Dedication

Dedication of this small work on Second Edition of Textbook of Pathology to the great scientists Juan Rosai (Rosai and Ackerman's Surgical Pathology), and Christopher DM Fletcher (Diagnostic Histopathology of Tumors), whose profound contribution to the field of Pathology has touched countless lives. Their legacy will continue to inspire and educate the generation of pathologists.

Dedication to our worthy teachers for teaching basics of pathology and excellence in medicine, Esteemed Faculty Members, and promising undergraduate and postgraduate Medical Students for enduring inspiration and encouragement, while working on Second Edition of Textbook of Pathology.

Dr Vinay Kamal
Dr Anubhav
Dr Vigyat

Dedication

Second Edition of Textbook of Pathology is dedicated to our family, who inspired, supported, encouraged, and patiently endured long hours of inattention and hearing from me during the creation of this final project to achieve an academic career. But for their understanding, it would be difficult to get away with the disproportionate amount of time that such projects consume.

Dr Mrs Manita Kamal

Section I: General Pathology

1. Cellular Pathology and Biology of Aging 3
Cell Unit of Life and Introduction to Pathology 4
Cellular Response to Stress and Harmful Stimuli 16
Cellular Adaptations 20
Cell Injury and Cell Death: Overview 34
Pathophysiology of Cell Injury, Morphologic Patterns and Outcome of Necrosis 45
Regulated Cell Death (RCD) 68
Apoptosis 80
Intracellular Accumulation of Substances 96
Extracellular Accumulation of Substances 109
Pathologic Calcification 113
Cellular Biology of Aging 116

2. Inflammation and Tissue Repair 127
Inflammation 128
Acute Inflammation 131
Chronic Inflammation 180
Tissue Repair 202

3. Hemodynamic Disorders, Thrombosis, Embolism and Shock 239
Edema and Effusions 239
Hyperemia and Congestion 247
Hemostasis 251
Hemorrhagic Disorders 268
Thrombosis 272
Embolism 289
Infarction 292
Shock 297

4. Immunopathology 305
Immune System 306
Innate Immune Response 315
Adaptive Immune Response 331
Vaccines and Immunization 376
Immunodeficiency Diseases 380
Hypersensitivity Reactions 404
Immunologic Tolerance 432
Autoimmune Diseases 440
Tissue/Organ Transplantation immunology 450
Amyloidosis 460

5. Genetic Disorders 471
Human Genome 472

Genetics and Molecular Biology 479
The Nucleus and DNA Replication 487
Gene Expression, Transcription, Translation and Protein Folding 492
DNA Damage and Repair Systems 503
Chromosomal Disorders 511
Human Gene Structure and Mutations 526
Mendelian (Monogenic) Disorders (Single-Gene Mutation) 536
Balanced Polymorphism 564
Polygenic and Multifactorial Disorders 567
Genetic Polymorphism 568
Disorders of Sexual Differentiation 570
Genome Imprinting Disorders 572
Diagnostic Approach of Genetic Disorders 573

6. Neoplasia 581

Neoplasia: General Considerations 582
Nomenclature and Classification of Tumors 602
Features used to Distinguish Benign Tumors from Malignant Tumors 651
Normal Processes that Regulate Cells and Inhibit Carcinogenesis 662
Epidemiology of Cancer 675
Preferential Routes of Metastasis of Tumors 698
Molecular Basis of Cancer 708
Carcinogenic Agents: Cellular Interaction and Carcinogenesis 779
Role of Oncogenes and Tumor Suppressor Genes in Carcinogenesis 809
Clinical Oncology 896
Molecular Diagnostics in Oncology 939

7. Nutritional and Infectious Diseases 963

Nutritional Disorders 964
Vitamins Deficiency 970
Bacterial Infections 984
Viral Infections 1014
Fungal Diseases 1034
Parasitic Infestations 1042

Section II: Hematology

8. Red Blood Cell Disorders 1055

Hematopoiesis 1056
Red Blood Cell, Hemoglobin, Anticoagulants and Anemias 1079
Iron Metabolism and Iron Deficiency Anemia 1090
Megaloblastic Anemia, Folic Acid and Vitamin B_{12} Deficiency 1097
Red Blood Cells Destruction and Classification of Hemolytic Anemia 1108
Hereditary Spherocytosis, Ovalocytosis and Stomatocytosis: RBC Membrane Defects 1115
Thalassemias 1120
Sickle Cell Disorders and Other Hemoglobinopathies 1129
Glucose-6-Phosphate Dehydrogenase Deficiency and Pyruvate Kinase Deficiency Disorders 1137
Immune-mediated Hemolytic Anemia 1140
Paroxysmal Nocturnal Hemoglobinuria 1146
Red Blood Cell Fragmentation Syndromes 1148
Diagnostic Approach of Hemolytic Anemia 1150
Bone Marrow Failure Syndromes 1154

9. White Blood Cell Disorders 1163

Leukopoiesis, Quantitative and Qualitative Disorders of Leukocytes 1164
Leukemias 1179
Acute Lymphoblastic Leukemia 1193
Acute Myelogenous Leukemia 1211
Myelodysplastic Syndromes 1238
Myelodysplastic/Myeloproliferative Neoplasms 1249
Chronic Myeloproliferative Neoplasms 1255
Chronic Lymphoproliferative Neoplasms 1300
Multiple Myeloma and Other Monoclonal Gammopathies 1313
Mononuclear Phagocytic System Disorders 1339
Hematopoietic Stem Cell Transplantation 1347

10. Platelet Disorders and Bleeding Diathesis 1355

Hemostasis 1355
Platelet Disorders 1366
Quantitative Platelet Disorders 1371
Qualitative Inherited Platelet Disorders 1375
Qualitative Acquired Platelet Disorders 1378
Diagnostic Approach and Treatment of Platelet Disorders 1380
Secondary Thrombocytosis and Essential Thrombocythemia 1381
Bleeding Associated with Vascular Disorders 1383

11. Coagulation Disorders and Diagnostic Approach of Bleeding Diathesis 1387

Blood Coagulation System 1387
Inherited Coagulation System Disorders 1392
Acquired Coagulation System Disorders 1403
Thrombophilia (Hypercoagulable State) 1407
Bleeding Diathesis: Diagnostic Approach 1410

12. Blood Banking and Transfusion Practices 1421
ABO and Hh Blood Group Systems 1422
Rh Blood Group System 1431
Bombay Phenotype and Para-Bombay Phenotype 1432
Other Blood Group Systems 1433
Blood Collection, Processing and Storage 1434
Blood Transfusion and Blood Component Therapy 1452
Adverse Blood Transfusion Reactions 1459
Blood Grouping 1466
Blood Cross-matching (Compatibility) Test 1470

13. Lymph Node, Spleen and Thymus Gland Disorders 1473
Disorders of Lymph Node 1474
Hodgkin's Disease 1488
Non-Hodgkin's Lymphomas 1500
Disorders of Spleen 1531
Disorders of Thymus Gland 1536

Preface to the Second Edition

Rudolph Virchow (1821–1902) is the father of 'Cellular Pathology' in terms of the dysfunction of cells. Many pathologic observations are being published in the Textbooks and Journals by great authors across world. Their outstanding contribution in the field of medical practice and education has been a great source of inspiration.

Second Edition of *Textbook of Pathology*, extensively revised, updated with recent developments as needed and amended as per the 'Competency-Based Medical Education Curriculum' is intended to provide undergraduate and postgraduate medical students with clear, and concise presentation of the pathologic basis of the human disorders.

The field of pathology emerged from the application of the scientific method to study of nature, etiology, molecular mechanism, and interrelated anatomical, functional, clinical manifestations and consequences of human diseases through examination of blood and tissue specimens.

The description of the human disorders evolved over time from gross morphology observation to the histologic examination of the diseased tissues based on the specific immunohistochemical stains, immunofluorescence microscopy, immunophenotyping, fluorescence *in situ* hybridization, molecular diagnostics and more recently to ultrastructural analysis of the disease with the advent of electron microscope. Thus, molecular pathology as a discipline represents the complementary intersection of medicine and basic science discoveries and the basis for the development of new strategies for disease prevention.

Textbook of Pathology has three sections: (i) General Pathology, (ii) Hematology including chapter on 'Blood Banking and Transfusion Practices', and (iii) Systemic Pathology and Molecular Diagnostics. This textbook contains approximately 1901 high-resolution colored figures and 1719 tables, which would complement quick revision of the chapters. It provides comprehensive coverage of etiology, molecular pathogenesis of human disorders, clinical manifestations, clinicopathological correlation and diagnostic approach.

Pathology is the fundamental bridging discipline linking the basic biomedical sciences to clinical medicine. Therefore, our basic aim is for our undergraduate as well as postgraduate medical students to use their knowledge of pathology to become scientifically grounded effective clinicians and healthcare professionals.

We hope that *Textbook of Pathology* will accomplish its purpose of providing medical students and researchers with in-depth coverage of molecular basis of a wide spectrum of human disorders in the context of understanding the molecular mechanisms of the disease and advancing the theory and practice of molecular medicine.

Preface to the First Edition

The study of pathology is essential for safe clinical practice. In modern era, tremendous growth is in progress in diagnostic pathology with recent advances in molecular methods, cytogenetics and immunohistochemistry. Rapidly changing hematology needs integration of guidelines and diagnostic criteria of hematological disorders.

I joined India's premier institution in Department of Pathology, Maulana Azad Medical College, New Delhi. I puzzled over the fact that students admitted of very high caliber still had problems in grasping the teaching material. I interacted with students and eminent faculty members across country. I discussed problems faced by the students in reproducing text. I analyzed their inputs and then started working on Textbook of Pathology in 2007. The primary aim of this book is to discuss complex topics in a 'straightforward', clear and organized manner.

All the chapters have been shared with the eminent teachers and young budding students across country. Their valuable opinion on various aspects has been taken positively during drafting of the chapters to meet the need of the young generation of pathologists. Each chapter focuses on the essentials necessary to build a broad fundamentals backed up with numerous colored figures, gross morphology, and light microscopy photographs, tables and flow diagrams.

I trust, you will enjoy reading this book. I have a great deal of time and energy ensuring easy grasp and retaining the topics. I am inviting your comments, valuable suggestions and criticism.

Foreword

It gives me great pleasure to write the Foreword for this wonderful Second Edition of *Textbook of Pathology* written by Dr Vinay Kamal, Ex-Director Professor of Pathology, Maulana Azad Medical College, New Delhi. His vast teaching experience for undergraduate and postgraduate medical students is well-known in the corridors in the premier institution, where medical students have interacted to seek the advice.

I have gone through many chapters of this *Textbook of Pathology* and find his unique teaching experience that has been successfully transformed into wonderful method of writing and communication. Textbook abounds with revised WHO classification of neoplasms, approximately 1901 high-resolution colored figures and 1719 tables, and molecular diagnostics that explain everything in simple language—always the best way to teach.

I have no doubt that this *Textbook of Pathology* will help undergraduate and postgraduate medical students to achieve a better understanding and create strong foundation for medical education.

Dr Venkateswaran K Iyer
Senior Professor and Head
Department of Pathology
All India Institute of Medical Sciences
New Delhi

Foreword

It is with great enthusiasm, I look forward to Second Edition of *Textbook of Pathology* written by Dr Vinay Kamal, Ex-Director Professor, Maulana Azad Medical College, New Delhi. The first edition of Textbook by him received a brilliant response from the undergraduate as well as postgraduate medical students throughout the country.

Bringing out the Second Edition of *Textbook of Pathology* within a short span of time, speaks volumes about the passion of the author to constantly update the information and share it in a presentable format to his medical students.

All the chapters of textbook have been updated with incorporation of revised WHO classification of neoplasms, new information on immunohistochemistry and molecular alterations. *Textbook of Pathology* contains around 1901 high-resolution colored figures and 1719 tables.

Enormous effort has been put in recreating the tables with additional content, making the flowcharts and illustrations as well as adding new and clear microphotographs. All these are the unique feature of this textbook to enable the medical students to learn pathology in context of etiology and pathogenesis making it a valuable source for gaining knowledge to build a solid foundation in pathology for the future doctors.

I hope the undergraduate and postgraduate medical students and teachers will benefit from the Second Edition of *Textbook of Pathology*.

Dr Nita Khurana
Director Professor and Head
Department of Pathology
Maulana Azad Medical College
New Delhi

Foreword

It is my privilege to write the Foreword to Second Edition of *Textbook of Pathology* written by Dr Vinay Kamal, Ex-Director Professor of Pathology, Maulana Azad Medical College, New Delhi, releasing in 2025. The author of this *Textbook of Pathology* has more than three-decade long teaching experience at one of the country's finest and reputed medical institutes.

I had an opportunity to read the preprint of few topics, and I am immensely pleased to express that the latest Second Edition of *Textbook of Pathology* is in accordance with the 'Competency Based Medical Education Curriculum' recommended by the National Medical Commission.

Textbook of Pathology contains around 1901 high-resolution colored figures and 1719 tables, which makes the understanding of concepts very lucid for the undergraduate and postgraduate medical students.

Textbook of Pathology includes important topics like tissue fixatives, microscopy, frozen/cryostat section techniques, and histochemical stains which covers the much-needed practical aspects of the subject. Topics like recent updates, molecular pathogenesis, revised WHO classification of neoplasms, immunohistochemistry, hematology, flow cytometry, cytogenetic study, fluorescence *in situ* hybridization (FISH), enzyme-linked immunosorbent assay (ELISA), DNA sequencing, tissue microarray (TMA), high-performance liquid chromatography (HPLC), and electrophoresis have been presented in such a way that it would help the postgraduate medical students, teaching faculty and fellow practitioners also. Updated content on 'Blood Transfusion' being included, makes the *Textbook of Pathology* a very comprehensive read.

I wish Dr Vinay Kamal for all the success and hope that this latest Second Edition of *Textbook of Pathology* will receive wide acceptance by the undergraduate and postgraduate medical students and faculty members.

Dr Srivani N
Senior Professor and Head
Department of Pathology
Government Medical College
Nalgonda, Telangana

Foreword

I have known Dr Vinay Kamal, Ex-Director Professor, Department of Pathology, Maulana Azad Medical College, New Delhi for more than two decades, and have been interacting with him on various issues of pathology. The importance of pathology can be summarized in a quote by Great Sir Boyd "*As good is your pathology, so good will be your clinical practice*."

The undaunted association with teaching undergraduate and postgraduate medical students for more than three decades as faculty at Maulana Azad Medical College, New Delhi, distinguishes him from many other academicians by way of his integrated innovative approach to make the subject of pathology simple, and easy with clinico-pathological correlation of various diseases for medical students.

It is my proud privilege to write the Foreword to Second Edition of *Textbook of Pathology* written by Dr Vinay Kamal, which consists of the essence of his teaching experience in academics. This textbook contains revised WHO classification of neoplasms, molecular pathogenesis, and chapters on Blood Banking and Transfusion Practices and Cellular–Molecular Diagnostic Techniques in Clinical Practice. This textbook contains numerous high-resolution colored figures, tabulated data analysis, and methodology for diagnosis of various diseases accurately.

I am confident that this *Textbook of Pathology* by Dr Vinay Kamal will open a whole new avenue for all students in world of pathology, which will go long away in making undergraduate as well as postgraduate medical students to understand pathology and its relevance, and significance in medicine. I wish great success of new release Second Edition of *Textbook of Pathology*.

Dr Hansa Goswami
Senior Professor and Head
Department of Pathology
BJ Medical College
Ahmedabad, Gujarat

Foreword

I joined MAMC as a postgraduate student. He connects with the students and takes keen interest in their learning and tries to help them out in all their personal and academic problems. A similar helpful attitude towards staff with all help extended to them has been his nature at all times.

It is my distinct pleasure and honour to endorse the Second Edition of *Textbook of Pathology* written by Dr Vinay Kamal, Ex-Director Professor, Department of Pathology, Maulana Azad Medical College, New Delhi, whom I have known for some years and interacted on various issues of pathology.

Second Edition of *Textbook of Pathology* written by Dr Vinay Kamal covers various aspects of the subject in a systematic manner. The content in this textbook is in simple language, which makes it reader-friendly and is well illustrated by numerous gross and microscopic pictures.

The beauty of the *Textbook of Pathology* is that it highlights the clinicopathological correlation, diagnostic approach and includes revised WHO classification of neoplasms. Various illustrations in the form of figures, tables, flow diagrams and incorporation of basics of immunohistochemistry and molecular biology in this textbook provide a comprehensive understanding to medical students in pathology. The key highlights in every section of textbook also helps in quick revision of the topics.

I congratulate Dr Vinay Kamal for his dedication and immense passion of teaching medical students, who will enjoy reading this textbook and understand the basic concepts along with updated knowledge in the subject.

Dr Ranjana Solanki
Senior Professor
Department of Pathology
SMS Medical College
Jaipur, Rajasthan

Foreword

A seasonal writer—is the most appropriate word for Dr Vinay Kamal, Ex-Director Professor, Department of Pathology, Maulana Azad Medical College, New Delhi, which has more than three decades of teaching experience in the premier institution.

It gives me an immense pleasure to write the Foreword to Second Edition of *Textbook of Pathology* with recent updates. I have gone through many chapters penned down by him in this textbook. Nothing can be more informative and more simplified for undergraduate as well as postgraduate medical students than this version.

Beautifully integrating numerous high-resolution colored illustrations, images, flowcharts, tables and providing relevant knowledge in a well-structured and designed text is an art and his textbook is a perfect example of these qualities. The contents not only include the knowledge of basic *Textbook of Pathology* for undergraduate students but also integrates trivial topics of recent diagnostic techniques and advancements, and molecular and genetic pathology for postgraduate students as well.

I congratulate Dr Vinay Kamal for having the insight to produce a novel *Textbook of Pathology* that allows the undergraduate as well as postgraduate medical students of all levels to understand pathology with clinicopathological correlation and relish it while reading it cover to cover.

I wish and hope that this splendid contribution of Dr Vinay Kamal gets the well-deserved acclamation and applause.

Dr Reeni Malik
Senior Professor and Head
Department of Pathology
Gandhi Medical College
Bhopal, Madhya Pradesh

Foreword

I have this proud privilege to write the Foreword to Second Edition of *Textbook of Pathology* written by Dr Vinay Kamal, Ex-Director Professor, Department of Pathology, Maulana Azad Medical College, New Delhi. He is a renowned Pathologist, who enjoys teaching undergraduate and postgraduate medical students and has put in dedicated efforts to facilitate teaching–learning methods.

Textbook of Pathology is in two volumes. The first volume deals with General Pathology and Hematology including chapter on Blood Banking and Transfusion Practices. The second volume deals with Systemic Pathology including a chapter on Cellular–Molecular Diagnostic Techniques in Clinical Practice.

This Second Edition of *Textbook of Pathology* is an integration of molecular pathology and routine histopathology and thorough in all aspects. The upcoming scientific discipline of molecular basis of disease development has been described in a simplified yet extensively detailed manner in this textbook. Numerous high-resolution colored illustrations are eye-catching and self-explanatory. All topics are covered comprehensively making it extremely student friendly for undergraduate and postgraduate medical students.

I congratulate Dr Vinay Kamal for his dedication and immense passion of teaching undergraduate and postgraduate medical students, I am confident that this splendid contribution of the author gets the well-deserved acclamation and applause.

Dr Roma Issacs
Senior Professor
Department of Pathology
Christian Medical College and Hospital
Ludhiana, Punjab

Foreword

It gives me an immense pleasure to write the Foreword to Second Edition of *Textbook of Pathology* written by Dr Vinay Kamal, Ex-Director Professor, Department of Pathology, Maulana Azad Medical College, New Delhi, who brings out new concepts defining various learning domains for the undergraduate as well as postgraduate medical students of pathology.

As all of us know that pathology is a very vast subject but it forms the basis for understanding the disease process. This textbook covers all the aspects of pathology in a systemic manner. Every effort has been made to make the subject interesting and easy to understand by using numerous well illustrated diagrams, flowcharts, tables as well as key points placed separately in the boxes for quick revision.

An attempt has also been made to include revised WHO classification of neoplasms, recent advances in pathology, molecular and immunohistochemical correlations in various aspects of tumor diagnosis, which are aimed at individualized treatment.

I congratulate Dr Vinay Kamal for this new venture and wish him all the success in his future endeavors.

Dr Sunita Singh
Senior Professor and Head
Department of Pathology
Pandit Bhagwat Dayal Sharma Post Graduate
Institute of Medical Sciences
Rohtak, Haryana

Foreword

The first edition of *Textbook of Pathology* authored by Dr Vinay Kamal released in the year 2017, was well appreciated by undergraduate as well as postgraduate medical scholars, and eminent faculty all over India. Textbook of Pathology was the result of years of hard work and commitment by a professional teacher and experienced pathologist.

I congratulate Dr Vinay Kamal, Ex-Director Professor, Department of Pathology, Maulana Azad Medical College, New Delhi for bringing out the Second Edition of *Textbook of Pathology*. Keeping in line with the recent advances in the field of pathology, the focus in this new venture is on the molecular pathogenesis of various disorders and clinicopathological correlation. The revised WHO classification of neoplasms has been incorporated in the discussions on various entities. Updated information on immunohistochemical markers has also been provided.

I am sure that Second Edition of *Textbook of Pathology* will be of immense help to the budding undergraduate as well as postgraduate medical students, and pathologists in reproducing their knowledge.

I wish great success to the latest endeavor by Dr Vinay Kamal.

Dr Syed Besina Yasin
Senior Professor and Head
Department of Pathology
Sher-I-Kashmir Institute of Medical Sciences
Srinagar, Jammu and Kashmir

Foreword

Dr Vinay Kamal, Ex-Director Professor, Department of Pathology, Maulana Azad Medical College, New Delhi, is well known name in the field of pathology, who needs no introduction. He has more than three decades of teaching experience in nation's most prestigious institution at Maulana Azad Medical College, New Delhi. I am delighted to know about the new release of his Second Edition of *Textbook of Pathology* with recent updates.

This is a very well written textbook with numerous high-resolution figures and tables which make it a handy tool to understand the fine nuances of the subject. This textbook would make the subject interesting for both the undergraduate as well as postgraduate medical students. Seldom we come across a thorough professional who is also a person with a kind heart, always keen to go extra mile to help others.

I congratulate Dr Vinay Kamal all the best for new release of *Textbook of Pathology*. I am sure this textbook is going to be a milestone for all the medical fraternity in the times to come.

Dr Geeta Pachori
Senior Professor and Head
Department of Pathology
Jawahar Lal Nehru Medical College
Ajmer, Rajasthan

Foreword

Second Edition of *Textbook of Pathology* written by Dr Vinay Kamal, Ex-Director Professor, Department of Pathology, Maulana Azad Medical College, New Delhi, is in your hands.

Dr Vinay Kamal has worked very hard and has rewritten all the chapters of textbook incorporating most of the contemporary knowledge and developments in the field as relevant within the scope of the book.

Many new tables, flow diagrams and illustrations have been added for easy remembrance. He has been constantly updating the content and has made tremendous efforts to present the content in a comprehensive yet concise style.

Revised WHO classification of neoplasms, concepts in the molecular pathogenesis, current Cellular–Molecular Diagnostic Techniques in Clinicale Practice of pathology and diagnostic approach have been incorporated.

I am sure the textbook is going to be useful not only to undergraduate but also to postgraduate medical students, and teachers of pathology.

Dr Rajeev Sen
Senior Professor and Head
Department of Pathology
Faculty of Medicine and Health Sciences
SGT University
Gurugram, Haryana

Foreword

Ever since the first edition of *Textbook of Pathology* by Dr Vinay Kamal was released in the year 2017, the author started working on its new edition as the book became so popular in just a couple of months that most of the undergraduate and postgraduate medical students, as well as faculty in pathology across the country procured this book for personal use and for the library of their institutions. This was due to numerous qualities of the textbook such as unique presentation, topics discussed in a simple, clear, and well-organized manner backed up with numerous colored figures, photographs of gross and microscopic lesions, tables, and diagrams along with the recent updates.

Second Edition of *Textbook of Pathology* by Dr Vinay Kamal, Ex-Director Professor, Department of Pathology, Maulana Azad Medical College, New Delhi, is releasing in 2025. In this textbook, all the chapters have been updated with incorporation of revised WHO classification of neoplasms, etiopathogenesis of the disease, clinical manifestations, clinicopathological correlation, and molecular diagnostics.

Textbook of Pathology contains around 1901 high-resolution colored figures, 1719 tables, chapters on Blood Banking and Transfusion Practices and Cellular–Molecular Diagnostic Techniques in Clinical Practice. All the chapters have been shared with eminent teachers and young budding residents across the country and their opinions have been given due weightage during drafting of the chapters.

While going through the chapters, the Author's honest, hard, and intelligent work is clearly felt by the reader. The book is designed to provide accurate, authoritative, and most current information and thus meets the need of the young generation of pathologists.

Dr Vinay Kamal's heart always beats for every medical student. I congratulate Dr Vinay Kamal on the Second Edition of *Textbook of Pathology* and wish good luck in his future endeavors.

Dr Kuldeep Kumar Kaul
Medical Advisor
J and K Thalassaemia Welfare Society
Former Professor and Head
Department of Pathology
Government Medical College
Jammu, Jammu and Kashmir

Foreword

It is indeed a pleasure and honour to write the Foreword to Second Edition of *Textbook of Pathology* written by Dr Vinay Kamal, Ex-Director Professor, Department of Pathology, Maulana Azad Medical College, New Delhi. The book is an excellent compilation of knowledge of pathology in a very organized manner.

I have been associated with Dr Vinay Kamal for the last fifteen years and had the opportunity to review many of the chapters in this textbook. All the chapters in this new release *Textbook of Pathology*, have been updated with recent advances with strong emphasis on molecular pathogenesis, immunohistochemistry, flow cytometry and other molecular techniques. The book is easy to read and comprehend and shall prove student-friendly for undergraduate as well as postgraduate medical students.

I wish all the best to Dr Vinay Kamal for success of Second Edition of *Textbook of Pathology* and sincerely hope that he will keep on contributing more to the knowledge of medical students.

Dr Subhash Chander Bhardwaj
Senior Professor and Head
Department of Pathology
Government Medical College
Jammu, Jammu and Kashmir

Foreword

Books are the best to windows of the world as they are best source to gain knowledge and discipline. Pathology is the scientific study of the diseases. I have known Dr Vinay Kamal, Ex-Director Professor, Department of Pathology, Maulana Azad Medical College, New Delhi for many years by reading an excellent *Textbook of Pathology* authored by him in the year 2017.

It is my pleasure, and an honour to write the Foreword for the Second Edition of *Textbook of Pathology* by Dr Vinay Kamal releasing in 2025. The only thing that surpasses his knowledge is his humility about capabilities.

Textbook of Pathology contains around 1901 high-resolution colored figures and 1719 tables with recent updates including revised WHO classifications of neoplasms, molecular pathogenesis, immunohistochemistry, flow cytometry and molecular diagnostic techniques. This textbook contains two chapters on Cellular–Molecular Diagnostic Techniques in Clinical Practice and Blood Banking and Transfusion Practices.

Undergraduate and postgraduate medical students seeking a resource should consider Second Edition of *Textbook of Pathology* written by Dr Vinay Kamal. I congratulate Dr Vinay Kamal for grand success of the textbook releasing in 2025.

Dr Soumitra Biswas
Senior Professor and Head
Department of Pathology
Calcutta National Medical College
Kolkata, West Bengal

Foreword

The influence of a good teacher can never be erased. Dr Vinay Kamal, Ex-Director Professor, Department of Pathology, Maulana Azad Medical College, New Delhi, besides being a dedicated teacher and pathologist par excellence, is an awakener.

It is my proud privilege and I feel honored to be given an opportunity to write the Foreword to Second Edition of *Textbook of Pathology*. All the chapters of the book have recent updates including molecular pathogenesis. Many features such as revised WHO classification of neoplasms, immunohistochemistry, microscopy, histochemical stains, flow cytometric analysis, cytogenetic study, fluorescence *in situ* hybridization, enzyme-linked immunosorbent assay, DNA sequencing and tissue microarray.

This textbook contains around 1901 high-resolution colored figures and 1719 tables that will help undergraduate and postgraduate medical students to understand pathology of diseases and their clinicopathological correlation.

I convey my heartfelt appreciation for the untiring efforts and the hard work done by Dr Vinay Kamal for conceptualizing and executing his work. This new release Textbook of Pathology is a great boon to the undergraduate and postgraduate medical students, and will enjoy reading this book.

I wish Dr Vinay Kamal a grand success in his endeavor and happy to release this Second Edition of *Textbook of Pathology*.

Dr Pranita Medhi
Senior Professor and Head
Department of Pathology
Assam Medical College and Hospital
Dibrugarh, Assam

Foreword

I am privileged to write the Foreword to Second Edition of *Textbook of Pathology* written by a well experienced and excellent talented teacher Dr Vinay Kamal, Ex-Director Professor, Maulana Azad Medical College, New Delhi.

Textbook of Pathology contains 1901 high-resolution colored images, 1719 tables, chapters on 'Cellular–Molecular Diagnostic Techniques in Clinical Practice' which makes the understanding of concepts very lucid for the undergraduate and postgraduate medical students, which make the book unique.

The author has meticulously considered valuable suggestions and criticism after thorough discussions with many subject experts in upgradation of this Second Edition of *Textbook of Pathology*. Inclusion of recent advances in diagnostic pathology, cytogenetics, molecular pathology, and immunohistochemistry are the added advantages of the textbook. Recently revised WHO classification of neoplasms has also been included in the book. All the chapters of textbook are written, and edited with recent updates.

I am sure this Textbook of Pathology will prove to be an asset for undergraduate and postgraduate medical students in view of the 'Competency Based Medical Education' implemented by National Medical Commission. Salient features given in the boxes will help the medical students in quick revision of the course prior to their formative and summative assessments.

I wish Dr Vinay Kamal all the best in his endeavor.

Dr Naval Kishore Bajaj
Senior Professor and Head
Department of Pathology
Osmania Medical College
Hyderabad, Telangana

Acknowledgments

Our motivation in writing Second Edition of *Textbook of Pathology* continues to share recent scientific concepts, clinical applications, and molecular diagnostics with colleagues and undergraduate and postgraduate medical students. We have strived to provide explanatory text, 1901 photographs and 1719 tables to enhance pictorial insights into human diseases.

We acknowledge the support and encouragement of colleagues and undergraduate and postgraduate medical students, who have critically revied the draft chapters and provided photographs related to surgical pathology and hematology section. Their constructive invaluable suggestions have served to significantly improve the work.

We gratefully recognize the continual invaluable support of Dr Naval Kishore Bajaj (Senior Professor and Head, Department of Pathology, Osmania Medical College Hyderabad, Telangana), Dr Nita Khurana (Director Professor and Head, Department of Pathology, Maulana Azad Medical College, New Delhi), Dr Jyoti Priyadarshini (Professor, Department of Pathology, GR Medical College Gwalior, Madhya Pradesh), Dr Tushar Kalonia (Assistant Professor, Department of Pathology), Dr Neha Kumari (Assistant Professor, Department of Pathology), Rajiv Aggarwal, Sh PL Jayant, Smt Shanti Devi, Dr Satya Pal Jayant, Dr Vijaya Jayant, Mr Arjun Jayant, Dr Rohan Jayant, Dr Vimal Singh, Dinesh Kumar, and Dr Divyark Singh.

Words are less to express our gratitude to eminent faculty colleagues for showering their blessings by endorsing Second Edition of *Textbook of Pathology*. Comments from eminent faculty and undergraduate and postgraduate medical students are always welcome.

CBS PUBLISHERS AND DISTRIBUTORS PRIVATE LIMITED, NEW DELHI

We express our gratitude to Mr Satish Kumar Jain CHAIRMAN AND MANAGING DIRECTOR, Mr Varun Jain MANAGING DIRECTOR and Mr Sunil Dutt MANAGER PROMOTION AND DEVELOPMENT of CBS Publishers and Distributors Private Limited for extending their whole hearted support at every step in completion of this book.

A special thanks to Ram Murti SENIOR GRAPHIC ARTIST, Ananda Mohanty SENIOR PROOF READER and Mrs Sunita Rautela SENIOR DTP OPERATOR for their invaluable support in the completion of the book.

Cellular–Molecular Diagnostic Techniques in Clinical Practice

Vinay Kamal, Anubhav and Vigyat

LEARNING OBJECTIVES

FROZEN/CRYOSTAT MICROTOMY TECHNIQUES

- Frozen section technique
- Cryostat section technique
- Cutting of tissue section
  - Ultramicrotomy
  - Laser microtomy

ELECTRON MICROSCOPY AND POLARIZING LIGHT MICROSCOPY

- Electron microscopy
- Polarizing light microscopy

TISSUE FIXATION, DECALCIFICATION, HANDLING OF SURGICAL SPECIMENS AND HISTOCHEMICAL STAINS

- Tissue fixatives
- Tissue decalcification
- Handling of surgical specimens
- Histochemical stains

IMMUNOHISTOCHEMISTRY TECHNIQUE

- Immunohistochemistry technique: overview
- Detection systems of immunohistochemistry
- Immunohistochemistry protocol

IMMUNOFLUORESCENCE MICROSCOPY

- Immunofluorescence microscopy: overview
- Types of immunofluorescence microscopy
  - Direct immunofluorescence microscopy
  - Indirect immunofluorescence microscopy

CHEMILUMINESCENCE VERSUS CHEMIFLUORESCENCE TECHNIQUES

- Chemiluminescence technique
- Chemifluorescence technique

MOLECULAR DIAGNOSTICS TO ANALYZE CELL PROLIFERATION

- Ki-67 (MB-1) analysis
- Mitotic cell count analysis
- Flow cytometry technique

CYTOGENETIC ANALYSIS

- Cytogenetic analysis: overview
- Cytogenetic analysis techniques
  - Metaphase fluorescence *in situ* hybridization (FISH) for chromosomal karyotyping technique
  - Multiplex metaphase FISH for chromosomal karyotyping technique
  - Comparative genomic hybridization (CGH) technique
  - Microarray analysis technique

IN SITU HYBRIDIZATION, CHROMOGENIC *IN SITU* HYBRIDIZATION AND FLUORESCENCE *IN SITU* HYBRIDIZATION

- *In situ* hybridization: overview
- Chromogenic *in situ* hybridization: overview
- Fluorescence *in situ* hybridization: overview

ENZYME-LINKED IMMUNOSORBENT ASSAY TECHNIQUE

- Enzyme-linked immunosorbent assay (ELISA) technique: overview

DNA SEQUENCING METHODS

- Polymerase chain reaction (PCR) technique
- Southern blot technique
- Northern blot technique

TISSUE MICROARRAY (TMA) TECHNIQUE

- Tissue microarray technique: overview

HIGH-PERFORMANCE LIQUID CHROMATOGRAPHY

- HPLC technique

HEMOGLOBIN ELECTROPHORESIS AND GEL ELECTROPHORESIS TECHNIQUES

- Hemoglobin electrophoresis technique
- Gel electrophoresis technique

FROZEN/CRYOSTAT MICROTOMY TECHNIQUES

FROZEN SECTION TECHNIQUE

Frozen section technique is used for rapid diagnosis, study of margins of malignant neoplasm, enzyme histochemistry, demonstration of lipid and molecular studies. Drawbacks of frozen section technique include distortion of morphology of tissue and cellular cytomorphologic details and poor staining. Tissue sample must reach the histopathology laboratory immediately. It should be kept in normal saline to prevent drying of sample. The tissue can directly be taken to the cryostat or can be fixed with 10% formalin or formalin-alcohol.

