terms of both industry competitors and adjacent industries. For example, in the initial months of the pandemic, as a result of a sharp decline on fuel demand, the production of gasoline plummeted and so did the production of one of its by-products: ethanol. This by-product is a key component in $CO_2$ generation and required for carbonation of soft drinks and beers. The result of such decline increased CO2 prices by 25% (Baertlein & Kelly, 2020).

## 3.2 Reactive by Deployment

Proactive resilient practices need to be complemented with reactive disruption responses. Once a disruptive event happens, firms need to quickly react and deploy a series of mitigating tools to minimize the negative disruption impact. The deployment of reactive approaches is of critical relevance, especially when disruptions persist and require adjustments to a new context. Two main reactive practices stand out among the analysis of best practices deployed by leading companies: risk management plans in the form of business continuity and incident management plans, and adaptation to new business models.

### Risk Management Practices

Risk management practices are a formal response to deal with disruptions. With disruptions happening more frequently and companies having an increased awareness of devastating consequences of being exposed to risks, risk management has become a formal responsibility in supply chain management. It includes new job roles, job titles, and entire departments dedicated to risk management.

Effective risk management approaches incorporate multidisciplinary teams from different functions of the supply chain that tailor responses based on the nature and impact of the disruption (Sáenz et al., 2018). They identify disruption signals and implement reactive mitigation measures through four steps or stages: risk identification, risk assessment, risk treatment, and risk monitoring and review (Dittman, 2014).

The first step consists of the identification of possible risks completed by mapping out nodes and links within a supply chain. Identified risks should then be categorized based on how its materialization would impact the normal operations, the probability of such materialization, and if the company is prepared to deal with such disruption. This second step allows risks managers to prioritize mitigation measures and may eventually lead to changes in the design of the supply chain. In the third stage, each of the risks identified is matched with a series of mitigating practices and response plans that would be developed to respond to the disruption caused by such risk. Finally, an effective approach to risk management needs to include continuous monitoring of the risks identified. The dedicated risk management teams may use different signals to detect potential disruption, for example, using control towers or other visibility platforms, and if something is detected that may trigger the deployment of contingency measures.

### Business Continuity Plans

Companies have traditionally embarked on risk management practices through Business Continuity Plans (BCP). These plans seek to deal with disruptions by ensuring a continuation of the operations with minimum interruptions (Sáenz et al., 2018). Therefore, when an unexpected crisis impacts the supply chain, a series of contingency measures are deployed to keep operating with the available resources.

BCP provides a roadmap to follow during a potential disruption. Such potential disruptions could include interruption of operations due to extreme weather events, extensive physical damage to a critical facility, cybersecurity breach, or power outage. For years now, CISCO Systems Inc. has enforced its Business Continuity Plan, which has proven successful in critical events such as the Tohoku earthquake. A dedicated team closely monitors each critical supply chain node information. In this way, when a disaster or unexpected event occurs, the company can automatically assess the extent of the disruption impact and implement previously developed corrective actions (Sáenz & Revilla, 2014). All these measures, once deployed, aim at mitigating the negative consequences of a materialized disruption.

### Incident Management Plans

Another widely used risk management practice is Incident Management Plans (IMP). IMP are developed to create an awareness culture of what may trigger a disruption and react if these disruptions materialize. Even though it may seem similar to BCP, there is a substantial difference between the two of them. BCP imply that a disruption has materialized and is causing an interruption to the operations. However, IMP are deployed to address and minimize the impacts of incidents by quickly detecting signals of disruptions. However, such disruptions may not necessarily cause an interruption of the operations.

As an example, Starbucks anticipates disruptions through a series of pre-established signals, and if needed its center of excellence activates the required mitigation strategies which are tailored to each specific disruption (Sáenz et al., 2018). While the existence of these risk management practices will not fully avoid the impact of a global crisis, previous experience indicates that only those companies with mature approaches to risk management can react to disruption faster and adapt their operations in a more favorable way.

### Dynamic Business Models

Depending on the type of disruption, it may not be possible to continue with the original operating model. Therefore, to be resilient it is necessary to design the firm's business model thinking that it is in a state of perpetual evolution, in which disruptions are seen as opportunities to exploit new markets.

We have seen plenty of successful and unsuccessful examples of agile adaptation triggered by the Covid-19 pandemic. We will continue to see them as the consequences of new lockdowns in China, such as the one in Shanghai in March 2022, or the economic implications and raw material shortages derived from the Ukrainian armed conflict. There will be other events to cause similar disruptions.

Before the pandemic, passenger aircraft were providing around 50% of the airfreight cargo capacity; with traffic down by 90% and tariffs increasing by more than 200%, some passenger companies saw an opportunity with new business opportunities and stayed afloat at the same time. This was the case of Wamos Air, a Spanish airline whose main business revenues came from transporting passengers to cruises in the Caribbean. With tourism virtually nonexistent during the Covid crisis, the company worked fast to react to the new circumstances. They adapted to the new demand by quickly converting 70% of their fleet into cargo planes. Wamos Air was the first Spanish operator, in June 2020, to get an exemption from the Civil Aviation Authority of Spain (AESA) to remove the seats from some of its A330s and carry cargo, reacting to the clear cargo demand in the market. Furthermore, as a consequence of this situation, the company has developed the ability to transform aircraft in just 2 days from cargo to passenger thanks to having its own Part 145 maintenance party.

A dynamic business model to adapt to new disruptive contexts can only be achieved if its workforce is also ready to adapt. To that end, it is important to develop a culture of permanent reskilling of the people and develop a collaborative framework with the latest digital tools and edge technology.

## 3.3 Grounded in Digitization

Building supply chain resilience requires two complementary approaches mentioned above (proactive and reactive). The supply chain risk is reduced through its design, and a series of particular mechanisms can be reactively deployed when a disruption materializes.

Supply chain managers have to aim clear and dynamic representations of supply chain tracks to be able to link both approaches. They need to do this while designing the supply chain structure and the product configuration. Digital technology and rich data can expand end-to-end in the supply chain, for digitization of supply chain processes, connected along with a combination of flexible alternatives.

End-to end data allow the connection between demand and supply being flexible in how to configure the product with complementary components. This visibility provides the representation of real time flows of supply chains that enhance the necessary awareness of risks, implement risk mitigations practices, and minimize its negative impacts.

### End-to-End Connectivity

Building end-to-end (E2E) connectivity facilitates the development of supply chain visibility, integrating it in the deployment of risk mitigation practices. To achieve this, E2E connectivity multiple sources of data must be accessed and integrated depending on the particular scenario of the disruption risks. Storing and sharing data through data lakes and data hubs requires access to the most traditional sources of data in supply chain settings. This situation would include historical formal data from forecasting systems, sales and operations integrated, inventory positions of the multiple parts, and final products, combined within the Enterprise Resource Planning Systems (ERPs), Warehouse and Transportation Management Systems. By integrating data with modern computing architecture, decision-making can be made on more solid inputs and reaction times can be substantially reduced.

Building supply chain resilience also requires the contextualization of real-time disruption risks and the learning after analyzing the potential threats behind. This implies access to sources of real-time data anywhere along the supply chain which represents the real context that the supply chain has to face as well as some threats to the operations. Examples of these sources of information are trade bodies, currency exchanges rates, web crawlers showing the dynamism of prices, behavior of competitors, online product reviews by customers, social media reactions, seasonal and weather forecast, threats of political instability, and reputational status of supply chain partners, among others.

### Monitoring Performance

One of the critical elements of successful resilient supply chains is the orientation to a value-driven supply chain that is enhanced by digitization, in which specific value propositions are guiding how to deploy the operational flows (Saenz et al., 2022). For this purpose, stablishing specific organizational and supply chain goals will help to navigate the creation of supply chain resilience. The establishment of these goals will facilitate a balance in the trade-offs eluded in this chapter such as resilience and efficiency or redundancies and cost-savings, among others.

Digitizing supply chain processes will create the availability of insightful data to better connect with the ecosystem of supply chain partners, suppliers, retailers, and customers, as well as key players such as logistics service providers. With the main aim of monitoring the creation of resilience, cohesive panels of comparable and comprehensive metrics are required. Key performance indicators should be created to align the two approaches mentioned before, while proactively designing the supply chain and monitoring the deployment and variation of that capability when a real disruption is threatening operations. Monitoring and visualizing this dynamic performance in real time will facilitate a setting for informed decisions. Every supply chain and business have to specify their way of measuring performance. Examples of the key performance indicators to monitor supply chain resilience are included in Table 2.

**Table 2** Resilience indicators

| Metric | Definition | How it is created |
|---|---|---|
| *Time to Recovery (TTR)* | TTR measures the time the system would need to recover after an unexpected event | TTR can be composed by multiple categories that can be weighted depending on the supply chain goals, the vulnerabilities exposed, and their importance on building resilience. This might include TTR at the level of supply chain nodes, in terms of components in product portfolio, suppliers, manufacturing facilities, or test equipment. A continuous learning loop when the TTR metric is assessed based on the supply chain design is monitored when a real disruption happens |
| *Time to Survive (TTS)* | Complementary to TTR, it assesses the duration of a supply chain satisfying demand with the current supply chain structure, especially after a disruption strikes | In a proactive approach, diverse scenarios can be developed and tested. The implications about cost-to-serve can be assessed in all those scenarios together with sensitivity analysis |
| *Value at Risk (VaR)* | VaR measures the potential economic or financial losses given a potential disruptive scenario | This metric is assessed using a risk exposure index, that is built based on the probability of a disruption, combined with real-time information that contextualize a particular facility, location, or flow. Unbiased measure of disruption risk complemented with the quantification of parameters of value, in terms, for example, of inventory hold, expected value of loss, investment made, or the opportunity cost of losing that facility if a disruption happens |

## Analytical Models

Once the key goals are defined and the sources of information are assessed and data is available, it is time to create the necessary insights to operate a resilient supply chain. Various analytical models can be created depending on the particular goals. For example, they can help to map business and supply chain processes as well as their interdependencies. They can detect vulnerabilities because some supply chain nodes do not have enough capacity to absorb disruptions or because they cannot adapt to new unexpected circumstances (defined by proactive by design mechanisms) or because the supply chain needs to deploy certain reactive practices when a disruption happens. In any case, both proactive and reactive mechanisms need to be closely monitored through a continuous collection of key data so as to ensure that the resilience creation mechanisms are aligned with the operating needs and external context.

Analytical models can be replicas of, for example, consumers and market behavior, geo-strategic models, value at risk of supply chain infrastructure and assets, industry behavior, or macroindicators that signal forward-looking trends in certain regions.

The engine that puts these models into action includes different analytics techniques, such as predictive, prescriptive analytics, or more advanced techniques based on machine learning and artificial intelligence (Gesing et al., 2018). These last two techniques are used in the context of supply chain risk management in order to actively learn from past experiences and project such learning in the day-to-day supply chain operation. Artificial intelligence emulates some cognitive functions associated with human minds such as perceiving the sources of vulnerability and uncertainty, interacts with the environment in real time with devices and users who can define or quantify the uncertain context, and learns as information changes, and as goals and requirements evolve. On the other hand, machine learning refers to systems that learn from the data they are given, drawing inferences after an evaluation and categorization of the received data. Both artificial intelligence and machine learning can augment the visibility and awareness of the supply chain, facilitating the monitoring of complex networks, sensing what is happening in the supply chain and its environment in real time, and even predicting disruptions (Gesing et al., 2018). Overall facilitating supply chain resilience.

## 4 Conclusion

In this chapter, we present the need for firms to integrate the development of supply chain resilience into their operational and business strategies to ensure their long-term viability. Resilient firms are more capable of developing supply chains with the capacity to persist, adapt, or transform in the face of disruptions. To effectively absorb and/or adapt to changes, supply chains need to embrace two different but complementary capabilities: robustness and agility, each of them coming from two different research field areas – engineering and ecology, respectively. Supply chain robustness facilitates, through anticipation, an efficient respond to disruptions, while agility prepares the supply chain to adapt operations so as to ensure a new desirable equilibrium.

Using these two complementary dimensions of resilience, we have created a comprehensive framework that facilitates a step-by-step resilience creation integrating the necessity of both proactive designs and reactive deployments of the supply chain elements. Overall, the framework presented in this chapter highlights a set of practices (redundancy, strategic location, logistics integration, product design, portfolio management, visibility, E2E connectiveness, monitoring performance, analytical models, incident management plans, business continuity management, and dynamic models) that companies should holistically implement to deal with unexpected events and achieve the much-desired supply chain resilience.

# Conflict in Supply Chain Relationships: A Review, Conceptualization, and Future Research Agenda

## Contents

### Abstract

Conflict in buyer–supplier relationships is a regular occurrence and, therefore, understanding its emergence, consequences, management, and resolution is a vital area for academics and managers alike. In recent times, studies have given more consideration to whether and how conflict in these relationships leads to (dys-)functional outcomes, but plenty of questions remain unanswered. Based on an analysis of 124 papers, and drawing upon core assumptions that underpin

supply chain relationships, we present descriptive and thematic analyses and synthesis to highlight what has been explored to date. Building on these analyses, we position a future research agenda by outlining key research avenues by which to advance our understanding of and insights into conflicts in supply chain relationships. We focus on four key themes: (i) conflict conceptualization; (ii) conflict antecedents; (iii) conflict management and resolution; and (iv) conflict outcomes. For each theme, gaps in prior study are outlined before identifying the opportunities for future research that will serve to address these lacunas in our knowledge and practice. Thus, we articulate fruitful research questions for each of these themes and discuss the significant managerial implications of current and future research.

## 1 Introduction

Conflict, defined as "the process that begins when one party perceives that its goal attainment is being impeded by another, with stress or tension the result" (Gaski, 1984: 11), is an inherent characteristic of buyer–supplier relationships. Companies face a variety of major challenges, such as digitalization, global competitiveness, supply chain uncertainty, and shortened time to market, and these provide a ripe environment for conflicts to emerge, as well as impacting the way companies resolve them (Eshghi & Ray, 2021).