- Frozen sections are stained normally, because this is faster for one or a few individual sections. Toluidine blue stain generally used as a progressive stain to demonstrate adipose tissue in which the section is left in contact with the stain until the desired tint is achieved.

Table 14.1 Examples of fresh frozen section evaluation

Anatomic Sites	Indications	Comments
Skin	▪ Squamous cell carcinoma (eyelid, nose or ear) ▪ Basal cell carcinoma (eyelid, nose or ear) for evaluation of margins	Not indicated for melanoma skin
Breast	Breast carcinoma	Evaluation of margins is sometimes required
Lymph nodes	Metastases of breast carcinoma in lymph nodes (sentinel node)	Sensitivity (60%)
Thyroid	Papillary carcinoma of thyroid (imprint smear cytology for nuclear groove)	Not suitable for follicular neoplasms
Female genital system	Intraoperative ovarian neoplasm (most important)	Not suitable for cervical carcinoma
Pancreas	Intraoperative pancreatic carcinoma to look for margins	Accuracy 98%

- The Oil red O (ORO) stain can identify neutral lipids and fatty acids in touch smears and tissues.
- Fresh touch smears or cryostat sections of tissue are necessary because fixatives containing alcohols, or routine tissue processing with clearing will remove lipids.
- The Oil red O stain is used to identify lipid-laden macrophages in bronchoalveolar lavage (BAL) cytologic samples to diagnose fat embolic syndrome (FES).
- Other fat stains are Sudan black, Sudan III and Sudan IV. Examples of fresh frozen section evaluation are given in Table 14.1.

CRYOSTAT SECTION TECHNIQUE

Cryostat is a device by which temperature can be maintained at a low level. In histopathology, cryostat consists of a microtome within its chamber for cutting sections of frozen tissue. The cryostat is essentially an ultrafine 'deli-slicer', called a microtome, placed in a freezer. It is usually stationary upright freezer, with an external wheel for rotating the microtome.

- The temperature within cryostat can be varied, depending on the tissue being cut—usually – 20° to –30°C. Low temperature may be maintained within cryostat by using various refrigeration methods, most commonly using cryogenic fluid bath such as liquid helium or nitrogen.
- Although cryosections are physically less stable than paraffin-embedded tissue sections. Cryosections are generally superior for the preservation of antigenicity and therefore the detection of antigens by immunohistochemistry. The preparation of cryosections does not involve the dehydration process. Rapid freezing of tissue reduces the formation of ice crystals, thus minimizes morphologic damage.

CUTTING OF TISSUE SECTION

ULTRAMICROTOMY

Ultramicrotomy is a technique for cutting tissue specimens into extremely thin transparent sections. The ultrathin sections can be studied at different magnifications in a transmission electron microscope (TEM).

- Ultrathin sections must be very thin because the 50–125 kV electrons of the standard electron microscope cannot pass through biological material much thicker than 150 nm. For best resolutions, tissue sections must be 30–60 nm in thickness.
- Prior to the cutting ultrathin sections, the biological materials are usually placed in a more rigid fixative used in the process known as embedding. This is achieved by the inflow of a liquid substance around the sample, such as paraffin or epoxy.

LASER MICROTOMY

Recent development in the microtomy is the use of a laser microtome, which has a capacity to cut in few seconds. No sample preparation is required. The thickness of tissue sections varies 10–100 nm. Using a vibrating knife improves the results when dealing with soft materials. This is the only technique yielding directly 30 nm sections of constant thickness. Laser microtomy technique cannot be applied to very heterogenous, very hard, very soft and very fragile samples.

ELECTRON MICROSCOPY AND POLARIZING LIGHT MICROSCOPY

ELECTRON MICROSCOPY

Electron microscope (EM) was invented by Ernst Ruska in 1933, for which he was awarded the Nobel Prize in Physics in 1986.

- Electron microscopes are scientific instruments that use a beam of energetic electrons to examine objects on a very fine scale. It was developed due to the limitations of resolution power of light microscope that is limited by physics of light.
- Electron microscopes are basically of two types: (a) transmission electron microscopy (TEM); (b) scanning electron microscopy (SEM).
- Principle of light microscopy, transmission electron microscopy and scanning electron microscopy is shown in Fig. 14.1A to C. Technical processes used for electron microscopy is given in Table 14.2.

Table 14.2 Technical processes used for electron microscopy

Process	Methodology
Fixation of tissue	2% glutaraldehyde
Processing of tissue	▪ Application of tetraoxide in post-fixed tissue ▪ Dehydration done in a graded ethanols ▪ Infiltration of tissue with EM epoxy resin
Embedding	Tissue embedded in mold
Sectioning of tissue	▪ Heating of resin infiltrated tissue hardened into blocks ▪ Sections obtained with microtome ▪ Sections but on a specimen grid
Electron microscopy	▪ Section image studied under electron microscope ▪ Digital image obtained and analyzed

TRANSMISSION ELECTRON MICROSCOPY

In transmission electron microscopy (TEM) source is a beam of high velocity electrons accelerated under vacuum, focused by condenser lens (electromagnetic bending of electron beam) onto specimen, which causes loss and scattering of electrons by individual parts of specimen. Emergent electron beam is focused by objective lens. Final image is formed on a fluorescent screen for viewing.

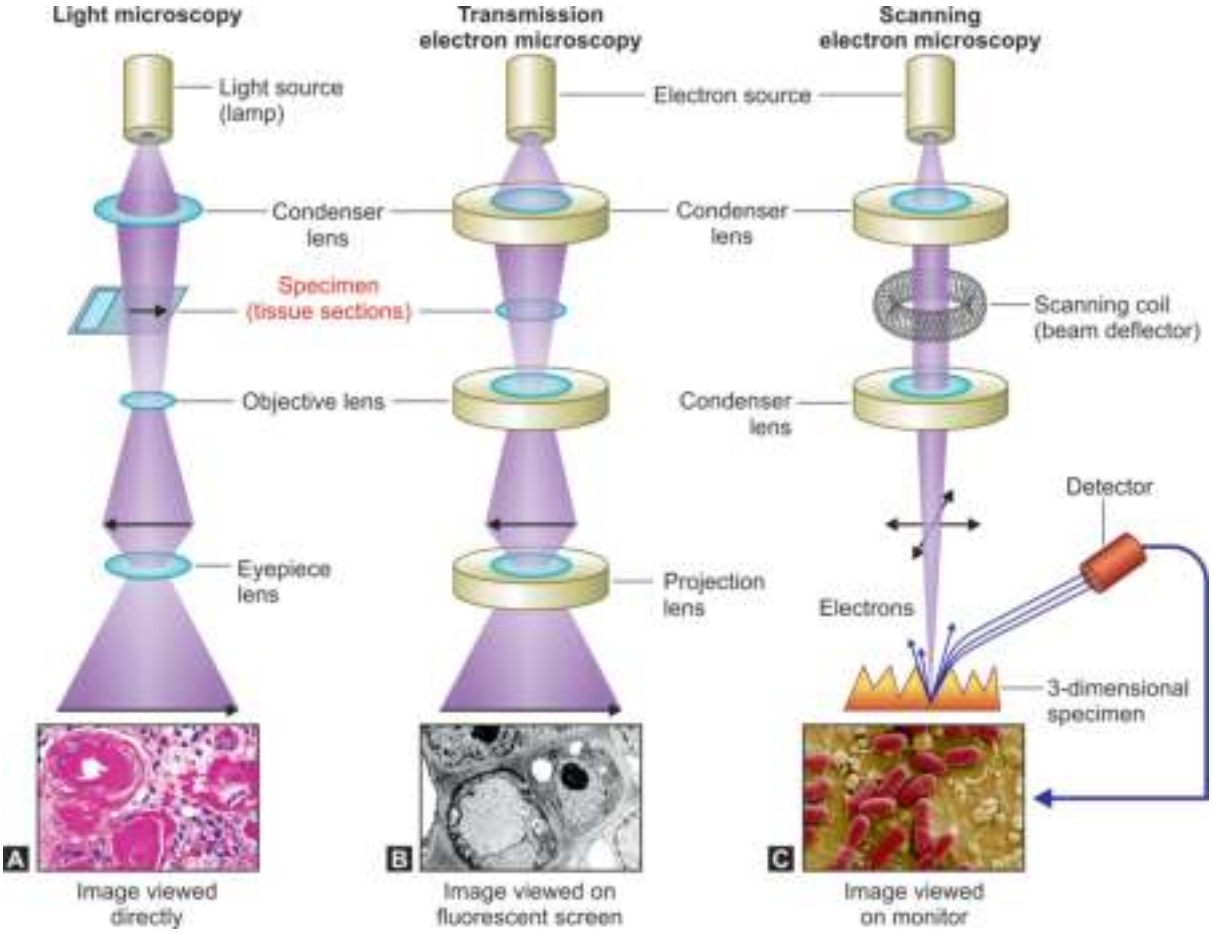

Fig. 14.1A to C: Principle of light microscopy, transmission electron microscopy and scanning electron microscopy.

- Standard transmission electron microscope has a resolving power to about 15–30 angstroms.
- Magnified images are typically formed from 1000X to 50,000X. By using fine grain photographic film, it is possible for further enlargements of images from 150,000X to 1,000,000X.

SCANNING ELECTRON MICROSCOPY

Scanning electron microscopy (SEM) differs from standard transmission electron microscopy in that the electrons are bounced off the surface of an object with SEM, not passed through it. The major advantages of SEM are the great depth of field (more of the specimen can be in focus at once) and simple specimen preparation.

Principle of Scanning Electron Microscopy

The basic principle of scanning electron microscopy is that a beam of electrons is generated by a suitable source, typically a tungsten filament or a field emission gun.

- The electron beam is accelerated through a high voltage and passes through a system of apertures and electromagnetic lenses to produce a thin beam of electrons. Then electron beam scans the surface of the specimen.
- Electrons are emitted from the specimen by the action of the scanning electron beam and collected by a suitably positioned detector.
- Comparison between light microscope and electron microscope is given in Table 14.3. Comparison between transmission electron microscopy and scanning electron microscopy is given in Table 14.4.

Applications of Scanning Electron Microscopy in Surgical Pathology

Scanning electron microscopy is a useful diagnostic technique to supplement morphologic, immunohistochemical, cytogenetic and molecular analysis of tissues, although immunoperoxidase techniques have largely replaced EM for tumor diagnosis in surgical pathology.

- Scanning electron microscopy is used to diagnose alcoholic liver disease, genetic disorders, neoplasms, glomerulonephritis and identification of microorganisms.
- Diagnostic utility of electron microscopy in various disorders is given in Table 14.5.

POLARIZING LIGHT MICROSCOPY

Some materials such as crystals or fibers have the property of birefringence which is the ability to pass light in a particular plane. Such materials (crystals or fibers) are called anisotropic substances because of this property.

- Normally, most materials are isotropic substances because any light that passes through them will be scattered in all directions.

Table 14.3 Comparison between light microscope and electron microscope

Light Microscope	Electron Microscope
Small and portable	Very large and operated in a special room
Resolution is 200 nm	Resolution is 0.4 nm (in SEM) or 0.5 Å (in TEM)
Magnification is 1000X	Magnification is 2 million (in SEM) or 50 million (in TEM)
It is unaffected by magnetic fields	It is affected by magnetic fields
Preparation of material is quick and simple	Preparation of material is lengthy and requires expertise
Preparation rarely distorts the material	Preparation may distort the material
Cheap to purchase and operate	Expensive to purchase and operate
Natural color of object is observed	Images are in black and white

Table 14.4 Comparison between transmission electron microscopy and scanning electron microscopy

Transmission Electron Microscopy (TEM)	Scanning Electron Microscopy (SEM)
TEM is based on transmitted electrons	SEM is based on scattered electrons
Electrons are directly pointed towards the sample in TEM	The scattered electrons in SEM produce the image of sample after the microscope collects and counts the scattered electrons
TEM shows the sample as a whole	SEM shows the sample bit by bit
TEM has up to 50 million magnification	SEM has up to 2 million magnification
TEM provides a two-dimensional image	SEM provides a three-dimensional image
The resolution in TEM is 0.5 Å (1 Å = 10^{-10} m)	The resolution in SEM is 0.4 nm (1 nm = 10^{-9} m)

Table 14.5 Diagnostic utility of electron microscopy in various disorders

Subcellular Features in Cell or Tissue	Diagnostic uses in Clinical Practice
Genetic disorders	
▪ Cilia in epithelial cells	▪ Primary ciliary dyskinesis
▪ Lysosomes in neurons	▪ Demonstration of lipids and mucopolysaccharides in tissues
▪ Absence of peroxisomes in liver and kidneys	▪ Zellweger syndrome and neonatal adrenoleukodystrophy
Acquired non-neoplastic disorders	
▪ Increased number of peroxisomes in hepatocytes	▪ Alcoholic liver disease, chronic venous congestion, oral contraceptives
▪ Siderosomes in mitochondria	▪ Sideroblastic anemia
Neoplasms	
▪ Intercellular junctions in epithelial neoplasms and lymphoma	▪ Distinction between carcinomas and lymphomas (intercellular junctions present in carcinomas and absent in lymphomas)
▪ Intracellular or intercellular in glandular epithelium	▪ Diagnosis of adenocarcinoma
▪ Microvillous core rootlets in glandular epithelium of intestines	▪ Diagnosis of metastatic deposits from gastrointestinal carcinoma
▪ Cytoplasmic tonofibrils in squamous epithelium	▪ Diagnosis of squamous differentiation of epithelial neoplasms
▪ Premelanosomes and melanosomes in melanotic cells	▪ Diagnosis of melanoma
▪ Neurosecretory granules in neuroendocrine and neuroectodermal cells	▪ Diagnosis of neuroendocrine and neuroectodermal neoplasms
▪ Birbeck granules in Langerhans' cells	▪ Diagnosis of Langerhans' cell histiocytosis
Miscellaneous disorders	
▪ Viruses and parasites in solid tissues, fecal specimens and body fluids	▪ Identification of infectious agents in tissues
▪ Electron dense deposits in glomeruli	▪ Identification and classification of glomerulonephritis
▪ Electron dense deposits present adjacent to vascular smooth muscle	▪ Cerebral autosomal-dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) syndrome

- When viewed under polarized light, however, anisotropic materials will be brightly visible in one plane (birefringent), but will be dark in a plane turned 90°. Principle of polarizing microscope is shown in Fig. 14.2A and B.

POSITIVE/NEGATIVE BIREFRINGENCE

The birefringence is categorized into positive or negative based on the property of birefringence in which rays of light travelling through the anisotropic material

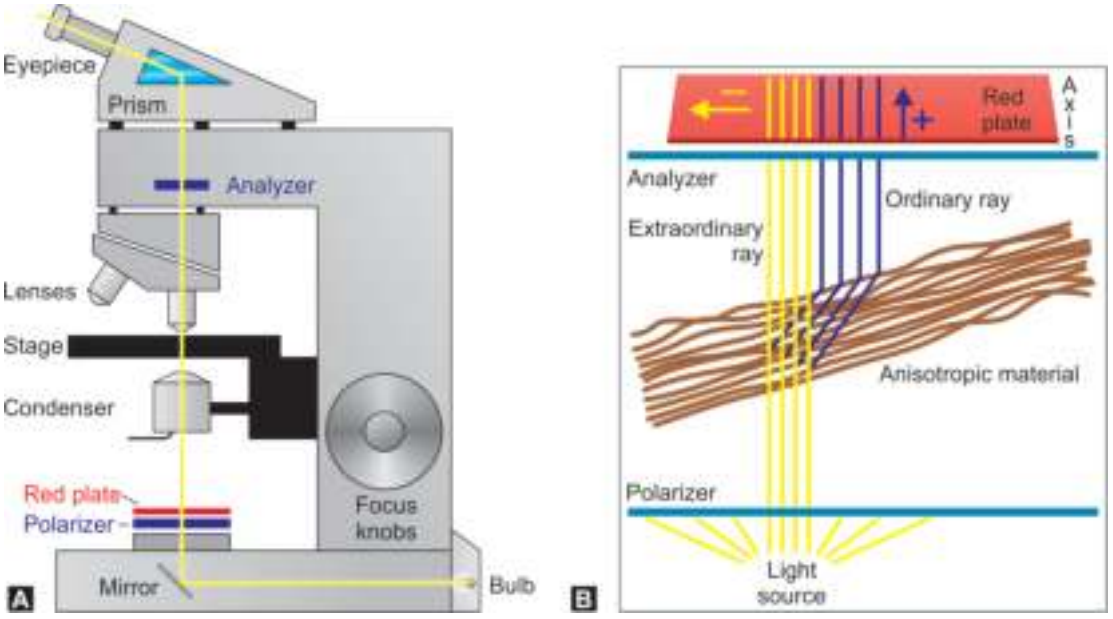

Fig. 14.2A and B: Principle of polarizing microscope.

in perpendicular planes (at right angles) will travel at different velocities through the material.

BIREFRINGENT MATERIAL REFRACTIVE INDEX

Birefringent material has two refractive indices: high for fast rays and small for slow rays. Fast rays travel in parallel with the crystalline structure of the birefringent material than the extraordinary's low rays traverses the material. Negative birefringence occurs when the ordinary ray becomes the slow ray when it is reflected and travels across the crystalline structures.

POLARIZER AND ANALYZER FILTERS IN POLARIZING MICROSCOPE

There are two polarizing filters made of glass or plastic material in polarizing microscope: polarizer and analyzer. These filters pass light in only one plane.

APPLICATIONS OF POLARIZING MICROSCOPY

Exogenous crystalline material, such as talc crystals, is demonstrated by polarizing microscopy found in subcutaneous injection site, lungs, and organs of the mononuclear phagocyte system of persons engaging in injection drug use. Applications of polarizing microscopy in clinical practice are given in Table 14.6.

Table 14.6 Applications of polarizing microscopy in clinical practice

Disorders	Characteristics
Sodium urate crystals gout	Negative birefringence
Calcium pyrophosphate crystals	Positive birefringence
Amyloid deposits in various organs	Apple green birefringence
Silicosis in organs	Insignificant finding in lungs and lymph nodes
Formalin-heme pigment (artefact of poor fixation)	Bright white birefringence
Collagen: Collagen fibrils	Dull yellow-white

TISSUE FIXATION, DECALCIFICATION, HANDLING OF SURGICAL SPECIMENS AND HISTOCHEMICAL STAINS

TISSUE FIXATIVES

Tissue fixatives preserve tissues in their natural state and fixes all components by denaturing or precipitating proteins. The ideal tissue fixative would prevent autolysis and bacterial decomposition. Microorganisms are also fixed and killed during tissue fixation. Most tissue fixatives act by denaturing or precipitating proteins which then form a sponge or meshwork tending to hold the other cell constituents. Formaldehyde is tissue fixative of choice.

CLASSIFICATION OF TISSUE FIXATIVES

Tissue fixatives are classified according to mechanism of action: aldehydes (formaldehyde and glutaraldehyde), mercurials, alcohols, oxidizing agents and picrates (Table 14.7), routine 10% formalin saline tissue fixative (Table 14.8), routine 10% buffered formalin tissue

Table 14.7 Tissue fixatives used in histopathology

Categories of Tissue Fixatives	Examples of Tissue Fixatives	Advantages of Tissue Fixatives	Disadvantages of Tissue Fixatives
Aldehyde fixatives	▪ Neutral formalin (10%) ▪ Buffered formalin (10%) ▪ Buffered glutaraldehyde (%)	▪ Immunoperoxidase techniques ▪ Immunoperoxidase techniques ▪ Prevents formalin-heme pigment ▪ Electron microscopy	▪ Formalin-heme pigment ▪ Nil ▪ Not good for immunoperoxidase techniques ▪ Nil
Mercurial fixatives	Zenker's fixative	Hematopoietic and reticuloendothelial tissues, i.e. lymph nodes, spleen, thymus, and bone marrow	Marked shrinkage and hardness of tissues. It reduces the amount of demonstrable glycogen
Alcohol fixatives	Carnoy's fluid	▪ Suitable for small biopsies giving nuclear details ▪ Preserves glycogen	Causes lysis of RBCs, dissolution of lipid and myelin; and shrinkage of tissue

Contd...

Table 14.7 Tissue fixatives used in histopathology (*Contd...*)

Categories of Tissue Fixatives	Examples of Tissue Fixatives	Advantages of Tissue Fixatives	Disadvantages of Tissue Fixatives
Chromate fixatives	Helly's fluid	Used to demonstrate chromaffin tissue (adrenal medulla), mitochondria and preservation of phospholipids	Glycogen preservation poor
Picrate fixatives	Bouin's fluid fixative (40% formalin, picric acid and glacial acetic acid)	▪ Testicular, gastrointestinal tract, and endocrine tissue biopsies ▪ Gives yellow color to the tissue and gives good nuclear details	▪ Makes tissue hard and brittle ▪ Lysis of RBCs, reduce amount of demonstrable ferric iron

Table 14.8 Routine 10% formalin saline tissue fixative

Constituents	Composition
Formalin	100 ml
Water	900 ml
Sodium chloride	8.5 g

Disadvantage: Routine 10% formalin saline fixative forms formalin-heme pigment giving black discoloration to tissues.

fixative (Table 14.9), composition of Zenker's tissue fixative (mercurial fixative) (Table 14.10), Schaudinn's sublimated alcohol tissue fixative (mercurial tissue fixative) (Table 14.11), composition of Carnoy's fluid (alcohol tissue fixative) (Table 14.12), Orth's fluid tissue fixative (chromate tissue fixative) (Table 14.13) and Regaud's (Moller's) fluid (chromate tissue fixative) (Table 14.14).

Table 14.9 Routine 10% buffered formalin tissue fixative

Constituents	Composition
Formalin	100 ml
Water	900 ml
NaH_2PO_4	3.5 g
Na_2HPO_4	6.5 g

Advantage: 10% buffered formalin prevents formation of formalin-heme pigment.

Table 14.10 Composition of Zenker's tissue fixative (mercurial tissue fixative)

Constituents	Composition
$HgCl_2$	50 g
Potassium dichromate	25 g
Sodium sulfate	10 g
Distilled water	1000 ml

Mercurial fixatives are used to fix lymph nodes, spleen, thymus, and bone marrow.

Table 14.11 Schaudinn's sublimated alcohol tissue fixative (mercurial tissue fixative)

Constituents	Quantity
$HgCl_2$	3 g
Distilled water	50 ml

Schaudinn's sublimated alcohol fixative is most useful fixative for making smears of loose cells on a slide.

Table 14.12 Composition of Carnoy's fluid (alcohol tissue fixative)

Constituents	Quantity
Absolute ethyl alcohol	60 ml
Chloroform	30 ml
Glacial acetic acid	10 ml

Table 14.13 Orth's fluid tissue fixative (chromate tissue fixative)

Constituents	Composition
Potassium dichromate (2.5%)	100 ml
Formalin solution	10 ml

Formalin solution is added just before using as fixative.
Chromate fixatives are used to demonstrate chromaffin tissue (adrenal medulla), mitochondria, Golgi apparatus and mitotic figures.

Table 14.14 Regaud's (Moller's) fluid (chromate tissue fixative)

Constituents	Composition
Potassium dichromate (3%)	80 ml
Formalin	20 ml

Formalin solution is added just before using it as fixative.
Chromate fixatives are used to demonstrate chromaffin tissue (adrenal medulla), mitochondria, Golgi apparatus and mitotic figures.

Table 14.15 Factors affecting fixation of tissue

Parameters	Characteristics
Concentration of fixative	▪ Formalin 10% used for tissue fixation ▪ Glutaraldehyde 0.25–4% used for electron microscopy
Volume of fixative	10–20 times of tissue sample
Agitation of specimen	Enhances tissue fixation
Buffers used to prevent formalin-heme pigment	▪ Neutral buffered formalin prevents excessive acidity and formation of formalin-heme pigment ▪ Common buffers (phosphate, bicarbonate, cacodylate and veronal)
Penetration of tissue fixative	▪ Formalin and alcohol fixatives (best penetration) ▪ Glutaraldehyde (worst penetration) ▪ Mercurial fixatives somewhat in between ▪ Sectioning of specimen 2–3 cm enhances fixation
Temperature	Increasing temperature of formalin enhances the speed of tissue fixation
Time interval between fixation and removal of tissue	Tissue should be fixed faster and removed within 6–8 hours. Longer tissue fixation leads to nuclear shrinkage and loss of organelles

Formalin used to fix tissue forms formalin-heme pigment.

FACTORS AFFECTING TISSUE FIXATION

There are a number of factors that will affect the fixation process: volume, buffering, penetration, temperature, concentration and time interval. Fixation is best carried out close to neutral pH, in the range of 6–8. Commercial formalin is buffered with phosphate at a pH of 7. Factors affecting fixation of tissue are given in Table 14.15.

TISSUE DECALCIFICATION

Bone and other tissues containing calcified areas and calcium deposits are extremely firm and which will not section properly with paraffin embedding owing to the difference in densities between calcium and paraffin. Hence, calcium must be removed prior to embedding to allow tissue sectioning. Mineral acids (nitric acid and hydrochloric acid), organic acids (acetic acid and formic acid), EDTA, and electrolysis are used to decalcify such tissues.

STRONG ACIDS

Strong acids, i.e. nitric acid and hydrochloric acid are used to decalcify dense cortical tissue at a rapid rate; but also damage cellular details. These are not recommended for delicate tissues such as bone marrow.

ORGANIC ACIDS

Organic acids such as acetic acid and 10% formic acid are better suited to bone marrow, because these act more slowly on dense cortical bone. Formic acid in 10% concentration is the best all-around decalcifier.

ETHYLENEDIAMINETETRA-ACETIC ACID

Ethylenediaminetetra-acetic (EDTA) acid can remove calcium slowly but is expensive in large amounts. Electrolysis removes calcium slowly, hence not suited for routine purpose.

COMMERCIAL DECALCIFYING SOLUTIONS

Commercial decalcifying solutions containing formic acid with formalin is available to decalcify tissues.

HANDLING OF SURGICAL SPECIMENS

Under normal circumstances, the specimens are received in 10% neutral buffered formalin. Tissue fixation process prevents autolysis and decomposition of specimen. Gross processing of surgical specimens comprises description of size, shape, color and overall appearance. The tissues placed in cassettes are designated number. When a malignancy is suspected, then the specimen is often covered with ink in order to mark the margins of the specimen.

AUTOMATIC TISSUE PROCESSOR

This multistep process is done by an automatic machine which has multiple jars containing different chemicals, i.e. formalin, ascending series of alcohols, xylene and paraffin through which tissue is passed on a preset time scale. Automatic tissue processor with digitally programmed schedule is given in Table 14.16.

PARAFFIN EMBEDDING OF PROCESSED TISSUE

Properly fixed and processed tissue in the tissue processor are embedded in the molds containing paraffin with melting point 54–62°C to prepare them for cutting in microtome. During paraffin embedding, the tissue is oriented with the surface placed down in the mold becoming the face of tissue block.

MICROTOMY

Tissue embedded in paraffin can be sectioned at 4–8 microns in thickness with microtome having thick metallic knife.

- Tissue ribbon is then floated on warm water bath at a temperature 6–8°C below the melting point of paraffin, which aids in mounting tissue sections on a glass slide properly labelled for light microscopy.

Table 14.16 Automatic tissue processor (histokinette) with digitally programmed schedule

Jar Numbers	Chemical Used	Time Variable Depending on Convenience and Fixation of Tissues	Step
1.	70% alcohol	½ hour	Dehydration of tissue is done to replace fixative and water by a dehydrating fluid
2.	95% alcohol	½ hour	
3.	100% alcohol	1 hour	
4.	100% alcohol	1 hour	
5.	100% alcohol	1 hour	
6.	100% alcohol	1 hour	
7.	100% alcohol	1 hour	
8.	100% alcohol + xylene	1 hour	Clearing is performed to replace dehydrating fluid with a medium totally miscible with embedding medium (molten paraffin wax)
9.	Xylene	1 hour	
10.	Xylene	2 hours	
11.	Molten paraffin wax	2 hours	A vacuum can be applied inside the tissue processor to assist penetration of the embedding paraffin agent. This process replaces water content of tissue and clearing agent by paraffin wax used in molten state
12.	Molten paraffin wax	2 hours	

- Thin tissue sections for electron microscopy are best obtained with a diamond knife which is very expensive. After embedding tissues in epoxy resin, a microtome equipped with a glass or diamond knife is used to cut very thin sections (typically 60–100 nm). Thin tissue sections are stained and examined with a transmission electron microscope.

HEMATOXYLIN AND EOSIN STAINING

The staining process makes use of a variety of dyes that have been chosen for their ability to stain various cellular components of tissue. Hematoxylin and eosin (H&E) stain is routinely done.

- Hematoxylin had been derived from the logwood tree in the past. Eosin at pH 4.6–5.0 has high affinity for positively charged tissue protein group.
- However, special histochemical stains are employed in specific situations according to the diagnostic need.
- Commercially ripened synthetic hematoxylin is commonly used due to less availability of logwood tree. Hematoxylin is the oxidized/ripened product of the logwood tree known as hematein.
- Hematoxylin, a basic dye has an affinity for the nucleic acids of the cell. Eosin, an acidic dye has affinity for cytoplasmic components of the cell. Problem with eosin may occur due to overstaining of decalcified tissues.
- Routine hematoxylin and eosin staining technique in surgical pathology is given in Table 14.17. Applications of hematoxylin stains for different purpose in surgical pathology are given in Table 14.18.

Table 14.17 Routine hematoxylin and eosin staining technique in surgical pathology

Steps	Purpose	Procedure
Step 1	Deparaffinization of tissue section	Deparaffinize the section with xylene (three changes)
Step 2	Rehydration of tissue section in graded alcohol	Rehydration is done by putting section in graded alcohol and then water for 1–2 minutes (2 changes)
Step 3	Nuclear staining by hematoxylin	Put hematoxylin on section and keep for 5–15 minutes
Step 4	Differentiation of tissue section	Differentiation of section is done by putting in 1% acid alcohol (2 dips and then wash section in tap water
Step 5	Bluing of tissue section in alkaline solution (ammonia water)	Wash in running tap water for 5 minutes until section becomes blue
Step 6	Counterstaining of tissue section by eosin	1% eosin Y for 2–3 minutes
Step 7	Dehydration of tissue section	Put section in graded alcohol (70%, 95%, 100%) for 3–5 minutes in each graded alcohol or until excess of eosin is removed
Step 8	Clearing of stained section	Clearing of section in xylene two charges of two minutes each
Step 9	Mounting of stained section	Mount section in DPX (mixture of distyrene, a plasticizer and xylene)

Table 14.18 Applications of hematoxylin stains for different purpose in surgical pathology

Hematoxylin Types	Purpose
Harris hematoxylin	▪ Routine stain on histologic sections and cytology smears (nuclei blue, cytoplasm pink) ▪ Stain acidophilic in nature and lacks alcohol
Mayer's hematoxylin	▪ Carbohydrates ▪ Stain contains alcohol
Baker's acid-hematein	Phospholipid
Tungsten hematoxylin	▪ Fibrin ▪ Cross striations of skeletal muscle
Verhoeff's iron hematoxylin	Strong affinity for connective tissue fibers
Iron hematoxylin	▪ *Entamoeba histolytica* ▪ *Wuchereria bancrofti*
Gill's hematoxylin	▪ Conventional stain used on histologic sections, cytology smears and immunohistochemistry ▪ Nuclear chromatin
Heidenhain's iron hematoxylin	▪ Photomicrography ▪ Skeletal muscle striations ▪ Mitotic structures blue black
Ehrlich's hematoxylin	▪ Counterstaining in immunohistochemistry and cytochemistry ▪ Nuclear stain

Mordant to Tissues

Hematoxylin will not directly stain tissues, but needs a mordant or link to the tissues, i.e. metal cation iron, aluminum, or tungsten. Depending on the mordant used, there is variety of hematoxylins, which vary in intensity.

Progressive Hematoxylin Staining

Hematoxylin and eosin staining can be either progressive or regressive. With a progressive staining the slide is dipped in the hematoxylin until the desired intensity of staining is achieved such as with a frozen section. This is simple for a single slide, but lends itself poorly to batch of slides processing.

Regressive Hematoxylin Staining

With a regressive hematoxylin and eosin staining, the slides are left in the solution for a set period of time and then taken back through a solution such as acid alcohol that removes part of the stain. This method works best for large batches of slides to be stained and is more predictable on a day-to-day basis.

HISTOCHEMICAL STAINS

Commonly used stains in histopathology are given in Table 14.19. Carbohydrate classification for the purpose of histochemical staining is given in Table 14.20. Mucin types and their origin for the purpose of histochemical staining are given in Table 14.21.

Table 14.19 Commonly used stains in histopathology

Special Stains	Uses	Result
Hematoxylin and eosin stain	Routine stain	Nucleus blue, cytoplasm pink, bone blue, mucoid and cartilaginous area pale blue, RBC and eosinophil granules orange red
Stains for carbohydrates		
Periodic acid–Schiff's stain	▪ Glycogen ▪ Fungi ▪ Neutral mucin ▪ Amyloidosis ▪ Basement membrane ▪ Glycoproteins ▪ Glycolipids	▪ Red color ▪ Red color ▪ Red color ▪ Red color ▪ Red color ▪ Red color ▪ Red color
Periodic acid–Schiff with diastase stain	Neutral mucin	
Alcian blue stain at pH 2.5	▪ All acidic mucopolysaccharides ▪ Sulphated mucin	▪ Blue color ▪ Blue color
Mucicarmine stain	▪ Acidic epithelial mucin ▪ Cryptococcus capsule	▪ Blue color ▪ Blue color

Contd...

Table 14.19 Commonly used stains in histopathology (*Contd...*)

Special Stains	Uses	Result
Colloidal iron stain pH 1	Prussian blue reaction (Perls reaction) to demonstrate hemosiderin	Blue color
Congo red	Amyloid	▪ Pink color under light microscope ▪ Green birefringence for under polarizing microscope
Methyl violet (metachromatic stain)	Amyloid	Rose pink color
von Gieson stain	Amyloid	Khaki color
Crystal violet (metachromatic stain)	Amyloid	Pink color
Thioflavin T and thioflavin S	Amyloid	Yellow to yellow green color under immunofluorescent microscopy
Stains for microorganisms		
Bacteria		
Ziehl-Neelsen (ZN) stain (20% H_2SO_4)	*Mycobacterium tuberculosis*	Red bacilli
Auramine-rhodamine	*Mycobacterium tuberculosis*	Yellow fluorescence in auramine-rhodamine stain
Fite acid-fast stain (5% H_2SO_4)	*Mycobacterium leprae*	Red bacilli
Papanicolaou's stain, May-Grünwald Giemsa stain and Gomori methenamine silver stain	Actinomycosis	Clustered bacilli with sunray appearance
May-Grünwald Giemsa stain, Gram stain, Modified acid-fast stain	Nocardia	Thin slender bacilli
May-Grünwald Giemsa stain, hematoxylin and eosin stain, Gram stain, Steiner's stain	*Helicobacter pylori*	Flying bird-like bacilli in row
Warthin-Starry stain	*Treponema pallidum*	Black color against yellow to pale brown background
Fungi		
Papanicolaou's stain, May-Grünwald Giemsa stain, Gomori methenamine stain and periodic acid–Schiff (PAS) stain	*Candida albicans*	Thin slender-like pseudohyphae and spores
Papanicolaou's stain, periodic acid–Schiff (PAS), hematoxylin and eosin stain, Gram stain	Aspergillus	Slender bacilli with acute angle branching
Papanicolaou's stain, hematoxylin and eosin stain, Gomori methenamine silver stain	Mucormycosis	Broad wide-angle branching, nonseptate
Mucicarmine stain, Masson-Fontana silver stain	*Cryptococcus neoformans*	Small 3–5 µm round structure
Gomori methenamine silver stain, periodic acid–Schiff (PAS) stain	*Histoplasma capsulatum*	Small 2–3 µm round structure
Gomori methenamine silver stain	*Pneumocystis jiroveci*	Organism appears as ping pong balls or folded spheres
Parasites		
Periodic acid–Schiff (PAS) stain, hematoxylin and eosin stain, iron hematoxylin and eosin stain	*Entamoeba histolytica*	Round-shaped small organism
Hematoxylin and eosin stain	*Giardia lamblia*	Pear-shaped small organisms
Hematoxylin and eosin stain, Gomori methenamine silver stain, periodic acid–Schiff (PAS) stain	*Echinococcus granulosus*	Hooklets demonstrated on fine needle aspiration cytology

Contd...

Table 14.19 Commonly used stains in histopathology (*Contd...*)

Special Stains	Uses	Result
Stains for connective tissue		
Reticulin stain (used to highlight outlines of parenchyma of organs and highlighting growth pattern of neoplasia)	Reticulin fibers	Black against clear background
Jones methenamine silver stain	Similar to reticulin stain	
Masson's trichrome stain (used in chronic active hepatitis with hepatocytes collapse, cerebral abscess and scleroderma with fibrosis of gastric submucosa)	▪ Elastic fibers ▪ Collagen fibers ▪ Background	▪ Black color ▪ Red color ▪ Yellow color
Verhoeff-van Gieson (VVG) stain (used to outline arteries)	Elastic fibers	Black color
PTAH (phosphotungstic acid hematoxylin)	Cross striations in muscle fibers	Deep purple color
Pentachrome stain	▪ Elastic fibers ▪ Collagen fibers ▪ Fibrin ▪ Muscle ▪ Mucin	▪ Black color ▪ Red color ▪ Red color ▪ Red color ▪ Red color
Oil red O	Fat stain	Red color
Stains for nervous system		
Bielschowsky's stain	Nerve endings, neuron fibrils, tangles and plaques	Black color
Luxol fast blue	Myelin	Blue color
Pigments and minerals		
Perls Prussian blue reaction	Iron	Blue color
Hall's bile	Bile pigments	Emerald green color
von Kossa stain	Calcium	Black color
Alzarin red S (pH 4.8)	Calcium	Red color
Rhodamine stain	Copper	Red to orange color
Gomori's methenamine silver stain	Urate crystals	Black color
Masson-Fontana stain (used in melanoma)	Melanin	Black color
Churukian-Schenk stain	Argyrophil granules	Black color

PAS reactive tissue components are glycogen, starch, mucin, α_1-antitrypsin, fungal capsule, pancreatic zymogen granules, thyroid, colloid, corpora amylacea and plasma cell of Russell bodies.

Table 14.20 Carbohydrate classification for the purpose of histochemical staining

Parameters	Simple Carbohydrates	Glycoconjugates
Composition	Composed of pure carbohydrate	Composed of carbohydrates and other molecules such as protein and lipid
Examples	▪ Monosaccharides (glucose, mannose, galactose) ▪ Oligosaccharides (sucrose, maltose) ▪ Polysaccharides (glycogen, starch)	▪ Proteoglycans ▪ Mucins ▪ Other glycoproteins

Table 14.21 Mucin types and their origin for the purpose of histochemical staining

Parameters	Neutral Mucins	Acidic Simple, Nonsulfated Epithelial Mucins (Sialomucins)	Acidic Complex, Sulfated Epithelial Mucins (Sulfomucins)	Acidic Simple, Mesenchymal Mucins Contain Hyaluronic Acid	Acidic Complex, Connective Tissue Mucins
Location of mucin	▪ Surface epithelia of gastric mucosa ▪ Brunner's glands and prostatic epithelia	▪ Bronchial submucous glands ▪ Salivary glands ▪ Goblet cells	Bronchial mucous glands	Sarcomas	Tissue stroma, cartilage, and bone (chondroitin sulfate or keratan sulfate)
PAS stain	Positive	Positive	Positive	Positive	Negative
Alcian blue at pH	Negative	Positive (pH 2.5)	Positive (pH 1)	Negative	Selectively positive at pH 0.5
Colloidal iron	Negative	Positive	Positive	Negative	Negative
Mucicarmine	Negative	Positive	Positive	Negative	Negative
Metachromatic stain	Negative	Positive	Positive	Negative	Negative

PAS stain is used to demonstrate mucin and glycogen. Mucicarmine stain is specific for epithelial mucins. Acidic sulfomucins resist hyaluronidase digestion.

IMMUNOHISTOCHEMISTRY TECHNIQUE

IMMUNOHISTOCHEMISTRY TECHNIQUE: OVERVIEW

Immunohistochemistry (IHC) technique is the most powerful and widely used ancillary methods in surgical pathology to detect antigens in tissue sections by use of labeled antibody through antigen–antibody reactions. These are visualized by using fluorescent dye, enzyme, radioactive element or colloidal gold.

- Immunofluorescence microscopy is still used in the evaluation of medical renal biopsies. Currently, antigens are detected in formalin fixed paraffin-embedded tissue sections by immunoperoxidase technique.
- Common indications for immunohistochemistry technique are characterization of neoplasms, detection of infectious organisms and evaluation of prognostic or predictive factors.

TISSUE FIXATION

Tissue should be fixed in neutral pH formalin for 12–48 hours at room temperature. It is worth mentioning that formalin induces crosslinks that may mask some epitopes resulting in loss of immunoreactivity. Decalcification of bone samples also reduces immunoreactivity.

TISSUE SECTION USED FOR IMMUNOSTAINING

Unstained tissue sections are cut from paraffin block and placed on charged slides coated with poly-L-lysine or gelatin or albumin. Immunostaining should be performed immediately because unstained sections exposed to air for prolonged time may lose antigen immunoreactivity.

Frozen Section

If the unfixed tissue is frozen, the tissue sections obtained may need to be used for immunoassays. Tissue antigens in frozen sections are not altered. Frozen tissue sections may fall off the slides.

Formalin-fixed Paraffin-embedded Section

If the tissue is formalin-fixed paraffin-embedded, deparaffinize tissue sections to remove the infiltrated paraffin wax by using organic solvents. The tissue section then needs to be rehydrated by sequential immersion in graded alcohols (100%, 70%, 50% and then PBS, i.e. phosphate buffered saline). The deparaffinized tissue section may need to be treated to expose buried antigenic epitopes with either proteases or by heating in low pH citrate buffer or high pH EDTA buffer (antigen retrieval).

CLASSIFICATION OF ANTIBODIES

Antibodies can also be classified as primary or secondary antibodies used in immunohistochemistry technique.

PRIMARY ANTIBODIES

Primary antibodies are immunoglobulin molecules that bind to the target antigen in the tissue sections. Antibodies used for specific detection can be

Table 14.22 Comparison between polyclonal antibody and monoclonal antibody

Parameters	Polyclonal Antibody	Monoclonal Antibody
Synthesis	Mixture of synthesis of different antibodies to a single antigen	Synthesis by single clone commonly raised in mice
Specificity	Multiple epitopes	Single epitope

monoclonal derived via the hybridoma technique or polyclonal obtained from an antiserum (Table 14.22). Primary antibodies are unconjugated antibodies. In general, monoclonal antibodies are considered to exhibit greater specificity than polyclonal antibodies.

SECONDARY ANTIBODIES

Secondary antibodies are raised against primary antibodies, which recognize immunoglobulin of a particular species. These secondary antibodies are not visible with standard microscopy, hence labeled with fluorochrome (fluorescein, rhodamine), enzymes (horseradish peroxidase, alkaline phosphatase). Labeling secondary antibody is done in such a manner that it does not interfere with their binding specificity. For electron microscopy study, scattering compounds such as ferritin and colloidal gold are used for labeling.

BACKGROUND STAINING

Background staining occurs due to binding of nonspecific antibody or endogenous enzymes to the chromogenic substrate. Therefore, working dilution of primary antibody must be done, that yields contrast between specific staining and background staining. Endogenous enzymes present in red blood cells, neutrophils, eosinophils, monocytes/macrophages and neoplastic cells yield background staining. Endogenous peroxidase activity can be blocked by incubation with hydrogen peroxide.

DETECTION SYSTEMS OF IMMUNOHISTOCHEMISTRY TECHNIQUE

The principle of immunohistochemistry technique is to localize antigens in tissue sections by the use of labeled antibodies as specific reagents through antigen–antibody interactions that are visualized by a marker such as fluorescent dye, enzyme, radioactive element or colloidal gold.

DIRECT CONJUGATE-LABELED ANTIBODY METHOD FOR IMMUNOSTAINING

Direct conjugate-labeled antibody method is the application of labeled nonspecific antibody directly to tissue section obtained from skin or renal biopsies. It is one step immunohistochemical staining technique, that utilizes only one antibody.

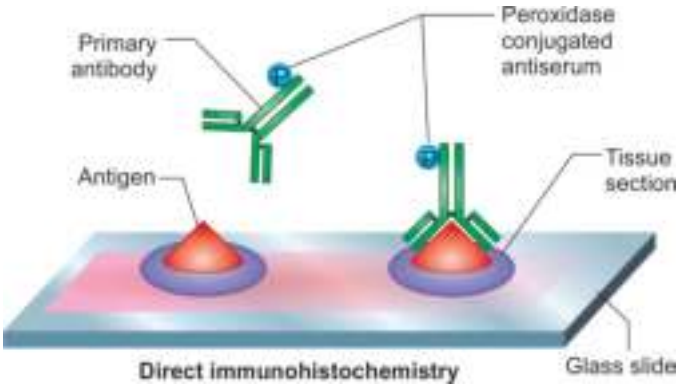

Fig. 14.3: Direct method. Enzyme-labeled primary antibody reacts with tissue antigen.

- The immunomarker then demonstrates the cellular location of the antigen in the tissue section. The label used can be an enzyme, biotin, fluorochrome or colloidal gold.
- There are several procedures that are being used to enhance the direct conjugate-labeled antibody method. The most common one is the biotin label to conjugate the antibody, and then the biotin will bind to the receptor of either the labeled avidin or streptavidin.
- With the second layer of labeling, the staining becomes simplified, which gives quick results, however, labeling intensity is low. Drawback of this procedure is requirement of large amount of antibody for labeling. Secondly, there is lack of signal amplification (Fig. 14.3).

INDIRECT OR SANDWICH METHOD FOR IMMUNOSTAINING

Indirect or sandwich method includes two major procedures: (a) indirect labeled procedure, and (b) indirect unlabeled antibody procedure.

- Indirect or sandwich medhod for immunostaining is more sensitive due to signal amplification through secondary reactions with different antigens. In addition, this method is also economical. Since one labeled second layer of antibody can be used with many first layer antibody to different antigens.
- Indirect labeled procedure has two layers of antibodies. The primary unlabeled antibody is specific

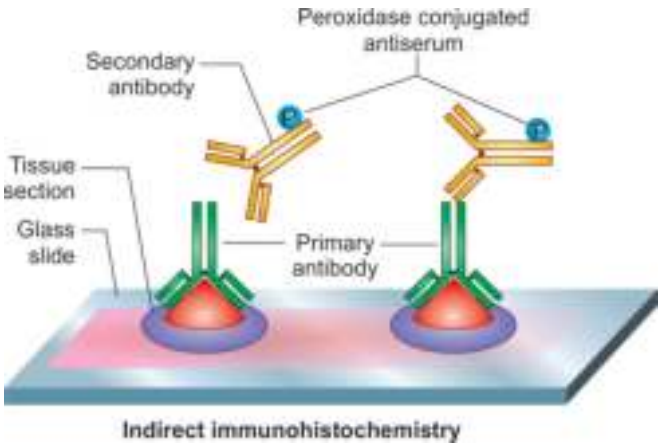

Fig. 14.4: Two-step indirect method of immunostaining. Enzyme-labeled secondary antibody reacts with primary antibody bound to tissue antigen, if the primary antibody is prepared in rabbit or mouse, the secondary antibody must be directed against rabbit or mouse immunoglobulins, respectively.

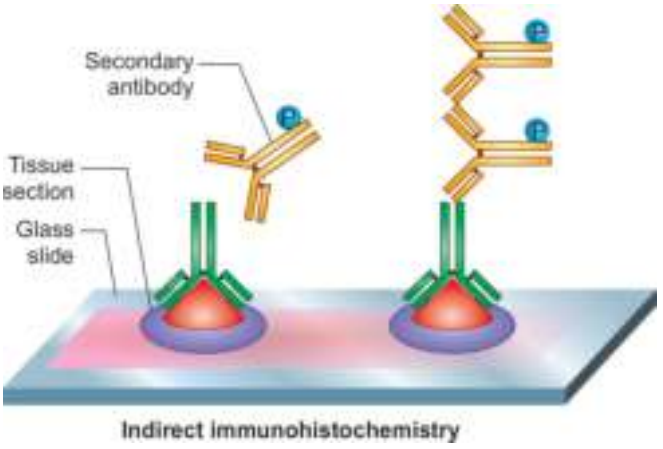

Fig. 14.5: Peroxidase–antiperoxidase (PAP) indirect method of immunostaining. In this three-step indirect method, enzyme-labeled tertiary antibody reacts with enzyme-labeled secondary antibody. Three-step indirect method provides a simple way to further increase the staining intensities compared to the two previous techniques.

for a particular tissue antigen. The secondary labeled antibody with fluorescent dye or peroxidase enzyme is an anti-immunoglobulin antibody. The marker then identifies the sites of the tissue antigen.

- The unlabeled antibody method has three layers of antibodies. The primary antibody is specific for a particular antigen. The secondary unlabeled antibody is an anti-immunoglobulin that reacts to both the primary antibody and to the tertiary antibody. The tertiary antibody is an anti-enzyme antibody, which reacts to a particular enzyme is demonstrated by its reaction with the substrate. Two-step indirect method of immunostaining is shown in Fig. 14.4.

Peroxidase–Antiperoxidase (PAP) Indirect Method

Unlabeled antibody technique is also known as peroxidase–antiperoxidase (PAP) indirect method, which uses an unlabeled primary antibody, an unlabeled bridge antibody and an antiperoxidase antibody and peroxidase molecule.

- Unlabeled bridge antibody directed against both primary antibody and the antiperoxidase antibody links the primary antibody to tissue antigen via signal generated by peroxidase. The sensitivity is about 100–1000 times higher since peroxidase molecule is not chemically conjugated with anti-IgG.
- Although peroxidase molecule is immunologically bound, yet it does not lose its enzymatic activity. It also permits much higher dilution of primary antibody resulting in elimination of many unwanted antibodies and reducing nonspecific background staining. Peroxidase–antiperoxidase (PAP) indirect method of immunostaining is shown in Fig. 14.5.

Pathology Pearls: Immunoperoxidase Staining

Tissue antigen markers that can be demonstrated by immunoperoxidase staining of formalin fixed paraffin sections as mentioned below:

- CD45 is a common hematopoietic lineage marker.
- S-100 is a neurological and neural crest cell marker. It is a calcium-binding protein soluble in 100% saturated ammonium sulfate.
- Synaptophysin is a neuroendocrine cell marker.
- Desmin is a skeletal muscle tissue marker.
- HMB-45 is human melanoma, black protein is common marker for melanoma and other tumors with melanocytic differentiation. It stains immature melanosomes.

Avidin–Biotin Complex (ABC) Indirect Method

Abiotinylated secondary antibody is used to recognize primary antibody. Avidin complexed with biotinylated peroxidase is then bound to secondary antibody. The peroxidase is then developed by DAB (3,3′-diaminobenzidine) used as chromogen in immunostaining or other substrate to produce different calorimetric end products. This reaction delivers several peroxidase molecules to the primary antibody sites and boosts its sensitivity. Disadvantage of this avidin–biotin complex method is background staining (Fig. 14.6).

Labeled Streptavidin–Biotin (LSAB) Indirect Method

Streptavidin derived from *Streptococcus avidin* is recent substitute of avidin. A biotinylated secondary antibody is used to recognize primary antibody. Streptavidin complexed with biotinylated peroxidase is then bound to secondary antibody. This labeled streptavidin–biotin technique is similar to standard avidin–biotin complex method. This reaction delivers several peroxidase molecules to the primary antibody

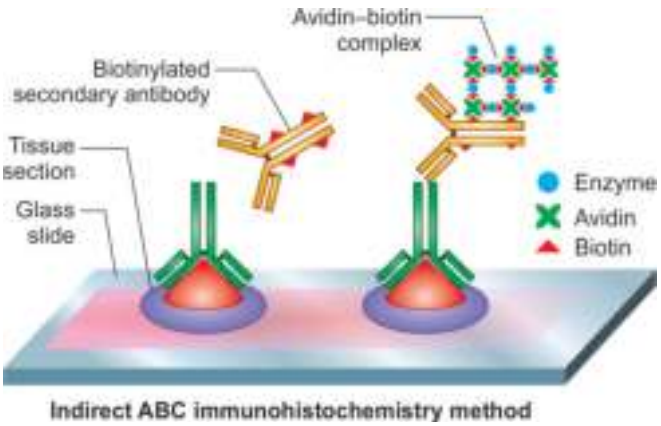

Fig. 14.6: Indirect avidin–biotin complex (ABC) immunohistochemistry method: in the ABC technology, the avidin or streptavidin–biotin enzyme complex reacts with the biotinylated secondary antibody.

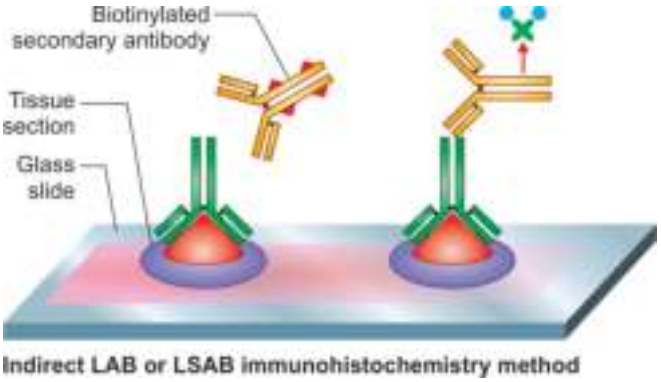

Fig. 14.7: Indirect labeled streptavidin-biotin (LSAB) immunohistochemistry method: Labeled streptavidin–biotin method. Labeled streptavidin reacts with biotinylated secondary antibody.

sites and boosts its sensitivity. The enzyme is then visualized by application of the substrate chromogen solutions to produce different calorimetric end products. Streptavidin–biotin method has decreased background staining (Fig. 14.7).

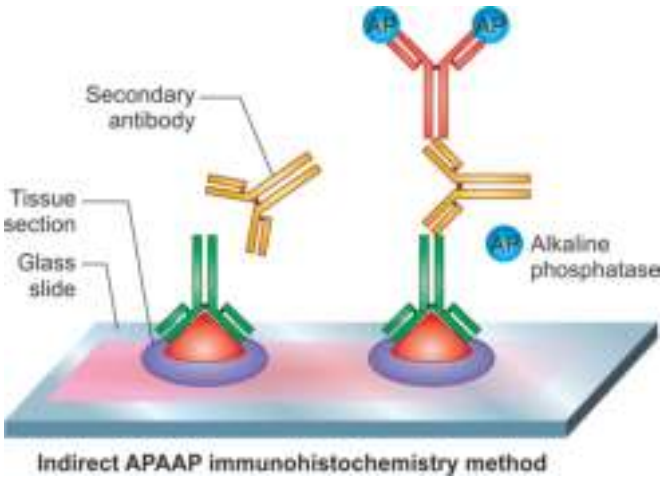

Fig. 14.8: Indirect alkaline phosphatase and antiphosphatase (APAAP) and immunohistochemistry method.

Alkaline Phosphatase and Antiphosphatase (APAAP) Indirect Method

Enzyme alkaline phosphatase and anti-alkaline phosphatase instead of peroxidase is widely used, which gives most sensitive results and can be applied on paraffin, cryostat sections or on smears (Fig. 14.8).

IMMUNOHISTOCHEMISTRY TECHNIQUE PROTOCOL

In order to visualize enzyme-substrate reactions, various chromogens, which get converted into visible colored end products, are used. Commonly used chromogens are diaminobenzidine (DAB), 3-amino-9-ethylcarbazole (AEC) and 4-chloro-1-naphthol (CN) producing brown, red and dark blue colors, respectively. Immunohistochemistry (IHC) technique protocol is given in Table 14.23.

Table 14.23 Immunohistochemistry (IHC) technique protocol

Protocol of IHC	Steps	Procedure
Tissue preparation	▪ Tissue fixation	▪ Immersion or perfusion fixation (neutral formalin, paraformaldehyde and Bouin's solution)
	▪ Tissue sectioning	▪ Microtome for paraffin blocks; cryostat for frozen tissue and vibratome for fixed hard tissue
Pre-incubation steps	▪ Deparaffinization of tissue section	▪ Paraffin is removed from tissue section
	▪ Removing the fixative	▪ Washing of tissue section in buffer solutions (phosphate buffer, tris-HCl buffer, HEPES, i.e. hydroxyethyl piperazine-ethane-sulfonic acid buffer, etc.)
	▪ Neutralization of endogenous peroxidase	▪ Endogenous peroxidase is removed
	▪ Blocking	▪ Covering the nonimmunological sticky sites on tissue section (bovine serum albumin, nonimmune normal serum, gelatin, milk)
	▪ Blocking the surface tension	▪ Triton X-100 and NaCl are used to block surface tension

Contd...

Table 14.23 Immunohistochemistry (IHC) technique protocol (*Contd...*)

Protocol of IHC	Steps	Procedure
Incubation with antibody	▪ Primary antibody application ▪ Secondary antibody application	▪ Used in a solution at different dilutions with the blocking agent. The incubation time changes according to the properties of the antigen or antibody as well as depending on the temperature ▪ Must be raised in the species other than the species of which the cells or tissues are taken or the primary antibody is raised. It should specifically recognize the immunoglobulin of the species in which the primary antibody is raised
Labeling	Labeling of antibody	Immunoenzyme, immunofluorescence, immunogold
Microscopical analyses	Microscopic study of tissue section	Slides are examined under microscope

TISSUE POSITIVE AND NEGATIVE CONTROL IN IMMUNOHISTOCHEMISTRY TECHNIQUE PROTOCOL

Tissue positive control is to test for immunohistochemistry technique protocol or procedure used. It will be ideal to use known tissue positive as a control. Tissue negative control is used to test for the specificity of the antibody involved.

APPLICATIONS OF IMMUNOHISTOCHEMISTRY

Immunohistochemistry is used for detection of intercellular antigens, cell surface antigens, tissue antigen for diagnosing autoimmune diseases, soluble antigens of the cell, protein hormones in histologic diagnosis, diagnosis of the endocrine tumors, small amounts of peptides in endocrine or neuroendocrine cells, immunodeposits and tumor markers and tumor typing.

IMMUNOPROFILE AS DIAGNOSTIC TOOL

Panel of immunohistochemical markers is applied on formalin-fixed paraffin-embedded sections in surgical pathology (Tables 14.24 to 14.67 and Figs 14.9 to 14.11). Kindly *refer* to immunohistochemical markers of soft tissue tumors and central nervous system in Chapters 28 and 30, respectively.

Table 14.24 Panel of immunohistochemical markers for various tissues differentiation as diagnostic tool

Markers	Expression
Epithelial tissue differentiation	
Basic cytokeratins	CK1 to CK8 (type B/class II) detected by AE3 antibody
Acidic cytokeratins (type A/class I) (HMWCK)	▪ HMWCK (CK9, CK10, CK11, CK16, CK17) is detected by CK903 and CK5/6 antibodies for demonstration of squamous keratins in squamous cell carcinoma ▪ LMWCK (CK18, CK19, CK20) is detected by CAM 5.2 antibody in colon carcinoma, prostatic carcinoma, renal cell carcinoma and hepatocellular carcinoma
Epithelial membrane antigen (EMA) common epithelial marker	Meningioma, breast adenocarcinoma, colorectal adenocarcinoma, pancreatic adenocarcinoma, Paget's disease of breast, choriocarcinoma, desmoplastic small round cell tumor, perineuroma, epithelioid sarcoma, plasma cell neoplasms, anaplastic large cell lymphoma, diffuse large B cell lymphoma, Hodgkin disease (lymphocytic predominance), renal cell carcinoma, thymic carcinoma, mesothelioma (epithelioid variant) carcinoid tumor, chordoma
Carcinoembryonic antigen (CEA)	Hepatocellular carcinoma (50–90%), colorectal carcinoma (70–80%), gastric carcinoma, lung adenocarcinoma (97%), pancreatic adenocarcinoma (90%), breast carcinoma, urinary bladder carcinoma, cervical carcinoma and another tumor (synovial sarcoma biphasic variant)
p53 protein	▪ TP53 tumor suppressor gene located on chromosome 17p13 encodes p53 protein that repairs damaged DNA before cell division by inducing cell cycle arrest to allow time for DNA repair or force the cell to undergo apoptosis via activation of BAX gene. ▪ Mutation in TP53 is detected in human neoplasia, however, its absence does not rule of malignancy. Germline heterogenous mutation in TP53 is demonstrated in Li-Fraumeni syndrome.

Contd...

Table 14.24 Panel of immunohistochemical markers for various tissues differentiation as diagnostic tool (*Contd...*)

Markers	Expression
	▪ The p53 immunomarker differentiates malignant conditions, which are most often p53 positive (carcinoma *in situ* and invasive carcinoma) from p53 negative conditions (reactive and metaplastic conditions) ▪ The p53 immunomarker can distinguish uterine serous carcinoma, which is p53 positive from p53 negative endometrioid carcinoma ▪ The p53 immunomarker may be useful as serum tumor marker
B72.3	Adenocarcinomas and epithelioid angiosarcoma
β-Catenin	Colon carcinoma, familial adenomatous polyposis (FAP) and other tumors (hepatoblastoma, pancreatoblastoma, craniopharyngioma, tubular adenoma)
α-Fetoproteins	Yolk sac tumor, hepatocellular carcinoma (except fibrolamellar variant) and another tumor (hepatoblastoma)
BerEP4/EpCAM	Metastatic adenocarcinoma to liver, cholangiocarcinoma, lung adenocarcinoma and another tumor (synovial sarcoma biphasic variant)
E-Cadherin	E-cadherin (present in ductal carcinoma and absent in lobular carcinoma of breast), E-cadherin loss in nonepithelial malignancies
Calretinin	Some carcinomas and other tumors (epithelial mesothelioma, synovial sarcoma, sex–cord stromal tumors, cardiac myxoma, adrenocortical tumors, adenomatoid tumors)
Desmoplakin	Epithelial tumors in general and other tumors (meningioma, Ewing sarcoma)
HBME-1	Adenocarcinomas (some cases), other tumors (mesothelioma, synovial sarcoma, chordoma, chondrosarcoma)
Mesothelin	Ovarian serous cystadenocarcinoma, adenocarcinomas (some others) and other tumors (mesothelioma, synovial sarcoma biphasic variant)
MOC31	Adenocarcinoma (most common)
TTF-1 (thyroid transcription factor 1)	Thyroid papillary carcinoma, thyroid follicular carcinoma, thyroid medullary carcinoma, and other tumors (small cell lung carcinoma in 90%, lung adenocarcinoma and small cell carcinomas of many organs)
Calcitonin	Thyroid medullary carcinoma and neuroendocrine tumors
Villin and CDX2	Intestinal differentiation (e.g. colon carcinoma), other tumors (carcinoid tumors, adenocarcinoma of urinary bladder)
Napsin A	Lung carcinoma, renal cell carcinoma (papillary variant), and thyroid carcinoma (weak positivity)
Gross cystic disease fluid protein (GCDFP)	Breast carcinoma (low sensitivity and specificity), and salivary gland carcinoma (low sensitivity and specificity)
Mammaglobin	Breast carcinoma, gynecological tumors (cross reactivity)
PAX8	Renal cell carcinoma (pan-renal marker broader than PAX2), pan-Müllerian tumors of uterus and ovary, thyroid carcinoma (papillary > follicular >> medullary variants)
PAX2	Renal cell carcinoma (pan-renal marker in 50%)
DPC4 (decapentaplegic homolog 4)	DPC4 negative in pancreatic carcinoma and cholangiocarcinoma (50%) due to loss of expression, cholangiocarcinoma (loss of expression in 50%), but positive staining is noncontributory
PSA (prostate-specific antigen), PSAP (prostate-specific acid phosphatase), PSMA (prostate-specific membrane antigen +ve), prostein	Prostatic carcinoma (note: PSAP reactivity in rectal carcinoids)
HepPar1	Hepatocellular carcinoma
Arginase 1 (new marker)	Hepatocellular carcinoma, hepatoid variants of carcinoma at other sites (also positive)
CAIX (carbonic anhydrase)	Renal cell carcinoma (clear cell variant), renal cell carcinoma (papillary variant) in areas of necrosis

Contd...

Table 14.24 Panel of immunohistochemical markers for various tissues differentiation as diagnostic tool (*Contd...*)

Markers	Expression
WT1 (Wilm's tumor 1) protein	Desmoplastic small round cell tumor, Wilm's tumor (nephroblastoma), malignant mesothelioma, ovarian serous cystadenocarcinoma
Vascular endothelial differentiation	
CD31 (PECAM1) endothelial marker	Blood vessel and lymphatic channels
CD34 (hematopoietic stem cell antigen)	Blood vessels
D2–40 (podoplanin) endothelial marker	Lymphatic channels, Kaposi sarcoma, angiosarcoma, lymphangioma
vWF VIII-related antigen (endothelial marker)	Epithelioid hemangioblastoma, angiosarcoma (some cases), vascular invasion in thyroid carcinoma
Ulex europaeus 1 (endothelial marker)	Angiosarcoma
CD141 (thrombomodulin) endothelial marker	Blood vessels and lymphatic channels
Fli-1 (endothelial marker)	Blood vessels and lymphatic channels, angiosarcoma
Flt-4 (VEGFR3) endothelial marker	Kaposi sarcoma, angiosarcoma and hemangioma
Smooth muscle differentiation	
Desmin (intermediate filament)	Pan-muscle marker (smooth muscle, skeletal muscle); and myofibroblasts, leiomyoma, leiomyosarcoma (70%), rhabdomyosarcoma
MSA (muscle-specific actin)	Pan-muscle marker (smooth muscle, skeletal muscle); and myofibroblasts, leiomyoma, leiomyosarcoma, rhabdomyosarcoma
SMA (smooth muscle actin also known as α-actin)	Smooth muscle, leiomyoma, leiomyosarcoma and myoblastic tumors (e.g. nodular fasciitis) but absent in skeletal muscle
SMMHC (smooth muscle myosin heavy chain) contractile apparatus associated protein encoded by CALD-1 gene	Smooth muscle, leiomyoma, leiomyosarcoma; but absent in skeletal muscle
Calponin (contractile apparatus associated protein encoded by CALD-1 gene)	Smooth muscle, leiomyoma, leiomyosarcoma, myoepithelial cells. myofibroblasts, myofibroblastic tumors; but absent in skeletal muscle
Caldesmon (contractile apparatus associated protein encoded by CALD-1 gene)	Smooth muscle, leiomyoma, leiomyosarcoma; but absent in skeletal muscle including skeletal muscle tumors (rhabdomyoma and rehabdomyosarcoma)
Skeletal muscle differentiation	
Desmin	Smooth muscle and skeletal muscle, leiomyoma, leiomyosarcoma (70%), rhabdomyosarcoma; and myofibroblasts (variable staining)
MSA (muscle-specific actin)	Smooth muscle, skeletal muscle, leiomyoma, leiomyosarcoma, rhabdomyosarcoma
MyoD1 (transcriptional factor)	Skeletal muscle, alveolar rhabdomyosarcoma (diffuse staining), embryonal rhabdomyosarcoma (focal staining), leiomyosarcoma but negative in normal smooth muscle and leiomyoma
Myogenin (transcriptional factor)	Skeletal muscle, alveolar rhabdomyosarcoma (diffuse staining), embryonal rhabdomyosarcoma (focal staining), leiomyosarcoma but negative in normal smooth muscle and leiomyoma
Myoglobin	Regenerating skeletal muscle and well-differentiated cells in rhabdomyosarcoma and tumors with heterologous skeletal muscle differentiation
Melanocytic lineage differentiation	
Melan A (A103)	Epithelioid melanoma positive (80–100%), but negative in spindle cell melanoma and desmoplastic melanoma
MART-1 (melanoma antigen recognized by cells)	Epithelioid melanoma positive (80–100%), but negative in spindle cell melanoma and desmoplastic melanoma
HMB-45 (human melanoma black 45) marker of immature melanocytes	Epithelioid melanoma positive (60–90%), but negative in spindle cell melanoma and desmoplastic melanoma, expressed in other tumors (clear cell sarcoma and angiolipoma family member PEComa)

Contd...