Scholars have argued that conflict has a double-edged nature in that it can act as a cohesive force that brings partners closer, or as a disruptive force that threatens the stability of the relationship. Researchers have demonstrated that conflicts among supply chain partners can disrupt their interaction, block their ability to gain the resources that are necessary to advance their goals, and may increase product development time and costs (Lam & Chin, 2004; Leonidou et al., 2006). Contrarily, researchers have also reported that a certain degree of conflict between parties in a relationship may intensify value-creation efforts, provide an opportunity to refine the ongoing relationship, and enhance future purchase intentions (Skarmeas, 2006).

The predominance of conflict in buyer–supplier relationships and the mixed findings regarding its impact require deeper exploration and synthesis of existing knowledge in order to understand the key factors involved in conflict emergence and management. Yet, prior studies largely lack any systematic review of conflict literature. An exception is the study by Lumineau et al. (2015), which provided a narrative review of the conflict literature, focusing particularly on the difference between conflict at the intra- and interorganizational levels. Yet, as the authors clearly stated, "our intent is not to conduct an exhaustive review of the literature, but rather highlight key studies of inter-organizational conflict" (Lumineau et al., 2015: 45). In addition, Johnsen and Lacoste (2016) developed a systematic review of conflict, power, and dependence, but only examined the downside of these constructs, largely ignoring the more positive aspects of conflict including the stream of prior studies concerned with "conflict management," considered a crucial component of conflict research.

In order to address this shortfall, this chapter synthesizes and extends understanding of the evolution of conflict within supply chain relationships by considering the following: (i) *What is the current state of buyer–supplier conflict research?* (ii) *What are the outstanding conceptual and empirical concerns in buyer–supplier conflict research?* (iii) *What can organizations and managers learn from prior conflict research when seeking to address conflicts in their supply chains?*

To address these questions, we draw on a synthesis of 124 conflict-related articles focusing on interorganizational relationships. We examine key theoretical, methodological, and empirical aspects of existing research, and build on core assumptions of supply chain relationships (Lumineau & Oliveira, 2018) to propose areas for research that will help in building, testing, and elaborating theoretical advances, and informing practice, when it comes to conflict. This chapter seeks to serve as a source of reference for future research and engagement, to position the avenues for this future research from a theoretical perspective, and to guide managerial decision-making.

The remainder of the chapter is organized as follows: first, we describe the methodology used for the review of the literature and the descriptive analysis of the papers identified; we then present our synthesis and thematic analysis, before concluding the chapter with a discussion of the managerial implications of our results.

## 2 Systematic Review Methodology and Descriptive Analysis

### 2.1 Methodology

The domain for the research synthesis consists of empirical (both qualitative and quantitative) and conceptual papers that examine conflict in supply chain relationships. The substantive relevance of the selected papers was ensured by requiring the presence of the terms "conflict," "disagreement," "tension" (De Wit et al., 2012), "conflict management," "conflict handling," and "conflict strategy" in the "Topic" category in the ISI Web of Knowledge, combined with at least one of the following terms in the articles' titles: "cooperat*," "interfirm/inter-firm," "inter-organizational/interorganizational/inter-organisational/interorganisational," "supply chain," "buyer," and "supplier." Further, because some supply chain conflict research was initially conducted in a distribution channel context, the term "distribution channel" was also incorporated to fully embrace interorganizational conflict. Given these elements, more detailed inclusion and exclusion criteria were discussed and agreed among the author team.

Overall, we reviewed 319 abstracts and only retained papers where conflict was the main subject, or where conflict/conflict management had been used as a variable to predict certain attitudinal and behavioral outcomes in supply chain relationships. Articles placed out of scope included mathematical modeling and operational research papers dealing with internal channel conflict, and those concerned with conflicts involving organizational or cross-functional teams, financial decision-making, and dispute management (litigation). The final data set consisted of 124 papers, which was then analyzed through both descriptive and thematic methods.

## 2.2 Descriptive Analysis

On the basis of our comprehensive analysis and synthesis, this section draws out key observations in relation to our data set of conflict studies.

In terms of distribution over time, the rate of journal publication has been increasing, which illustrates the growing importance of this research area among scholars and practitioners. Two major periods can be distinguished: 1969–2002 and 2003–2021. Forty of our papers were published in the first of these (over 33 years), with the number increasing by more than 50% in the latter period (just 18 years). The resurgence of interest in the field from 2003 onwards can be explained by the refinement of the conceptualization of the conflict construct, and the emergence of two paradigms for handling conflict: (i) as a problem to be eliminated; and (ii) as a resource for improvement (Samaha et al., 2011). This conceptual clarification encouraged a vigorous and renewed attention to the study of the underlying psychological, structural, and environmental factors that induce, support, and diminish conflict.

In terms of the research methods used in prior conflict studies, surveys were the dominant form (75%; see Fig. 1). Within the specific context of interorganizational conflicts, survey research provided insights into antecedents that might explain variance in the amount of conflict within a dyad, as well as conflict outcomes, in a wide range of industrial and national contexts. However, the practicalities of a survey-based

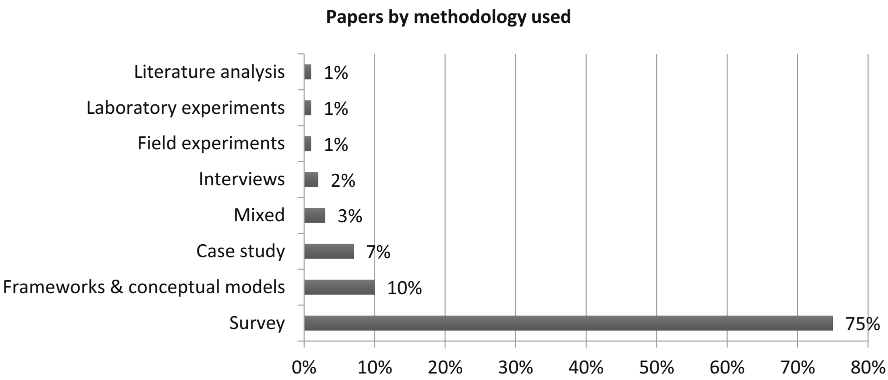

**Fig. 1** Publications by methodology

methodology also mean that dynamics are overlooked. Thus, surveys provide little insight as to how and why conflict levels change, and do not illustrate how firms make decisions in the course of the conflict resolution process. Moreover, surveys do not indicate the sequence of events, making it impossible to infer causality (Krafft et al., 2015). Case study methods were employed in just 7% of the empirical papers yet, given that conflict is defined as a process, are particularly valuable in substantiating the evolving nature of conflict and unraveling the complexities inherent in its resolution, including the why, what, when, and how. The confidentiality issues that researchers encounter when investigating a sensitive phenomenon such as conflict (Lumineau et al., 2015) may have inhibited the wider use of case studies within this context.

Although conflict in buyer–supplier relationships is a dyadic phenomenon, most empirical papers describe studies in which researchers examined the subject from the perspective of a focal company (80%) within the dyad, with the perspective of both sides of the dyad (matched dyads 16%; unmatched dyads 4%) studied to a much lesser extent. This is consistent with the results of Krafft et al. (2015), who found that, in a sample of 362 studies in marketing channels, dyadic empirical research was low in comparison to non-dyadic studies. Dyadic research designs enable researchers to measure both the magnitude of the phenomenon across the dyad and the (a)symmetry in partner perceptions (Liu et al., 2012).

The dyadic studies reviewed in this chapter used dyadic data either for triangulation purposes in understanding different perspectives (e.g., how the position in the dyad impacts the hypothesized relationship), or for determining magnitude by measuring the mean value score from paired dyads (Luo et al., 2009; Liu et al., 2017). This situation means that *conflict asymmetry* has been significantly understudied. The advancement of conflict research must move beyond the perspective of a single actor because conflict episodes involve partners with different perceptions, in which symmetry is not a typical state (Hingley, 2001).

Of the selected papers, only 37 explicitly referred to theories, meaning that most articles are not grounded in theory. This result is surprising because the need for extensive use of theory in operations and supply chain management research has long been advocated (Harland & Roehrich, 2022). Analysis of theory frequencies indicates that social exchange theory (SET) and transaction cost economics (TCE) provide the dominant theoretical perspectives, which is unsurprising because these two theories have been fundamental in explicating the nature of buyer–supplier relationships.

## 3 Synthesis and Thematic Analysis: Emergent Concerns and Gaps in Prior Studies

In order to clarify the state of the art of knowledge on conflict in supply chain relationships, and pave the way for future research efforts and managerial insights and implications, this section provides a synthesis of and critical reflection on the key themes and research gaps identified by the review and analyses. Thus, we categorize our analysis and synthesis according to four themes, discussed in turn below: (i) conflict conceptualization; (ii) conflict antecedents; (iii) conflict management and resolution; and (iv) conflict outcomes. A final subsection brings together other observations from prior conflict studies to support the synthesis.

### 3.1 Conflict Conceptualization

As conflict gained importance as a research area over the last three decades, scholars have sought to refine its conceptualization (Jehn, 1995). Two types of conflict emerged initially, namely task conflict and relationship conflict. Task conflict refers to "disagreements among group members about the content of the tasks being performed, including differences in viewpoints, ideas, and opinions" (Jehn, 1995: 258); relationship conflict, on the other hand, refers to "personal incompatibilities among group members, which typically includes tension, animosity, and annoyance among members within a group" (Jehn, 1995: 258).

Although this categorization has gained resonance in the organizational behavior literature over the last two decades (De Wit et al., 2012), the supply chain conflict literature showed a vast majority of studies still considering conflict as a single construct in which factors pertaining to both task and relationship conflicts were combined. A handful of prior studies have explicitly considered either task conflict or relationship conflict, while others have included both conflict types in one study. Thus, a significant gap exists in this respect, because the conceptualization of different conflict types has been recognized as constituting a critical theoretical distinction in several meta-analyses (e.g., De Dreu & Weingart, 2003) because they have differential impacts on conflict outcomes.

Further refinement of the conflict construct has resulted in the addition of a third type of conflict, referred to as process conflict and defined as "controversies about aspects of how task accomplishment will proceed (. . .) pertains to issues of duty and resource delegation, such as who should do what and how much responsibility different people should get" (Jehn & Mannix, 2001, 239). However, to date, this type of conflict has been largely neglected in empirical studies on supply chain conflict. An exception is the recent study by Cai et al. (2020), investigating how the three conflict types impact green supplier integration. In essence, prior studies have failed to obtain discriminant validity because of the strong overlap between task conflict and process conflict, intercorrelation of which is high, ranging from 0.44 to 0.90 (e.g., Jehn & Mannix, 2001). Accordingly, researchers have argued that process conflict is merely one kind of task conflict (Barki & Hartwick, 2004), and it is the dual distinction, task versus relationship, that has formed the basis of much of the prior conflict research in relation to management.

### 3.2 Conflict Antecedents

A considerable amount of literature has been published on conflict antecedents in order to highlight the causes of conflict occurrence, with the *power* antecedent being the most investigated. The relationship between power and conflict was reported in the first studies by Lusch (1976), who found that coercion tends to increase the frequency of conflict, whereas noncoercive power leads to fewer disagreements, although these findings were not consistent across subsequent studies. Inconsistencies in results emerged from differing approaches to measurement of the conflict construct, which could be based on frequency (Lee, 2001), intensity (Zhang & Zhang, 2013), or a combination of frequency and importance (Schul & Babakus, 1988).

Scholars have also studied how buyer–supplier governance mechanisms are associated with conflict, with researchers starting to examine contracts and contract types as conflict antecedents. For instance, when an output-based contract governs the buyer–supplier exchange, a buyer has minimal involvement in the supplier's processes, which in turn reduces conflict over how to perform the cooperative task. Conversely, the use of behavior-based contracts generates conflict, because buyers are given increased power to legitimately monitor a supplier's operations, which may in some instances be considered inappropriate and lead to conflict (Bai et al., 2016). You et al. (2019) investigated how governance mechanisms are linked to different types of conflicts, and other antecedents that have been investigated include opportunism (Skarmeas, 2006) and environmental dynamism (Cai et al., 2017).

Further research should continue to investigate conflicts and the role and impact of, for instance, different types of contracts (e.g., performance-based contracts), contract clauses (e.g., control vs. coordination), specific boundary objects in the contract (e.g., timelines), and phases of the contracting process (e.g., Roehrich et al., 2021; Karaba et al., 2022), as well as wider market dynamics, and economic, social, and political disruption and change (e.g., BREXIT, the COVID-19 pandemic, natural disasters, climate change, carbon emissions – Phillips et al., 2022a, b). These factors could variously suppress or support the emergence of conflict in supply chain relationships.

Overall, three major limitations can be distinguished in the stream of antecedent research: the predominance of factors associated with relationship conflict, a tendency to consider each level of analysis in isolation, and a lack of replication across studies. First, conflict involves mechanisms from other levels of analysis besides those at relationship level (Lumineau et al., 2015). By focusing on just one level of analysis, researchers only provide a partial picture of conflict. Moreover, by considering each level separately, conflict researchers neglect the interaction between levels, and may attribute effects from the dimensions of one level to those of another level, thereby creating a cross-level fallacy (Rousseau, 1985). Accordingly, a multilevel theoretical lens that encompasses the dynamic interplay across levels should provide a more insightful description of the conflict phenomenon. Finally, few replication studies have been published. Yet, replication is essential to the extent that it enables researchers to confirm past findings and to examine a phenomenon from various points of reference – such as different contexts, timing, and/or perspectives – and thereby grant original theories greater legitimacy.

## 3.3 Conflict Management and Resolution

Conflict management refers to the approaches and strategies used by parties to reduce and manage the tension. Researchers have attempted to classify these strategies, and hence various models have emerged. These frameworks differ in the terms used to describe the strategies, but their classifications are broadly based on two dimensions, which reflect people's concerns for their own interests, and their concerns for those of the other party. Figure 2 illustrates these dimensions and the classifications of the strategies identified in prior studies.