Table 14.24 Panel of immunohistochemical markers for various tissues differentiation as diagnostic tool (*Contd...*)

Markers	Expression
S-100 (calcium binding protein)	Epithelioid melanoma, spindle cell melanoma and desmoplastic melanoma and other tumors
MITF (microphthalmia transcription factor)	Epithelioid melanoma, and other tumors neurothekeoma and osteoclastic giant cells
SOX 100	Epithelioid melanoma
PNL2	Epithelioid melanoma
MUM1	Epithelioid melanoma
Tyrosinase	Malignant melanoma
CD63	Nevi and malignant melanoma, and also positive in other tumors (some carcinomas, neurothekeoma, alveolar soft part sarcoma)
PNL2	Melanoma
MUM1	Melanoma
Neural and neuroendocrine-specific markers	
Synaptophysin	Neuroblastoma, medulloblastoma, Ewing sarcoma/PNET, paraganglioma, neuroendocrine carcinoma, pheochromocytoma, thyroid medullary carcinoma
Chromogranin A	Neuroblastoma, medulloblastoma, Ewing sarcoma/PNET, paraganglioma, neuroendocrine carcinoma, pheochromocytoma, thyroid medullary carcinoma and another tumor (malignant melanoma)
NSE (neuron-specific enolase)	Neuroblastoma, medulloblastoma, Ewing sarcoma/PNET, paraganglioma, neuroendocrine carcinoma, pheochromocytoma, thyroid medullary carcinoma
Neurofilament proteins	Neuroblastoma, paraganglioma, Merkel cell carcinoma
α-Internexin	Neuroblastoma, paraganglioma, Merkel cell carcinoma
Myofibroblastic tissue differentiation	
Immunomarkers for myofibroblastic tissue differentiation	Calponin (+), smooth muscle actin (+), desmin (variable staining), caldesmon (–)
Myoepithelial differentiation (polyphenotype)	
Immunomarkers for myoepithelial differentiation (polyphenotype)	GFAP (+ glial fibrillary acidic protein), S-100 protein (+), p53 (+), cytokeratin (+), SMMHC (+ smooth muscle myosin heavy chain), calponin (+), caldesmon (+)
Histiocytic differentiation	
CD163 (high specificity)	Histiocytes, histiocytic sarcoma, juvenile xanthogranuloma
XIIIa (high-specificity)	Histiocytes especially dendritic cells
CD68 (low-specificity)	Histiocytes, melanoma, paraganglioma, schwannoma, granular cell tumor
Lysozyme also called muramidase (low-specificity)	Histiocytes, myelomonocytic cells, goblet cell carcinoid, breast lactating lobules, acinic cell carcinoma, acute myelomonocytic leukemia (AML-M4), acute monocytic leukemia (AML-M5), adenocarcinoma (various sites), chordoma, oncocytoma of conjunctiva, histiocytoma, histiocytic sarcoma, Rosai-Dorfman disease, Langerhans cell histiocytosis, mastocytosis, myeloid sarcoma, renal collecting duct/Bellini duct carcinoma, spleen angiosarcoma, xanthogranuloma
HAM56	Histiocytes, vascular endothelium and adenocarcinoma
MAC387	Histiocytes
α-Antitrypsin	Histiocytes
Neuroendocrine (NE) differentiation	
Immunomarkers for neuroendocrine differentiation	Synaptophysin, chromogranin A, NSE (neuron-specific enolase), CD56 (neuronal cell adhesion molecule)
Glial differentiation	
Immunomarker for glial differentiation	Glial fibrillary astrocytic protein (GFAP)

Contd...

Table 14.24 Panel of immunohistochemical markers for various tissues differentiation as diagnostic tool (*Contd...*)

Markers	Expression
Neuronal differentiation	
Immunomarker for neuronal differentiation	Sm31 (pan-NF), Sm32 (cell body) in glioma or meningioma, Sm31 (axon), NeuN (neuronal nuclei)
Schwann (nerve sheath) cells	
Immunomarker for Schwann (nerve sheath) cells	S-100 protein, Leu-7 (CD57)
Hematopoietic tissue	
Pan-hematopoietic marker	CD45/Leukocyte common antigen
Pan-T cell markers	CD3, cCD3 (flow cytometry only)
Pan-B cell markers	CD20, CD79a, PAX5, CD138 and κ/λ light chains
Myeloblast	Lineage-specific markers (CD13, CD15, CD33, CD11b)
B lymphoblast	Lineage-specific markers (CD19, CD79a), and TdT (terminal deoxynucleotidyl transferase); and variable expression of CD20, CD34, CD10, HLA-DR
T lymphoblast	CD33 and TdT (terminal deoxynucleotidyl transferase); and variable expression of CD10, CD34
Serous acinar cells	
PAS (periodic acid–Schiff) stain	General serous marker
Trypsin	Pancreas serous acinar cells
Chymotrypsin	Pancreas serous acinar cells
Lipase	Pancreas serous acinar cells
S-100 (calcium binding protein) and other multispecific markers	
S-100 protein	Epithelioid melanoma, spindle cell melanoma, desmoplastic melanoma, schwannoma, neurofibroma, nerve sheath myxoma, chondroma, chondrosarcoma, extraskeletal myxoid chondrosarcoma (<30%), liposarcoma, synovial sarcoma (20–30%), rhabdomyosarcoma, myoepithelioma/mixed tumor, Rosai-Dorfman disease, Langerhans cell histiocytosis, interdigitating reticulum cell sarcoma, ossifying fibromyxoid tumor (>90%)
p75 nerve growth factor	Nerve sheath tumors and dermatofibrosarcoma protuberans and other sarcomas
CD66 (NCAM)	Neuroendocrine carcinoma, rhabdomyosarcoma and other sarcomas
Other important tumor markers	
Anaplastic lymphoma kinase (ALK)	Large cell anaplastic lymphoma, inflammatory myoblastic tumors (variable expression)
Basement membrane proteins	Schwannoma, angiosarcoma
BCL-2 (B cell lymphoma 2)	Follicular lymphoma, CLL/SLL, MCL (mantle cell lymphoma), MZL (marginal zone lymphoma)
BCL-6 (B cell lymphoma 6)	Follicular lymphoma, Burkitt lymphoma and synovial sarcoma
ALK (anaplastic lymphoma kinase) expression as a result of t(2;5)/NMP-ALK	Anaplastic large cell lymphoma, lung adenocarcinoma with EML4-ALK rearrangement
CD10	Endometrial stromal tumors, myoblastic tumors
CD99	Ewing sarcoma, widespread metastasis in different tumors
CD117	Gastrointestinal stromal tumors (GISTs), Ewing sarcoma, mast cell neoplasms, angiosarcoma, neuroblastoma, seminoma/ dysgerminoma, clear cell sarcoma, adenoid cystic carcinoma of salivary gland, thymic carcinoma, melanoma (some cases)
ER/PR (estrogen/ progesterone receptors)	Breast carcinoma (prognostic and therapeutic markers), uterine leiomyoma, retroperitoneal leiomyoma, angiomyoblastoma, aggressive angiomyxoma, endometrial carcinoma (some cases), ovarian carcinomas (some cases)
GFAP (glial fibrillary acidic protein)	Glial tumors, schwannoma, myoepithelial tumors
Inhibin	Granulosa cell tumor of ovary, adrenal cortical carcinoma, granular cell tumor
Osteocalcin	Osteosarcoma, osteoid tissue

Contd...

Table 14.24 Panel of immunohistochemical markers for various tissues differentiation as diagnostic tool (*Contd…*)

Markers	Expression
Brachyury	Chordoma, hemangioblastoma
Cathepsin K	Xp translocation renal cell carcinoma, chordoma, PEComas
Vimentin	Mesenchymal tumors, renal cell carcinoma (clear cell variant), endometrial carcinoma, mesothelioma, salivary gland carcinoma, sweat gland carcinoma, spindle cell carcinoma of any site
CD1a	Langerhans cell histiocytosis, T cell lymphoblastic lymphoma (some cases), thymoma with admixed thymocytes
CD2	T cell lymphoma, NK cell lymphoma/leukemia
cCD3 (flow cytometry only)	Most lineage-specific marker for T cell differentiation
CD3	Pan-T cell marker, T cell leukemia/ lymphoma
CD4 and CD8	T cell lymphoma/leukemia
CD5	CLL/SLL, MCL, blastoid marginal cell lymphoma, DLBCL (diffuse large B cell lymphoma in some cases)
CD7	T-ALL (100%), B cell lymphoma
CD10 (CALLA, common acute leukemia antigen)	T cell ALL (100%)
CD11b	Myelogenous leukemias with differentiation, NK cell tumors
CD11c	Hairy cell leukemia
CD13, CD14, CD33	Myelogenous leukemias
CD15	AML differentiation, adenocarcinoma, Reed-Sternberg cells in classic Hodgkin disease
CD19, CD20, CD22 (pan B cell markers)	B cell lymphoma, B-precursor ALL, DLBCL (diffuse large B cell lymphoma)
CD21, CD35	Follicular lymphoma, mantle cell lymphoma, angioimmunoblastic T cell lymphoma
CD23	Low-grade lymphoma (CLL/SLL), follicular lymphoma, mantle cell lymphoma
CD25 (IL-2 receptor)	Hairy cell leukemia, adult T cell leukemia/lymphoma, anaplastic large cell lymphoma, neoplastic mast cells
CD30 (Ki-1)	Reed-Sternberg cells in classic Hodgkin disease, anaplastic large cell lymphoma, embryonal carcinoma
CD38	Mantle cell lymphoma, chronic lymphocytic leukemia
CD41, CD42b, CD61 (flow markers)	AML-M7 with megakaryocytic differentiation
CD43	Low-grade lymphoma (e.g. CLL/SLL, mantle cell lymphoma, marginal zone lymphoma; but not follicular lymphoma), myeloid sarcoma (chloroma)
CD44	Small cell carcinoma of prostate
CD45 (leukocyte common antigen—LCA)	Classic Hodgkin disease Lymphoblastic lymphoma, anaplastic large cell lymphoma (some cases)
hCG-β (human chorionic gonadotropin-β)	Choriocarcinoma
Cell cycle progression inhibitors	
$P16^{INK4a}$ and $P14^{ARF}$ protein (CDKN2A gene) indirectly activate p53 gene	Familial melanoma, breast carcinoma (sporadic), pancreatic carcinoma (sporadic), esophageal carcinoma (sporadic)
RB1 (RB1 gene codes for RB1 protein, master break in cell cycle, that inhibits nuclear transcription factor)	Retinoblastoma (familial/sporadic), osteosarcoma (familial/sporadic), breast carcinoma (sporadic), colon carcinoma (sporadic), prostate carcinoma (sporadic), urinary bladder carcinoma (sporadic), lung carcinoma (sporadic)
Genome stability enabler proteins	
p53 protein transcriptional factor encoded by TP53 gene	Li-Fraumeni syndrome (cancers of breast and adrenal gland; sarcoma, leukemia and brain tumors) in more than 50% of cases

**Cytokeratin-positive other tumors include synovial sarcoma, epithelioid sarcoma, epithelioid angiosarcoma, yolk sac tumor, embryonal carcinoma, trophoblastic tumors, mesothelioma, chordoma, thymoma, leiomyosarcoma, malignant peripheral nerve sheath tumor.*

Table 14.25 Applications of immunohistochemistry in surgical pathology

Features	Applications
Diagnosis of neoplasms	
Diagnosis of poorly differentiated neoplasms such as carcinoma, lymphoma and melanoma	▪ Carcinoma (cytokeratin +) ▪ Lymphoma (CD45 +) ▪ Melanoma (melanocytic markers, e.g. S-100 calcium-binding protein), HMB-45 (human melanoma black 45) positive for epithelioid melanoma, melan A (A-203), MART1 (melanin antigen recognized by T cells 1), MITF (microphthalmic transcription factor), tyrosinase, SOX 100, PNL2, MUM1)
Diagnosis of carcinoma of unknown primary	▪ Colon carcinoma (CDX2 +) ▪ Lung carcinoma (TTF-1 +) ▪ Prostatic carcinoma (PSA +)
Diagnosis of invasion of neoplasm	▪ Loss of myoepithelial cells (breast carcinoma) ▪ Loss of basal cells (prostatic carcinoma) ▪ Loss of basement membrane/collagen type 4 (various carcinomas, but rarely used)
Analysis of prognostic markers	
Progniostic markers examples	▪ Ki-67/MIB1 (general proliferative marker) ▪ p53 (general apoptosis marker) ▪ HER2/neu expression in breast carcinoma has adverse prognosis ▪ CD38 expression in chronic lymphocytic leukemia has adverse prognosis
Analysis of markers reflecting a therapeutic response	
Predictive markers	▪ ER/PR (ER/PR positive breast carcinoma treated by 'Tamoxifen therapy') ▪ HER2/neu positive breast carcinoma treated by 'Herceptin therapy' ▪ c-KIT (Gleevec for gastrointestinal stromal tumor, chronic myelogenous leukemia)
Detection of micrometastases	
Detection of micrometastases by immunohistochemistry	▪ Melanoma (melanocytic markers, e.g. S-100 calcium binding protein), HMB-45 (human melanoma black 45) positive for epithelioid melanoma, melan A (A-203), MART1 (melanin antigen recognized by T cells 1), MITF (microphthalmic transcription factor), tyrosinase, SOX 100, PNL2, MUM1) ▪ Breast carcinoma (cytokeratins)

Table 14.26 Primers on location of antigens in the cells demonstrated by immunohistochemical markers

Primer on Location of Antigens in the Cells	Immunohistochemical Markers
Cell membrane reactivity	
Cell surface receptors	Epidermal growth factor (EGFR), HER2/neu
Cell adhesive molecule protein	E-cadherin
Cluster of differentiation (CD)	CD3 (T cell marker), CD20 (B cell marker), CD45, CD30 (Golgi region), CD15 (Golgi region), CD138, pan-T cell antigens
Cytoplasmic reactivity	
Intermediate filaments of cytoskeleton	Cytokeratins, desmin, vimentin, GFAP (glial fibrillary acidic proteins), neurofilament
Contractile proteins	SMA (smooth muscle actin also known as α-actin), calponin, caldesmon, SMMHC (smooth muscle myosin heavy chain)
Cytoplasmic proteins	S-100 protein, α_1-antitrypsin, NSE (neuron-specific enolase)
Melanocyte associated proteins in melanosomes	HMB-45 (human melanoma black 45), S-100 protein, MITF (microphthalmic transcription factor), SOX-100, PNL2, tyrosinase
Secretory products	ACTH
Mitochondria	BCL-2

Contd...

Table 14.26 Primers on location of antigens in the cells demonstrated by immunohistochemical markers (*Contd...*)

Primer on Location of Antigens in the Cells	Immunohistochemical Markers
Cytoplasmic granules and vesicles	Chromogranin, synaptophysin
Lysosome	MPO (myeloperoxidase)
Nuclear reactivity	
Steroid hormones	ER/PR (estrogen and progesterone receptors)
Transcriptional factors	BCL-1, BCL-6, TdT (terminal deoxynucleotidyl transferase), EBER, PAX-5, BOB-1, OCT-2, HHV-8, TTF-1 (thyroid transcription factor 1), CDX2, myogenin, WT1, p53, p63RB1, p21, p27
Proliferative marker	Ki-67
Nuclear as well as cytoplasmic reactivity	
Nuclear and cytoplasmic reactivity	S-100 protein, calretinin, ALK-1, ZAP70, β-catenin (only nuclear reactivity is specific)
Patterns of cytoplasmic reactivity	
Cytoplasmic granular reactivity pattern	Racemase, prostein (P501S), napsin A, Hep Par 1
Cytoplasmic dot-like reactivity pattern	CD30 and CD15 (Hodgkin disease), cytokeratins in neuroendocrine tumors

Table 14.27 Reactivity code of immunohistochemical markers

Expression	Interpretation
Positive (+++)	Overexpressed or consistently diffuse
Positive (+)	Positive
Positive/negative (+/–)	Usually, positive
Negative/positive (–/+)	Usually, negative
Negative (–)	Negative

Table 14.28 Expression of vimentin in various epithelial and mesenchymal human tumors

Vimentin Positive Tumors	Vimentin Negative Tumors
Mesenchymal tumors	Renal cell carcinoma (chromophobe variant)
Renal cell carcinoma (clear cell variant)	Lung carcinoma
Endometrioid carcinoma	Breast carcinoma
Mesothelioma	Endocervical carcinoma
Salivary gland carcinoma	Ovarian carcinoma
Serous ovarian carcinoma	Prostatic adenocarcinoma
Spindle cell carcinoma of any site	Colorectal adenocarcinoma
Malignant mixed Müllerian tumor	Hepatocellular carcinoma

Vimentin is a type 3 intermediate filament protein expressed in mesenchymal cells. It has been used in the past to differentiate sarcoma (vimentin positive) from carcinoma (vimentin negative). But is variably expressed in various carcinomas. Current application of vimentin is to confirm immune-reactivity, when all markers are negative.

Table 14.29 Applications of immunohistochemistry technique in analysis of cytokeratins

Monoclonal Antibody Used	Analysis of Various Types of Cytokeratins	Comments
AE1 antibody	All acidic cytokeratins except CK9, CK12, CK17, CK18	Not applicable
AE3 antibody	All basic cytokeratins	Not applicable
AE1/AE3 antibody (pan-CK)	▪ First line mark broad-spectrum pan-cytokeratin antibody to identify both LMWCK and HMWCK in various carcinomas ▪ Variable in neuroendocrine tumors should be taken in interpretation of results	Squamous cell carcinoma, colon adenocarcinoma, prostatic carcinoma, hepatocellular carcinoma, renal cell carcinoma, adrenocortical neoplasms

Contd...

Table 14.29 Applications of immunohistochemistry technique in analysis of cytokeratins (*Contd...*)

Monoclonal Antibody Used	Analysis of Various Types of Cytokeratins	Comments
OSCAR, PANK (MNF-116) antibody	Broad spectrum cytokeratins similar to AE1/AE3 antibody identify both LMWCK and HMWCK	Squamous cell carcinoma, colon adenocarcinoma. prostatic carcinoma, hepatocellular carcinoma, renal cell carcinoma, adrenocortical neoplasms
CAM 5.2 (34bH11) antibody	CAM 5.2 (34bH11) antibody is a good complement to AE1/AE3 antibody (pan-CK). It detects those carcinomas missed by AE1/AE3 antibody (pan-CK)	▪ Simple/nonsquamous keratins in glandular epithelia (colon adenocarcinoma, prostatic adenocarcinoma) ▪ Visceral parenchyma (hepatocellular carcinoma, renal cell carcinoma
CK903 (K903; 34bE12) antibody and CK5/6 antibody	Demonstrates HMWCK (CK1, CK5, CK10, CK14) without LMWCK (CK1, CK5, CK10, CK14) expressed in keratinizing squamous epithelia and in majority of squamous cell carcinoma; however, some nonkeratinizing poorly differentiated carcinomas show positivity for both HMWCK and LMWCK	Keratinizing squamous epithelia (squamous cell carcinoma positive for HMWCK, and some nonkeratinizing poorly differentiated carcinomas show positive for both HMWCK and LMWCK)

HMWCK (CK9, CK10, CK11, CK16, CK17) detected by CK903 and CK5/6 antibodies for demonstration of squamous keratins in squamous cell carcinoma.

LMWCK (CK18, CK19, CK20) detected by CAM 5.2 antibody in colon carcinoma, prostatic carcinoma, renal cell carcinoma and hepatocellular carcinoma

Expression of cytokeratins and EMA is key diagnostic feature of carcinomas. Cytokeratin positivity may also be seen synovial sarcoma, epithelioid sarcoma, epithelioid angiosarcoma, nonseminomatous germ cell tumors (yolk sac tumor, embryonal carcinoma), trophoblastic tumors, mesothelioma, chordoma and thymoma; and aberrant expression of leiomyosarcoma, malignant peripheral nerve sheath tumor.

Table 14.30 Immunohistochemical markers expression profile of CK7 and CK20 in human cancers

CK7 and CK20 Immunohistochemistry	Human Cancers
CK7 +ve/CK20 +ve	Gastric carcinoma, pancreatic adenocarcinoma (some cases), biliary tree malignancy, urinary bladder carcinoma
CK7 +ve/CK20 –ve	Breast carcinoma, lung carcinoma, mesothelioma, well-differentiated thyroid carcinoma, salivary gland malignancy, including renal cell carcinoma (papillary variant), pancreatic carcinoma, gynecologic endometrioid carcinomas, gynecologic serous carcinoma
CK7 –ve/CK20 +ve	Colorectal carcinoma, ovarian mucinous adenocarcinoma, urinary bladder carcinoma, some appendiceal carcinomas (some cases)
CK7 –ve/CK20 –ve	Hepatocellular carcinoma, renal cell carcinoma, prostatic carcinoma, adrenocortical malignancy

Table 14.31 Expression of epithelial membrane antigen (EMA) in various neoplasms

Meningioma	Plasma cell neoplasms
Breast adenocarcinoma	Anaplastic large cell lymphoma
Colorectal adenocarcinoma	Diffuse large B cell lymphoma
Pancreatic adenocarcinoma	Hodgkin disease (lymphocyte-rich)
Paget's disease of breast	Renal cell carcinoma
Choriocarcinoma	Thymic carcinoma
Desmoplastic small round cell tumor	Mesothelioma (epithelioid variant)
Perineuroma	Carcinoid tumor
Epithelioid sarcoma	Chordoma

Contd...

Table 14.32 Expression of carcinoembryonic antigen (CEA) in human cancers

Colorectal carcinoma (70–80%)
Hepatocellular carcinoma (50–90%)
Lung adenocarcinoma (97%)
Pancreatic adenocarcinoma (90%)
Gastric carcinoma
Breast carcinoma
Urinary bladder carcinoma
Cervical carcinoma

Variable expression of carcinoembryonic antigen (CEA), urothelial carcinoma, breast carcinoma and cervical carcinoma.

Table 14.33 TP53 gene mutation and associated cancers

Li-Fraumeni syndrome
Perineuroma
Epithelioid sarcoma
Plasma cell neoplasm
Anaplastic large cell lymphoma
Diffuse large B cell lymphoma (DLBCL)
Hodgkin disease (lymphocytic predominance)
Renal cell carcinoma
Thymic carcinoma
Mesothelioma (epithelioid variant)
Carcinoid tumor
Chordoma

Table 14.34 Vascular endothelial immunomarkers in normal human tissues and some human cancers

CD31 (PECAM1): Blood vessel and lymphatic channels
CD34 (hematopoietic stem cell antigen): Blood vessels
D2–40 (podoplanin): Lymphatic channels
vWF VIII-related antigen: Epithelioid hemangioblastoma, angiosarcoma (some cases), vascular invasion in thyroid carcinoma
Fli-1: Blood vessels and lymphatic channels including angiosarcoma
Flt-4 (VEGFR3): Kaposi sarcoma, angiosarcoma and hemangioma
CD141 (thrombomodulin): Blood vessels and lymphatic channels
Ulex europaeus 1: Endothelial marker in vascular tumors

Table 14.35 Desmin expression in various human tumors

Leiomyoma
Leiomyosarcoma
Angiolipoma
Benign stromal spindle cell tumor of breast
Phyllodes tumor of breast
Chondrosarcoma dedifferentiated
Desmoplastic small round cell tumor
Giant cell tumor of tendon sheath
Endometrial stromal tumor
Atypical fibroxanthoma of skin
Epithelioid sarcoma
Malignant fibrous histiocytoma
Malignant mixed Müllerian tumor
Inflammatory myofibroblastic tumor
Lymphangioleiomyomatosis

Table 14.36 Melanocytic lineages differentiation immunomarkers

HMB-45 (human melanoma black 45): Epithelioid melanoma
Melan A (A-203)
MART1 (melanin antigen recognized by T cells)
MITF (microphthalmic transcription factor)
S-100 protein
Tyrosinase
SOX 100
PNL2
MUM1
The melanocyte lineage is derived from the neural crest, which has its origin in the neural tube.
Melanocytes produce melanin in the skin
LDH is prognostic serum marker for melanoma that has been validated for metastatic disease

Table 14.37 Intermediate filaments, microtubules, cytokeratins and their locations

Component	Location
Microfilaments (actin, nonmuscle myosin) and intermediate filaments	Cytoskeleton of all cells
Glial fibrillary acidic protein (GFAP)	Astrocytes
Neurofilament	Neural tissue
Vimentin	Mesenchymal tissue
Desmin	Smooth and skeletal muscles
Microtubules	Neural derivatives (e.g. neuroblastoma)
Cytokeratins (CK)	Epithelial cells

Table 14.38 Tissue specificity of MUC genes and their expression in tumors

MUC Gene	Expression of MUC in Various Tumors
MUC1	Adenocarcinoma (diffuse staining), hepatocellular carcinoma
MUC2	Breast carcinoma (mucinous variant), pancreatic carcinoma (mucinous variant), ovarian mucinous cystadenocarcinoma, gastric adenocarcinoma (mucinous variant), but downregulation in colon carcinoma
MUC3	Colon carcinoma, pancreatic carcinoma
MUC4	Colon carcinoma, pancreatic carcinoma, lung carcinoma, ovarian carcinoma
MUC5	Endocervical adenocarcinoma, gastric carcinoma, but downregulation in colon carcinoma
MUC6	Gastric carcinoma (diffuse staing)
MUC7	Urothelial carcinoma, micrometastases in lymph node from urothelial carcinoma of urinary bladder

Table 14.39 Distribution of S-100 (calcium binding protein) in normal cells and selected soft tissue neoplasms analyzed by immunohistochemistry

S-100 Protein Expression in Normal Cell	S-100 Protein Expression in Soft Tissue Tumors
Melanocyte	Nevi, malignant melanoma (epithelioid, spindle cell and desmoplastic variants)
Schwann cell	Schwannoma, neurofibroma nerve sheath myxoma
Cartilage	Chondroma, chondrosarcoma, extraskeletal myxoid chondrosarcoma (<30%)
Adipocyte	Liposarcoma (variable expression)
Regenerating skeletal muscle	Rhabdomyosarcoma
Myoepithelial cells	Myoepithelioma/mixed tumor
Langerhans cell/interdigitating reticulum cell	Rosai-Dorfman disease, Langerhans cell histiocytosis, interdigitating reticulum cell sarcoma
Unknown normal cell	Ossifying fibromyxoid tumor (>90%), synovial sarcoma (20–30%)

Table 14.40 Panel of immunohistochemical markers of myoepithelial cells in breast in assessment of benign noninvasive lesion and invasive breast neoplasms

Myoepithelial Cell Markers Feature	Immunohistochemistry (Benign/Noninvasive Breast Lesion)	Immunohistochemistry (Invasive Breast Neoplasm)
Myoepithelial cells	Present	Absent
SMMHC (smooth muscle myosin heavy chain)	Positive	Negative
Calponin	Positive	Negative
Caldesmon	Positive	Negative
GFAP (glial fibrillary acidic protein)	Positive	Negative
S-100 protein	Positive	Negative
p53 protein	Present	Negative

Table 14.41 Panel of immunohistochemical markers applied in breast carcinoma

Tumor	Immunohistochemical Markers
Ductal carcinoma of breast (*in situ*/invasive)	ER/PR (+ 50%), GCDFP-15 (+ 50%), mammaglobin (+ 50%), HER2/neu (+ 50%), Ki-67 (+ 10–50%), p53 (+ poor prognosis), CK7 (+), GATA3 (+)
Lobular carcinoma of breast (*in situ*/invasive)	GCDFP-15 (+100%), E-cadherin (–)
Medullary carcinoma of breast	Triple negative (ER/PR, HER2/neu)
Metaplastic carcinoma of breast	CK903.p63, CAM 5.2 (most reliable marker), CK7 (most reliable marker)
Undifferentiated carcinoma of breast	NY-BR1 (highly specific marker)
Typical ductal hyperplasia	E-cadherin (+), CK903 (–), CK5/CK6 (–), ER (+), p120 catenin (+)
Atypical ductal hyperplasia/ductal carcinoma *in situ*	E-cadherin (+), CK903 (–), CK5/CK6 (–), ER (+), p120 catenin (+)
Atypical lobular hyperplasia/lobular carcinoma *in situ*	E-cadherin (–), CK903 (+), CK5/CK6 (+), ER (+), p120 catenin (+)

Table 14.42 Panel of immunohistochemical markers for vulva and vagina tumors of female genital system

Tumor	Immunohistochemical Markers
Vulva Tumors	
Angiomyoblastoma of vulva	Desmin (+), CD34 (+), ER (+), PR (+)
Extra-mammary Paget disease	CK7 (+), CK20 (+), CEA (+), EMA (+)
Vagina Tumors	
Botryoid rhabdomyosarcoma	Desmin (+), vimentin (+), myogenin (+), MyoD1 (+), α-actin (+)
Leiomyosarcoma	SMA (+), S-100 protein (+)
Melanoma	HMB-45 (+), S-100 protein (+), melan A (+), MART1 (+), tyrosinase (+), SOX 100 (+), PNL2 (+), MUM1 (+)

Table 14.43 Panel of immunohistochemical markers for tumors of uterus and cervix

Tumor	Immunohistochemical Markers
Uterine cervical tumors	
Cervical adenocarcinoma	HPV (+), p16 (+), Ki-67 (+), p53 (–/+ focal staining)
Uterine endometrial tumors	
Type 1 endometrioid carcinoma (ER dependent)	ER/PR (+ >90%), PAX8 (+), CA125 (+), PTEN (+), p16 (–/+ patchy staining)
Type 2 endometrial carcinoma (serous papillary variant)	PAX8, ER/PR (+ >50%), p53 (+), p16 (+), HER2/neu (+), EGFR (+)
Type 2 endometrial carcinoma (clear cell variant)	HNF-1b (+), HER2/neu (+), EGFR (+)
Endometriosis of any site	ER/PR (+ glands and stroma), CD10 (+ stroma)
Uterine smooth muscle tumors	
Leiomyoma	SMA (+), desmin (+), MSA (+), h-caldesmon (+), SMMHC, calponin (+), ER/PR (+)
Leiomyosarcoma	SMA (+), desmin (+), MSA (+), h-caldesmon (+), SMMHC, calponin (+), ER/PR (+)
Endometrial stromal tumors of the uterus	CD10 (+), ER/PR (+), JAZF1-JJAZ1 gene fusion protein (+), SMA (–/+), desmin (–/+), h-caldesmon (–)

Table 14.44 Role of immunohistochemistry technique in differential diagnosis of uterine endometrioid carcinoma, serous carcinoma and clear cell carcinoma

Immunohistochemical Markers	Endometrioid Carcinoma (Type 1)	Serous Carcinoma of Endometrium (Type 2)	Clear Cell Carcinoma of Endometrium (Type 2)
Estrogen/progesterone receptors (ER/PR)	Positive	Positive (50%)	Negative/positive
Ki-67 (proliferative marker)	Positive (low expression)	Positive (high expression)	Positive (variable expression)
p53	Negative/positive (patchy/ rare weakly cells)	Positive (strong diffuse staining)	Negative
p16	Negative/positive (patchy)	Positive (strong diffuse staining)	Positive/negative
HNF-1β	Negative	Negative	Positive
WT1	Negative	Negative/positive	Negative

WT1 is positive in ovarian carcinoma, but negative/positive in serous carcinoma of endometrium.
PTEN is positive in endometrioid carcinoma.

Table 14.45 Panel of immunohistochemical markers for ovarian surface epithelial tumors of female genital system

Tumor	Immunohistochemical Markers
Borderline ovarian surface epithelial tumor	S-100 protein (+)
Serous cystadenocarcinoma of ovary	CA125 (+), SMO47 (+), CK7 (+), CK20 (+), CEA (+), B72.3 (anti-TAG72) (+), Ber EP4 (+), PAX2 (+++ strong staining) PAX8 (+), PLAP (+), ER/PR (+), WT1 (+), BRAC1 (+ indicates high-grade), p53 (+ indicates low-grade), p53 (– indicates high-grade)
Mucinous cystadenocarcinoma of ovary	CK7 (+), CEA (+), CD29 (–/+ focal staining), CDX2 (–/+ focal staining)
Endometrioid cystadenocarcinoma of ovary	ER/PR (++++ in >90%)
Clear cell carcinoma of ovary	HNF-1β (+), CA125 (+), CEA (+), EMA (+), PAX8 (+), CK7 (+), CAM (+), CD15/LeuM1 (+), vimentin (+), BCL-2 (+), p53 (+), ER/PR (variable staining)
Brenner tumor of ovary	CK (+), CEA (+), EMA (+)

Table 14.46 Panel of immunohistochemical markers for ovarian germ cell tumors, sex-cord tumors and Krukenberg tumor of female genital system

Tumor	Immunohistochemical Markers
Ovarian germ cell tumors	
Dysgerminoma	PLAP (+), CD117/c-KIT (+), SALL4 (+ nuclear staining), D2–40 (podoplanin) (+ membranous staining), PAS (+), OCT4/POU5F1 (+), CAM 5.2 (–), AE1/AE3 (–), EMA (–),
Embryonal carcinoma	PLAP (+), OCT4/POU5F1 (+), SALL4 (+), CD30 (+), D2–40 (podoplanin) (+/–), CD117/c-KIT (–)
Yolk sac tumor	PLAP (+), SALL4 (+), CAM 5.2 (+), AE1/AE3 (+), AFP (+), α_1-antitrypsin (+), CD117/c-KIT (–), D2–40/ podoplanin (–)
Choriocarcinoma	CAM 5.2 (+), β-HCG (+++ specific marker), inhibin (+), human placental lactogen (+ hPL), CK7 (+), LK26/folate binding protein (+), SALL4 (+/–), PLAP (+/–), CD117/c-KIT (–), OCT4 (POU5F1) (–), D2–40 (podoplanin) (–)
Struma ovarii (monodermal teratoma)	EMA (+), TTF-1 (+), thyroglobulin (+)
Sex cord-stromal tumors of the ovary	
Ovarian granulosa cell tumors/Leydig cell tumors	CD99 (+), inhibin (+), calretinin (+ most sensitive), (+), melan A (Mart-1), clone A103 (+), ER/PR (+)
Krukenberg tumor (primary tumors metastasizing to ovary)	
Gastric adenocarcinoma	CK (+), EMA (+), CEA (+)
Colon adenocarcinoma	CK7 (+++), CK20 (+++), CDX (+++), MUC1 (+++), CEA (+), β-catenin (+), SAT2 (+), p53 (+)
Breast lobular carcinoma	ER/PR (+), E-cadherin (–), HER2/neu (–)

Table 14.47 Panel of immunohistochemical markers applied in differential diagnosis of ovarian germ cell tumors of female genital tract

Immunohistochemical Markers	Dysgerminoma (Counterpart to Testicular Seminoma)	Embryonal Carcinoma	Yolk Sac Tumor	Choriocarcinoma
OCT4 (POUC5F1) (nuclear staining)	Positive	Positive	Negative	Negative
SALL4 (nuclear staining)	Positive	Positive	Positive	Positive/negative
Placental alkaline phosphatase (PLAP)	Positive	Positive	Positive	Negative
c-KIT	Positive	Negative	Negative	Negative
D2–40 (podoplanin) membrane staining	Positive	Negative/positive	Negative	Negative
CAM 5.2 and AE1/3 (epithelial marker)	Negative	Positive	Positive	Positive
EMA (epithelial membrane antigen)	Negative	Negative	Negative	Positive (50%)
PAS positive	Positive	Negative	Negative	Negative
CD117 (c-KIT)	Positive (membranous staining)	Negative	Negative	Negative
CD30	Negative	Positive	Negative	Negative
α-Fetoproteins positive	Negative	Negative	Positive (nonspecific)	Negative
β-hCG	Negative	Negative	Negative	Positive
Inhibin	Negative	Negative	Negative	Positive
hPL (human placental lactogen)	Negative	Negative	Negative	Positive
CD146	Negative	Negative	Negative	Positive
CK7 (cytokeratin 7)	Negative	Negative	Negative	Positive
LK26 (folate binding protein)	Negative	Negative	Negative	Positive

Table 14.48 Panel of immunohistochemical markers for tumors of kidney

Tumors	Immunohistochemical Markers
Renal cell carcinoma (clear cell variant)	CAIX (+++++), PAX8 (+), PAX2 (+), EMA (+)
Renal cell carcinoma (papillary variant)	CK7 (+), racemase (+), PAX8 (+), PAX2 (+), CAIX (– except areas of necrosis)
Renal cell carcinoma (chromophobe variant)	Hale's colloidal iron (+), EpCam (epithelial cell adhesive molecule) (+), c-KIT (CD117) (+), TFE3 (+), cathepsin K (+), PAX8 (+)
Renal cell carcinoma with Xp11 chromosomal translocation	TFE3 (+), TFEB transcription factor (+), cathepsin K transcription factor (+)
Renal clear cell sarcoma	Vimentin (+)
Wilms' tumor	WT1 (+ epithelial component), CK (+), EMA (+)
Renal mixed epithelial stromal tumor (MEST)	ER/PR (+), desmin (+), SMA (+), CD10 (+)
Renal angiomyolipoma	HMB-45 (+), melan A (+), SMA (+), vimentin (+), TFE3 (–/+), cathepsin K (–/+)

Table 14.49 Role of immunohistochemistry in differential diagnosis of renal tumors

Immunohistochemical Markers	Renal Cell Carcinoma Clear Cell Variant (Chromosome 3p Loss)	Renal Cell Carcinoma Papillary Variant with Clear Cell (Trisomy 7 and 17)	Chromophobe Renal Cell Carcinoma	Xp11 Translocation Renal Cell Carcinoma
CAIX	Positive (diffuse staining)	Negative	Negative	Negative/Positive
Vimentin	Positive	Negative	Negative	Positive
CD10	Positive	Positive/Negative	Negative/positive	Positive
Cytokeratin 7 (CK7)	Negative	Positive	Positive	Negative/positive
Racemase	Negative	Positive	Negative	Positive
c-KIT, Hale's colloidal iron stain	Negative	Negative	Positive	Negative
TFE3	Negative	Negative	Negative	Positive
Cathepsin K	Negative	Negative	Negative	Positive

Renal cell carcinoma (clear cell and papillary variants) is a low-grade tumor occurring in end stage renal disease, which shows positivity for CAIX and CK7

Table 14.50 Panel of immunohistochemical markers for urinary bladder tumors

Tumors	Immunohistochemical Markers
Normal urothelium or reactive urothelial atypia	CK20 (+ umbrella cells), E-cadherin (+ all layers), CD44 (+), p53 (–)
Urothelial carcinoma *in situ*	p53 (+ 89%), CK20 (+ all layers), E-cadherin (–/reduced), CD44 (–/reduced)
Urothelial carcinoma	CK903 (+), p63 (+ more specific marker), thrombomodulin (+), uroplakin (+), GATA3 (+), CK7 (+++), CK20 (+++), PSA (–), PSAP (–), prostein (–), PSMA (–)
Adenocarcinoma of urinary bladder	β-Catenin (–), PSA (–), PSAP (–), prostein (–), PSMA (–), racemase (–), CDX 2 (variable staining), CK20 (variable staining), CK7 (variable staining), thrombomodulin (variable staining)
Inflammatory myoblastic tumor	Vimentin (+), ALK (+ 66%) SMA (+/–), desmin (+), CK (variable)

Table 14.51 Panel of immunohistochemical markers for germ cell tumors and Sertoli-Leydig cell tumors of testis

Tumor	Immunohistochemical Markers
Germ cell tumors of testis	
Seminoma and intratubular germ cell neoplasm	LIN28 (++++), OCT4 (+++), SALL4 (+++), PLAP (+), D2–40 (+), PAS (+), CD117/c-KIT (+), LDH (+), CAM 5.2 (–), AE1/AE3 (–), EMA (–)
Embryonal carcinoma	OCT4 (POU5F1) (+), SALL4 (+), CAM 5.2 (+), AE1/AE3 (+), CD30 (+), PAS (–), PLAP (–), D2–40 (podoplanin) c-KIT (CD117) (–)
Yolk sac tumor	LIN28 (+), SALL4 (+), PLAP (+), CAM 5.2 (+), AE1/AE3 (+), AFP (+), Glypican-3 (+), D2–40 (–), CD117/c-KIT (–)
Choriocarcinoma	CAM 5.2 (+), AE1/AE3 (+), EMA (+ 50%), β-hCG (+++), inhibin (+), human placental lactogen (hPL) (+), HLA-G (+), glypican 3 (+), SALL4 (+), PLAP (+/–), D2–40/podoplanin (–)
Teratoma	CAM 5.2 (+), AE1/AE3 (+), EMA (+), PLAP (+), OCT4 (POU5F1) (–), SALL4 (+/–), D2–40 (podoplanin) (–)
Sertoli-Leydig cell tumors of testis	
Sertoli-Leydig cell tumors	Inhibin (+), melan A (+), CD10 (+), CD99 (+), calretinin (+), OCT4 (POU5F1) (+), SALL4 (–), EMA (–), PLAP (–),

CD117 (c-KIT) shows membrane staining in seminoma; and cytoplasmic staining in other germ cell tumors. Epithelial membrane antigen (EMA) is always negative in germ cell tumors of testes. Cytokeratins may be positive in some Sertoli cell tumors and granulosa cell tumors of the ovary.

Table 14.52 Panel of immunohistochemical markers in the assessment of benign/noninvasive prostatic lesions

Prostatic Cells	Immunohistochemistry (Benign/Noninvasive Prostatic Lesion)	Immunohistochemistry (Invasive Prostatic Neoplasm)
Prostatic basal cells	▪ Prostatic basal cells present ▪ CK903+ (cytoplasm) ▪ p63+ (nucleus)	▪ Prostatic basal cells absent ▪ CK903 negative ▪ p63 negative
Prostatic acinar cells	▪ Prostatic acinar cells present ▪ Recemase negative	▪ Prostatic acinar cells present ▪ Recemase positive (cytoplasmic staining)

Table 14.53 Panel of immunohistochemical markers for tumors of prostate gland

Tumors of Prostate	Immunohistochemical Markers
Prostatic adenocarcinoma	Prostate specific antigen (PSA) (+++), prostate-specific acid phosphatase (PSAP) (+++), racemase (+++), prostein (P501S) (+), prostate-specific membrane antigen (PSMA) (+), p63 (+), racemase (P504S, AMACR) (+)
Prostatic stromal tumor of uncertain malignant potential (STUMP)	CD34 (+), PR (+), ER (–), desmin (+/–), SMA (+/–)
Prostatic stromal sarcoma	CD34 (+), ER (–), PR (+), SMA (–), desmin (–)
Prostatic and urinary bladder inflammatory myoblastic tumor (IMT)	Vimentin (+), ALK (+ 66%) SMA (+/–), desmin (+), CK (variable)

Basal cell markers: p63 (nuclear staining), CK903 (cytoplasmic staining) negative/positive.

Table 14.54 Panel of immunohistochemical markers for tumors of sinonasal tract

Tumors	Immunohistochemical Markers
Nasopharyngeal carcinoma (NPC)	CK (HMW) (+), EBV (+ FISH), p63 (+), synaptophysin (–)
Sinonasal undifferentiated carcinoma (SNUC)	CK (LMW) (+), EMA (+), synaptophysin (+ 25%), p53 (+ patchy/–)
NUT-midline translocation carcinoma	NUT (+), NUT translocation (+ diagnostic marker) CK (+), EMA (+), p63 (+), CD34 (+/–), synaptophysin (–), EBV (–)
Olfactory neuroblastoma/esthesioneuroblastoma	Synaptophysin (++++ 100%), chromogranin A (+ 25%), neuron-specific enolase (NSE) (+), calretinin (+), CD56 (+), CD57 (+), CK (–/+ focal staining), EMA (–/+), EBV (–)
Nasal NK/T cell lymphoma (lethal midline granuloma)	HBV analyzed by FISH (+), CD45 (+), CD2 (+), CD3ε (+), cytotoxic protein perforin (+), CK (–), EMA (–)

Table 14.55 Panel of immunohistochemical markers for lung (bronchopulmonary) tumors and mesothelioma

Tumors	Immunohistochemical Markers
Squamous cell lung carcinoma	p40 (+), p63 (+), CK5/CK6 (+ diffuse staining), CK903 (+ diffuse staining), CEA (+), CK7 (+/–), CK20 (–), TTF-1 (–), napsin A (–), synaptophysin (–), chromogranin A (–), neuron-specific enolase (NSE) (–), CD56 (neuronal cell adhesion molecule—NCAM) (–)
Small cell lung carcinoma	TTF-1 (+), synaptophysin (+), chromogranin A (+), neuron-specific enolase (NSE) (+), CD56 (neuronal cell adhesion molecule—NCAM) (+), CAM 5.2 (+), AE1/AE3 (+), CK7 (–/+), CK20 (–), p63 (–), CK5/CK6 (–), CK903 (–), napsin A (–)
Adenocarcinoma (mucinous variant) of lung	TTF-1 (+10–20%), CDX2 (+ focal staining), napsin A (+/–), p63 (+/–), CK20 (+/–), CK5/K6 (+/–), CK903 (+/–), synaptophysin (–), chromogranin A (–), neuron-specific enolase (NSE) (–), CD56 (neuronal cell adhesion molecule—NCAM) (–)
Adenocarcinoma (non-mucinous variant) of lung	TTF-1 (+), napsin A (+), CK7 (+/–), p63 (+/–), synaptophysin (–), chromogranin A (–), neuron-specific enolase (NSE) (–), CD56 (neuronal cell adhesion molecule—NCAM) (–), CK20 (–)
Bronchopulmonary carcinoids	TTF-1 (+ 50%), synaptophysin (+), chromogranin A (+), neuron-specific enolase (NSE) (+), CD56 (neuronal cell adhesion molecule—NCAM) (+), napsin A (–), CK7 (–), CK20 (–), p63 (–)
Mesothelioma	Calretinin (+), WT1, CK5/CK6 (+), CK7 (+), CK903 (+), thrombomodulin (CD141) (+), HBME-1, N-cadherin (+), D2–40 (+), mesothelin (+/–), thyroid transcription factor 1 (TTF-1) (–), napsin A (–), CK20 (–), p63 (–), synaptophysin (–), chromogranin A (–), neuron-specific enolase (NSE) (–), CD56 (neuronal cell adhesion molecule—NCAM) (–)

Thyroid transcription factor 1 (TTF-1) is positive in small cell lung carcinoma (90%), lung adenocarcinoma (mucinous variant, 20%) and lung adenocarcinoma (non-mucinous variant), extrapulmonary small cell carcinoma (40%).
It is difficult to differentiate metastatic adenocarcinoma of pancreas and upper gastrointestinal tract from mucinous adenocarcinoma of lung. Both metastatic tumors are CK7 positive, CK20 positive but TTF-1 negative. DPC4 is deleted in 55% cases of adenocarcinoma of pancreas but not lung origin.

Table 14.56 Panel of immunohistochemical markers used in differential diagnosis of bronchopulmonary neuroendocrine neoplasms

Immunohistochemical Markers	Typical Carcinoid Tumor	Atypical Carcinoid Tumor	Small Cell Lung Carcinoma	Large Cell Neuroendocrine Carcinoma
TTF-1 (thyroid transcription factor 1)	Positive (<30% weak staining)	Positive (<30% weak staining)	Positive (90%)	Positive (50%)
Cytokeratins	Positive (<80%)	Positive (<80%)	Positive (dot-like)	Positive
Synaptophysin	Positive (strong diffuse staining)	Positive (strong diffuse staining)	Positive (weak focal staining)	Positive (diffuse or focal staining)
Chromogranin A	Positive (strong diffuse staining)	Positive (strong diffuse staining)	Positive (weak focal staining)	Positive (diffuse or focal staining)
Neuron-specific enolase (NSE)	Positive (strong diffuse staining)	Positive (strong diffuse staining)	Positive (weak focal staining)	Positive (diffuse or focal staining)
CD56 (neuronal cell adhesion molecule)	Positive (strong diffuse staining)	Positive (strong diffuse staining)	Positive (weak focal staining)	Positive (diffuse or focal staining)
Ki-67	Positive (<2%)	Positive (<20%)	Positive (>20%)	Positive (>20%)

Ki-67 expression is helpful in evaluation of small biopsy specimens, particularly if crushed.

Table 14.57 Panel of immunohistochemical markers and histochemical stains applied in the assessment of tumors of salivary glands

Tumors	Immunohistochemical Markers and Histochemical Stains
Tumors with epithelial glandular and myoepithelial component ▪ Pleomorphic adenoma ▪ Adenoid cystic carcinoma ▪ Epithelial-myoepithelial carcinoma	▪ Epithelial glandular component: CK (+), EMA (+), CEA (lumen: c-KIT) (+) ▪ Myoepithelial cell component: calponin (+), caldesmon (+), glial fibrillary acidic protein (GFAP) (+), SMMHC (+), S-100 protein (calcium binding protein) (+), p63 (+)
Mucoepidermoid carcinoma	▪ Goblet cells: mucicarmine (+) ▪ Intermediate cells: p63 (+) ▪ Myoepithelial cell component: calponin (–), caldesmon (–), glial fibrillary acidic protein (GFAP) (–), S-100 protein (calcium binding protein) (–), p63 (–)
Acinic cell carcinoma	PAS (+), PAS/diastase (+)
Tumors with oncocytic cells (Warthin's tumor, oncocytoma and oncocytic carcinoma)	Phosphotungstic acid hematoxylin (PTAH) (+), PAS/diastase (+)
Polymorphous low-grade adenocarcinoma	CK (+ 100%), vimentin (+ 100%), S-100 protein (calcium binding protein) (+ 97%), CEA (+ 55%), glial fibrillary acidic protein (GFAP) (+), MSA (+), EMA (+), BCL-2 (+)
Myoepithelioma	Myoepithelial cell component: calponin (+), caldesmon (+), glial fibrillary acidic protein (GFAP) (+), SMMHC (+), S-100 protein (calcium binding protein) (+), p53 (+)
Clear cell adenocarcinoma	▪ PAS/Diastase (+) ▪ Myoepithelial cell component: calponin (–), caldesmon (–), glial fibrillary acidic protein (GFAP) (–), SMMHC (+), S-100 protein (calcium binding protein) (–), p63 (–)
Salivary duct carcinoma	Androgen receptors (+), gross cystic disease fluid protein (GCDFP) (+), HER2/neu amplification (–/+)
Low-grade cribriform cystadenocarcinoma	S-100 (calcium binding protein) (+)

Immunohistochemistry technique has a limited role (except to confirm myoepithelial differentiation); diagnosis of salivary gland tumors is primarily based on hematoxylin and eosin histological examination. Proper sampling of tumor will reveal a component of the tumor that shows classic features of the tumor (i.e. not dominated by clear cells).

Tumors with clear cells include epithelial-myoepithelial carcinoma, mucoepidermoid carcinoma, acinic cell carcinoma, oncocytoma, oncocytic carcinoma, Warthin's tumor, myoepithelioma, myoepithelial carcinoma, clear cell adenocarcinoma and metastatic clear cell renal cell carcinoma.

Table 14.58 Immunohistochemistry technique of gastrointestinal tract tumors

Tumors	Immunohistochemical Markers
Barrett's esophagus (intestinal metaplasia at the gastroduodenal junction)	CK7 (surface and deep region) (+), CK20 (surface region) (+), Das (+), MUC1 (+), MUC2 (+)
Gastric adenocarcinoma	CDX2 (transcription factor, specific marker) (+), CK (+), EMA (+), CEA (+)
Colon adenocarcinoma	CDX transcription factor (+ specific marker associated with poor prognosis), CK7 (+), CK20 (+), EMA (+), CEA (+), SAT transcription factor (+), β-catenin (+), p53 (+), villin (+)
Gastrointestinal stromal tumors (GISTs)	DOG1 (+ most specific marker), c-KIT (CD117) (+ in 05%), PDGFα (+), CD171 (+), vimentin (+), SMA (+), desmin (+)
Gastrointestinal tract carcinoids (neuroendocrine tumors)	Synaptophysin (+), chromogranin A (+), NSE (+), CD56 (neuronal cell adhesion molecule—NCAM) (+), CDX2 (+ 50%)
Gastrointestinal tract mucosa-associated lymphoid tissue (MALT) lymphoma	CD20 (+), CD43 (+), IgM > IgA > IgG (+), IgD (–), CD5 (–), CD10 (–), BCL-16 (–), cyclin D1

There is no definite immunohistochemical marker for gastric MALT lymphoma. Panel of immunohistochemical markers is applied to assess architecture of infiltration lymphoid cells, immunophenotype and chain restriction.

Table 14.59 Panel of immunohistochemical markers for tumors of liver

Tumors	Immunohistochemical Markers
Hepatocellular carcinoma (conventional variant)	Hepatocyte paraffin 1 (Hep Par 1) (+95%), p-CEA (highly specific canalicular marker) (+ 80%) α-fetoproteins (AFP) (+30–60%), CD10 (canalicular) (+), villin (canalicular) (+), CK20 (+ ≤20%), AE1/AE3 (+), CAM 5.2 (+ in 5–20%), CK903 (HMWCK) (+), glypican 3 (+ promising new marker of hepatocellular differentiation) (+), arginase 1 (new marker of hepatocellular differentiation) (+), α_1-antitrypsin (+ up to 50%), thyroid transcription factor 1 (TTF-1) (+), CK7 (–), epithelial membrane antigen (EMA) (–), MOC-31, mucicarmine (–)
Hepatocellular carcinoma (fibrolamellar variant)	CK7 (+), α-fetoproteins (AFP) (–)
Hepatoblastoma	α-fetoproteins (AFP) (+), hepatocyte paraffin 1 (Hep Par 1) (+), delta-like protein (DLK) (+), hCG (+), CK (+), CEA (+), glypican 3 (+), EMA (+), vimentin (+)
Cholangiocarcinoma	CK19 (+70–100%) (+), carcinoembryonic antigen monoclonal (m-CEA) (+), p-CEA (+), CK7 (+), CK20 (+), AE1/AE3 (+), CAM 5.2 (+), CK903 (+), α-fetoproteins (AFP) (–/+), hepatocyte paraffin 1 (Hep Par 1) (–), CD10 (–), villin (–), glypican 3 (–) arginase 1 (–)

Primary tumors metastasizing to liver include breast carcinoma, lung carcinoma, gastric carcinoma, colorectal carcinoma, pancreatic adenocarcinoma, renal cell carcinoma, prostatic carcinoma, endometrial carcinoma and thyroid carcinoma.

Table 14.60 Panel of immunohistochemical markers for tumors of pancreas

Tumors	Immunohistochemical Markers
Pancreatic adenocarcinoma*	CK7 (+), CK20 (+), CA19.9 (+), DPC4 (+) (SMAD4, MADH4 allelic loss), CEA (+), MUC1 (+), MUC5 (+), EMA (–).
Pancreatoblastoma (pancreatic element with ductal, acinar and neuroendocrine differentiation)	Trypsin (+ acinar marker), chymotrypsin (+ acinar marker), lipase (+ acinar marker), CK (+ ductal marker), CEA (+ ductal marker), synaptophysin (+), chromogranin A (+), neuron-specific enolase (NSE) (+), CD56 (neuronal cell adhesion molecule—NCAM) (+)
Pancreatic endocrine neoplasm (formerly known as islet cell tumor)	Synaptophysin (+), chromogranin A (+), NSE (+), CD56 (neuronal cell adhesion molecule—NCAM) (+), AE1/AE3 (+), CAM 5.2 (+), insulin hormone (variable staining), glucagon hormone (variable staining), somatostatin hormone (variable staining)
Mucinous cystic neoplasm	ER/PR (+), inhibin (+)
Intraductal papillary mucinous neoplasm (IPMN)	DPC4 (+), MUC1 (+), MUC4 (+), MUC2 (–), CDX2 (–)
Serous cystadenoma	CK (+), EMA (+ 33%), inhibin (+), MUC6 (+), calponin (+), CD31 (+), factor VIII (+)
Lymphoplasmacytic sclerosing (autoimmune) pancreatitis	IgG4 + plasma cells infiltration (>20 per high power field)

Gene mutation and loss of expression of DPC is demonstrated in 55% of pancreatic adenocarcinoma.
**Serum tumor markers for pancreatic adenocarcinoma include CA 19-9, CEA, glucagon, proinsulin, C-peptide, IGFBP-1, pancreatic polypeptide and serotonin.*

Table 14.61 Panel of immunohistochemical markers for tumors of thyroid, parathyroid, adrenal, pituitary and thymus glands

Tumors	Immunohistochemical Markers
Thyroid gland	
Papillary thyroid carcinoma	TTF-1 (+), thyroglobulin (+), PAX8 (+), CAM 5.2 (+), AE1/AE3 (+), CK903 (+), CK10 (+), HBME-1, CK903, CK19, HBME-1, and galectin 3 favors thyroid papillary carcinoma over benign follicular carcinoma.
Follicular thyroid carcinoma	TTF-1 transcription factor (+), thyroglobulin (+), PAX8 (+), CK (+ CAM 5.2, AE1/AE3) (+), Ki-67 (+)
Medullary thyroid carcinoma	TTF-1 transcription factor (+), CAM 5.2 (+ 70%), AE1/AE3 (+ 75%), calcitonin (+), CEA (+), synaptophysin (+), chromogranin A (+), neuron-specific enolase (NSE) (+), CD56 (neuronal cell adhesion molecule—NCAM) (+), Congo red (+ amyloid deposit in the tumor, PAX8 (–/+), thyroglobulin (–)
Thyroid anaplastic carcinoma	CAM 5.2 (+), AE1/AE3 (+ 75%), PAX8 (–/+), TTF-1 (–), thyroglobulin (–)
Parathyroid glands	
Parathyroid adenoma	CAM 5.2 (+), AE1/AE3 (+), parathormone (PTH) (+), synaptophysin (+), chromogranin A (+), neuron-specific enolase (NSE) (+), GATA3 (+), CD56 (neuronal cell adhesion molecule—NCAM) (+), parafibromin (CDC73) (+), TTF-1 (–), thyroglobulin (–), PAX8 (–)

Table 14.61 Panel of immunohistochemical markers for tumors of thyroid, parathyroid, adrenal, pituitary and thymus glands (*Contd...*)

Tumors	Immunohistochemical Markers
Parathyroid carcinoma	CK903 (+), CK19 (+), HBME-1 (+), galectin 3 (+), parafibromin (–)
Parathyroid neuroendocrine tumors	Synaptophysin (+), chromogranin A (+), neuron-specific enolase (NSE) (+), CD56 (neuronal cell adhesion molecule—NCAM) (+), CK (AE1/AE3 and CAM 5.2) (+), PTH (+), S-100 protein (–)
Adrenal glands	
Adrenocortical neoplasms	Melan A (+), inhibin (+), calretinin (+), S-100 protein (–), HMB-45 (–), CK (AE1/AE3 and CAM 5.2) (–/+), synaptophysin (variable staining), chromogranin A (variable staining), neuron-specific enolase (NSE) (–), EMA (–)
Pheochromocytoma	Synaptophysin (+), chromogranin A (+), neuron-specific enolase (NSE) (+), CD56 (neuronal cell adhesion molecule—NCAM) (+), S-100 protein (+), CK (–)
Neuroblastoma/ganglio-neuroblastoma	Synaptophysin (+), chromogranin A (+), neuron-specific enolase (NSE) (+), CD56 (neuronal cell adhesion molecule—NCAM) (+), S-100 protein (+), CD56 (neuronal cell adhesion molecule) (–), CD99, CK (AE1/AE3 and CAM 5.2) (–)
Pituitary gland	
Pituitary neuroendocrine neoplasms	Synaptophysin (+), chromogranin A (+), neuron-specific enolase (NSE) (+), CD56 (neuronal cell adhesion molecule—NCAM) (+), S-100 protein (–)
Thymus gland	
Thymoma	Terminal deoxynucleotidyl transferase (TdT+), CD99 (+), CD1a (+), CD5 (+)
Thymic carcinoma	CD5 (+), glucose transporter 1 (GLUT-1+), CK (+)

Table 14.62 Panel of immunohistochemical markers applied in assessment of selected skin tumors

Tumors	Immunohistochemical Markers
Melanoma *in situ*	Melan A (A103) (80–100%). MART-1 (melanoma antigen recognized by cells (+80–100%). HMB-45 (human melanoma black 45) (+ 60–90%), MITF (microphthalmia transcription factor) (+), S-100 protein (+)
Melanoma (epithelioid variant)	Melan A (A103) (80–100%), MART-1 (melanoma antigen recognized by cells (+80–100%). HMB-45 (human melanoma black 45) (+60–90%), MITF (microphthalmia transcription factor) (+), S-100 protein (+), SOX (+), PNL2 (+), MUM1 (+)
Melanoma (desmoplastic variant)	S-100 protein (+), melan A (A103) (–), MART-1 (melanoma antigen recognized by cells) (–), HMB-45 (human melanoma black 45) (–), MITF (microphthalmia transcription factor) (–), SOX 100 (–), PNL2 (–),
Mycosis fungoides (MF)	T cell markers: CD45 (+), CD3 (+), CD20 (–), CD2 (–), CD5 (–), CD7 (–)
Squamous cell carcinoma *in situ*	CK903 (HMWCK) (+)
Squamous cell carcinoma (spindle cell variant)	CKs (+), p63 (+), desmin (–/+), SMA (smooth muscle actin) (–/+)
Sebaceous carcinoma	BerEP4 (+), CK7 (+), EMA (epithelial membrane antigen) (+)
Merkel cell carcinoma	CK20 (+), neurofilament (100%) (+), synaptophysin (+), chromogranin-A (+), NSE (neuron-specific enolase) (+), CD56 (neuronal cell adhesion molecule—NCAM) (+), cytokeratins (AE1/AE3, CAM 5.2) (+), merkel cell polyomavirus
Metastatic small cell carcinoma	TTF-1 (+), cytokeratins (AE1/AE3, CAM 5.2) (+), synaptophysin (+), chromogranin A (+), NSE (neuron-specific enolase) (+), CD56 (neuronal cell adhesion molecule—NCAM) (+), cytokeratins (AE1/AE3, CAM 5.2) (+), CK20 (–), neurofilament (–)
Dermatofibroma	Factor XIIIa (+), D2–40 (+), CD34 (–)

Tumors	Immunohistochemical Markers
Dermatofibrosarcoma protuberans (DFSP)	CD34 (+), factor XIIIa (–), D2–40 (podoplanin) (–)
Atypical fibroxanthoma	CD10 (+)
Primary cutaneous marginal zone lymphoma	CD20 (+), CD79a (+), BCL-2 (+), IgM (+/–), CD43 (+/–), CD5 (+/–), CD23 (–)
Primary cutaneous follicular cell lymphoma	CD20 (+), CD79a (+), BCL-2 (–/+)
Primary cutaneous diffuse large B cell lymphoma	CD20 (+), CD79a (+), BCL-2 (+), MUM1 (+), monotypic k or l (+), IgM (+), BCL-6 (+/–)

Table 14.63 Immunohistochemistry of round blue cell tumors (SRBCT)

Tumors	Immunohistochemical Markers
Wilm's tumor, blastema predominant	Cytokeratin (CK) (+), epithelial membrane antigen (EMA) (+), WT1 (+), WT2 (+), desmin (blastemal component) (+)
Ewing sarcoma/PNET	CD99 (+), synaptophysin (+), neuron-specific enolase (NSE) (+), periodic acid–Schiff (PAS) (+), cytokeratin (CK) (+ focal staining), epithelial membrane antigen (EMA) (focal staining) (+)
Lymphoblastic lymphoma	CD45 (+), CD99 (+), Terminal deoxynucleotidyl transferase (TdT) (+), CD4 (+), CD3 (+)
Rhabdomyosarcoma (solid alveolar variant)	Desmin (+), smooth muscle actin (SMA) (+), myogenin (+), MyoD1 (+), cytokeratin (CK) (+ focal staining), epithelial membrane antigen (EMA) (focal staining) (+), CD99 (focal staining) (+), synaptophysin (focal staining)

Table 14.64 Immunophenotyping of myeloblasts, B lymphoblasts and T lymphoblasts

Tumors	Immunophenotyping Markers
Myeloblast	Lineage-specific markers (CD13, CD15, CD33, CD11b) (+), CD34 (+/–), c-KIT (CD117) (+/–), HLA-DR (+/–)
B lymphoblasts	Lineage markers (CD19, CD79a) (+), terminal deoxynucleotidyl transferase (TdT) (+), CD20 (+/–), CD34 (+/–), CD10 (+/–), HLA-DR (+/–)
T lymphoblasts	Lineage marker (CD3), terminal deoxynucleotidyl transferase (TdT) (+), CD34 (+/–), CD10 (+/–), HLA-DR (–/+), c-KIT (CD117) (–/+), HLA-DR (–/+)

Table 14.65 Comparison of fibroblasts, smooth muscle cells and myofibroblasts and correlation of ultrastructure with hematoxylin and eosin staining

Characteristics	Fibroblasts	Smooth Muscle Cells	Myofibroblasts
Ultrastructure features	Rich in endoplasmic reticulum	Rich in myofilaments	Rich in both endoplasmic reticulum and myofilaments
Hematoxylin and eosin (H&E) stain	Cytoplasm stains—blue	Cytoplasm stains—deep blue	Cytoplasm stains—purple

Table 14.66 Commonly used immunohistochemical stains in surgical pathology

Immunohistochemical Markers	Expression and Cellular Localization	Classic use for Diagnosis
α_1-Antitrypsin (AAT-1)	Positive (cytoplasmic staining)	▪ Globules of α_1-antitrypsin (which accumulate in liver in α_1-antitrypsin deficiency) ▪ Hepatocellular carcinoma (Hep Par 1 is more specific) ▪ Histiocytic lesions (but CD68 is more specific)
α-Fetoproteins	Positive (cytoplasmic staining)	Yolk sac tumor (not specific), hepatocellular carcinoma except fibrolamellar variant, hepatoblastoma

Contd...

Table 14.66 Commonly used immunohistochemical stains in surgical pathology (*Contd...*)

Immunohistochemical Markers	Expression and Cellular Localization	Classic use for Diagnosis
ALK (anaplastic lymphoma kinase) expression as a result of t(2;5)/NMP-ALK	Positive (nuclear, cytoplasmic, membranous staining)	Anaplastic large cell lymphoma, lung adenocarcinoma with EML4-ALK rearrangement
Arginase 1 (new marker)	Positive (cytoplasmic staining)	Hepatocellular carcinoma
B72.3	Positive (cytoplasmic, membranous staining)	Adenocarcinoma
β-Catenin	Positive (nuclear staining)	Colon carcinoma, hepatoblastoma, pancreatoblastoma, craniopharyngioma, tubular adenoma, familial adenomatous polyposis
BCL-2 (B cell lymphoma 2)	Positive (cytoplasmic, membranous staining)	Follicular lymphoma, CLL/SLL, MCL (mantle cell lymphoma), MZL (marginal zone lymphoma)
BCL-6 (B cell lymphoma 6)	Positive (nuclear staining)	Follicular lymphoma, Burkitt lymphoma, synovial sarcoma
Ber-EP4	Positive (membranous staining)	Adenocarcinoma, lung adenocarcinoma
Brachyury	Positive (nuclear staining)	Chordoma, hemangioblastoma
CAIX (carbonic anhydrase)	Positive (membranous staining)	Renal cell carcinoma (clear cell variant), renal cell carcinoma (papillary variant in areas of necrosis)
CA125	Positive (luminal staining)	Serum tumor marker for monitoring ovarian carcinoma
CA 19-9 (carbohydrate antigen)	Positive (cytoplasmic staining)	Serum tumor marker for monitoring pancreatic carcinoma
Calcitonin	Positive (cytoplasmic and extracellular staining)	Medullary thyroid carcinoma, neuroendocrine tumors
Caldesmon (h-caldesmon)	Positive (cytoplasmic staining)	Leiomyosarcoma
CALLA (common acute leukemia antigen) CD10	Positive (membranous staining)	T cell ALL (100%)
Calponin	Positive (cytoplasmic staining)	Smooth muscle, myoepithelial cells, myofibroblasts (variable)
Calretinin (CRT)	Positive (cytoplasmic and nuclear staining)	Epithelial mesothelioma, sex–cord stromal tumors, cardiac myxoma, adrenocortical tumors, adenomatoid tumors
Cathepsin K	Positive (cytoplasmic staining)	Xp translocation renal cell carcinoma, chordoma, PEComas
CD1a	Positive (membranous staining)	Langerhans cell histiocytosis. T cell lymphoblastic lymphoma (some cases), thymoma with admixed thymocytes
CD2	Positive (membranous staining)	T cell lymphoma, NK cell lymphoma, leukemia
cCD3 (flow cytometry only)	Positive (cytoplasmic staining)	Most lineage-specific marker for T cell differentiation
CD3	Positive (membranous and cytoplasmic staining)	Pan-T cell marker, T cell lymphomas/leukemias
CD4, CD8	Positive (membranous staining)	T cell lymphomas/leukemias
CD5	Positive (membranous staining)	Low-grade lymphomas: CLL/SLL and MCL, high-grade lymphoma (blastoid marginal cell lymphoma, occasional DLBCL)

Contd...