In general terms, five distinct conflict management strategies have been identified, as shown in the figure: (1) *accommodating*, which implies offering help and acceding to the desires of the other party; (2) *collaborating*, which is oriented toward achieving maximum satisfaction of both parties' concerns through high levels of cooperation; (3) *compromising*, which presumes a mutual give and take so as to at least gain partial fulfillment of one's desires; (4) *avoiding*, which involves ignoring the associated concerns and downplaying the importance of the issue; and (5) *forcing*, which involves imposing one's will on the other party.

Conflict management has not been sufficiently investigated. Of the 124 papers we reviewed, only 27 recognized conflict management strategies as part of their theoretical framework. Of these 27, the vast majority (73%) explored the direct relationship between strategies and outcomes, followed by a group that incorporated conflict (as a single construct) into their strategy models (19%), and only a few studies that combined conflict management strategies with specific conflict types (8%). This represents a significant limitation, and the nature and level of conflict may account for as much variance in outcomes as the conflict management process and strategies.

Studies related to conflict management strategies cover a variety of theoretical domains. Prior research suggests that various factors have a bearing on the use of any

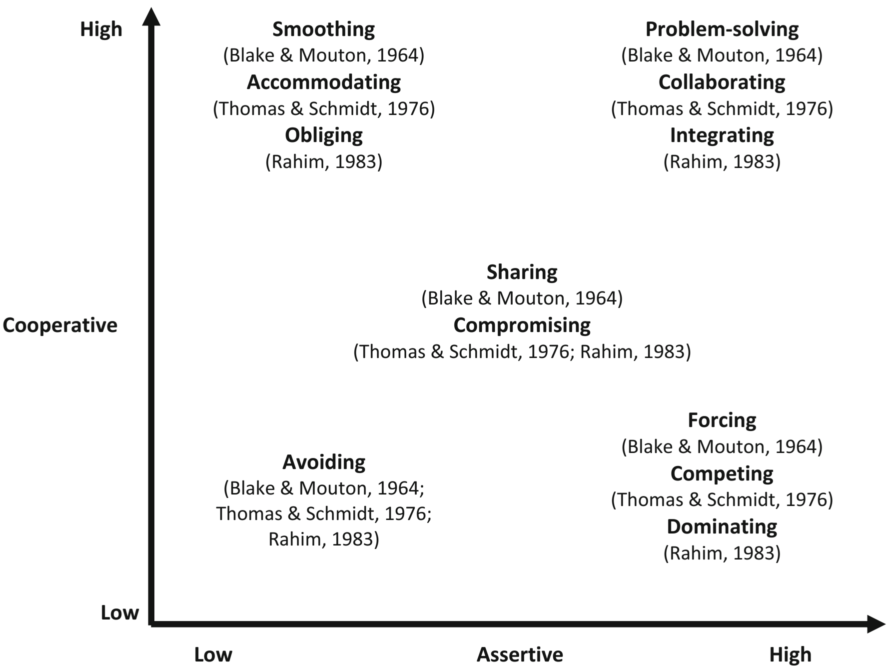

**Fig. 2** Conflict management strategies and some representative studies

given conflict strategy, with determinants including relational aspects such as power (Lam & Chin, 2004), fairness (Strutton et al., 1993), governance mechanisms (Shahzad et al., 2020), and project-related aspects such as product technological complexity (Lam & Chin, 2004).

Another stream of research explores the effectiveness of conflict management strategies through the investigation of their positive or negative outcomes (e.g., Ndubisi, 2011), particularly in terms of relationships. With the exception of a collaborative management strategy that was positively related to relationship outcomes in every such study, the results for other strategies were inconsistent or singular. For instance, while Bobot (2011) reported a negative relationship between *accommodation* and trust and commitment, Ndubisi (2011) demonstrated a positive relationship. Bobot (2011) also reported a negative relationship between a *forcing* strategy and trust and commitment.

Hypotheses concerning the effectiveness of an *avoiding* strategy were not supported in any of the associated studies, which might be explained by the fact that an avoidance strategy fails to address the root causes of a conflict, with the conflict problem persisting if parties choose to ignore it (Le Nguyen et al., 2016). Moreover, this strategy tends to undermine a relationship's goal of mutual gain and thus seems inconsistent with the norms and values advocated in supply chain relationships (Mohr & Spekman, 1994).

Other factors involved in the process of conflict management were investigated without testing the direct relationship of a conflict management strategy. For instance, Pulles and Loohuis (2020) examined how buyer openness and directness impact a supplier's willingness to adapt during a conflict episode.

Although this body of research has provided insights into conflict management, several limitations can be noted. First, few studies investigated the conditions (moderators) that might influence the relationship between a conflict management strategy and conflict outcomes. Similarly, few papers considered conflict types in conjunction with conflict management strategies, even though a small number of studies provided strong evidence of the necessity to combine them in order to understand conflict outcomes. For instance, Bobot (2011) found that when retailers use collaboration, rather than confrontation, the relationship between task conflict and relationship quality is amplified. One further limitation of existing studies is their cross-sectional nature, which largely overlooks changes in conflict intensity and the consequent changes required in conflict management. Finally, while a *strategic* approach to conflict can be useful, recent studies have criticized its applicability in practice and have advocated the use of a more fine-grained approach based on specific tactics oriented toward conflict resolution (Carton & Tewfik, 2016).

## 3.4 Conflict Outcomes

Researchers distinguish between the functional outcomes of conflict, which are the positive performance results that conflict generates, and dysfunctional ones, which are adverse effects on the performance of partners and are the more evident. Murfield et al. (2016) found that conflict is associated with the perception of lower levels of relationship quality on the part of suppliers, with a reduced motivation to accommodate buyers' request in the future. Other detrimental effects of conflict include relational betrayal (Leonidou et al., 2017), lack of cooperation and flexibility (Samaha et al., 2011), decreased relational investment (Luo et al., 2009), and reduced trust and commitment (Leonidou et al., 2006). Conversely, a few studies have shown that a certain degree of conflict between parties in a relationship may strengthen partner efforts toward value-creation, provide an opportunity to refine the ongoing relationship, and decrease switching intentions (Skarmeas, 2006).

Following analysis of conflict outcomes in the extant literature, two main observations can be made: (1) the predominance of conflict dysfunctionality; and (2) the focus on firm or dyadic outcomes. Empirical evidence about the benefits of conflict in supply chains is limited, and this could be explained by the conceptualization of the conflict construct. Researchers typically used a unidimensional conceptualization incorporating "conflict," "incompatibilities," and "tensions," which tend to be interpreted negatively by respondents (O'Neill et al., 2015). These conceptualizations are not only indicative of a degree of conflict between partners but also imply dysfunctional outcomes. Moreover, a one-dimensional conceptualization of conflict fails to capture the true effect of conflict on relationship outcomes (Ren et al., 2009). In addition, prior studies have very often theorized the conflict–outcome link as linear, and hence there has been little investigation of the mechanisms through which conflict gives rise to (dys)functional outcomes (mediating variables), and of the contextual factors that could moderate these relationships.

Lastly, conflict outcome measures considered in existing research focus largely on firm or dyadic outcomes. However, as previously discussed, supply chain relationships are nested in other relationships involving a variety of levels (e.g., individual, dyad, network), and conflict outcomes could very well pertain to interorganizational issues, and to other levels, lower and higher.

## 3.5 Other Observations from Prior Conflict Studies

Figure 3 summarizes the key research themes discussed in the preceding sections. We also derived three other observations from our analysis, concerning: (1) time insensitivity; (2) lack of cross-level analysis; and (3) focus on a single point of view.

First, the majority of supply chain conflict research is time-insensitive. This means that prior studies appear to consider conflict episodes to be invariant over time, particularly in their use of cross-sectional surveys. Despite the long-term nature of interorganizational relationships, and the importance of investigating conflict dynamics over time, few publications apply a longitudinal or a processual perspective to the subject. However, "if we want to acknowledge the dynamic nature of conflict, our theorization must allow for time and not ignore it" (Mikkelsen & Clegg, 2017: 9).

Second, supply chain conflicts are considered to be inherently cross-level phenomena (Lumineau et al., 2015). Therefore, a more comprehensive understanding of [conflict] dynamics may further add to our current understanding and mitigate

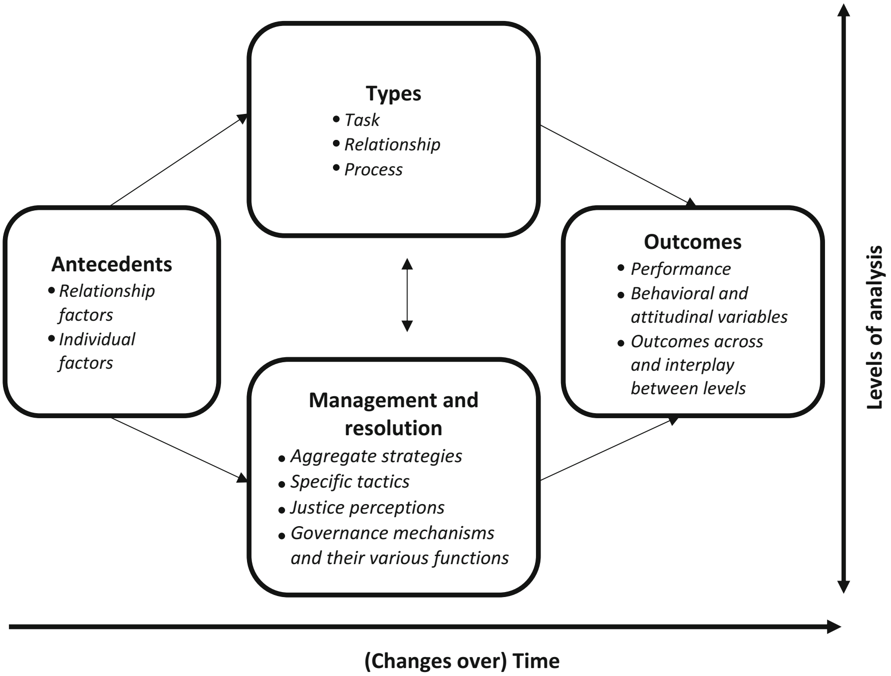

**Fig. 3** Conflict research – summary of key research themes and their relationships

against "cross-level fallacy" (Rousseau, 1985). However, prior studies have largely ignored more than one level of analysis when investigating relationship conflicts.

Third, supply chain relationships "undergo a continual balancing act where symmetry is not a typical state" (Hingley, 2001: 850). Yet, most of the empirical papers included in this review represent studies in which researchers examined the perspective of one focal company (80%) within a dyad and, to a far lesser extent, the perspective of both sides of a dyad (matched dyads 16%; unmatched dyads 4%). Typically, exchange partners exhibit asymmetry in their perceptions of various relational constructs such as trust, dependence, justice, and knowledge, and these asymmetries have been argued to be significant determinants of the behaviors of relationship partners (Gundlach & Cadotte, 1994).

## 4 Emerging Research Directions

Through our descriptive and thematic analyses, we identified and categorized gaps in terms of the major assumptions underlying conflict research in supply chain relationships. The following subsections outline the most significant areas in need of further investigation, setting the foundations for a research agenda to support advances in our understanding of and insight into such conflict. These emerging research directions are presented according to the same four key themes previously identified: (i) conflict conceptualization and the evolution and interplay of conflict types; (ii) conflict antecedents; (iii) conflict management and resolution; and (iv) conflict outcomes.

## 4.1 Conceptualization and the Evolution and Interplay of Conflict Types

Existing conflict research has demonstrated that conflict types are interrelated. However, their patterns of temporal change have not yet been investigated. One approach to investigating conflict type patterns is to use the concept of *velocity*. Velocity represents the rate and direction of change over a specified period of time. While the rate of change refers to the amount of change, the direction of change refers to its degree of continuity/discontinuity, where continuity reflects an extension of past change, and discontinuity represents a shift in direction (McCarthy et al., 2010).

Building on the multidimensional conceptualization of conflict and on the concept of velocity, each type of conflict could exhibit a particular velocity at a specific point in time. Accordingly, scholars could study the differences and relationships between *task* and *relationship conflict velocities*. Researchers could follow McCarthy et al. (2010) and study three dimensions of velocity: velocity homology – the similarity between the rate and direction of change of conflict types; velocity coupling – the extent to which the velocities of conflict types are causally connected; and velocity regimes – the various patterns that emerge from differences in velocity homology and velocity coupling.

Integrating a temporal perspective would enable understanding of periods of time in a conflict situation when task and relationship conflicts prevail and those when they do not occur simultaneously. These patterns could be linked to particular mechanisms throughout the conflict process. Examining changes in conflict types will advance our understanding of how these types emerge in supply chain relationships and how they evolve – either singularly, in parallel, or interactively – during the conflict episode. It would also inform conflict theory by explicating the direction and rate of change in conflict types in temporal terms, which could eventually lead to a better understanding of (dys)functional outcomes.

## 4.2 Conflict Antecedents

Human agency plays a major role in explaining idiosyncratic behaviors in buyer–supplier relationships, specifically in terms of developing trust, exercising power, reducing opportunism, and preventing relationship dissolution. For instance, Tangpong et al. (2010) found that the interaction of agent cooperativeness (an individual personality trait) and relationship norms (an organizational-level factor) mitigates opportunism in buyer–supplier relationships. These findings demonstrate that individuals at the interfaces of supply chain relationships can have an essential impact on conflict. A study by Cai et al. (2017) demonstrated how guanxi between boundary-spanners mitigates interorganizational conflict through the reciprocal exchange of favors between exchange partners. Besides the impacts of such interpersonal relationships, another fertile research opportunity relates to the characteristics of individuals and their impact on the conflict management process. For example, by applying personality trait theory (Weiss & Adler, 1984), conflict scholars could investigate how different traits or characteristics that explain behavioral difference among individuals – for example, cooperativeness, temporal orientation, attitude toward risk – interact with other interorganizational factors to mitigate or amplify conflict.