Table 14.66 Commonly used immunohistochemical stains in surgical pathology (*Contd...*)

Immunohistochemical Markers	Expression and Cellular Localization	Classic use for Diagnosis
CD7	Positive (membranous staining)	T-ALL (100%), B cell lymphoma
CD10 (CALLA, common acute leukemia antigen)	Positive (membranous staining)	T cell ALL (100%)
CD11b—a flow marker	Positive (membranous staining)	Myelogenous leukemias with differentiation, NK cell tumors
CD11c—a flow marker	Positive (membranous staining)	Hairy cell leukemia
CD13, CD14, CD33	Positive (membranous staining)	Myelogenous leukemias
CD15	Positive (membranous and paranuclear dot-like staining)	AML differentiation, adenocarcinoma, Reed Sternberg cells in classic Hodgkin disease
CD19, CD20, CD22 (pan-B cell markers)	Positive (cytoplasmic, membranous staining)	B cell lymphoma, B precursor ALL (CD19), variable CD20, CD22; diffuse large B cell lymphoma (DLBCL) constantly CD19 positive), and CD20 reactivity is lost after treatment with rituximab
CD21	Positive (membranous staining)	Follicular lymphoma, mantle cell lymphoma, angioimmunoblastic T cell lymphoma
CD35	Positive (membranous staining)	Follicular lymphoma, mantle cell lymphoma, angioimmunoblastic T cell lymphoma
CD23	Positive (membranous staining)	Low-grade lymphoma (CLL/SLL), follicular lymphoma, mantle cell lymphoma
CD25 (IL-2 receptor)	Positive (membranous and cytoplasmic staining)	Hairy cell leukemia, adult T cell leukemia/lymphoma, anaplastic large cell lymphoma, neoplastic mast cells
CD30 (Ki-1)	Positive (membranous and paranuclear dot-like staining)	Reed-Sternberg cells in classic Hodgkin disease, anaplastic large cell lymphoma, embryonal carcinoma
CD31 (more sensitive and specific than CD34)	Positive (cytoplasmic and membranous staining)	Endothelial cell differentiation (e.g. vascular tumors like angiosarcoma, Kaposi sarcoma)
CD34	Positive (cytoplasmic and membranous staining)	Angiosarcoma, Kaposi sarcoma, hemangiopericytoma, dermatofibrosarcoma protuberans, gastrointestinal stromal tumors (70%), solitary fibrous tumor, nerve sheath tumors (e.g. schwannoma, neurofibroma, malignant peripheral nerve sheath tumor), epithelioid sarcoma (50%), adipocytic tumors
CD38	Positive (membranous staining)	Plasma cell differentiation, poor prognosis in CLL/SLL
CD41, CD42b, CD61 (flow markers)	Positive (membranous staining)	AML with megakaryocytic differentiation (AML-M7)
CD43	Positive (cytoplasmic staining)	Low-grade lymphoma (e.g. CLL/SLL, mantle cell lymphoma, marginal zone lymphoma; but not follicular lymphoma), myeloid sarcoma (chloroma)
CD44	Positive (cytoplasmic staining)	Small cell carcinoma of prostate

Contd...

Table 14.66 Commonly used immunohistochemical stains in surgical pathology (*Contd...*)

Immunohistochemical Markers	Expression and Cellular Localization	Classic use for Diagnosis
CD45 (leukocyte common antigen—LCA)	Cytoplasmic, membranous staining	Classic Hodgkin disease, lymphoblastic lymphoma, anaplastic large cell lymphoma (some cases)
CDX2	Positive (nuclear staining)	Gastrointestinal tract especially colon
CK (AE1/AE3, CAM 5.2)	Positive (cytoplasmic staining)	Epithelial cells, carcinoma
Desmin	Positive (cytoplasmic staining)	Smooth and striated muscle differentiation
E-cadherin	Positive (membranous staining) (mainly) and cytoplasmic (some) staining	Favors ductal over lobular breast carcinoma
ER/PR (estrogen and progesterone receptors)	Positive (nuclear staining)	Breast carcinoma—prognostic and therapeutic factor
HER2/neu	Positive (membranous staining)	Breast carcinoma—prognostic and therapeutic factor
GFAP (glial fibrillary astrocytic protein)	Positive (cytoplasmic staining)	Astrocytes and neural tumors
Human chorionic gonadotropin-β (hCG-β)	Positive (cytoplasmic staining in syncytiotrophoblastic component)	Choriocarcinoma
Hep Par 1	Positive (cytoplasmic staining)	Hepatocellular carcinoma
Melan A (MART1)	Positive (cytoplasmic staining)	Melanoma
HMB-45	Positive (cytoplasmic staining)	Melanoma
Ki-67 proliferative marker	Positive (nuclear staining)	Mitotic activity
p63	Positive (nuclear staining)	Epithelial cells (squamous, transitional)
Placental alkaline phosphatase (PLAP)	Positive (cytoplasmic staining)	Seminoma
Prostatic specific antigen (PSA)	Positive (membranous staining)	Prostatic carcinoma
S-100 (calcium binding protein)	Positive (cytoplasmic and nuclear staining)	Melanoma, neural differentiation
Synaptophysin	Positive (cytoplasmic staining)	Neuroendocrine differentiation (carcinoid)
Chromogranin A	Positive (cytoplasmic staining)	Neuroendocrine differentiation (carcinoid)
Thyroid transcription factor 1 (TTF-1)	Positive (nuclear staining)	Thyroid carcinoma, lung carcinoma
Vimentin	Positive (cytoplasmic staining)	Mesenchymal marker to confirm antigenicity

Table 14.67 Monoclonal antibodies used in immunohistochemistry in leukemias and lymphomas

CD Antigen (Cluster Designation)	Cell Specificity	Clinical Application
Anaplastic large cell lymphoma		
ALK (anaplastic lymphoma kinase)	ALCL cell	Anaplastic large cell lymphoma (ALCL)
B cell derived lymphomas/leukemias		
▪ BCL-2 ▪ BCL-6	▪ B cell ▪ B cell	▪ B cell NHL ▪ B cell NHL
▪ CD20 ▪ CD23 ▪ CD79a ▪ CD79b	▪ B cell ▪ B cell ▪ B cell ▪ B cell	B cell NHL

Table 14.67 Monoclonal antibodies used in immunohistochemistry in leukemias and lymphomas (*Contd...*)

CD Antigen (Cluster Designation)	Cell Specificity	Clinical Application
▪ Cyclin D1 ▪ DBA-44 ▪ CD10	▪ B cell ▪ B cell ▪ Immature B cell	▪ Mantle cell lymphoma ▪ Hairy cell leukemia ▪ ALL (acute lymphoblastic leukemia) and lymphoma of follicular cell origin
B cell-derived classic variants of Hodgkin's disease		
▪ CD30 ▪ CD15	▪ Reed-Sternberg cell ▪ Reed-Sternberg cell	Classic variants of Hodgkin's disease
Activated T cell		
▪ CD3 ▪ CD5 ▪ CD4 ▪ CD8	▪ T cell ▪ T cell ▪ T-helper cell ▪ T-suppressor cell	T cell leukemia/T cell lymphoma
T cell/B cell subset derived lymphomas		
▪ CD43 ▪ CD45 RA ▪ CD45 RO	T cell, B cell subset	▪ T/B cell lymphoma/myeloid sarcoma ▪ T/B cell lymphoma ▪ T/B cell lymphoma
Natural killer cell (NK cell)-derived leukemias/lymphomas		
▪ CD56 ▪ CD57	NK cell (natural killer cell)	NK cell leukemias/lymphomas
Precursor T cell/B cell-derived lymphomas		
TdT (terminal deoxynucleotidyl transferase)	Percursor T cell/B cell	Precursor T cell/B cell lymphoma
Thymocyte/Langerhans cell derived leukemias/lymphomas		
CD10	Thymocyte, Langerhans cell	Precursor T cell/B cell leukemias/lymphomas
Follicular dendritic (T) C cell-derived tumor		
CD21	FDC (follicular dendritic cell)	FDC (follicular dendritic cell tumor and follicle differentiation)
Hematopoietic stem cell-derived leukemias		
▪ CD34 ▪ CD117	Hematopoietic stem cell	▪ Acute myelogenous/lymphoid leukemias ▪ Acute myelogenous leukemia
All leukocytes derived leukemias/lymphomas		
CD45	All leukocytes	Leukemias/lymphomas
Monocyte/histiocytic derived tumors		
CD68	Monocyte/histiocyte	Monocytic/histiocytic tumors
Platelet/megakaryocyte derived leukemia		
▪ CD42b ▪ CD61	Platelet/megakaryocyte	Acute megakaryoblastic leukemia
Proliferation fraction		
Ki-67	Proliferation fraction	High-grade lymphoma

Adapted from flow cytometry, immunohistochemistry and molecular genetics for hematolymphoid malignancies.

EPITHELIAL TISSUE DIFFERENTIATION

Cytokeratins

Cytokeratins are cytoskeleton proteins, which belong to a family of intermediate filaments. These are detected by immunohistochemistry technique in tumors showing epithelial differentiation. Cytokeratins exist as heterodimers formed by two protein dimers and composed of acidic and basic subunits. Therefore, certain pairs of cytokeratins are expressed jointly, e.g. CK8/CK18 and CK1/CK10. Based on the nature, cytokeratins are categorized into basic (type B/class II) and acidic (type A/class I). Applications of immunohistochemistry in analysis of cytokeratins are given in Table 14.29.

Abbreviations: MSA: Muscle specific actin, SMA: Smooth muscle actin, SMMHC: Smooth muscle myosin heavy chain

IHC markers for smooth muscle differentiation

Desmin (intermediate filament)
- Universal pan-muscle marker for smooth muscle and striated muscle and also expressed variable in myofibroblasts
- Leiomyoma
- Leiomyosarcoma (70%)
- Rhabdomyosarcoma
- Also expressed in various epithelial neoplasms, e.g. renal cell carcinoma (clear cell variant), endometrioid carcinoma, thyroid carcinoma, mesothelioma, salivary gland carcinoma, sweat gland carcinoma and spindle cell carcinoma of any site

Muscle specific actin (MSA)
- Pan-muscle marker for smooth muscle and striated muscle

Smooth muscle actin (also known as actin)
- Expressed in smooth muscle, but absent in striated muscle
- Smooth muscle tumors (e.g. leiomyoma, leiomyosarcoma)
- Myoblastic tumors like lesion (nodular fasciitis)

Contractile apparatus associated proteins
- Expressed in smooth muscle, but absent in skeletal muscle
- Smooth muscle myosin heavy chain (SMMHC)
- Calponin (contractile apparatus associated proteins encoded by CALD-1 gene) expressed in smooth muscle, leiomyoma, leiomyosarcoma, , myofibroblasts, myofibroblastic tumors and myoepithelial cells
- Caldesmon (encoded by CALD-1 gene) expressed in normal smooth muscle, leiomyoma and leiomyosarcoma

IHC markers for skeletal muscle differentiation

Desmin (intermediate filament)
- Universal pan-muscle marker for smooth as well as striated muscle (antibody clone D33)
- Expression of desmin variable in myofibroblasts
- Leiomyoma
- Leiomyosarcoma (70%)
- Rhabdomyosarcoma
- Also expressed in various epithelial neoplasms, e.g. renal cell carcinoma (clear cell variant), endometrioid carcinoma, thyroid carcinoma, mesothelioma, salivary gland carcinoma, sweat gland carcinoma and spindle cell carcinoma of any site

Muscle specific actin (MSA)
- Like desmin, muscle specific antigen is pan-muscle marker for smooth muscle and striated muscle. HHF-35 antibody recognizes epitope common to α-skeletal, α-cardiac and γ-smooth muscle actin

MyoD1 and myogenin (transcriptional factors)
- Expressed in striated muscle but absent in smooth muscle
- Expressed in leiomyosarcoma but absent in leiomyoma
- Embryonal rhabdomyosarcoma shows focal positivity staining pattern
- Alveolar rhabdomyosarcoma shows diffuse positivity staining pattern

Fig. 14.11: Immunomarkers for smooth muscle and skeletal muscle differentiation.

Immunohistochemical markers expression profile of CK7 and CK20 in human cancers is given in Table 14.30. Based on gel electrophoresis, cytokeratins are categorized into high-molecular weight cytokeratin (HMWCK) and low-molecular weight cytokeratin (LMWCK).

- **High molecular weight cytokeratins (HMWCKs):** These are also known as squamous keratins, which form a dense cytoplasmic network of filaments and account for resistance to mechanical stress of surface epithelia. These are also known as tonofilaments demonstrated in squamous epithelia and squamous cell carcinoma. HMWCKs (CK9, CK10, CK11, CK16, CK17) are detected by CK903 and CK5/6 antibodies for demonstration of squamous keratins in squamous cell carcinoma.
- **Low molecular weight cytokeratins (LMWCKs):** These are also known as 'nonsquamous keratins' or simple keratins. These are loosely distributed in the cytoplasm but unable to form bundle. LMWCK experiences little mechanical stress as seen in liver, kidney and various glandular epithelia. It is worth mentioning that glandular epithelia of breast, high-grade squamous cell carcinoma, pancreatic adenocarcinoma and endometrial adenocarcinoma co-express both LMWCK and HMWCK cytokeratins. LMWCK (CK18, CK19, CK20) is detected by CAM 5.2 antibody in colon carcinoma, prostatic carcinoma, renal cell carcinoma and hepatocellular carcinoma.

Epithelial Membrane Antigen

Epithelial membrane antigen (EMA) is common epithelial cell marker demonstrated in meningioma, breast adenocarcinoma, colorectal adenocarcinoma, pancreatic adenocarcinoma, Paget's disease of breast, choriocarcinoma and desmoplastic small round cell tumor. Expression of epithelial membrane antigen (EMA) in various neoplasms is given in Table 14.31.

Carcinoembryonic Antigen

Carcinoembryonic antigen (CEA) is a protein normally present in very low levels in the blood of adults. Its blood level may be increased in certain types of human cancers and benign conditions. CEA analysis is most commonly performed in patient of colorectal carcinoma, in which CEA level is elevated. After treatment, if elevated CEA level returns to normal, it indicates that the colorectal carcinoma has responded to treatment. CEA level that rises steadily after treatment of complete excision of colorectal carcinoma often indicates that the cancer has recurred. Expression of carcinoembryonic antigen (CEA) in human cancers is given in Table 14.32.

TP53 Gene Product (p53 Protein)

TP53 is a tumor suppressor gene mapped at 17p13 that encodes p53 protein. The p53 protein ensures that cells repair any damaged DNA before cell division by inducing cell cycle arrest to allow time for DNA repair or to force the cell to undergo apoptosis via activation of proapoptotic BAX gene. Mutation in TP53 gene is most commonly demonstrated in human cancers. TP53 gene product analysis can differentiate human cancers, which as often p53 positive (carcinoma *in situ* and invasive epithelia of different sites) from metaplastic conditions, which are usually p53 negative. Germline heterozygous mutations in TP53 gene cause Li-Fraumeni syndrome. TP53 gene mutation and associated cancers are given in Table 14.33.

VASCULAR ENDOTHELIAL CELL DIFFERENTIATION

Many studies have been published comparing the expression and distribution of vascular endothelial cell markers such as CD31, CD34, D2–40, von Willebrand factor-related antigen, Fli-1, Fli-4, CD141 and Ulex europaeus 1 in different vascular beds in normal human tissues. Formalin fixed paraffin-embedded sections are applied vascular endothelial immunomarkers to study angiogenesis in human cancers. Vascular endothelial immunomarkers are shown in Fig. 14.10.

SMOOTH AND SKELETAL MUSCLE DIFFERENTIATION

Immunomarkers for smooth muscle and skeletal muscle differentiation are given in Fig. 14.11.

Smooth Muscle Differentiation Immunomarkers

Desmin

Desmin is intermediate filament present near the Z line in sarcomeres in smooth muscle, skeletal muscle and cardiac muscle. There is variable expression of desmin in myofibroblasts. Desmin stain is used in panel of immunomarkers for mesenchymal tissue, which helps to differentiate smooth muscle tumors (desmin positive) from gastrointestinal stromal tumors (c-KIT positive but always desmin negative). In serous effusion, reactive mesothelial cells are desmin positive (84%). However, desmin is expressed in mesothelioma (8%) or carcinoma (2%).

Muscle-specific Actin

Muscle-specific actin (MSA) is expressed in smooth muscle and skeletal muscle. Nonmuscle sarcomas, carcinomas, lymphomas and melanomas do not express muscle specific actin. MSA expression is demonstrated in soft tissue tumors with muscle differentiation such as leiomyomas, leiomyosarcomas and rhabdomyosarcomas subtypes.

Contractile Apparatus Associated Proteins

Contractile apparatus associated proteins are demonstrated in the cytoplasm of smooth muscle fibers that consist of the myofilaments, myosin and actin.

- Examples of contractile apparatus associated proteins are SMMHC (smooth muscle myosin heavy chain), calponin (contractile apparatus associated protein) and caldesmon (contractile apparatus associated protein).
- SMMHC is expressed in smooth muscle, leiomyoma, leiomyosarcoma; but absent in skeletal muscle.
- Calponin is expressed in smooth muscle, leiomyoma, leiomyosarcoma, myoepithelial cells, myofibroblasts, myofibroblastic tumors; but absent in skeletal muscle.
- Caldesmon is demonstrated in smooth muscle, leiomyoma, leiomyosarcoma; but absent in skeletal muscle.

Skeletal Muscle Differentiation Immunomarkers

Desmin

Desmin is intermediate filament present near the Z line in sarcomeres in smooth muscle, skeletal muscle and cardiac muscle. It is expressed in myoblasts. Desmin stain is used in panel of immunomarkers for mesenchymal tissue. Desmin is expressed in leiomyoma, leiomyosarcoma (70%), rhabdomyosarcoma; and myofibroblasts (variable staining).

Muscle-specific Actin

Muscle-specific actin (MSA) is expressed in smooth muscle and skeletal muscle. MSA expression is demonstrated in soft tissue tumors with muscle differentiation such as leiomyomas, leiomyosarcomas and rhabdomyosarcomas of various subtypes.

MyoD1 (Transcriptional Factor)

MyoD1 gene encodes a nuclear protein MyoD1 that belongs to the basic helix-loop-helix (bHLH) family of transcription factors. MyoD1 regulates muscle

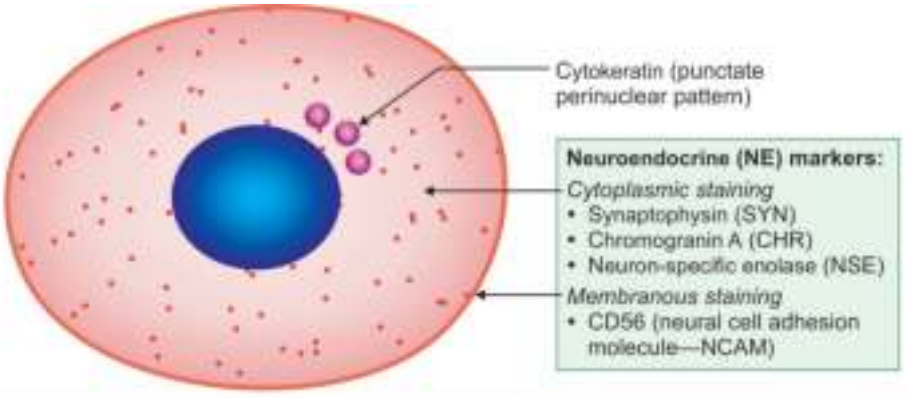
cell differentiation by inducing cell cycle arrest, a prerequisite for myogenic initiation. MyoD1 is expressed in skeletal muscle, alveolar rhabdomyosarcoma (diffuse staining), embryonal rhabdomyosarcoma (focal staining), leiomyosarcoma but negative in normal smooth muscle and leiomyoma.

Myogenin (Transcriptional Factor)

Myogenin is expressed in skeletal muscle, alveolar rhabdomyosarcoma (diffuse staining), embryonal rhabdomyosarcoma (focal staining), leiomyosarcoma but negative in normal smooth muscle and leiomyoma.

Myoglobin

Myoglobin is expressed in regenerating skeletal muscle and well-differentiated cells in rhabdomyosarcoma and tumors with heterologous skeletal muscle differentiation.



NEUROENDOCRINE DIFFERENTIATION

Neuroendocrine differentiation marks a structural and functional feature of certain benign and malignant tumors. Neuroendocrine tumors may arise at almost any anatomical site, including paraganglia and are distributed throughout the body in organs including soft tissues.

- Malignant neuroendocrine tumors contain a significant proportion of cells displaying neuronal, endocrine or mixed features. Neuroendocrine tumors may contain higher than normal quantity of hormones into the circulation in response to signal from the nervous system which can cause various clinical manifestations.
- Some examples of neuroendocrine tumors are prostatic neuroendocrine tumor, carcinoid tumors, islet cell tumors, medullary thyroid carcinoma, pheochromocytoma, neuroendocrine carcinoma of the skin (Merkel cell carcinoma), small cell lung carcinoma and large cell neuroendocrine carcinoma of lung.
- Three grading parameters of prognostic relevance in neuroendocrine tumors are the mitotic index, Ki-67 labeling index and presence or absence of necrosis defined by morphologic criteria.
- Immunohistochemical stains for neuroendocrine differentiation include neuron-specific enolase (NSE), chromogranin A, chromogranin B, synaptophysin and CD56 as well as site-specific markers such as hormones and transcription factor. Panel of immunohistochemical markers of neuroendocrine and neuroectodermal neoplasms is shown in Fig.14.12.

MYOFIBROBLASTIC TISSUE DIFFERENTIATION

Myofibroblasts are activated fibroblasts, essential for wound healing and tissue remodeling following insult. These can also be derived from epithelial cells, endothelial cells, and mononuclear cells. Local resident

Immunohistochemical markers of neuroendocrine (NE) and neuroectodermal neoplasms

- Carcinoid tumors (SYN, CHR, NSE, CD56, CK, TTF1)
- Medullary carcinoma of thyroid (SYN, CHR, NSE, CD56, CK, TTF1, calcitonin, CEA, amyloid)
- Pancreatic endocrine neoplasm (SYN, CHR, NSE, CD56, CK)
- Pheochromocytoma (SYN, CHR, NSE, CD56, CK, S-100 protein)
- Paraganglioma (SYN, CHR, NSE, CD56, S-100 protein)
- Small cell neuroendocrine carcinoma (SYN, CHR, NSE, CD56, TTF1)
- Merkel cell carcinoma (SYN, CHR, NSE, CD56, CK, neurofilament, Merkel cell polyomavirus)
- Pituitary neoplasms (SYN, CHR, NSE, CD56, CK, GH, ACTH, TSH, LH, FSH)
- Parathyroid neoplasms (SYN, CHR, NSE, CD56, CK, parathormone)
- Neuroblastoma (SYN, CHR, NSE, CD56, S-100 protein)
- PNET/Ewing sarcoma (NSE, CK, CD99, PAS)

Fig. 14.12: Flow chart represents panel of immunohistochemical markers of neuroendocrine and neuroectodermal neoplasms

fibroblasts are activated by mechanical stretch such as TGF-β. Myofibroblasts and activated fibroblasts proliferate and synthesize extracellular matrix. Infiltrating macrophages synthesize cytokines that contribute to many of cellular processes. Myofibroblasts express calponin, smooth muscle actin, desmin (variable expression), however do not express caldesmon.

MYOEPITHELIAL DIFFERENTIATION (POLYPHENOTYPE)

Myoepithelial cells are usually present in glandular epithelium as thin layer above the basement membrane but generally beneath the luminal cells, which may be positive for smooth muscle actin (also called α-actin), p53, glial fibrillary acidic protein (GFAP), S-100 protein, CK14, smooth muscle myosin heavy chain (SMMHC), calponin and caldesmon. Smooth muscle actin can contract and expel the secretions of exocrine glands.

MELANOCYTIC LINEAGE DIFFERENTIATION

Melanocyte lineage is derived from neural crest. The neural crest has its origin in the neural tube. Following neural crest formation, neural crest cells delaminate from the dorsal-most aspect of the neural tube by a process of epithelial–mesenchymal transition (EMT).

- The neural crest cells migrate and go onto form many specialized structures and tissues in the developing embryo by migration, proliferation and differentiation.
- Melanoblasts are derived from neural crest cells via a SOX10 positive melanoblasts/glial bipotent progenitor. The key step during melanocyte formation is the activation of microphthalmia transcription factor (MITF).
- Melanocytes express Melan A (A103), melanoma-associated antigen recognized by T cells 1 (MART-1), human melanoma black 45 (HMB-45) marker of immature melanocytes, S-100 protein, microphthalmia transcription factor (MITF), SOX100, PNL2, MUM1, tyrosinase and CD63.
- Immunomarkers for epithelioid melanoma are Melan A (A103), melanoma-associated antigen recognized by T cells 1 (MART-1), human melanoma black 45 (HMB-45), SOX100, PNL2 and MUM1. S-100 protein is expressed in epithelioid melanoma, spindle cell melanoma and desmoplastic melanoma and other tumors. Other markers for malignant melanoma are SOX100, tyrosinase, CD63, PNL2 and MUM1.

IMMUNOFLUORESCENCE MICROSCOPY

IMMUNOFLUORESCENCE MICROSCOPY: OVERVIEW

Immunofluorescence microscopy is a powerful technique that utilizes fluorescent labeled antibodies to detect specific target antigens. Fluorescein dye emits greenish fluorescence under UV light, which can be tagged to immunoglobulin molecules.

- Sometimes, immunofluorescence microscopy technique is used to make viral ocular plaque more readily visible to human eye. Immunofluorescent labeled tissue sections are studied using a fluorescent microscopy. It is very sensitive method.
- Disadvantages of immunofluorescence microscopy are expensive equipment and its reagents, cross reactivity and nonspecific immunofluorescence.

PRINCIPLE

Principle of immunofluorescence microscopy involves usage of fluorescein isothiocyanate labeled immunoglobulin to detect antigens or antibodies according to test systems under a fluorescent microscope.

The second layer antibody can be labeled with fluorescent dye such as fluorescein isothiocyanate (FITC), rhodamine or texas red in indirect immunofluorescence microscopy.

TYPES OF IMMUNOFLUORESCENCE MICROSCOPY

There are two types of immunofluorescence microscopy: direct and indirect (Table 14.68). Immunofluorescence microscopy by using probe is shown in Fig. 14.13.

DIRECT IMMUNOFLUORESCENCE MICROSCOPY

Direct immunofluorescence microscopy is simple and very common procedure. Antigen is fixed on a slide and fluorescein labeled antibodies are layered over it. Then the slides are washed to remove unattached antibodies and examined under UV light in fluorescent microscope. The site where the antibody attaches to its specific antigen shows apple green fluorescence. This technique is used for direct detection of pathogens or their antigens in tissue or in pathologic samples.

Table 14.68 Differences between direct and indirect immunofluorescence microscopy

Parameters	Direct Immunofluorescence Microscopy	Indirect Immunofluorescence Microscopy
Time	Shorter procedure, single labeling step	Longer procedure, double labeling step
Cross reactivity	Minimized	May cross react with other than the target
Sensitivity	Less	High due to amplification of signal
Cost	Expensive	Relatively inexpensive

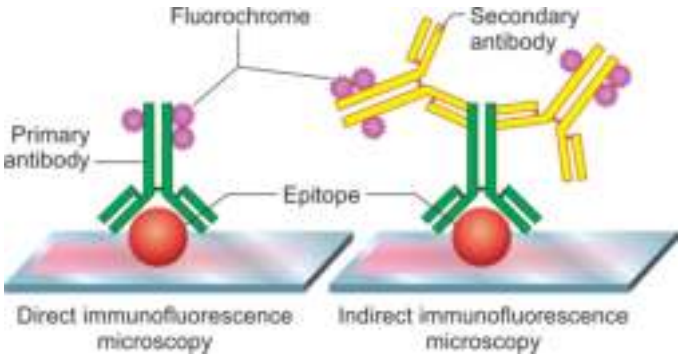


Fig. 14.13: Direct and indirect immunofluorescence microscopy.

INDIRECT IMMUNOFLUORESCENCE MICROSCOPY

Indirect immunofluorescence microscopy utilizes a two-step procedure to detect antigens on the slides. In the first step, a primary unlabeled antibody is used to bind and detect antigen. Then a second fluorescent labeled antibody binds the Fc portion of the primary antibody. This technique is more sensitive because multiple secondary antibodies can bind to a single primary antibody, thus amplifying the signal strength. Clinical applications of immunofluorescence microscopy are given in Table 14.69.

Table 14.69 Clinical applications of immunofluorescence microscopy

Type of Immunofluorescence	Sampling	Systems Involved	Applications in Diagnosing Disorders
Direct immunofluorescence microscopy	Tissue sample	▪ Skin and mucosa	▪ Bullous pemphigoid ▪ Pemphigus vulgaris ▪ Dermatitis herpetiformis ▪ Discoid lupus
		▪ Kidney (evaluation with fluorescein isothiocyanate—FITC conjugated method against IgG, IgM, IgA, C3, C1q, fibrinogen, albumin, κ and λ)	▪ Glomerulonephritis
		▪ Kidney (evaluation of C4D) ▪ Lung (evaluation of C4D)	▪ Humoral renal transplant rejection ▪ Humoral lung transplant rejection
Indirect immunofluorescence microscopy	Blood sample without anticoagulant (serum dilutions is removed and applied to an epithelial substrate together with fluorescein-labeled IgG)	Skin lesions	▪ Pemphigus vulgaris ▪ Paraneoplastic pemphigus ▪ Bullous and/or cicatricial pemphigoid

Other applications of immunofluorescence are to detect viruses (herpes, varicella-zoster, cytomegalovirus, influenza, HIV), bacteria (Mycobacterium tubercle bacilli and Treponema pallidum), and Entamoeba histolytica.

CHEMILUMINESCENCE VERSUS CHEMIFLUORESCENCE TECHNIQUES

Traditionally, radioisotopic protocols have been used in the laboratory. Keeping in view of high cost of isotopes and difficulty in their disposal, many scientists are turning to nonisotope methods as a substitute to isotopes. Currently, chemiluminescence and chemifluorescence techniques are used in the laboratories.

CHEMILUMINESCENCE TECHNIQUE

Chemiluminescence is nonisotope technique based on chemical reaction occurring between an enzyme horseradish peroxidase (HRP) and luminol resulting in light emission. The light emission is detected by changed couple device (CCD), X-ray film, photomultiplier tube (PMT) based detectors. This technique is more sensitive than calorimetric methods.

The antibody based systems provide target specificity. Enzyme component provides signal amplification. This has now become a protocol for substituting radioisotopes worldwide. Schematic diagram of chemiluminescence technique is shown in Fig. 14.14. Applications of chemiluminescence in clinical pratice are given in Table 14.70.

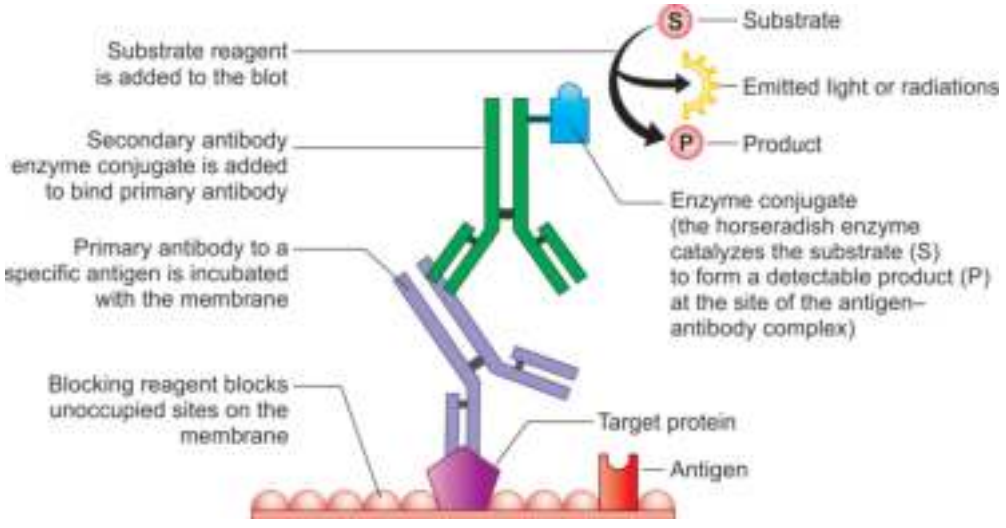

Fig. 14.14: Schematic diagram of chemiluminescence technique.

Table 14.70 Applications of chemiluminescence technique in clinical practice

Categories	Uses
Chemiluminescence immunoassay	Chemifluorescence is a sensitive technique used alternative to conventional colorimetric methodologies. Principle is same as ELISA technique and uses a chemiluminescent substrate for detection of the following: ▪ Hormones: Insulin, thyroxin, estradiol, testosterone, progesterone ▪ Vitamin: Vitamin B_{12} ▪ Tumor markers: Bone morphogenic protein 2, carcinoembryonic antigen (CEA), α-fetoprotein (AFP) and human β-chorionic gonadotropin (β-hCG) ▪ C-reactive protein and tumor necrosis factor: during inflammation
DNA hybridization detection	DNA hybridization technique uses specific chemiluminescent detecting reagents containing H_2O_2 and luminol for the following uses: ▪ Identifying DNA in crime case ▪ Paternal dispute ▪ Classify DNAs of various organisms
Western blotting	Western blotting (or protein immunoblotting) is a technique widely used to detect specific proteins in samples of tissue, cell lysates, cell culture supernatants or body fluids
Food analysis	Chemiluminescence technique is used to determine N-nitroso compounds, sugar, anabolic hormone, metabolites, food oxidations, metals and other interesting compounds
Forensic science	Chemiluminescence technique is used by criminalists to detect traces of blood at crime scene. Tiny amount of iron from hemoglobin in blood serves as catalyst for the chemiluminescence reaction that causes chemiluminescent reagent luminol to glow

CHEMIFLUORESCENCE TECHNIQUE

Chemifluorescence is an alternative technique used for molecular study, which combines fluorescence and chemiluminescence. Difference between chemiluminescence and chemifluorescence is based on detection mechanism. In chemiluminescence technique, light is generated based on enzymatic reaction, in which fluorescent molecule is attached to either secondary or tertiary antibody, which requires excitation via laser or some other high intensity light source. Excitation of fluorescent molecule generates a light emission collected by CCD or photomultiplier tube (PMT) based detector.

Chemifluorescence technique provides greater sensitivity, targeted specificity and amplification of signal as compared to calorimetric methods as well as chemiluminescence. Comparison between chemiluminescence and chemifluorescence technique is given in Table 14.71. Schematic diagram of chemifluorescence technique is shown in Fig. 14.15.

Table 14.71 Comparison between chemiluminescence and chemifluorescence technique

Parameters	Chemiluminescence Technique	Chemifluorescence Technique
Detection system	CCD, X-ray film, PMT based detectors	CCD, PMT based detector
Excitation	None	Required
Detection levels	Femtogram	Femtogram
Shelf life	Up to one year	<1 month
Cost	Inexpensive	Expensive

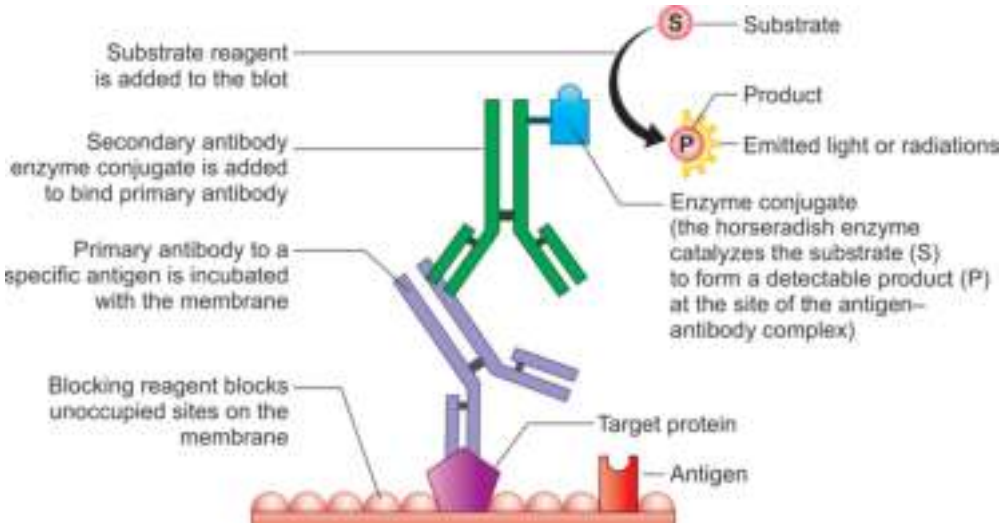

Fig. 14.15: Schematic diagram of chemifluorescence technique.