A further research opportunity is to theorize the role of the relationship network in dyadic conflict. For instance, in the context of multinational corporations (MNCs) with centralized purchasing and sales centers, relationships in a given country are embedded within the relationship between the regional offices. An interesting research avenue is therefore to investigate how multiple ties operate and constrain relationship management in general, and conflict in particular. Team conflict research has embraced such reasoning. For instance, Ren (2008) demonstrated that network bridging ties act as a buffer against conflict. Along similar lines, Li and Hambrick (2005) investigated international joint-venture groups and found that parent company affiliations can generate fault lines – dividing lines that can split a group into subgroups – that lead to relationship conflict. Apart from the embeddedness of relationships in a wider network, the nature of the product/service being procured – such as its complexity or servitization (Johnson et al., 2021) – may have an impact on how conflicts emerge and are subsequently managed.

Finally, relationships are influenced by the external environment, including institutional, political, economic, cultural, environmental, and historical contexts (Lumineau et al., 2015; Zhu & Sarkis, 2007). Therefore, the study of conflict between organizations should take into consideration the environment in which the relationship is embedded. An exemplary study by Bai et al. (2016) integrated the macro-level (institutional environment: legal enforceability and government support), with the interorganizational level (contract structure) to provide a more refined picture of the impact of contracts on conflict, thereby circumventing the single-level-of-analysis limitation. The researchers found that interorganizational control grounded in an output-based contract was negatively related to buyer–supplier conflict when legal enforceability was high but not when it was low. An extension of this research would consider other institutional characteristics, including stringency of environmental control, regulatory ambiguity, and regulatory interference (Luo et al., 2009) such as experienced in public–private partnerships and/or other relationships with public sector involvement. Relationships between public and private organizations may be particularly subject to conflict and coordination failures as a result of, for instance, divergent objectives, values, and aims (Roehrich et al., 2014; Caldwell et al., 2017; Kalra et al., 2021; Roehrich & Kivleniece, 2022).

In addition, future research might also explore how the characteristics of a competitive business environment, including complexity and dynamism, impact conflict in supply chain relationships.

### 4.3 Conflict Management and Resolution

As already discussed, conflict management and resolution has mainly been researched from the perspective of strategies. Although enlightening, this approach is limited in not offering tangible tactics that can be used in practice. To circumvent this limitation, researchers could employ a justice theory lens (Bouazzaoui et al., 2020). Four justice dimensions have been identified in the existing literature (Liu et al., 2012): *distributive* justice ensures that parties to an exchange receive benefits that are commensurate with their inputs into the relationship; *procedural* justice refers to the process of resource allocation and is evaluated on the basis of six rules covering consistency, bias-suppression, accuracy, correctability, representativeness, and ethicality; *interpersonal* justice refers to the interpersonal treatment received during the enactment of procedures; finally, *informational* justice is concerned with the accuracy and adequacy of the information provided. Future conflict studies could investigate how perceptions of justice drive the conflict management process – such as the efficacy of tactics associated with each justice dimension in relation to the intensity and type(s) of conflict.

Conflict management and resolution could also be investigated from a governance perspective. Scholars distinguish between relational (e.g., trust) and contractual mechanisms (Roehrich et al., 2020). While a few prior studies have started to investigate how both mechanisms prevent or trigger conflict – see the preceding subsection on *antecedents* – how governance mechanisms are used when conflict emerges requires further investigation. Shazad et al. (2020) found that contract completeness is positively associated with problem-solving and legalistic conflict management strategies and inversely related to a compromising strategy. Moreover, the investigators found that when trust exists between partnering organizations, they tend to adopt problem-solving and compromising strategies rather than legalistic ones. A further exploration of governance mechanisms could involve the use of contractual functions (coordination vs. control) when invoking or managing conflict.

Future conflict research should consider conflict episodes as being embedded in a relationship context. Accounting for the simultaneous existence of conflict and collaboration may bolster relationship ambivalence (e.g., Rees et al., 2013), impact how partners work out their disagreements, and, potentially, produce different ranges of conflict management strategies than those so far considered in the conflict management and resolution literature. For instance, an anticipation of future collaboration, foreshadowing the future, should create a disincentive to further escalate conflict, because it could substantially diminish access to partner resources and threaten the continuity of the exchange. In essence, the simultaneous experience of both the valence and ambivalence that emerges invites further investigation of the antecedents, forms, and consequences of conflict–collaboration coexistence.

The tendency in conflict management and resolution research has been to analyze conflict strategies at a single point in time. However, conflict management is characterized by an interaction process in which two parties react to one another, wherein individuals alter their behavior to adapt to the situation, to achieve the best possible outcomes. An effective management tactic might not emerge in the immediate aftermath of conflict (Olekalns et al., 2020), and when an initial tactic is unsuccessful in providing a fair response to conflict, an alternative is required.

Integrating a temporal perspective into the conflict management process will provide a more fine-grained understanding of precisely what happens in a conflict situation in terms of partnering parties' behaviors and conflict intensities. It will also allow evaluation of how these dynamics evolve within the buyer–supplier relationship during the conflict situation and over the relationship life cycle. This temporal evaluation should allow researchers to better concentrate on conflict management strategies and their utility within different organizational settings. Understanding conflict management as it occurs would draw a more complete picture of its trajectory by highlighting factors that contribute to conflict resolution or, in its absence, the migration of the relationship toward termination (Johnsen & Lacoste, 2016).

## 4.4 Conflict Outcomes

Conflict outcomes may pertain to various levels. While supply chain conflicts are often conceptualized at firm level, their management is an inherently individual-level activity with potential consequences for the managers involved. There is a research opportunity to investigate whether successful conflict management is prized by the executive and leads to professional advancement. Service recovery research has embraced this perspective in exploring the combination of recovery metrics with employee reward systems (Michel et al., 2009) and could provide a template for developing research propositions in the context of supply chain conflict.

Another research direction worth exploring is *conflict contagion* (Sinha et al., 2016). For instance, utilizing emotional contagion theory, organizational team researchers demonstrated that dyadic conflict spills over to the teams involved (Jehn et al., 2013). Given that supply chain relationships are embedded within a network of relationships, this *spillover* or *contagion* process is worthy of further investigation; for example, it would be interesting to investigate conflict contagion across tiers of the supply chain over time.

Debate around conflict outcomes has been ongoing for decades in intra- and interorganizational conflict research. Results among studies have been inconsistent – sometimes positive, sometimes negative. Researchers have incorporated a variety of factors to try and unpack this paradox, including conflict types and conflict management strategies. However, a universal conclusion has not been achieved. De Wit et al. (2012) suggested that one way to further decode conflict outcomes is to distinguish between those that are distal and those that are proximal. Proximal outcomes refer to short-term effects – that is, emergent states, which include the cognitive, motivational, and affective states of individuals. Distal outcomes refer to long-term effects and include performance outcomes such as innovation, productivity, and effectiveness. Consequently, one way to advance theory on conflict outcomes is to conduct studies through a temporal lens and assess both the short- and long-term effects of different conflict types. This approach could better explain how conflict disrupts relationship function and how partners might overcome conflict to improve relationship performance.

Supply chain partners can exhibit perceptual differences with regard to a conflict situation. Recent organizational studies have touched upon this aspect under the theme of *conflict about conflict* to describe situations where there is a perceptual incongruity among team members about the conflict episode (De Wit et al., 2012). Two types of asymmetries might emerge: (1) *within-conflict types*, wherein partners do not share the same perception of the *intensity* of task (relationship) conflict and (2) *across-conflict types*, wherein partners perceive the *nature* of the conflict differently – one party perceives the conflict to be task-related and the other perceives it to be relationship-related.

Past studies of conflict in supply chain relationships have often ignored such notions of asymmetry and assumed that buyers and suppliers work together on a task as if they had similar perceptions. Consequently, we still do not know much about the *perceptual convergence/divergence* regarding conflict within supply chain relationships. This line of study is particularly significant because researchers have argued that perceptual conflict asymmetry predicts conflict outcomes (Ma et al., 2018). Empirical results have demonstrated that asymmetrical task conflict perceptions decrease both performance and the creativity of interacting employees (Jehn et al., 2010).

Consequently, to advance research in conflicts in supply chain relationships, a rich area for research is that of understanding the antecedents of conflict asymmetry, particularly the factors that amplify, attenuate, or obfuscate incongruence in conflict perceptions among exchange partners. The investigation of asymmetry is also important because its existence may drive inappropriate and/or inefficient conflict management processes; for example, if a supplier perceives a conflict as task-related, it will deploy tactics targeted at managing the task, but if the buyer perceives the same conflict as relationship-based, it may perceive the supplier's actions as inappropriate, exacerbating the situation and making dysfunctional outcomes more likely.

In addition to understanding the antecedents of asymmetry, further research could explore the specific impacts of asymmetries on conflict outcomes, particularly in the context of different conflict types; for example, is high task-conflict asymmetry more or less related to specific outcomes than high relationship-conflict asymmetry? Another fertile research direction would involve study of the impact of asymmetry on the features (including intensity and duration) and outcomes of conflict, using a magnitude–symmetry approach (Liu et al., 2012). The study of asymmetries in relation to time is another promising area, specifically, the timing of their emergence, as well as their dynamics over time.

We have highlighted a rich future research agenda for scholars on the topic of conflict in supply chain relationships. Broadly taken, this research agenda covers many aspects, exploring the nature and dimensions of key constructs (the "what"), actors (the "who"), contextual and environmental conditions (the "where"), temporal or change-related dimensions (the "when"), and process or dynamic development aspects (the "how"). Table 1 provides a comprehensive overview of the opportunities we have identified to advance our understanding of and insights into conflict in supply chain relationships. Pursuing these various questions in future research will help address the fundamental gaps identified and discussed in this chapter.

## 5 Managerial Implications

Conflict resolution represents a core obligation and responsibility for managers. Moreover, supply chain scholars have indicated that supply chain agents spend 1 in every 6 h of their time dealing with conflict (Bobot, 2011). Therefore, it is critical that managers understand how and under what conditions conflict can emerge, escalate, and be resolved.

This chapter is useful to managers, because it reveals the complexities inherent in conflict and the variety of challenges that need to be addressed when it arises within supply chain relationships. The identified themes can help practitioners develop a fuller understanding of the various dimensions of conflict, the relevant topics (and issues) for practice, and how they may be addressed. For instance, the theme of conflict asymmetry is particularly useful to managers in enabling them to comprehend the perspective of the other party in relation to a conflict situation and thus work to ensure mutual understanding. Being on the same page in this way helps managers to deal better with conflict by crafting resolution approaches that are tailored to the specifics of the situation.

Managers should understand that a conflict with a buyer or supplier is embedded in the bigger picture of the relationship, and that conflict dynamics, resolutions, and outcomes can involve factors beyond the dyadic relationship. Moreover, understanding the dynamics of conflict resolution should enable managers to avoid negative inflection points in the resolution process, to assuage the severity of conflict impact on buyers and suppliers, and to build long-lasting collaborative relationships. Managers should not only understand different resolution strategies and tactics but also appreciate how these strategies are likely to work across a wide variety of conflict situations of differing intensities.

Much is already known about conflict management in the supply chain as a result of the many studies conducted to date. Organizations and managers should find this resource valuable to them as they develop training programs and effective implementations of some of the research observations. Given different contextual situations, organizations may wish to experiment with a variety of considerations and strategies. The antecedents of conflict are also significant in that managers

## 6 Conclusion

Although we have learned much about conflict in supply chain relationships, its various antecedents and outcomes, and its management and resolution, there remains much that needs further exploration if we are to advance our understanding and gain new insights. In this chapter, we have proposed multiple research areas that will help advance conflict theory, particularly as it pertains to conflict types, their antecedents, their outcomes, and the process of their management and resolution. We suggest specific research questions and position a detailed agenda for further research efforts. We hope this chapter both motivates such research and informs business practice so as to augment our understanding and management of conflict in supply chain relationships.

**Abstract**

Human resources (HR) are a fundamental asset and vital resource in achieving organizational goals and objectives. Appropriate understanding of the workforce and their management and strategic decision-making to train and enhance them are important considerations for supply chain firms. Through examining international human resource management (IHRM), the chapter discusses the international nature of supply chain firms and how this has not only brought increased competition for talent but added complexities and cultural dimensions that need to be appropriately managed. Strategic human resource management (SHRM), workforce analytics, and various environmental forces – customer demands, complexity in global supply chains, and uncertainty from global pandemics – and their impact on HRM are also discussed. Digital transformation of the supply chain has also meant that HRM practices may be disrupted. The chapter covers these various issues and the challenges facing supply chain firms along with identifying key trends in HR practice. It also highlights key managerial concerns for the future of HR and how these may affect supply chain firms.

## 1 Introduction and Background

The complex mix of cross-cultural global forces, the Fourth Industrial Revolution, and growing digital transformation all have a great impact on the workforce. To weather these uncertainties, requires strong leadership, analytical thinking, and employee development (Ozkan-Ozen & Kazancoglu, 2021; Srinivasan et al., 2020). These forces, alongside an ever-demanding customer base, have an inevitably effect human resources (HR) and, with it, the overall success of supply chains.

Industry 4.0 (I4.0) has created opportunities to embed and adopt impactful technologies that not only streamline supply chain management but provide avenues to create greater impact across different stakeholders. A subsequent product of this is the need to develop the workforce accordingly through aspects of training and upskilling as well as to focus upon creating stable human resource activities for the future. Middle and senior managers increasingly find themselves managing and leading in a global marketplace fraught with complexity, where dimensions such as cross-cultural knowledge, change management, and the digital disruption require new skillsets.

Constant global marketplace uncertainties and ever-changing end-user demands require supply chains to be both reactive and proactive to these dynamics. Often this response requires quick shifts, agility, and flexibility not only in systems and processes, but in HR realignment (Butcher, 2007). This realignment has meant companies need to not only hire the best but also train and develop their employees for this dynamic environment.

Supply chains have also been altered as part of digitalization and similarly, with the shift away from brick-and-mortar stores, toward rapid growth in e-commerce platforms. New skills are required to continue to keep up with shifting customer demands. COVID-19 and the pandemic have only accelerated this trend, where heightened demands for online shopping and home deliveries have placed new pressures on supply chain firms (Butt, 2021).