MOLECULAR DIAGNOSTICS TO ANALYZE CELL PROLIFERATION

There are three techniques to analyze proliferation of cells, which include Ki-67 (MB-1), mitotic cell count and flow cytometry technique/fluorescence activated cell sorting (FACS) analysis. FACS is a derivative of flow cytometry technique that adds an exceptional degree of functionality.

Ki-67 (MB-1) ANALYSIS

Ki-67 (MB-1) is applied on formalin-fixed paraffin-embedded tissue. It establishes prognostic marker for some malignant tumors. It captures all cells undergoing proliferation irrespective of the stage in the cell cycle. Therefore, Ki-67 (MB-1) is not a true analysis of mitosis.

MITOTIC CELL COUNT ANALYSIS

Mitotic cell count analysis is specific for mitotic cells. Technique can detect aberrant mitoses, aneuploidy in hematoxylin and eosin stained sections. It is unable to measure proliferating cells outside mitotic phase of cell cycle.

FLOW CYTOMETRY TECHNIQUE

By using a panel of selected monoclonal antibodies, flow cytometric analysis can determine cell lineage (i.e. B cell, T cell, natural killer cell or myelomonocytic cell), developmental stage (mature vs immature cells, thymic vs post-thymic cells) and clonality (monoclonal or polyclonal) of a given cell population. Flow cytometric analysis can also determine the heterogenous and aberrant morphologic features and percentage of malignant tumor cells.

- Flow cytometry can count cells in each phase of cell cycle and determine ploidy status, which can also be used as an ancillary technique in cytology. Cells are labeled with fluorochrome dyes, that can be attached to the antibodies for detection of specific proteins, e.g. cell lineage markers. Fluorochrome dyes can bind directly to cellular DNA or lipids.
- Fluorescence of the dyes is analyzed after exposure to an argon laser. Fluorescence occurs as the cells in liquid medium 'flow' past the laser. Cell size and number can also be determined by flow cytometry.

Table 14.72 Color of fluorochromes used in flow cytometry

Fluorochrome	Color
Propidium iodide	Red color
Peridinin chlorophyll	Red color
Texas red	Red color
Phycocyanin	Red color
Allophycocyanin	Red color
Cyanin 5	Red color
Fluorescein isothiocyanate	Green color
Phycoerythrin	Orange color
Rhodamine	Orange color

- A flow cytometer is versatile in its capability of measuring multiple parameters simultaneously, which analyzes multiple suspended cells ranging from 0.2 to 150 μm flowing in a fluid stream through a beam of light. Various parameters in flow cytometric analysis include cell size, cytoplasmic granularity, surface antigen, cytoplasmic antigen, nuclear antigen and DNA-RNA contents of individual cells in a cell suspension.
- Antigen expressed on cell surface, cytoplasm and nucleus are detected by means of fluorochrome conjugated antibodies. Color of fluorochromes used in flow cytometry is given in Table 14.72.
- Samples analyzed by flow cytometer include blood, bone marrow aspirate, fine needle aspirate, body fluids and fresh solid malignant tissue suspension.
- Cellular parameters are analyzed through an optical system. The light signal generated is registered in an electronic system. The computer system is responsible for data storage and graphic display on a screen.
- Samples are prevented clotting by addition of anti-coagulants such as disodium EDTA, sodium citrate or heparin. Concentration of white blood cells is enhanced by lysis of red blood cells by addition of ammonium chloride. Cells can also be obtained from solid malignant tissue suspension and converted into suspension for flow cytometric analysis suspensions. Comparison between immunohistochemistry and flow cytometry technique is given in Table 14.73.

COMPONENTS OF FLOW CYTOMETER

The flow cytometer is composed of flow system, optical system and electronic system. The flow system transports cells in a stream to the laser beam for analysis. The optical system consists of lasers to illuminate the cells in the sample stream and optical fibers to direct

Table 14.73 Comparison of immunohistochemistry and flow cytometry technique

Parameters	Immunohistochemistry Technique	Flow Cytometry Technique
Specimen required	Formalin fixed paraffin-embedded and frozen sections	Blood, bone marrow, body fluids, fine needle aspirates and fresh solid tissues
Equipment cost	Less expensive equipment	More expensive equipment
Morphologic correlation	Excellent visual correlation	No visual correlation
Available monoclonal antibodies	Limited monoclonal antibodies but gradually expanded	Abundant monoclonal antibodies
Dual stain applied on same cells	Limited	5–6 color staining
Quantitation	Estimation with imaging techniques	Accurate and reproducible
Distinction between surface and cytoplasmic staining	Difficult	Easy
Turn around time	4 hours with hematoxylin and eosin stained section	3 hours

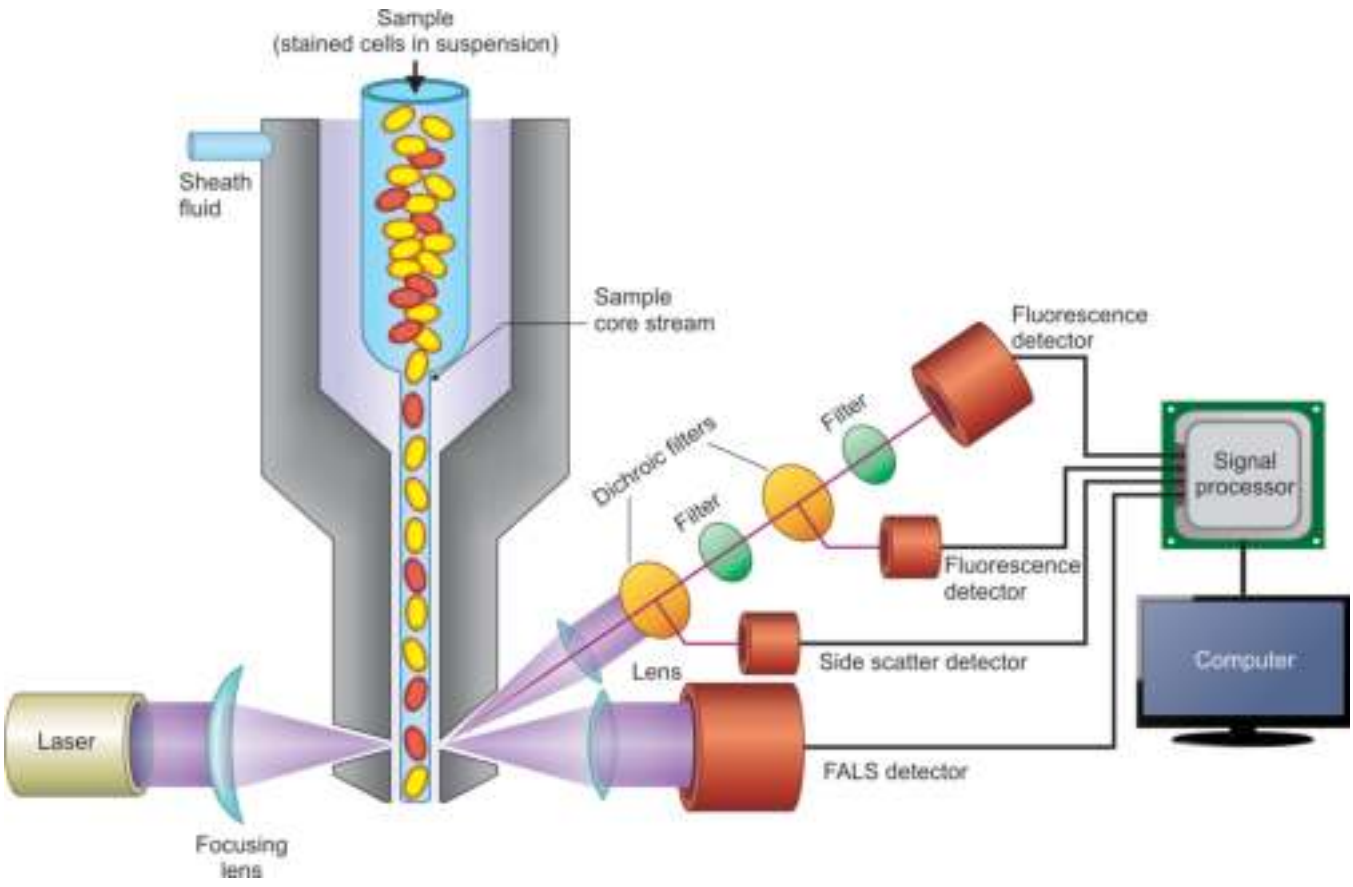

Fig. 14.16: The flow cytometer is composed of a flow system, optical system and electronic system.

the resulting light signals to the appropriate detectors. The electronic system converts light signals into electronic signals that are processed by the computer (Fig. 14.16). Flow cytometry is used in classification of leukemias and DNA analysis.

Flow System

Sample obtained from peripheral blood and bone marrow aspirate or solid malignant tissue suspension mixed with anticoagulant are injected into a stream of sheath. Cell particles are forced into center of the stream enabling transporting of single cell. Higher-flow rate is used for the immunophenotyping of cells. Lower flow rate is used for DNA analysis.

Optical System

Optical system consists of light scattering and fluorescence. Laser beam in flow cytometer participates in illumination of particles in the sample stream. Filters direct the generated light signals to the appropriate detectors. Most flow cytometers have argon ion laser as a source of light. The light signals are generated when laser beam strikes the cells. A system comprising optical mirrors and filters direct the specialized wavelength of light to the designated photodetectors.

Light Scattering

Light scattering occurs when cell deflects laser light. Leukocytes can be separated into different subpopulations of cells using forward scatter (FSC) and side scatter (SSC) are shown in Table 14.74. Neutrophils contain granular cytoplasm and complex nuclei, therefore, show both high forward light and side scatter. On the other hand, lymphocytes lack cytoplasmic granules and hence show both low forward light and low side scatter.

Conjugation of Fluorescent Dyes to Monoclonal Antibodies

Conjugation of fluorescent dyes to monoclonal antibodies directed toward antigens on a particular cell subset help in identification of cell subpopulations. There are two types of fluorescence staining procedures: direct and indirect (Table 14.75). Argon ion lasers are most common lasers used in most flow cytometers because 488 nm light emitted may be absorbed by more than one fluorochrome. Fluorescent dyes such as fluorescein isothiocyanate (FITC) and phycoerythrin (PE) are used to conjugate with monoclonal antibodies (Table 14.76).

Table 14.74 Type of light scattering

Type of Light Scattering	Characteristics
Forward scatter (FSC)	▪ Collected in the line with laser light beam ▪ Analyzes measurement of the cell surface size
Side scatter (SSC)	▪ Collected perpendicular to the laser light beam ▪ Analyzes internal complexity of a cell

Table 14.75 Type of fluorescence staining procedures

Steps	Direct Fluorescence Staining Procedure	Indirect Fluorescence Staining Procedure
First incubation	Incubation of cells with single fluorescence staining	Incubation of cells with a nonfluorescence staining directed towards specific antigen
Washing	Incubated cells are washed to remove non-specific bound antibodies	Incubated cells are washed remove nonspecific bound antibodies
Second incubation	Not required	Required with fluorescent dye directed against monoclonal antibody

Table 14.76 Comparison between fluorescein isothiocyanate (FITC) and phycoerythrin (PE)

Parameters	Fluorescein Isothiocyanate (FITC)	Phycoerythrin (PE)
Range of absorption of light and then fluorescence	460–510 nm	448–555 nm
Then fluorescence	510–60 nm giving green fluorescence	480–565 nm giving red fluorescence

Staining pattern of subpopulation of cells and percentage are defined.

Electronic System

Photodetectors convert the generated forward and side scattered cells, and fluorescent light signals into electrical impulses.

- There are two types of photodetectors in flow cytometer: photomultiplier tubes (PMTs) and photodiodes.
- Photomultiplier tubes (PMTs) amplify the electric current generated from light signals. Long amplifiers are used to negative from dim positive signals from cells stained with fluorochrome-labeled antibodies. Linear amplifiers are used to detect forward and side scatter signals.
- Photodiodes are used to detect strong forward scatter (FSC) signals. The intensity of the electronic impulses derived from the photodetectors is analyzed by digital converter.

APPLICATIONS OF FLOW CYTOMETER

Flow cytometry is an ancillary diagnostic technique to analyze cell marker/cell type in classification of leukemias/lymphomas (CD antigens), DNA ploidy analysis in molar pregnancy and cell cycle (G1, S, G2, M phases).

Classification of Leukemias

Flow cytometry is an ancillary method for classification of acute leukemias and lymphomas. Monoclonal antibodies specific to nuclear, cytoplasmic and surface antigens and characteristic of particular cell subsets are used in flow cytometer. These are organized as clusters of differentiation (CD) antigens, which differentiate hematopoietic malignancies and lymphomas.

- In cases of acute leukemias, it is essential to know the myeloid or lymphoid lineage required to know the prognosis and line of treatment in those cases in which routine cell morphology and cytochemistry fail to subtype or assign proper lineage in acute leukemias.
- Immunophenotyping using flow cytometry improves the diagnosis of acute lymphoblastic leukemia and differentiation of B cell ALL and T cell ALL (Table 14.77).
- Lineage markers of AML while analyzing on flow cytometric analysis include anti-MPO cytoplasmic, CD13, CD33 and CD117. Immunophenotyping of acute myelogenous leukemia (AML) is given in Table 14.78. Immunophenotyping of chronic lymphocytic leukemia (CLL) is given in Table 14.79.

Table 14.77 Immunophenotying of ALL (B cell) and ALL (T cell)

Characteristics	ALL (B Cell)	ALL (T Cell)
HLA-DR	Positive	Negative
cCD1	Negative	Positive
CD2	Negative	Positive
CD3	Negative	Positive
CD5	Negative	Positive
CD7	Negative	Positive
CD10 (CALLA)*	Positive	Negative
CD19	Positive	Negative
CD20	Positive	Negative

**CD10 (CALLA) is favorable prognostic marker and most amenable to therapy.*

Table 14.78 Lineage markers of acute myelogenous leukemia (AML) analyzing on flow cytometry technique

Parameters	Lineage Markers of AML
Myeloid lineage	▪ Anti-MPO is cytoplasmic lineage marker of AML ▪ CD13 ▪ CD33 ▪ CD117
Markers of immaturity	CD34
Monocytic differentiation	▪ CD14 ▪ CD64
Megakaryocytic differentiation	▪ CD41 ▪ CD61
Erythroid differentiation	▪ CD235A ▪ Glycophorin A

Table 14.79 Immunophenotyping of chronic lymphocytic leukemia (CLL)

Immunophenotype (Pan-B Cell Markers)	Expression
CD5*	Positive
CD23	Positive
CD19	Positive
CD20	Positive

**CD5 is positive in normal B cell and T cell.*

DNA Content Analysis

Flow cytometry technique can be used in analyzing DNA content of cell by using fluorescent stains, which target different DNA nucleotide base pairs within double helix.

- Fluorescent stains such as **HOECHST 33342** or **4', 6-diamino-2-phenylindole (DAPI)** are specific for the adenine/thymine nucleotide base pairs. Mithramycin and chromomycin A3 are target guanine/cytosine nucleotide base pairs.
- **Propidium iodide** stains all double-stranded nucleic acids, hence it is used in conventional flow cytometers with low power argon lasers because it absorbs light at 488 nm. DNA content analysis helps in differentiating normal cells from aneuploid malignant cells. The histograms from malignant tumors show abnormal peaks than normal cells.

Cell Cycle Analysis

Cell cycle shows G0 (resting phase), G1 (pre-synthetic phase), G2 (synthetic phase), S and M (mitotic) phases. Cells of G2 have finished DNA synthesis with double the amount of DNA. In M phase, two daughter cells are formed. G1/S and G2/M are checkpoints of cell cycle. The cell cycle can be plotted as a histogram with the number of cells per channel on the Y axis and fluorescence intensity of the cells stained for DNA content on the X axis.

CYTOGENETIC ANALYSIS

CYTOGENETIC ANALYSIS: OVERVIEW

The milestones in the history of clinical cytogenetics comprise preparation of chromosomes from blood cultures.

- Chromosomal spread is enhanced by development of hypotonic methods. Discovery of fluorescent quinacrine compounds helped in the demonstration of unique banding pattern for each human chromosome.
- Cytogenetic analysis is commonly used in the evaluation of congenital disorders, diagnosing syndrome associated with chromosomal abnormality, screening karyotypic abnormalities in patients with multiple birth defects and prenatal diagnosis. In surgical pathology, cytogenetic analysis recognizes cytogenetic abnormalities in patients with leukemias, lymphomas and soft tissue sarcomas.
- Cytogenetic analysis in cancers has aided targeted therapy, prognosis, and risk-based stratification of intensive therapy. Fresh tissue is required for cell culture and subsequent G-banding metaphase cell preparations or metaphase FISH procedures.

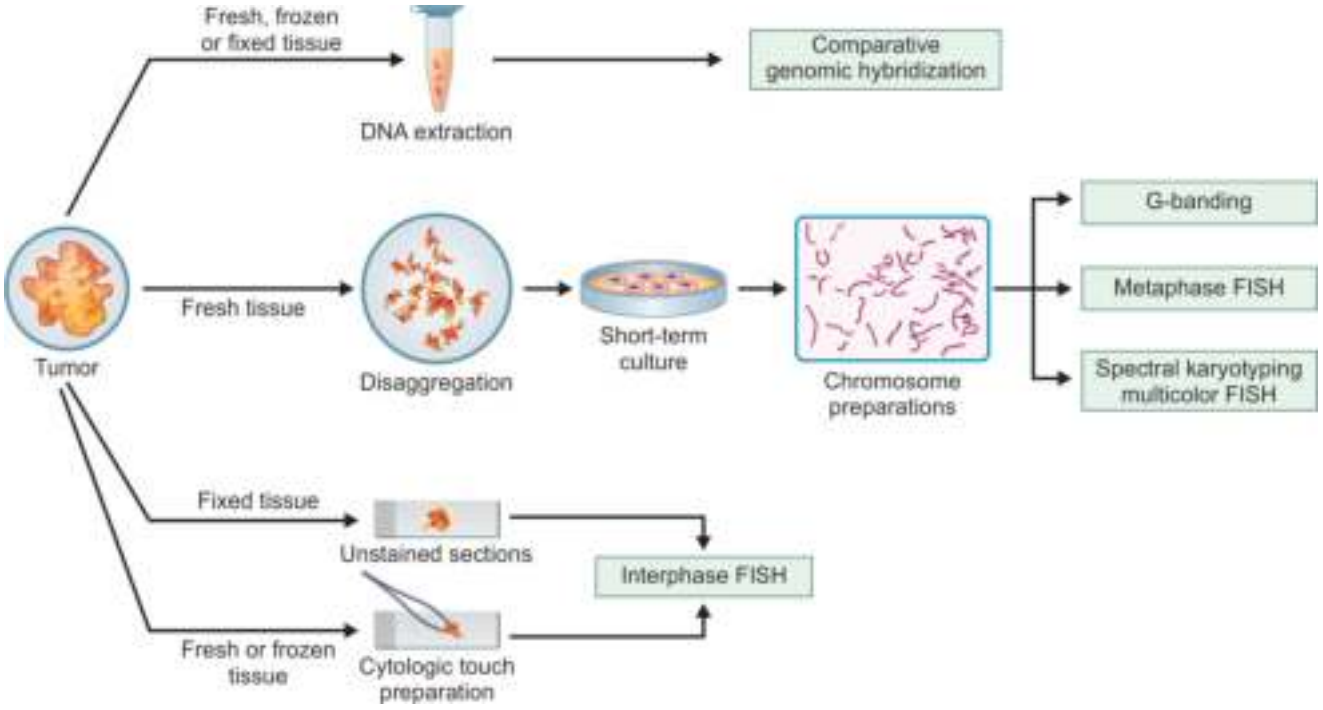

Fig. 14.17: Basic specimen requirements for cytogenetic analysis: Fresh tissue is required for cell culture and subsequent G-banded metaphase cell preparations or metaphase FISH procedures. DNA is extracted from fresh, frozen, or formalin-fixed paraffin-embedded tissue for comparative genomic hybridization platforms, and interphase FISH analysis can be conducted on cytologic touch preparations or formalin-fixed paraffin-embedded tissue sections.

- DNA is extracted from fresh, frozen, or formalin-fixed paraffin-embedded tissue for comparative genomic hybridization platforms, and interphase FISH analysis can be conducted on cytologic touch preparations or formalin-fixed, paraffin-embedded tissue sections (Fig. 14.17).
- Conventional cytogenetic analysis has ability to evaluate entire genome without any prior knowledge of the chromosomal regions involved in the disease process.
- Conventional cytogenetic analysis is performed on viable tissue specimens, which contain proliferating cells. It is only suitable for detection of numerical and structural chromosomal abnormalities. Cytogenetic technique lacks sensitivity to detect mutations such as deletions, amplifications, single nucleotide base substitutions and so on.

CYTOGENETIC ANALYSIS METHODOLOGY

Overall scheme for the production of metaphase chromosomes for conventional cytogenetic analysis is shown in Fig. 14.18.

Cell Culture Initiation

Blood sample is withdrawn and mixed with anticoagulant. Blood is kept in culture bottle with mitogen for 72 hours at 37°C. Different specimens are collected for traditional cytogenetic analysis as given in Table 14.80. Bone marrow and solid tumor consist of cells, which proliferate at slow rate. Therefore, mitogen is added to enhance proliferation (Table 14.81).

Cell Culture Maintenance

The length of *in vitro* culture depends on cell type is given in Table 14.82.

Cell Harvesting

Colcemid is added to the bottle to arrest cell division at metaphase. Colcemid, a synthetic analogue of colchicine (an alkaloid derived from the bulb of Mediterranean plant colchicine) prevents separation of sister chromatids and blocks proliferation of cells in metaphase stage.

- Cell cycle is asynchronous *in vitro* cells are obtained in acceptable mitotic index by addition of thymidine followed by deoxythymidine to obtain normal DNA replication. Alternately, 5-fluorodeoxyuridine may be used to stall cells at G1/S transition by addition of thymidine.
- The blood is now centrifuged in test tube. Then add hypotonic solution to the test tube to rupture red blood cells and swelling of white blood cells. Again centrifuge the test tube and then add methanol and acetic acid to the test tube to fix cells. Now centrifuge the test tube containing fixed white blood cells and place a few drops on glass slide. Dry the smear and

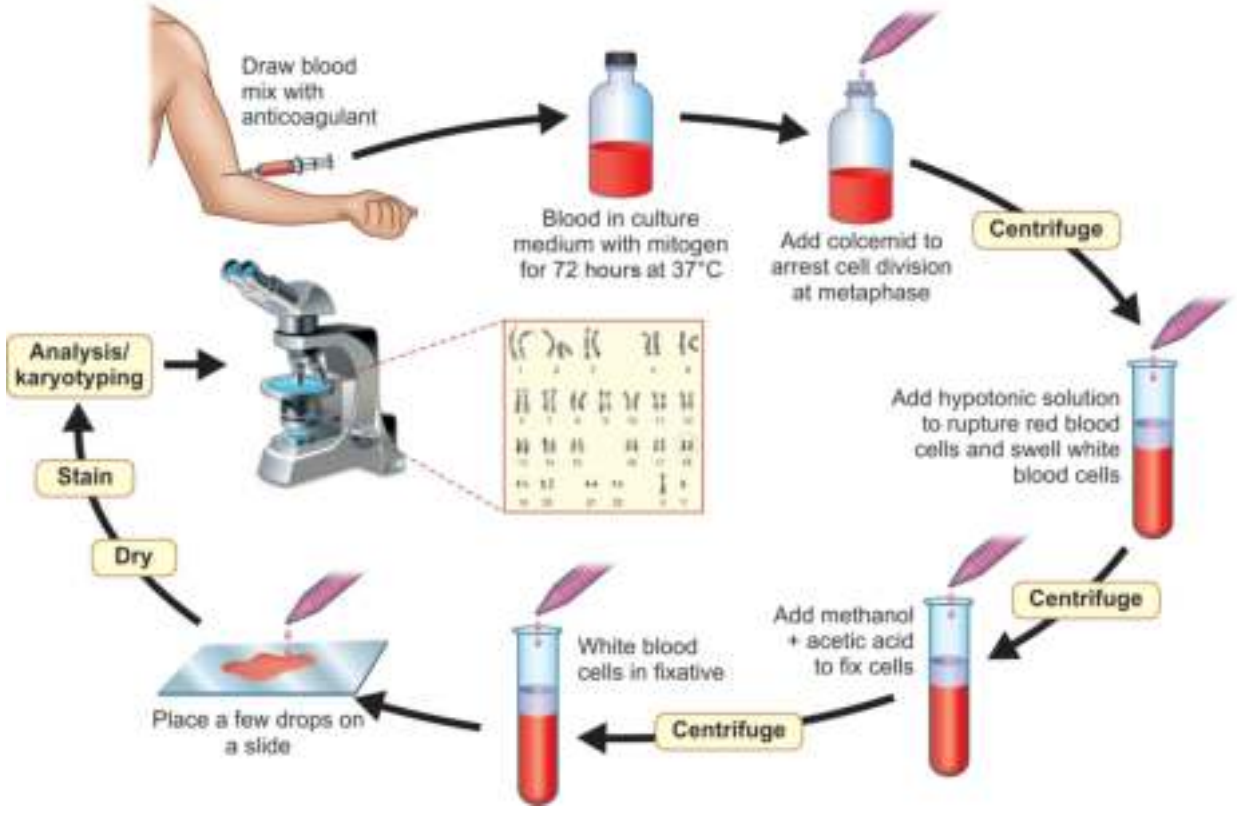

Fig. 14.18: Overall scheme for the production of metaphase chromosomes for conventional cytogenetic analysis.

Table 14.80 Specimen requirements for traditional cytogenetic analysis

Type of Sample	Sample Collection
Peripheral blood	Blood sample with anticoagulant kept in refrigerator or at room temperature
Bone marrow aspirate	Bone marrow aspirate with anticoagulant kept at room temperature
Solid tissue from tumor	▪ Viable tumor sample kept in sterile container containing broad spectrum antibiotics to prevent microbial overgrowth and autolysis ▪ Sterile container is transported on ice

Table 14.81 Mitogens used to enhance proliferation of cells of bone marrow and solid neoplasms

Mitogen	Cell Proliferation in Culture
Phytohemagglutinin (PHA)	T cells
Lipopolysaccharide (LPS)	B cells
Protein A	B cells
12-O-tetradecanoylphorbol-13-acetate (TPA)	B cells
Epstein-Barr virus	B cells
Synthetic oligonucleotides	B cells
Pokewood mitogen	B cells

then stain. The slide is analyzed for karyotyping. Quinacrine banding technique allows detection of the region containing repetitive DNA.

Table 14.82 Time required for proliferation of cells in culture medium

Cell Proliferation	Time Required
Peripheral blood cells	72 hours
Bone marrow cells	24 to 48 hours
Solid malignant neoplasms	≥2 weeks

CYTOGENETIC ANALYSIS TECHNIQUES

Bright field microscopy or fluorescence microscopy is used to visualize chromosomes. Electronic imaging system is used to capture the images. Assay failure occurs due to sampling from necrotic tumor, overgrowth of microbes, overgrowth of nonrepresentative clone of tumor cells, post-culture failure and wrong interpretation of results.

METAPHASE FLUORESCENCE *IN SITU* HYBRIDIZATION FOR CHROMOSOMAL KARYOTYPING TECHNIQUE

All metaphase chromosomes *in situ* hybridization analysis is performed by using probes labeled with fluorophores. Metaphase FISH technique is a modified Southern blot in which the target DNA comprises chromosomes rather than membrane bound DNA. Cytogenetic technique is used to stain metaphase chromosome as given in Table 14.83. Four steps of metaphase fluorescence *in situ* hybridization for chromosomal karyotyping are given in Table 14.84. Type of probes used in metaphase *in situ* hybridization is shown in Table 14.85.

MULTIPLEX METAPHASE FLUORESCENCE *IN SITU* HYBRIDIZATION FOR CHROMOSOMAL KARYOTYPING TECHNIQUE

Multiplex metaphase FISH technique is also known as **multicolor FISH**. Special karyotyping (SKY) is related technique. In both techniques, metaphase chromosome is hybridized with combination of probes labeled with different fluorophores. Five different fluorophores can produce different color combinations to uniquely labeled

Table 14.83 Cytogenetic technique is used to stain metaphase chromosome

Staining Technique	Staining Patterns
Technique producing specific alternating bands along each chromosome	
Giemsa banding (G-banding)	▪ Dark bands are AT-rich ▪ Light bands are CG-rich
Quinacrine banding (Q-banding)	Bright regions are AT-rich
Reverse banding (R-banding)	▪ AT-rich regions stain lightly (dull fluorescence) ▪ CG-rich regions staining darkly (bright fluorescence)
4,6-Diamidino-2-phenylindole (DAPI) staining	DAPI binds AT-rich regions produces a pattern similar to Q-banding (bright regions are AT-rich)
Technique staining selective chromosome regions	
Constitutive heterochromatin banding (C-banding)	▪ Stains heterochromatin (α-satellite DNA) around the centromere ▪ Used to demonstrate some inherited polymorphisms
Telomere banding (T-banding)	Technical variation of R-banding used to stain telomeres
Silver staining for nuclear organizer regions (NOR staining)	Stains the NORs (which contain rRNA genes) on the satellite stalks of acrocentric chromosome
Fluorescence *in situ* hybridization (FISH)	Staining pattern dependent on the probe

Table 14.84 Four steps of metaphase fluorescence *in situ* hybridization for chromosomal karyotyping

Steps	Procedure
Step 1	Denaturing of probe and metaphase target by high temperature and formamide
Step 2	Hybridization of probe to the chromosomal target
Step 3	Removal of unbound post-hybridization probe by washing
Step 4	Detection of bound probe by fluorescent microscopy

Table 14.85 Type of probes used in metaphase *in situ* hybridization

Characteristics	Repetitive Sequence Probes	Unique Sequence Probes	Whole Chromosome Probes (WCPs) also known as Painting Probes
Basis of development of probe	Differences in α-satellite sequences of centromeres	Derived from genomic clones or cDNA by using vectors such as bacterial artificial chromosomes (BACs) and yeast artificial chromosomes (YACs)	Probes isolated through flow sorting of specific chromosomes, microdissection of specific chromosomes accompanied by PCR amplification
Use	Most widely used to detect repetitive sequence	Used to detect sequences present on given chromosome	Used to identify chromosomal re-arrangements

WCPs to visualize 24 different human chromosomes, X and Y chromosomes in one hybridization.

- Multiplex FISH and special karyotyping techniques (SKY) are used to detect aneuploidy, interchromosomal rearrangements and marker chromosome (extrachromosomal material of unknown origin).
- Multiplex FISH and SKY do not provide direct information of the involved chromosomal bands. Both techniques do not detect intrachromosomal rearrangements such as inversions. These do not provide information on regions with repetitive DNA.
- Multiplex FISH and SKY techniques are modified by mixing with partial chromosome paints. These modified techniques detect translocation breakpoints and interchromosomal rearrangements.

COMPARATIVE GENOMIC HYBRIDIZATION TECHNIQUE

Comparative genomic hybridization (CGH) technique has higher sensitivity than conventional cytogenetic analysis. Different types of dyes are also used to label

Comparative genomic hybridization (CGH) technique in cancer

1. Comparative genomic hybridization technique allows a comprehensive analysis of multiple DNA gains and losses in entire genomes within a single analysis.
2. Equal amounts of test and reference DNA samples are fluorescently labeled respectively and mixed from the same individual.
3. Test DNA from tumor is fluorescently labeled as red and reference DNA from normal tissue as green. The mixture is applied to an array and allowed to hybridize *in situ* to normal metaphase chromosome. Microarray has 1,000,000 probes covering the human genome.
4. Red and green signal intensity is detected and mapped to genome location. Software clusters high and low intensity probes according to ratio of the concentrations of sequences in the two samples.
5. By comparing the fluorescence intensities of test DNA and reference DNA, changes in signal intensities caused by imbalances of the test tumor DNA can be identified.
6. The ratio of the binding intensities of test tumor DNA and control normal tissue DNA is proportional to the concentrations of sequences in the two samples.
7. Comparative genomic hybridization technique is performed to analyze alterations in DNA copy number which are involved in cancer associated with changes in the gene expression that occur in tumor development. Loss of DNA sequences contributes to the inactivation of tumor suppressor genes, while amplifications may activate oncogenes.
8. Comparative genomic hybridization technique application in Down syndrome is to demonstrate extra copy of DNA sequences from a portion of chromosome 21.