People are an important parameter across all dimensions of the supply chain, and therefore appropriate resourcing and investment is needed to develop this vital resource. Where tangible equipment can be purchased and repurposed, the nature of the workforce as an intangible resource requires different forms of development, nurturing, and management to achieve the best from employees and leaders within the field of supply chain.

## 2 What Is Human Resource Management?

Human resource management (HRM) is aligned to a number of people management functions – hiring, training, performance management, and ultimately rewarding employees (Cascio, 2016). The gamut of functions reflects the ever-changing needs and complexity in organizations and the global marketplace. The study of HRM is focused upon strategic methods to effectively drive the workforce to achieve organizational objectives. Armstrong and Taylor (2016) defines HRM as a strategic and coherent approach toward the management of people working within an organization, in order for them, individually or collectively, to contribute to the achievement of planned objectives. HRM is also broadly defined as the coordination and utilization of labor toward the production of goods and services, where the workforce is viewed as one of the organization's most valued asset (Armstrong & Taylor, 2016).

Cultural considerations, developmental opportunities, and current innovations in HR analytics are all within the remit of HRM. HRM or HR is a function within organizations created to maximize employee performance with the overarching aim to meet strategic organizational goals (Armstrong & Taylor, 2016).

HRM has great potential in impacting organizational performance, where strategic decision-making aligned to the deep understanding of the workforce can create synergies that support the delivery of business objectives (Ozkan-Ozen & Kazancoglu, 2021). The global presence of supply chain firms and the complex links across its networks only further highlight the vital importance of employees as a resource and the inherent difficulties in managing such an intangible asset. HRM's focus is not only to support the organization's strategic initiatives but to align the workforce and motivate it accordingly (Gowen & Tallon, 2003). It is also focused on positioning talent in the right place and right time, across the different departments and locations.

## 3 Human Resources Management Historical Foundations

HRM emerged as a product of the human relations movement in the early twentieth century. Academic research emerged from this movement by examining the strategic management and value of staff and the workforce. Early examination into this area was dominated by a highly procedural and transactional aspect with bureaucratic dimensions such as payroll, staff leave, and benefits taking overarching precedence. Early employee specialists were known as personnel managers, focusing on these transactional activities, delivering compliance but with little greater understanding on how they fit into the large organizational dimension or its objectives. Rotich (2015) indicates four major stages in the development of the HR perspective.

- *Stage one (1900–1940s) – Welfare stage*
  Early understanding of staffing, more greatly focused on personnel functions. These were performed by supervisors, line managers, and early functional specialists. The profession of HR or HRM was non-existent with early notions focused on scientific management theories and behavioral sciences in the management of staff.

- *Stage two (1940s–mid-1970s) – Welfare and administration stage*
  Here greater understanding and the development of more professional approaches to HR started to develop. A focus upon staff welfare was utilized both to ensure staff well-being but similarly to attract, retain, and ensure continued workforce productivity. Deeper understanding of behavioral and management theories leads organizations to invest in employing specialists to undertake early HR functions of recruitment, training, and staff welfare (Rotich, 2015). Strengthening of unions and industrial relations with expansions into work and pay conditions (McIlroy, 2009). Overall, this was a period of growth, although these functions were often still conducted in silos and in isolation away from the wider organizational objectives.

- *Stage three (mid-1970s–late 1990s) – HRM and SHRM*
  This stage saw increasing understanding and refinement in HR focused theories, leading to the creation of sources of knowledge dissemination aligned to research in HRM. Personnel management functions were developed toward HRM practices with greater understanding and integration with organizational strategies. A major shift was the view that staff were no longer employees but rather a vital human resource. Here, HR were viewed as a vital and important asset to their organizations that required careful management of their future potential, aligned to, and integrated with organizational management strategies, leading to birth of strategic human resource management (SHRM) in 1984 (Kaufman, 2015). A more holistic view of the different personnel functions was achieved, delivering on new thinking on the people-related aspects of managers. Control, management, and monitor of staff was now within the hands of line

managers, creating new dimensions of performance-related systems and pay and reward structures along with flexibility in recruitment approaches.

- *Stage four (Beyond 2000) – The present and future of human resource management*
  Continued globalization and the transformation of HR practices leading toward fundamental changes of workforce management and planning in the future. Employment and workplace conditions along with the value placed on staff as an asset to the organization are likely to continue to expand where global shifts in demographics, economic stability, compensation systems, and wealth will play a role (da Silva et al., 2022; Sivathanu & Pillai, 2018). The highly intertwined nature of global economies would also impact and add complexity in the management of HR, regulations, and cultural perspectives, bringing into the fore international human resource management (IHRM). Growing demands for a HR architecture focused on value development and maximization of workforce talents could alter resourcing priorities, with the potential move toward greater outsourcing or devolution of HR functions such as through consultants.

The evolutionary nature of HR has altered this traditional dimension toward more strategic aspects such as talent management and succession planning, alongside contemporary issues such as sustainability, ethics, and employment relations. Similarly, as both workforce size and complexity has expanded, a greater focus on metrics and analytics emerged, as managers and strategic decision-makers look to capitalize and plan on how best to enhance their human capital. Staff well-being, agility, and expertise alongside with the push toward Industry 4.0 set the scene for an interesting future of HRM (Srinivasan et al., 2020; Hohenstein et al., 2014). This shift toward HRM away from personnel management provided more insightful knowledge of HR, enriching the value of the workforce and the philosophies of its management (see Table 1).

## 4 The Value of HRM in Supply Chain Management

HRM in supply chain management can provide value as an intangible measure that can contribute to competitive advantage a network of organizations. Hohenstein et al. (2014) and Sweeney (2013) cite the importance of human capital across the interorganizational logistical concerns and how communication and the relationships between people help facilitate both efficiency and effectiveness. Supply chain network links are bolstered by the strength of these relationships, social engagement, and employee belonging all contributing to a human-centric environment (Myers et al., 2004; Nahapiet & Ghoshal, 1998).

Sweeney (2013) contends that supply chains essentially reflect a “human chain” where people are charged with managing its operations and overall effectiveness. Employees and people across the network of firms are part of the framework and connections across the supply chain. Similarly, with growing complexity in logistics,

**Table 1** Differences between personnel and human resource management

| | Personnel management | Human resource management |
|---|---|---|
| Timescales and approach | Short-term focus, transactional and end-goal orientated | Long-term ideology, strategic alignment, and collaborative |
| Staff viewpoint | Mechanistic, low value, compliance based | Welfarist, value-added concerns, loyalty and commitment based |
| Ideology | Bureaucratic, formalized, directional, centralized and highly structured/ defined. Cost focused | Dynamic, inclusive, holistic, integrated. Human resources as an asset |

Adapted from Vardarlıer (2016), Lundy 1994 and Ahammad (2017)

supply chain personnel need more skills, new abilities, and expertise to function in the global marketplace (Akbari et al., 2022a). New demands on HR practices and workplace planning along with its management have placed more importance on HRM concepts. Managers in supply chain firms are moving away from solely operational oversight toward more strategic understanding and management of global networks (Sweeney, 2013; Ellinger & Ellinger, 2014).

Growing international demand for goods and services has resulted in additional pressures on supply chain firms to maintain operational activities (Akbari, 2018) while being able to recruit appropriately skilled labor (Akbari et al., 2017). There are concerns with a lack of available talent within no short-term solution to remedy this need. The perfect storm of increasing demand for talent alongside a limited pool of upcoming workforce to match the skilled needs of the marketplace has further highlighted the value of HRM in supply chains.

Geographical and demographic disparities are also concerns – with aging populations, there is likely to be considerable shortages in skilled labor (Wolff et al., 2009). The contrasting scenarios affect supply chain firms, where logistics and operations in a global network require organizations to control for these predicaments. Overall, the limited pool of talent is a result of labor market shortages, economic uncertainties, and the lack of sufficiently skilled individuals (Cottrill, 2010).

Realizing the full HR potential provides great opportunities and challenges to supply chain managers in the highly specialized and technical knowledge required for global supply chain firms (Sweeney, 2013; Ellinger & Ellinger, 2014). Similarly, engaging, motivating, and retaining talent ensure knowledge management and knowledge transfer that benefits supply chain firms. Supply chain firms gain efficiency and effectiveness from a skilled and motivated workforce – these workforce characteristics also improve employee retention and loyalty.

The international perspective of logistics today has given rise to "boundaryless" careers where skills are no longer limited by geography, but rather talent is acquired globally (Carr et al., 2005; Goffnett et al., 2012). This situation has led to both a struggle to retain and increasing competition to attract, where pay has led to labor movement. Likewise, with labor costs being an important factor in organizational profitability, geographical clustering of cheap labor and niche expertise have added further complexity to workforce hiring and management. HR provides a vital conduit to ensure elements of the supply chain and the scattered workforce are not only aligned to organizational goals but effectively operate as one "boundaryless" entity.

## 5 Human Resource Development

Another vital aspect of HR is focused upon training and development. Ellinger and Ellinger (2014) discuss the shortage of supply chain managers with suitable expertise and broad skills set to address the growing changes and demands of the role. Given the impetus of cost savings but yet the enhanced role and relationships between customers and suppliers that supply chain managers have, the relative lack of human resource development (HRD) is a future worry (Sweeney, 2013).

Likewise, Aguinis and Kraiger (2009) support the use of training to improve performance, overall profitability, effectiveness, productivity, and revenue per employee. Sweeney (2013) states that human interactions permeate and influence supply chain practices – HRD would naturally lend itself to performance enhancement and achievement of these business goals. Hamlin and Stewart (2011) identified key HRD objectives to:

- Enhance the individual and group effectiveness and overall range of functions
- Support the effectiveness and performance of the organization
- Foster, nurture, and enhance skills, expertise, and competencies
- Provide avenues for enhancing HR and individual growth

Akbari et al. (2022b) suggest that there is also value in HRD early in employee careers, providing authentic learning experiences related to supply chain management to better adopt and reflect the needs of organizations. HRD has both a short-term and longer-term focus to ensure appropriately skilled workforce for now and the future. Rana and Sharma (2019) view three functional areas where development opportunities should be focused upon for the benefit of supply chain:

- Personal development (competencies)
- Team development (collaboration)
- Organizational development (structure and processes)

Given the dilemmas in cross-functional collaboration, the unstructured, informal communication channels used by HRD can support better organizational alignment of the workforce and thus, help remove restrictive silos that may exist within supply chain networks.

Cottrill (2010) suggests that several key skills are required for HRD focus in supply chains:

- Higher-order problem-solving – technical acumen to deal with operational issues alongside analytical mindsets and critical thinking toward solutions and the wider context of their role
- Managing ambiguity – in a world of constant uncertainty, be able to utilize experiences, learning, and expertise to apply knowledge toward complex and individualized situations
- Multi-level communicator – ability to communicate and work across organizational units (horizontally and vertically) and a network of firms with equally diverse business entities
- World citizen – manage, relate, and understand the multiple contexts, nations, and cultures that supply chain teams and firms span

## 6 International Human Resource Management

The global nature of supply chain firms aligns with the theoretical considerations of IHRM where a set of defined activities, functions, and processes are focused on facilitating and effecting the workforce operating in international organizations (Taylor et al., 1996). A similar definition by Schuler et al. (2002) considers the specific nature of multi-national enterprises (MNEs) where IHRM functions in the worldwide management of HR to ensure business success globally. Likewise, globalization has created a highly networked and interlinked international marketplace of manufacturers, retailers, and customers, where industries no longer solely focus on regional marketplaces, but essentially have widened their sourcing and targeted end users. The nature of business today is focused on internationalization and through the global procurement of materials and supplies has transformed how supply chain firms operate. This situation creates opportunity, but in an increasingly global marketplace, the challenges aligned to workforce management have followed suit. Here, IHRM's remit extends not only to the deeper understanding and needs of the business but also the globalized nature of the workforce and its inherent diversity.

Briscoe et al. (2009) examine this situation, by considering the multiple stakeholders alongside internal and external contexts that IHRM can impact as part of its global perspective. Supply chain firms, the network of organizations, and the varied workforce across its chain of activities and processes indicate complexity as well as multifaceted dimensions in managing the workforce. These notions are not lost in IHRM where multiple dimensions affect and have an impact upon workforce effectiveness.

González-Loureiro et al. (2014: p699), for instance, position "context, culture and institutions" as a vital IHRM focus, where there exist convergent and divergent patterns of practice. Here IHRM is focused on finding equilibrium and an appropriate balance between standardization of organizational practices while still retaining the local context. Ensuring both contexts co-exist provides a balanced approach to organizational operations, facilitates deeper understanding and harmony of the workforce, and breaks barriers, ultimately bridging geographical differences toward developing beneficial synergies.

Inevitably culture barriers and conflicts exist both in the differences due to geography but also due to varying stakeholders and institutions within the chain. The different approaches and cultural permutations that are unique to each provide interesting dimensions but also increase the chances of conflict. Thus, workforce management and getting the best out of the different institutions that form part of the supply chain are difficult and often a minefield, with many potential unintended consequences. As such through effective IHRM, the broader contexts which supply chain firms operate within are considered, managed, and where possible allowed to flourish to the benefit of the organizations.

## 7 Strategic HRM

While the various functions of HRM focus a range of activities aligned to the workforce, strategic human resource management (SHRM) involves wider understanding of the future needs of the business. SHRM seeks to develop or implement HR approaches to support long-term organizational goals. As such, SHRM plays a vital role in supporting the strategic decisions of organizations, seeking to mobilize, hire, or develop the current workforce and labor practices in its own strategic manner to contribute to these business objectives.

Wright and McMahan (1992) view SHRM as a pattern of planned workforce deployments to enable an organization to achieve its goals. This perspective is aligned to the view that the pattern of movement of HR is not constant, but rather reflects dynamism and change that develops over time into steady states that supports the achievement of the organization’s strategic aims.

González-Loureiro et al. (2014) suggest that SHRM is equally aligned to IHRM. Globalization, the impact of international events on strategic decision-making, and the global positions of talented individuals support joint SHRM and IHRM consideration. For SHRM to be successful in attracting and retaining the most talented employees, supply chain firms need to be ready to actively compete at international levels and cope with the challenge of talent management. Overcoming competitors and being able to manage the global challenges of IHRM will support the development of strategic capabilities within the organization.

Lepak and Shaw’s (2008) literature review of SHRM in North America reflects these issues, where SHRM can be examined from a macro-level perspective aligned to a business unit or firm. Similarly, and in accord with supply chain firms, SHRM views HR as an interdependent system of practices and pattern of activities where different aspects of the business are associated and linked together. Here, the different parties as well as patterns of HR practice are both associated in strategic movements and equally impacted by environmental forces, where strategic decision-making encompasses the different parties and dimensions that affect organizational success. SHRM seeks to facilitate performance outcomes, impacting the practices and interdependent units toward positive achievements.

Given the vital importance of HR in firms, strong strategic alignment between HR practices and business goals ensures not only sufficient critical mass in the workforce today but also for the future. SHRM is particularly dominant in large global firms and MNEs, where a scattered workforce requires appropriate management and development and where growth strategies are aligned with the need to recruit talent (De Cieri & Dowling, 2006). These are similar factors affecting supply chain firms, where the scattered nature of organizations and employees across the network need not only operational alignment, but strategic oversight to ensure efficiency and effectiveness and that the HR function is successfully embedded.

The term alignment is often used with SHRM and the strategic decisions of the organization. The closer and more aptly attuned both are, the more likely organizational goals are achieved. A sufficiently motivated and critical workforce mass for now and the future provides both opportunities and resources strategic organizational success. SHRM and strategic organizational goals alignment also supports agility and flexibility, allowing the organization to pivot and change quickly, as well as anticipate and respond to customer demands. These aspects are similarly true in supply chain firms. In particular, benefits of SHRM include (SHRM, 2022):

- Addressing key issues in a timely manner to avoid crises
- Promoting employee productivity and overall organizational success
- Providing a sense of direction to positively affect how work gets done
- Keeping employees focused on organizational goals
- Providing a strategic focus to guide training and development initiatives
- Giving leaders tools to help focus and implement their strategic initiatives

In order to ensure organizational success, there is a need to have definitive understanding of the current capacities and future growth of the workforce to ensure critical mass of qualified employees. Recruiting, training, and developing effective HR require extensive strategic planning and foresight. These strategic planning processes need to assess current organizational situations and then create a vision of a future state, with clarity and robust metrics to monitor its successful transitions. A SHRM organizational structure begins with four critical questions that assess the current and future desired HR position and then identifying the best approach to achieve this (SHRM, 2022):

- Where are we now? (Assess the current situation.)
- Where do we want to be? (Envision and articulate a desired future.)
- How do we get there? (Formulate and implement a strategy and strategic objectives.)
- How will we know if we are on track toward our intended destination? (Establish a mechanism to evaluate progress.)

The greatest mistake by firms is in not sufficiently understanding difficulties in future workforce planning, underestimating the resourcing needs of the process, cross-cultural dimensions, and understanding organizational requirements to be effective for the future (Vance & Paik, 2015). Strategic planning requires understanding of an organization's vision including how to manage the global nature of supply chain firms, the diversity of its workforce, and the often-transient nature of employees. Global events such as the COVID-19 pandemic, geo-political tensions, and the uncertain nature of economic factors have had a major impact on strategic decision-making and with it the movement of people, labor markets, and socio-demographic changes of the workplace.

To address these uncertainties and to navigate past these numerous hurdles, the Society for HRM (2022) indicates that a result-oriented focus, broadly considering different metrics and assessments, can aid in:

- Correctly assessing staffing and skills needs for now and the future
- Ensuring competitive pay and reward structures
- Performance management and rewards that continue to drive motivation
- Understanding competitors approaches to recruitment and HR
- Developing regulations, training, and practices that uphold and support the organization's values

SHRM remains a great challenge as well as an opportunity for businesses. Given the complex nature of supply chain firms and their multidimensional geographical operations, effective SHRM has the potential to strengthen strategic decision-making and create synergies across HR functions for the benefit for all stakeholders within the network. Its alignment to organizational strategic decision-making provides avenues for long-term proactive planning, which, given the increasingly turbulent external environment, will assist in ensuring the achievement of business goals.

## 8 Electronic Human Resources Management and Human Resources Metrics

Early definitions of e-HRM or electronic-HRM identify the use of web technology in the implementation of HRM strategies, approaches, and regulations within organizations, networking two or more individuals in the performance of HR-focused activities (Marler & Fisher, 2013). These basic notions of e-HRM are technological aspects merged with people management or of the HR function within organizations. They provided a simple but forward-looking trend of information management applied to the workforce (Marler & Fisher, 2013). These early definitions and approaches have led toward more advance analytical tools which not only visualize but can help provide predictions of the workforce.

E-HRM provides opportunities to support the increasingly complex landscape of workforce management and development. The approach provides useful computerized tools for supply chain managers to not only manage but plan and identify long-term needs in staffing.

Analytical tools and dashboards allow managers to examine the landscape of their workforce, visualizing demographic datasets as well as identifying capacity requirements and training needs to effectively forecast for the future. Succession planning, an aging workforce, recruitment metrics, and training resources provide additional datasets and information sources to make informed decisions. Nonetheless, with all these extensions to HR practices, workforce challenges are still one of the major challenges in the implementation of I4.0.

In addition to e-HRM, the terms HR metrics and workforce analytics have been used to describe the advances in HR and the adoption of technological tools to support staffing decisions. Huselid (2018: p680) defines workforce analytics as the processes involved with “understanding, quantifying, managing, and improving the role of talent in the execution of strategy and the creation of value.” Huselid (2018) also suggests that the term in this case is not to focus only on metrics but rather analytics where deeper understanding of how best to manage and improve functions that are critical for business success are undertaken.

Rana and Sharma (2019) view workforce analytics as a form of Smart Human Resources 4.0 (SHR4.0), highlighting several benefits in its use. Not only do the approaches help streamline and create more efficient HR processes but it enables futureproofing of talent. They indicate that the main benefits of SHR4.0 are in:

- Drawing, developing, and retaining new age talent
- Efficient and quicker HR operations
- Leaner HR departments

As the network of supply chain firms grows and with the increasingly complexities and demands of the marketplace, the HR dimension is overwhelmed with significantly larger volumes of data. The range of HR policies, across a global workforce and the increasing number of organizations, mean that supply chain firms are often drowned in paperwork and data. There is a vital need to turn these data sources into valuable forms of information, where strategic, operational, and forward-looking decisions can be made effectively.

Expanding these concerns across different links within supply chain firms provides specific targeted data as well as more holistic understanding of the entire chain. Such information allows informed decision-making through real-time data sharing, aligning strategic initiatives with workforce planning.

Expansions, mergers, and acquisitions or reacting to changes in the marketplace can each be undertaken in a more agile manner through e-HRM and HR analytics. Staff deployment and shortfalls are more effectively managed and their performance better charted, monitored, and understood. The quality of information is vital in making robust and impactful decisions for the workforce and organizational strategy (Marler & Fisher, 2013). Here the various transactions of supply chain firms and their workforce are not only mapped but charted to provide meaningful data to steer, provide progress reports, and even accelerate successful initiatives. The value of human capital is effectively monitored and maximized.

HR analytics are forward looking, utilizing previously collected data to help forecast and support future decisions, driving organizational strategies and objectives in a performance-based manner aligned with staff career orientation (Huselid, 2018). The nature of HR is intangible, and this resource is often hard to fill; forward-looking plans provide strong avenues to ensuring business success. The value of interventions can also be measured and identified using HR analytics. It can help identify causes of workforce deficiencies as well as how well investment in training and development supports employee performance.

Real-time mapping and monitoring of employee performance provide a multi-faceted, data-driven approach to people management and interventions (Edwards & Edwards, 2019). Similarly, deeper understanding of demographics and workforce segments also provides avenues to develop specific and targeted initiatives that can help enhance their performance. These deeper insights into employee motivations and drivers can help shape training, rewards, and approaches to retention across the supply chain.

Career trajectory, age, and years of experience or seniority (Edwards & Edwards, 2019) can each be monitored with employees deployed in different guises across the supply chain. Here, a senior mentor or a young energetic employee placed in the most appropriate organizational setting can be supported to develop and rewarded accordingly with each success. Indeed, these differences similarly exist in the different firms within the supply chain which can also be addressed in a positive manner, affording targeted interventions that are not only appropriate but impactful.

These many datasets and deeper understanding of the workforce through HR analytics allow greater strategic oversight and a more informed understanding of SHRM opportunities (Edwards & Edwards, 2019; Marler & Fisher, 2013). Given the expansive nature of supply chain firms, HR analytics provides a scientific and evidence-based approach to ensuring the diverse workforce is appropriately managed.

## 9 Current Issues and Challenges in Human Resource Management in Supply Chains

There are also several major challenges facing HRM in supply chains, namely, in the form of change and performance management, the global competition for talent, and the inherent difficulties in recruitment and retention. Addressing these issues effectively is necessary for long-term success of this integration.

### 9.1 Change Management

The changing demands of the consumer market and supply chain have added new pressures on supply chain firms with aspects of last mile delivery, online shopping, and shorter lag and delivery times. This has meant that HR dimensions such as training and skills development, which are very costly, have not always been at the forefront of logistical considerations. There is a need to do more with less with a similar ideology applied to staffing and the workforce – requiring a change in thought and practice. While automation and technology are vital for these new demands, Machado et al. (2019) highlight the often lack of readiness, robust training, or dissemination of knowledge.

Similarly, with technology there is also a vital need for knowledge management and information dissemination – to aid in change management of organizations in the supply chain. How can these information sets be utilized and applied within an international setting or within a network of supply chain firms? The notion of IHRM and how the knowledge can be shared, passed, and spread across the workforce is a major challenge facing supply chain firms. With larger and more complex networks, how to embed as well as disseminate knowledge across the various departments, firms, and staff is a growing concern for HRM. Indeed, Collins et al. (2010) suggest that the ability to create systems and approaches where knowledge management and supply chains align and intersect with HRM practices, would create significant synergies and competitive advantage as part of a highly integrated workforce.

Change is inevitable within supply chains. While systems, infrastructure, and investments in tangible assets can be altered, change management approaches need to be more carefully and appropriately managed in the workforce. Aspects of culture, organizational dynamics, and management styles are less straightforward to alter. In an industry of constant change, change can be hard to manifest in the workforce, requiring active understanding and planning along with the multidimensional aspects of staffing. Here IHRM supporting the cultural and the multifaceted dimensions of the workforce as well as longer-term planning through SHRM is needed to deal with such challenges.

## 9.2 Performance Management of HR

Performance management remains an important and difficult process in organizations, let alone supply chain firms. Identifying the appropriate measurements and tools in the management of people is not an easy task – especially given the many tangible and intangible measures that exist. Appropriate use of intangible resources – not just tangible ones – are more likely to yield a competitive advantage (Hitt et al., 2001).

With increasing complexity and diversity in the workforce along with the cultural and international dimensions of IHRM, supply chain managers need to be able to motivate and deliver actionable outcomes. HRM needs to set suitable foundations for appropriate metrics to be achieved by employees, with appropriate rewards and penalties. That being said, international variations and different cultures within the supply chain may not support uniform approaches but rather result in various tiers of HR policies.

White (2010) suggests instances where overmanagement or micro-managing hinders highly talented people or teams. This type of management would hinder employee performance rather than foster innovative solutions and performance endeavors. This is the quandary faced by supply chain managers and by HR departments, where traditional notions of quality and performance are appropriate for transaction and repetitive tasks, but less so for processes that involve innovation and problem-solving. Yet, highly skilled individuals – emblematic of many supply chain workers – do not align to such metrics. While there are inherent benefits across the supply chain such as sharing of best practice, cross fertilization of values and knowledge and working practices, performance management attuned to traditional frameworks of excellence, and key performance indicators can be restrictive. The challenge for HR managers and supply chain firms is to find a balance in autonomy and empowerment while still being able to manage and achieve the strategic desires of the organization.

### 9.3 Global and Cross-Cultural Competition for Employees

Global supply chain firms and their international operations often compete for the same global talent pool. In order to have the best employees, they do not limit their recruitment and selection processes to a regional pool, but rather focus on hiring the best and brightest globally. As a product of this and given increasing demands and pressures on supply chains, there has been fierce competition between firms in a talent selection pool that is decreasing in size and options. As such, increasingly HRM plays a vital aspect in business operations. This competition is likewise heightened when focusing upon specialist roles where high-potential employees are in short supply. Chambers et al. (1998) view this as the *war for talents*.

Similarly, managerial abilities and technical expertise alone no longer suffice with recruitment and retention along with globalized skills increasingly asked of managers. These skills are even more important when viewed from a middle to senior management perspective. Reflecting the dynamics of global supply chains, senior employees are required to have a widened understanding of operations, culture, and their workers in order to effectively compete and manage in an increasingly diverse world. Harvey et al. (2013) suggest that the need to manage and understand global interorganizational relationships, requires supply chain managers to have deeper awareness of international marketplaces and with it a multi-faceted mindset. Harvey and Richey (2001) highlight the importance of global orientation, where deeper understanding of cultural differences and diversity, along with respect, are required knowledge sets for supply chain managers. Open-mindedness is a vital and important element for the benefit of the global operations. Given how these skills and traits promote compatibility and better working relationships, it is important that managers either have or are trained to have better understanding of how best to build bridges rather than become hurdles themselves (Fawcett et al., 2008).

Hiring managers with the knowledge and deep understanding of these multiple dimensions adds difficulties to an already limited talent pool. This further reflects the difficulties and restrictive recruitment patterns that exist in supply chain firms at all levels of the workforce. Given the many arguments on the value of HR on the overall performance and successes of the firm, the lack of available expertise alongside the increasingly complex international patterns of work practice suggests a growing concern in the area of logistics and supply chains.

### 9.4 Recruitment and Retention

Globally, firms are increasingly considering multiple avenues to recruit given the highly competitive environment in talent recruitment. The nature of global supply chain firms means that this competition is not only enhanced but retention of their best and brightest talent is also of great concern. Ultimately, the aim of any recruiter is to identify the largest pool of appropriately qualified and experienced employees that possess all skills, knowledge, and acumen required to perform the role well (Hohenstein et al., 2014).

Unfortunately, the pool of talent in supply chains is not only limited, but the niche expertise of certain roles mean that many companies are often seeking to hire from a small pool of potential employees. This has led to recruitment packages and compensation that include a multitude of incentives, to entice, retain, and also display the value of their worth. The global marketplace also adds further complexity, with remuneration packages being adapted to match the local or international parameters of the role. Aligned to employee retention and loyalty is the aspect of incentivization, where performance is recognized and appropriately rewarded and other aspects of the employee lifestyle – such as work-life balance and non-financial benefits – are applied. The difficulty for HR managers and supply chain firms is creating clear targets while balancing rewards structures where "internal and system-wide performance metrics used for managing supply chain performance would need to be identified and associated with specific offices or roles" and indeed at different levels (Menon, 2012: p783).

## 10 Emergent Concerns and Future Directions

A number of prevalent HR trends (see Fig. 1) can have either a positive or negative impact on the performance of the workforce and on organizational success in the short- and long-term future. In particular, the changing trends in the world of work and ways of working along with technological shifts have an impact on the future directions of people management in supply chains.

### 10.1 Workforce Transformation and Analytics

Workforce transformation and analytics is a growing concern. The ever-changing external environment which supply chain firms operate within requires an agile workforce that is constantly being developed to fit changing demands. Workforce transformation takes the guise of training and development, along with sufficient upskilling to *futureproofing* employees across the supply chain.

Transformation in the form of ensuring sufficient knowledge and the appropriate upgrading of workplace tools are vital to enable the workforce to deal with highly disruptive environments. For example, Eaton et al. (2021) highlight – as part of the

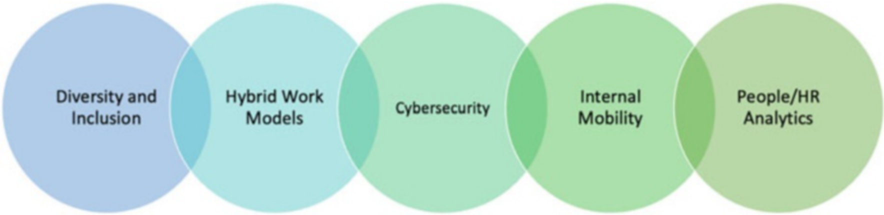

**Fig. 1** HR trends for the future

digital revolution and as a product of the impact of COVID-19 – competencies and capabilities in the digital and virtual sphere are part of the reimagined workplace. Being able to upskill employees and transform the workplace not only limits lost productivity but facilitates seamless transitions into different modes of working – offline, online, and hybrid.

The future workforce is influenced by transformational ideologies. Stepwise improvements can help build on basic knowledge toward expansion of expertise to ultimately staff taking a leading role in the new workplace. COVID-19 pandemic's push toward new ways of working toward a new normal is indicative of the need for workforce transformation. For supply chain employees and managers, the pandemic has brought about change toward a *new normal* (Akbari et al., 2022a). Adaptability, resilience, and a *creator's mindset* where employees have the agency to shape the organization are also skills necessary in this new environment (Eaton et al., 2021). Any organization that can transition their workforce to deal with adversity and then set about delivering new approaches to the workplace successfully can benefit supply chain performance and competitive advantage.

The market for talented individuals is becoming much more efficient. The workforce is becoming more expensive, easily lost to competitors, with the ability to recover from movements in staff becoming more difficult. Workforce quality as a differentiator, while valuable, is becoming much more difficult to maintain. Workforce quality requires HR strategies, investment, and managerial knowledge to recruit and retain employees for the future. This situation has meant that supply chain managers are facing increasing pressures and accountability upon them as their role in the management of staff toward organization strategies (Collins et al., 2010).

This situation has also meant investment in middle to senior level managers in the form of training, stakeholder, and change management approaches, along with HRM, to become more agile, efficient, and effective in talent management. There needs to be greater understanding of the subsequent results of the actions of supply chain managers, especially given the globalized purview (González-Loureiro et al., 2014). Human activities are the main compound that helps promote or hinder changes in organizations (Bui et al., 2020); therefore in order for technological implementations to be successful, HR needs to be supported to achieve operational excellence and deliver workforce transformation practices to suit the needs of the business.

## 10.2 Diversity and Inclusivity

A key future HR focus is an inclusive workforce recognizing diversity, equality, and equity as a vital for ensuring the brightest talent is recruited and retained (da Silva et al., 2022). HR is also responsible for developing strategies that help support these goals. Gupta et al. (2022) suggest that while much has been done to ensure equity and diversity, significantly more work and understanding is required. Gender inequality and wage disparities, harassment, ageism, and discrimination in the workplace further suggest that there are still avenues for improvement (Barrientos et al., 2019; Gupta et al., 2022). Supply chain firms with the amount of diversity they exhibit with their global presence will need to abide by the legal frameworks in the countries that they operate in, but similarly have an opportunity to go further. These issues are barely addressed within a supply chain context.

A diverse workforce brings with it new knowledge and creativity, where differences are not only celebrated but where their specific characteristics can become a strength (Carrero et al., 2019). Different approaches to problem-solving, the sharing of wisdom, and the knowledge that comes with such experiences are a vital asset for the complex world that supply chain firms operate within.

## 10.3 Hybrid Work

The global pandemic has forced almost all organizations to look at new approaches to work practices. The shift to virtual online approaches in the workplace and work practices has accelerated the digital transformation. Appropriate resourcing and training of staff often lagged behind investments in digital infrastructure.

Haleem et al. (2020) highlight the mental toil and stresses that the workforce underwent during the lockdown periods of COVID-19 and the uncertain nature of global, regional, and local travel restrictions. Alonso et al. (2021) discuss how improvisation, bricolage, and the appropriate mindset were part of the drive toward organizational survival in such unprecedented difficulties. While the world is emerging from these difficulties, a positive outcome has been greater engagement with the notion of hybrid and remote working arrangements (Deloitte, 2021).

The complementary approaches of offline and online – hybrid – mediums of staff work and human-automation mix have changed the way organizations function. Supply chain firms and partnerships are not immune to these changes and, similarly, have embraced such approaches. Virtual meetings across continents and time zones, and reducing cost implications while still ensuring productivity, are seen as issues and goals. Hybrid work patterns have also allowed staff to have better work-life balances, performing well at work while still being able to complete their personal or home-life obligations. Similarly, investments in infrastructure toward automation of non-human-dependent tasks have also helped ensure safety and well-being while still protecting the jobs of employees (Korinek and Stiglitz, 2021). The question is whether face-to-face meetings across organizations in the future will be online or otherwise.

In essence – and aligned to employee well-being – these hybrid workplace changes have provided an additional option for supply chain managers to support their staff and free up wasted time (often due to commuting) while still ensuring a chain of command and monitoring that continues to develop on organizational objectives. Nonetheless, Korinek and Stiglitz (2021) suggest that while automation and technology may reduce the reliance on labor, real benefit exists through the human element of interactions, where post-pandemic ideologies of technology should seek to complement rather than exacerbate the fear of being made redundant.

## 10.4 Cybersecurity

With I4.0 and the digital transformation of people analytics and HR metrics, there is also a need to ensure appropriate awareness of cybersecurity, privacy, and confidentiality. Increasingly, there are negative forces seeking to profit from lapses in digital security, and with HR departments retaining much sensitive and private information, protective measures are required.

Indeed, Kache and Seuring (2017) indicate that companies only have limited or fragmented understanding of the true concerns around data security. Cybersecurity training along with awareness of digital vulnerabilities will need to be undertaken not only with the workforce but with senior managers to ensure that appropriate safety measures are put in place and adhered to (Mullet et al., 2021). Mullet et al. (2021) suggest that employee awareness is a priority for HR as staff are often the root of successful cyberattacks, due to a lack of knowledge, negligence, malicious behavior, or process failures. They also advocate that HR departments themselves need to address cybersecurity concerns and their own awareness as they are often the main conduit for employees in the organization.

## 10.5 Staff Mobility

The strain of recruitment has led organizations to consider more creative solutions toward staffing. Not only are a growing number of firms investing in appropriate training and upskilling of staff members, but they are also similarly examining the opportunity for different forms of staff mobility (Roy et al., 2019; Deloitte, 2021). Mobility is aligned to several common facets (see Fig. 2) such as a desire for talent development or the need to create a line of succession for longer-term organizational stability. Once utilized as a form of staff development or to enhance motivation, increasingly, internal mobility or job rotation and transfers of staff have been undertaken as a means to fill gaps in knowledge and expertise across organizational units or levels (Mahato et al., 2021). The internal transfer also allows for the sharing of best practice alongside different forms of management to the benefit of the organization as a whole.

The opportunity to gain new knowledge and attempt differentiated work and avenues toward promotion has also enhanced staff morale, retention, collaboration,

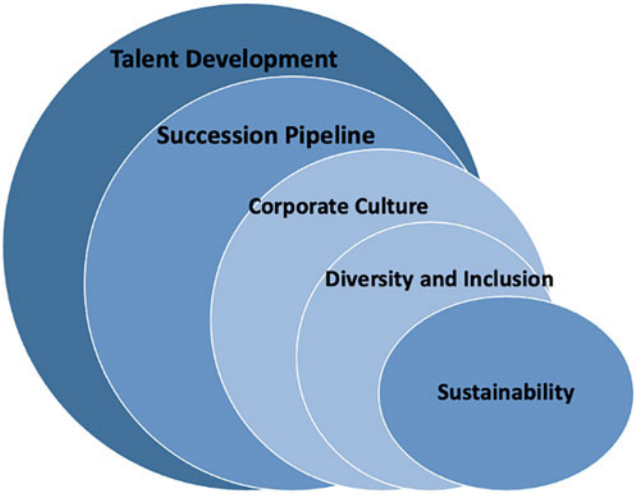

**Fig. 2** Main reasons for staff mobility

and performance (Roy et al., 2019; Deloitte, 2021). The protection of both critical sectors of work through appropriate staff redeployment and active retention of key talent within the organization, during increasingly competitive environment of recruitment, has meant that internal mobility is not only a current trend but will be one for the short- and medium-term future of HR.

## 11 Managerial Implications

Ultimately, these changing dimensions together with growing uncertainty in the global economies have meant that managers increasingly require a strategic human resource focus and wider understanding of workforce implications. The digital transformation, shrinking of the talent pool, and changes in the workforce demographics add more complexity in managerial decision-making.

### 11.1 Leading During the Digital Transformation

Co-evolution in multi-national corporations (MNCs) (Madhok & Liu, 2006) suggests that the different firms within a supply chain form a network of valuable entities, where talent within each of organization has the potential to affect the entire supply chain. Therefore, supply chain entities have the potential to affect processes, culture, and context of the entire supply chain positively or negatively. Indeed, the institutional approach within the country of origin and its destinations can have a significant impact on its success. Managerially, these issues suggest that effective management and deeper cultural understanding of the institution and its origins may provide a means to effect other aspects of the supply chain. There needs to be a phased approach to workforce transformation for a digital world, with a myriad of different approaches and factors that position the human at the center of these changes (see Fig. 3).

In line with culture and organizational paradigms, supply chain managers will need to take heed of these changes and the potential opportunities and ramifications that emerge or impact the workforce, where people-driven technologies, digital leadership, and futureproofing skills (Catlin et al., 2017; Deloitte, 2017) are vital considerations. Motivational incentives and approaches to HRM will need to be considered against the diverse demands of the workforce, where clashes and differences exist not only through culture but against different levels, units, and stakeholders within the supply chain.

While I4.0 progresses, changing in infrastructure, technology, and innovation need to be matched with developments and expertise in the workforce. There is still much unknown about the future implementation of I4.0 technologies. The range of technologies – including augmented reality, Internet of Things, robotics, blockchain, and multiple others (Akbari & Hopkins, 2022) – suggest that there is still much skilling required in the modern workforce; these technological characteristics cover multiple firms in a supply chain. The digital disruption provides opportunity but similarly uncertainty, where systems thinking is important against the dynamic structure of I4.0. Staff are often fearful of their role or lack of it as technologies become more permeated. Aligned with the turbulent nature of the marketplace, stakeholders, and the environment which supply chain firms operate, workforce agility and a resilient mindset are particularly important.

Adobor and McMullen (2018) highlight the importance of instilling an employee mindset focused upon embracing change, growth, adaptability, and resilience. How can middle and senior supply chain managers instill these intangibles but highly valuable traits to their highly disparate and global workforce? The investment in training and workforce technologies has sought to address this issue. There is also a

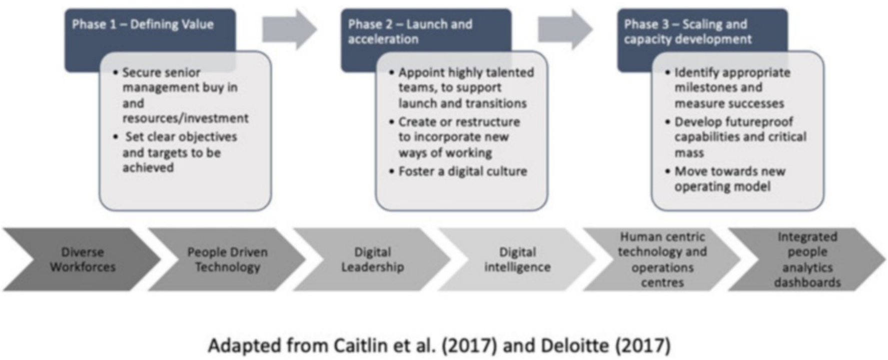

**Fig. 3** Digital transformation of the workforce

growing focus on staff well-being with a community of practice and employee-centered policies. Under the global pandemic, welfare support and virtual social and networking events facilitated social interactions to bolster a sense of community and display genuine organization care for their staff.

Digital transformation means closer relationships through different mediums of communication, human contact, and engagement are still vital in managing, motivating, and synergizing the workforce, particularly informal mechanisms, which facilitate exchanges such as in negotiations.

## 11.2 Strain on Workforce Supply

Even with the numerous remedies and approaches being put in place, the shortage of talent will continue to affect supply chains. A shortage of qualified professionals along with the lag time in training new staff (Horváth & Szabó 2019) will mean that supply chain firms will continue to suffer what we call a talent shortage *tsunami* (Cottrill, 2010; Ellinger & Ellinger, 2014). Even with a pipeline of young and driven employees, the evolutionary nature of the supply chain and its constantly advancing demands upon a set of skills and competencies add to these difficulties. The globe-spanning perspective, knowledge set, and wide-ranging expertise required of supply chain professionals highlight the importance of HRM, in both its international and strategic value.

## 11.3 Accountability and Deeper Understanding of the Role of Talent

The workforce is critical for firm success of firms. Fuller et al. (2019) suggest that this notion is not always universally shared nor are activities to recognize this situation fully developed or aware. While SHRM provides a holistic perspective of HRM, the wider understanding of how one firm supports another in the chain is not always clear to line managers. As such, there needs to be more expansive training and clearer understanding of the role of talent in driving and achieving business processes and objectives.

The diverse skillset of supply chain employees needs to be matched with appropriate line management expertise. HR analytics and metrics provide data and potential sources of information; thus appropriate training and understanding of complex points of information is vital for managers and organizations to make informed decisions (Ozkan-Ozen & Kazancoglu, 2021). Managers need to identify useful data and similarly the right questions concerning data and information needs across the supply chain.

Huselid (2018) indicate that generic analytics and datasets are unlikely to afford strong insight or any value in developing the workforce as a source of competitive advantage. Huselid (2018) also suggests that with increasing demands, and increasing rewards, managers need to be held accountable to their direct reports and the talent that they oversee. The workforce is often one of the largest costs and financial outgoing, where mismanagement and faulty decision-making have greater ramifications upon the organization's bottom line and success. Additionally, upskilling managers for the future is challenging. Senior managers have not only been developing their skills for many years but similarly through professional training, work experience, and performance evaluation opportunities. It is rare to see truly low performers at this level where enhancements are likely to lead to only minimum percentage gains in their individual performance. There are challenges to identify suitable training for further development. Therefore, investment in different levels of the organization and across firms in the supply chain will need to identify where the most impact on performance can be had through enhancing their workforce skills.

### 11.4 A Multi-Generational Workforce

In industries that require both technical expertise and experience, a multi-generational workforce is vital in creating a mix of talent that encompasses these two distinct needs. A multi-generational workforce provides a safety net where more experience and senior staff would mentor or coach junior or younger employees.

The transfer of knowledge and sharing of best practice, along with detailed insights into workplace operations, ensures a competitive advantage. Likewise, organizations that embed such dimensions in their workforce benefit from the innovation and creativity that is emergent from more junior colleagues who may not be stuck in operational paradigms, although they will need to support their employees' adaptation or re-adaptation (Matt et al., 2020). The notion that new energy, thinking and innovation is supported through the wisdom of previous and multi-generational knowledge. In supply chains where technical know-how and operational real-world knowledge intersect, a multi-generational workforce provides a strong bridge between these two needs.

## 12 Summary and Conclusion

It is clear that staff, personnel, employees, and the workforce, no matter which term is being utilized, are an important and vital resource for successful and competitive organizations. Supply chain firms are no different – but the relationships among the chain of firms must be aware of the various HR concerns both within and external to their organizations.

With global networks and span of organizational units across the chain, even more priority and value are to be placed upon the workforce. The need for this deep strategic oversight and operationalization over continents brings prominence to

SHRM and IHRM. If the workforce is a vital asset, then it needs to be mobilized appropriately to match the goals of the business, developing a strategic perspective and plan for how staffing and the workforce can be recruited, trained, or retained to achieve these. IHRM provides a global perspective, examining the cultural dimensions and the cross-cultural hurdles that can impact the global operations of supply chain firms.

The challenges of digital transformation and I4.0 provide both opportunity and risk where the demanded skills of the workforce require constant upskilling along with a digital mindset. The increasing use of HR metrics and analytics, which utilises technology to support HRM decision-making, planning, and strategies for the short- and long-term future, has an enormous potential to assist supply chain managers accordingly.

Yet while people are a strength, by their very nature, their management, development, and motivations are complex and difficult to fully manage. Huselid (2018) suggests that impact of talent on business success is "both longitudinal and multivariate" where long-term ideologies, plans, and considerations on the workforce will take time to fully realize their full potential.

HRM and the management of the workforce are not linear but rather multidimensional, with culture, demographics, geography, and a multitude of other variables at work. This complexity is similarly a part of the beauty of people, spurring innovation, agility, and adaptability. These are all powerful and vital traits within the workforce of the future. Given the upcoming challenges that are yet to be seen or identified by supply chain firms (and others) realizing the full potential of the workforce would help not only remedy these hurdles but provide opportunities to deliver on organizational goals.

# Putting Worker Safety at the Heart of Supply Chain Management

Mark Pagell, Mary Parkinson, and Anthony Veltri

## Contents

**Abstract**

The emphasis of this chapter is on humanizing supply chain management in a manner that benefits workers and the supply chain. This chapter is based on two suppositions with foundations in the extant literature. First, that the safety of the workers in the supply chain is foundational to supply chain management outcomes. Second, that operational or supply chain managers should be responsible for safety management systems. We interrogate these suppositions considering that the COVID pandemic has arguably changed the role of both supply chain and safety management. This likely has significant implications for the relationship between supply chain management and safety, especially when it comes to managing risks. We delve into these recent events and suggest that safety managers might be best placed to manage supply chains risks. Finally, the chapter

## 1 Introduction

Workers are strangely absent from a great deal of supply chain management thinking, practice, and research. And when they do appear it is often as an undifferentiated human resource where interchangeable "workers" are optimally scheduled to minimize costs or maximize flexibility (e.g., Hashemi-Petroodi et al., 2021). This optimization is almost always done from the perspective of the focal firm doing the scheduling, and with little thought to how this might impact workers' performance at work – let alone their wider well-being.

This perspective is strange on multiple levels. First, the roots of the supply chain discipline are in scientific management, where maximizing the productivity of individual operational workers was the initial concern. Second, one of the foundations of supply chain management thinking and practice for most of the last 30 years has been the centrality of lean management principles, as best practice in managing supply chain operations. A key component of lean is empowering workers to help in continuously improving the supply chain, an activity that only occurs if workers are well trained, highly valued, and hence willing and able to accumulate and use firm- or supply chain–specific knowledge. Finally, focusing on worker knowledge and motivation ties well into the human capital perspective on how firms and supply chains create and maintain competitive advantage via the firm-specific knowledge created by their workforce.

Hence, the well-being, training, and motivation of workers should be central to optimizing supply chain outcomes. Workers whose well-being is either not prioritized or worse, or whose well-being is at risk, will not be motivated to engage in any activities that benefit the supply chain (e.g., Das et al., 2008). In other words, to leverage the human capital in a supply chain, worker well-being needs to be protected. And, while workers who are safe may still be in precarious jobs (e.g., Wiengarten et al., 2021) or have low levels of well-being; workers who are not safe in their jobs cannot have the needed levels of well-being. This chapter's first supposition is that the safety of the workers in the supply chain is foundational to supply chain management.

Safety is defined as the degree of certainty that operations are in a state where potential risks, dangers, and loss have been avoided or controlled in a proper manner to ensure freedom from loss, and that this state is maintained (Black et al., 2011). Workers who are safe are protected from physical and psychological harm. In most firms, safety is managed by a stand-alone safety function, as part of a larger environment, health, and safety (or compliance) function, or via the human resources department (e.g., Veltri et al., 2013). This structure seems intuitive, but it is misguided. One of the core principals of lean or other continuous improvement-based operational management systems is that quality is everyone's job; quality cannot be managed by a quality department alone. The same holds for safety, which needs to be an operational or supply chain responsibility, not managed as a separate safety silo or sidecar (Pagell et al., 2015; Hasle et al., 2021).

Safety needs to be an operational or supply chain responsibility for multiple reasons. First, the workers most likely to suffer physical harm at work are operational workers in the supply chain (Pagell et al., 2020). Supply chain decisions about what rules are or are not enforced, how fast work needs to be done, how workspaces are maintained, and so on can be significant determinants of worker safety. Equally, safety management systems are mainly designed to protect workers from hazards as they do their jobs, once more with a focus on supply chain workers (Pagell et al., 2015; Shevchenko et al., 2018). Even in firms where the supply chain and safety are managed separately, the safety management system is designed to help control hazards in supply chain operations.

Finally, the best practices associated with safety management include a preventative focus, continuous improvement, and valuing human capital; effectively the same best practices associated with supply chain excellence via lean and other excellence programs (e.g., Pagell et al., 2015). The management of safety focuses on the same workers in the same supply chain system and often uses the same "best practices" as managing the supply chain (e.g., Pagell et al., 2014a; Shevchenko et al., 2018). Hence, it has been argued safety should be an operational responsibility (e.g., Pagell et al., 2014b, 2015). Our second supposition is that operational or supply chain managers should be responsible for safety management systems.

These two suppositions result from much of our own previous work and guide the chapter. However, the theory and empirical evidence linking safety to supply chain management does not always agree with these predictions. While there is no debate over supply chain workers being the focus of safety management systems and therefore the interdependency between safety and supply chain management systems and outcomes, there is s still a robust debate as to the nature of these relationships (e.g., Neri et al., 2022). Equally, much of this debate is based on research conducted prior to the COVID pandemic. The pandemic has arguably changed the roles of both supply chain and safety managers and hence likely has significant implications for the relationship between supply chain management and safety especially when it comes to managing risks.

The rest of the chapter first reviews the debate on the nature of the interdependency between supply chain management and safety, then discusses recent events that suggest that safety managers might be best placed to manage supply chains risks, and finally concludes with a future research agenda so that workers are no longer absent from supply chain management thinking, practice, and research.

## 2 Relationship Between Supply Chain Worker Safety and Operational and Firm Performance

The relationship between worker safety and operational and supply chain performance has been hotly debated (e.g., Tompa et al., 2016; Neri et al., 2022). The managerial literature typically posits that the well-being of the workforce goes hand in hand with operational performance (e.g., Das et al., 2008; Pagell et al., 2014a, 2015). In other words, safe workers are associated with more profitable and operationally effective supply chains. This proposition is typically grounded in the idea of building human capital (Becker, 1993; Hatch & Dyer, 2004).

Human capital theory draws from the resource-based view of the firm, and economic theory, to propose that workers' capacities to learn constitute value for the firm comparable to other firm resources (Becker, 1993). These capacities offer unique, long-term competitive advantage because they are thought to be intangible, firm specific, and socially complex (Hatch & Dyer, 2004). According to this view, firms which care for their employees' well-being cultivate human capital – leading to greater productivity. For example, one study indicated employees whose health was improved by corporate wellness programs increased their productivity by about 10% (Gubler et al., 2018).

Workplace accidents negatively impact both the victims of accidents, and those who work alongside them (Gonçalves et al., 2008) – destroying human capital. Occupational illnesses and injuries are associated with decreased job satisfaction and distrust of management (Barling et al., 2003). Therefore, it is no surprise that perceptions of a poor safety climate in the workplace lead to increased stress and decreased psychological well-being (Griffin & Curcuruto, 2016), and greater turnover intention when combined with occupational illnesses and injuries (McCaughey et al., 2013). Workers that perceive their working environment as safe do not need to self-protect, will be more motivated in their work, and more invested in improving operational performance (Das et al., 2008). In this way, worker safety is paramount to the development of unique capabilities offering long-term competitive advantage (Das et al., 2008).

Poor worker safety can also impose financial and reputational costs on supply chains. Accidents with days away from work have direct costs for firms, such as lost work time and some workers compensation costs (Landsbergis, 2003). Further, stakeholder theory suggests that firms need to satisfy a broad range of stakeholders, beyond just shareholders (Freeman & Reed, 1983). This approach suggests that employees, customers, and a wide range of interested parties influence firm strategy and outcomes. Poor workplace safety may be perceived negatively by stakeholders including employees, customers, and financial analysts, harming the supply chain's reputation. Examples of this effect are that environmental incidents (Lo et al., 2018) and supply chain controversies (Tamayo-Torres et al., 2019) have been associated with a decline in firm value.

In closer relation to the safety context, there is some evidence within the ESG (environmental, social, and governance) literature that also supports this argument. Some studies find a positive relationship between social sustainability performance (of which worker safety is just a part) and firm financial performance (e.g., Waddock & Graves, 1997; Aouadi & Marsat, 2018). Similarly, increased levels of coverage from financial analysts have been found to reduce workplace accidents – presumably because of increased monitoring from stakeholders (Bradley et al., 2021).

The goals of occupational health and safety regulation are also aligned with this argument. Occupational health and safety regulation is designed to keep workers safe and offer competitive advantage to firms which do so (Purse & Dorrian, 2011; Occupational Safety and Health Administration (OSHA), 2019). Firms which do not comply with regulation are sanctioned by the regulator, leading to direct costs, but also censure from stakeholders (e.g., Johnson, 2020). Studies of the effectiveness of OSHA inspections have mostly focused on whether the inspections lead to improved workplace safety (e.g., Johnson et al., 2020). However, Levine et al. (2012) found that inspections improve safety for workers, without negatively impacting firm survival. In a similar vein, the introduction of legislation to protect workers, such as the modern slavery act in the UK, may offer competitive advantage to firms which have a history of socially responsible sourcing (Cousins et al., 2020).

Moreover, the processes and challenges of keeping workers safe could make firms more effective and innovative. First, the limitations imposed by well-designed regulation could drive improvements to operational efficiency and innovation. Porter and Van der Linde (1995) proposed that environmental regulation leads to firms becoming more effective and innovative. Their argument rests on the idea that necessity is the mother of invention; when firms need to become more efficient to comply with environmental regulation, they will innovate to do so. This argument would just as well apply to worker safety. If firms need to keep workers safe to survive, then they will find ways of doing so, and in the process improve their operational capabilities.