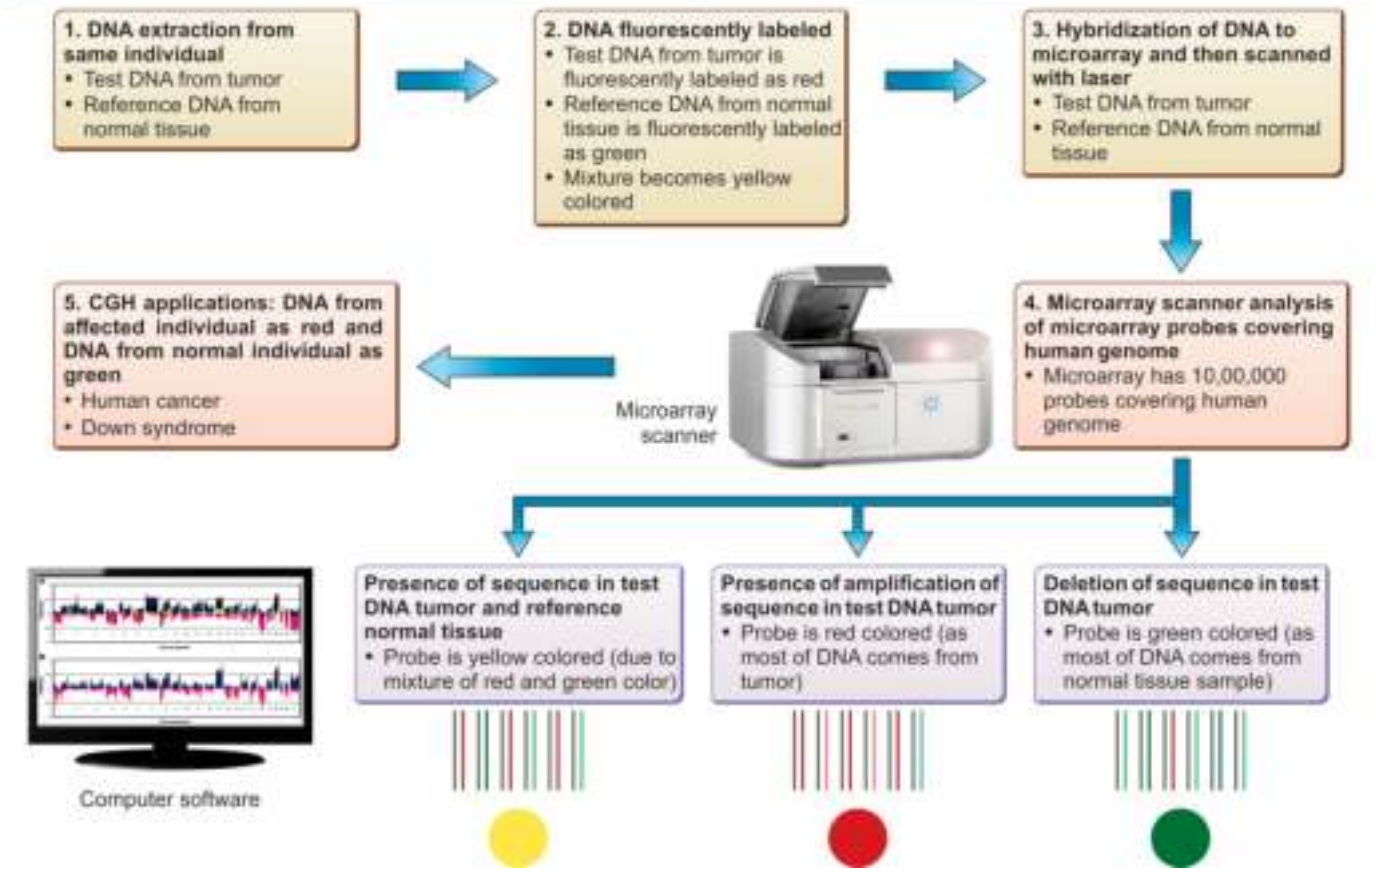

Fig. 14.19: Comparative genomic hybridization (CGH) technique

genomic DNA obtained from normal and diseased tissues. Microarray DNA gene probe is fixed to the slide. The major advantages of comparative genomic hybridization (CGH) technique is to detect copy number variations as small as several hundred nucleotide base pairs by DNA extraction from formalin fixed tissue. Level of fluorescence is compared with specific gene. CGH technique in cancer is shown in Fig. 14.19.

Metaphase Comparative Genomic Hybridization Technique

Metaphase comparative genomic hybridization (CGH) technique is a variation of metaphase FISH technique. Metaphase CGH technique is used to survey entire genome for chromosomal deletions and amplifications.

- For typical CGH test, genomic DNA extracted from tumor is labeled with red fluorophore, and genomic DNA from paired normal issue is labeled with green fluorophore. Both red and green probes are now mixed and used in single hybridization.
- The relative difference in DNA content between the normal and specimen DNA is represented by a difference in the green:red fluorescence ratio. Conventional chromosomal CGH is shown in Fig. 14.20.

Array Comparative Genomic Hybridization Technique

Array comparative genomic hybridization (CGH) technique utilizes a microarray comprising an orderly arrangement of DNA molecules linked to a solid matrix support. The labeled probe mixture is hybridized to the microarray. Ratio of green to red fluorescent signals is measured for each feature. Genomic microarrays are currently employed to detect genomic copy number changes, copy neutral changes and loss of heterozygosity. Comparative genomic hybridization *vs* conventional cytogenetic analysis is given in Table 14.86.

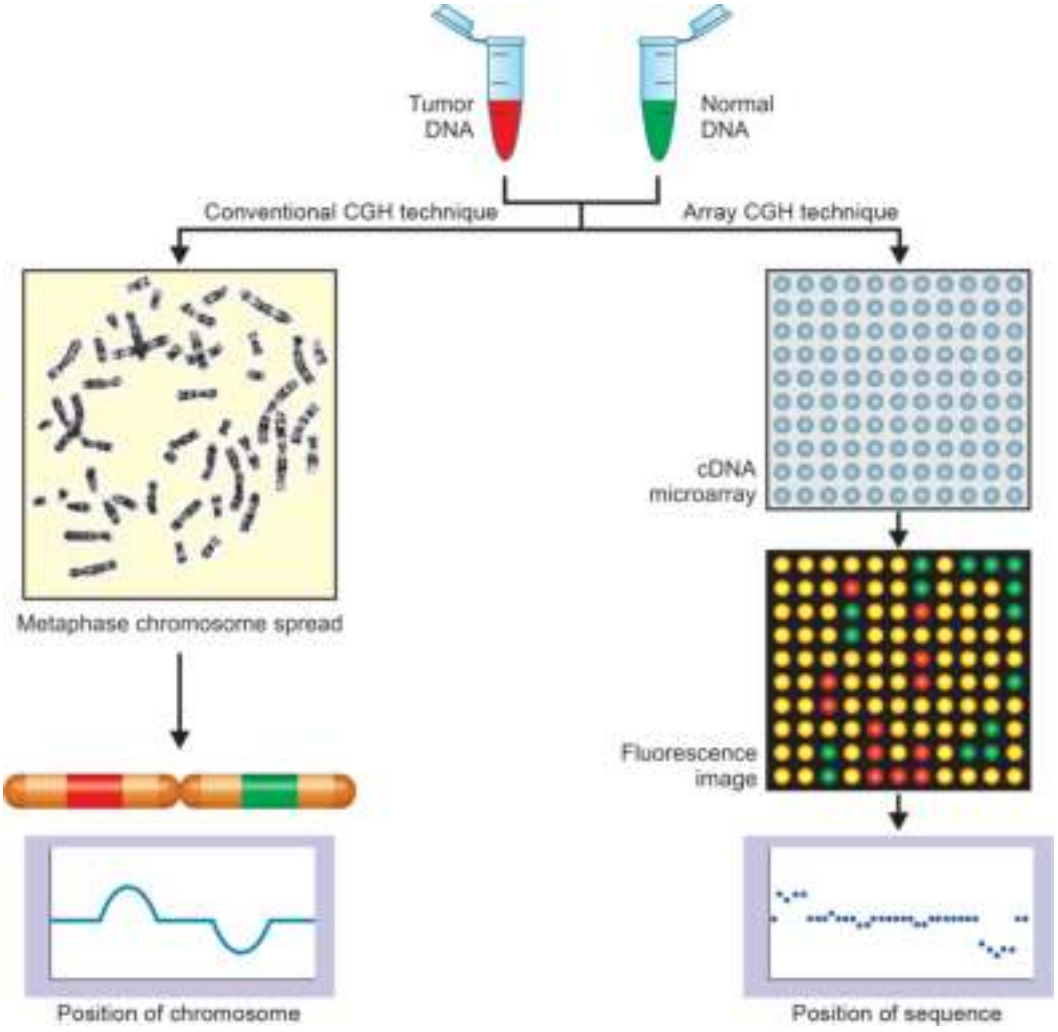

Fig. 14.20: Conventional chromosomal CGH: In conventional chromosomal CGH, the ratio of fluorescence intensities along each chromosome is analyzed. Increased DNA copy number in the tumor sample will be detected by increased red fluorescence, whereas decreased copy number will allow more binding of the normal DNA and increased green fluorescence. On the right, a similar hybridization to a cDNA array permits measurement of copy number at a higher resolution.

Table 14.86 Comparative genomic hybridization *versus* conventional cytogenetic analysis

Parameters	Comparative Genomic Hybridization (CGH)	Conventional Cytogenetic Analysis
Sensitivity	High sensitivity	Low sensitivity
Sample obtained	DNA extraction from fixed as well as fresh tumor	Peripheral blood, bone marrow aspirate and solid tumor
Utility	Genomic wide scan for structural alterations	Genomic wide scan for structural alterations is not possible

MICROARRAY ANALYSIS TECHNIQUE

Microarray analysis technique is used to detect the expression of thousands of genes at same time from experiments on DNA (gene chip analysis), RNA and protein microarrays. DNA microarrays are microscope slides that are printed with thousands of tiny spots in defined positions, with each spot containing a known DNA sequence (e.g. single-nucleotide polymorphisms, SNPs).

- Microarray analysis is used to evaluate patients with genomic imbalance especially in diagnostic testing for congenital anomalies, developmental delay and intellectual disabilities.
- However, this technique is not widely used in diagnosis of solid malignant tumors.
- Microarray analysis depends on the nucleic acid composition of the array (probe) and the test material (target) that is hybridized to it. Microarray application and technology are shown in Fig. 14.21A and B. SNP array procedures are shown in Fig. 14.22A and B.

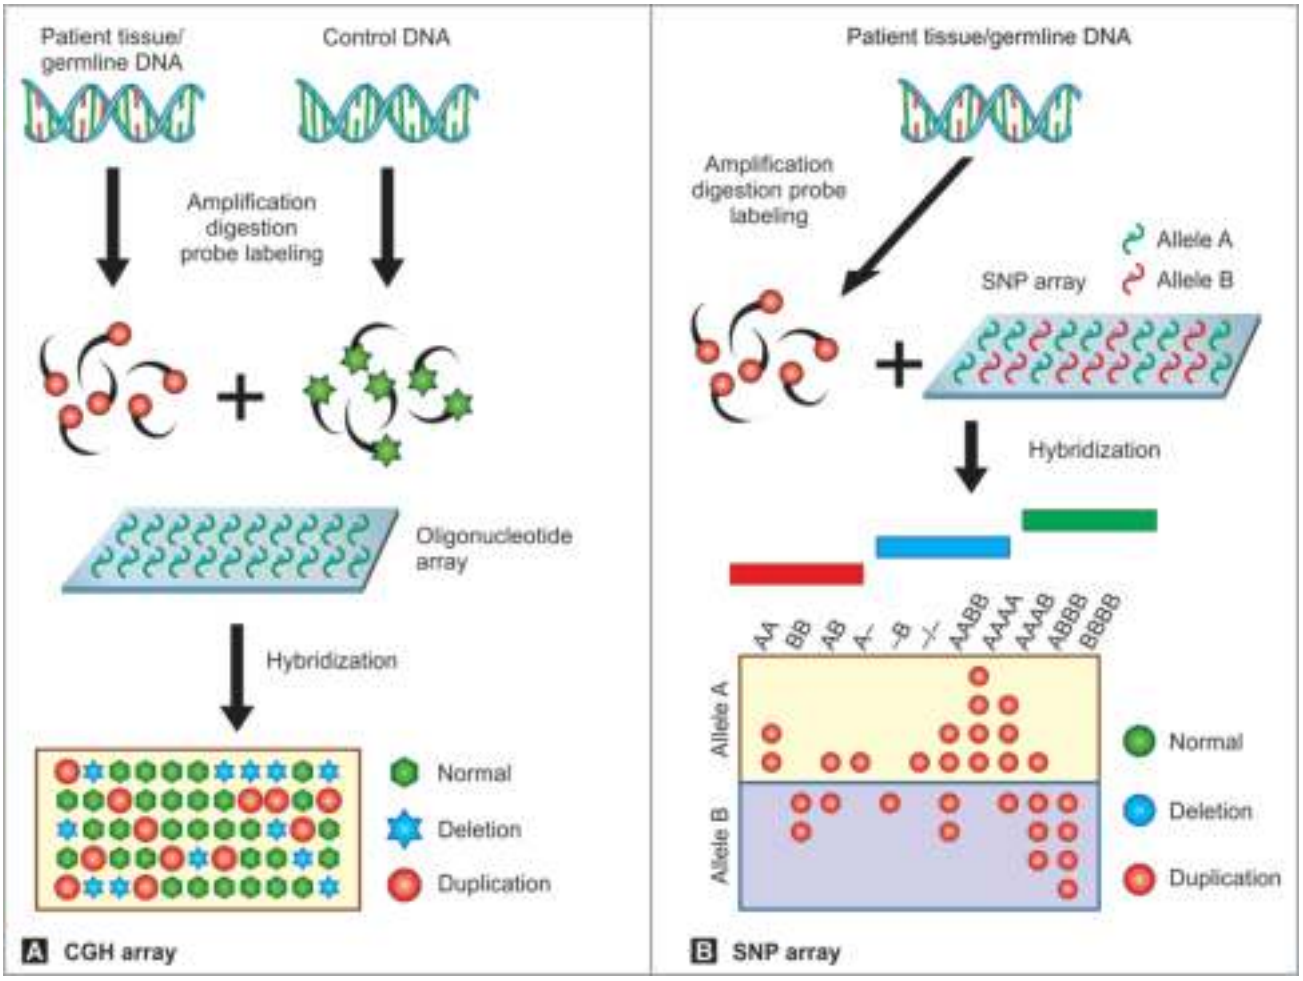

Fig. 14.21: Microarray application and technology. Microarray technology can be used in many different applications depending on the nucleic acid composition of the array (probe) and the test material (target) that is hybridized to it. (A) CGH array: in CGH array, fragments of genomic DNA are spotted as probes onto the microarray surface using robotics. Genomic DNA from the patient's tissue and germline are then co-hybridized to the array to identify regions of chromosomal gain or loss, (B) SNPs/re-sequencing: alternatively, genomic DNA sequence can be used to computationally design oligonucleotide probes that detect specific alterations in DNA samples (either germline or tissue) for either SNP genotyping or DNA sequencing studies.

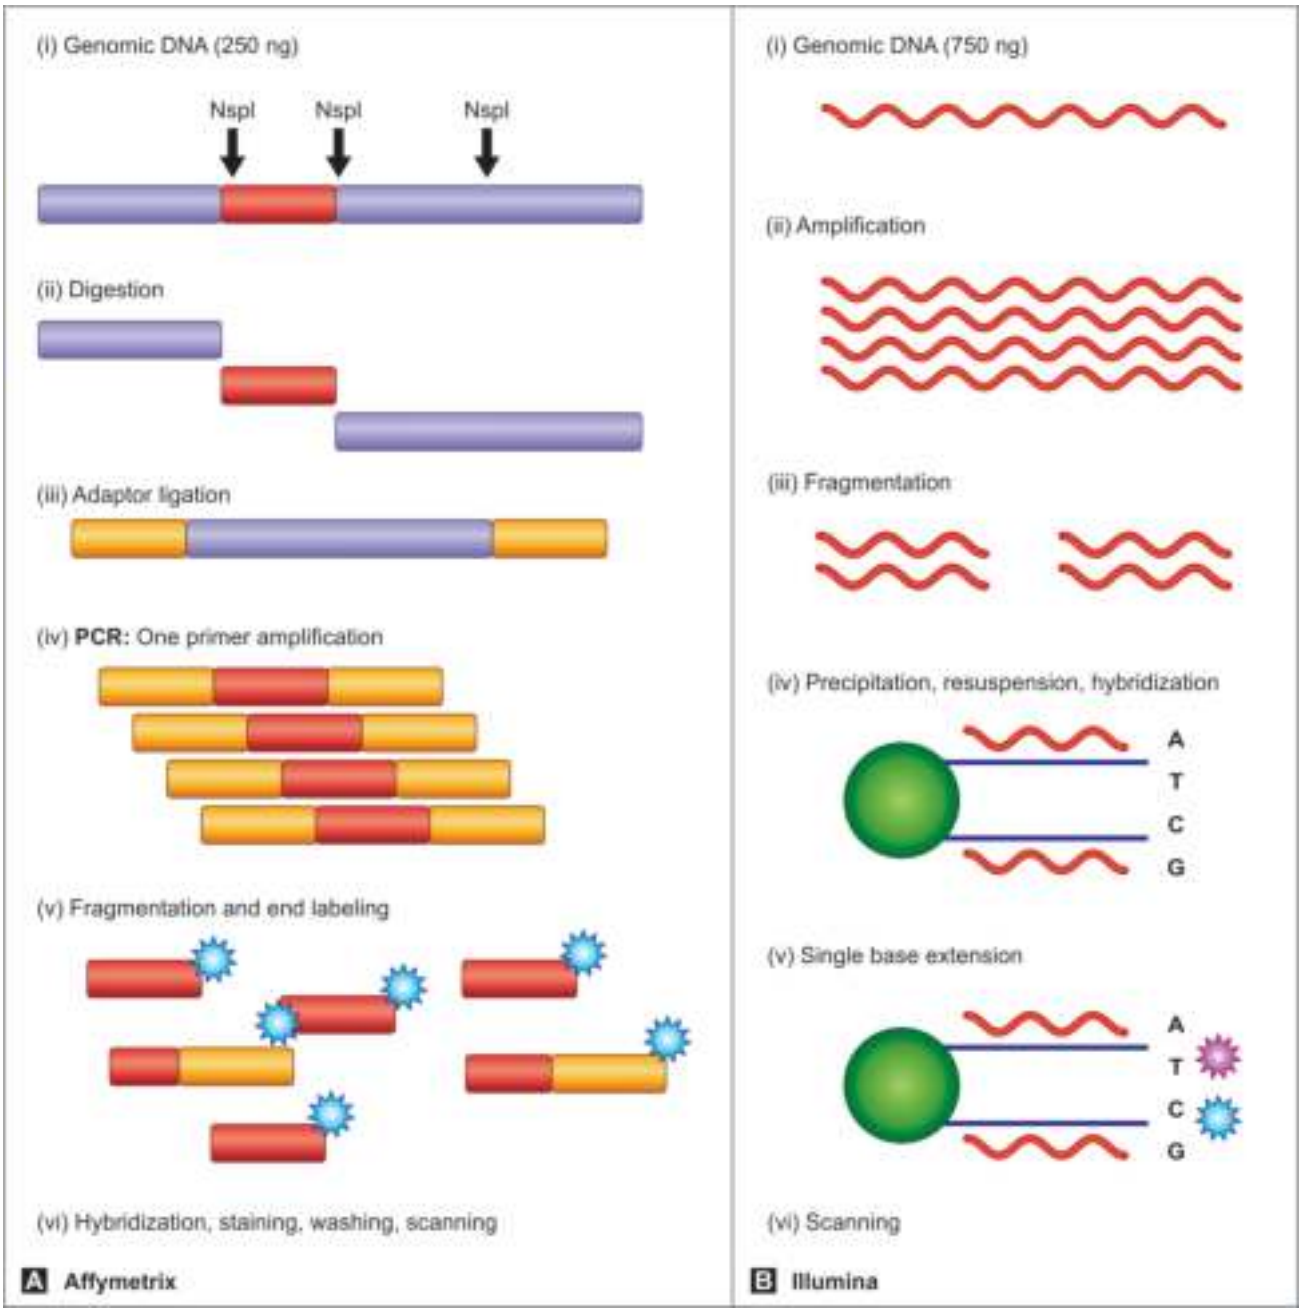

Fig. 14.22: SNP array procedures. (A) Affymetrix platform: genomic DNA is digested with NspI restriction enzyme. The resulted DNA fragments are ligated to adaptors and subsequently amplified. Amplification products are end-labeled and hybridized to the array. (B) Illumina platform: the entire genome is amplified and then hybridize to a bead array; allelic discrimination is achieved by single base extension reaction. In both platforms, the probe intensity is measured and compared with a silicoreference to evaluate DNA copy number.

Microarray Analysis Technique: Application and Technology

In microarray analysis technique, fragments of genomic DNA are spotted as probes onto the microarray surface using robotics. Genomic DNA from the patient's tissue is hybridized to the array to identify regions of chromosomal gain or loss.

Single-Nucleotide Polymorphism (SNP) Technique

Polymorphism is generic term that means 'many shapes'. Single-nucleotide polymorphism or SNP is most common type of gene variation among people. Each SNP represents a difference in single DNA building block, called a nucleotide. It is DNA sequence variation occurring when a single-nucleotide A, T, C

or G in the genome differs between members of species. For example, two sequenced DNA fragments from different individuals AAGCCTA to AAGCTTA contain a difference in a single-nucleotide base.

- In human beings, 99.9% nucleotide base pairs are same. Remaining 0.1% makes a person unique/ (different characteristics/traits). These variations can be harmless (change in phenotype) or harmful (diabetes mellitus, cancer, cardiovascular diseases, hemophilia).
- Single-nucleotide polymorphism (SNP) is present in coding (mostly) and noncoding regions of gene. In coding region, DNA/RNA sequences code for proteins. In noncoding regions, a segment of DNA

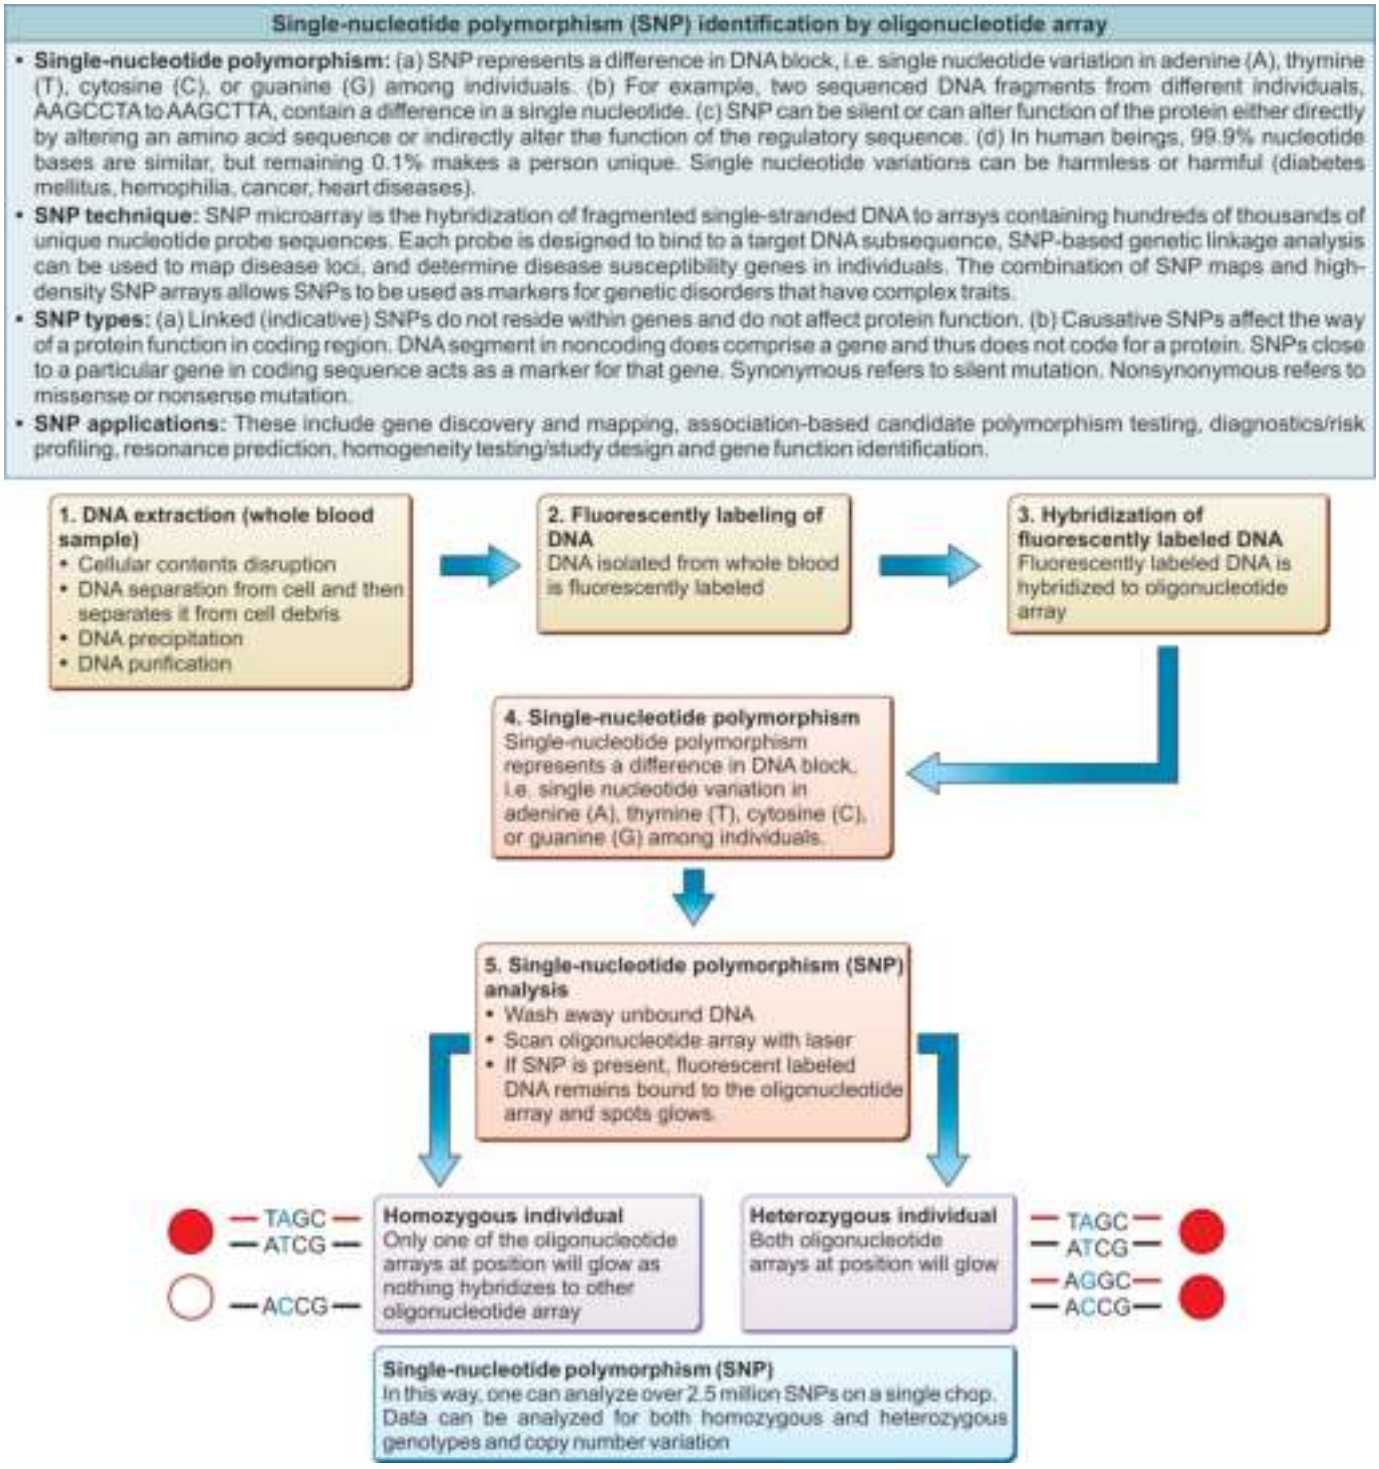

Fig. 14.23: Single-nucleotide polymorphism (SNP) identification by microarray.

does comprise a gene that does not code for a protein. Single-nucleotide polymorphism occurs with a very high frequency (1 in 100 nucleotide base pairs to 1 in 100–300 nucleotide base pairs).

- SNP close to a particular gene, acts as a marker for that gene. SNPs in coding regions may alter the protein structure made by that coding region. Single-nucleotide polymorphism (SNP) detection by microarray analysis and small format genotyping are shown in Figs 14.23 and 14.24. Comparison of single-nucleotide polymorphism and oligonucleotide arrays is given in Table 14.87.

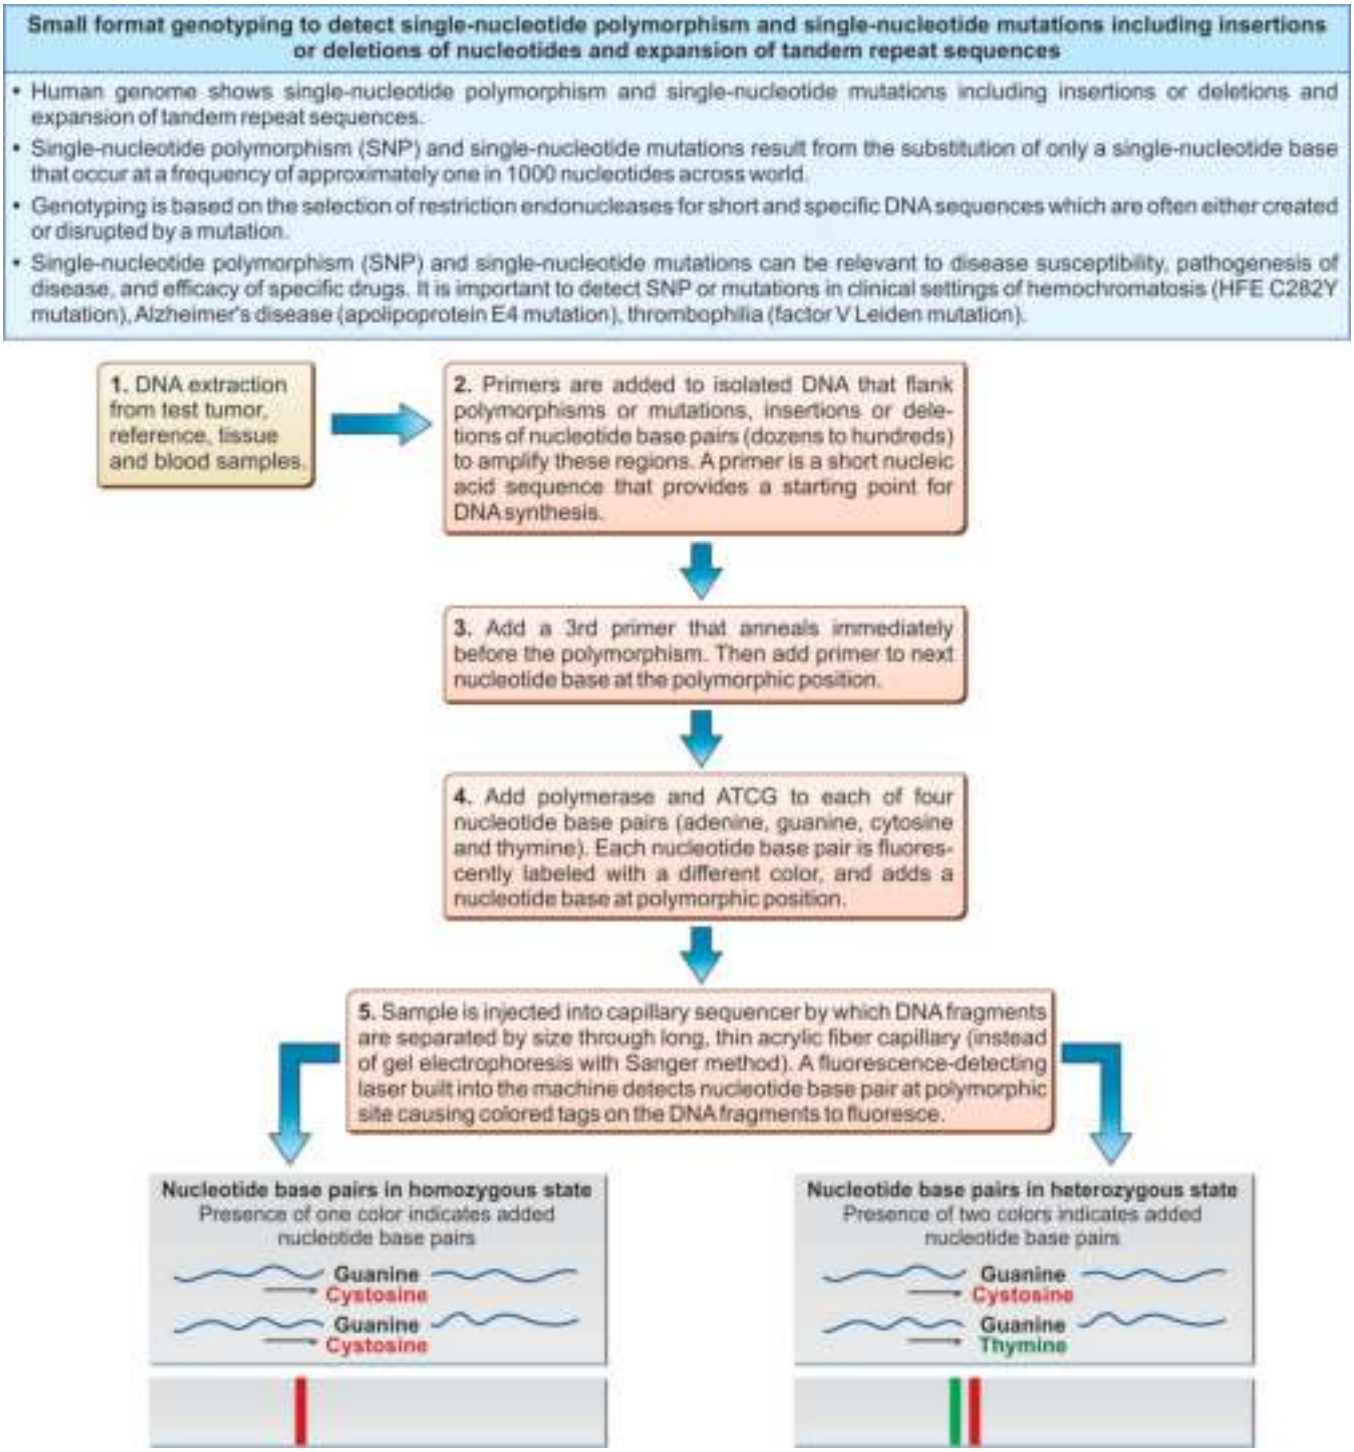

Fig. 14.24: Small format genotyping for detection of single-nucleotide polymorphism (SNP) and single-nucleotide mutations including insertions or deletions of nucleotide base pairs.

Table 14.87 Comparison between single-nucleotide polymorphism and oligonucleotide arrays

Array Attribute	Single-Nucleotide Polymorphism (SNP) Arrays	Oligonucleotide Arrays
Method of assessment of copy number imbalance	Probe signal intensities derived from patient's sample compared to a silicoreference mode	Patient's sample is directly hybridized against control DNA to detect relative gains or loss
Detection of balanced chromosomal rearrangements	Not detected	Not detected
Detects number of markers	1,000,000 markers	<2000,000 markers
DNA input requirement	200–500 ng	1–5 µg
Type of probe	SNP and oligo probes	Oligo probes
Limits of resolution	<10–20 kb	As low as 10–20 kb
Threshold for detection of mosaicism	As low as 5%	20–30%
Ability to detect copy of neutral LOH	Yes	No
Ability to detect uniparental disomy	Yes	No
Ability to detect consanguinity	Yes	No

Clinical Applications of Microarray Analysis Technique

Clinical applications of microarray analysis technique include molecular classification of breast cancer and lymphomas; defining origin of metastatic tumor, prediction of tumor behavior, response to therapy, prognosis and pathogenesis.

Advantages of Microarray Analysis Technique

Microarray analysis technique has markedly increased resolution of chromosomal analysis. It does not require cell viability since DNA serves as the starting material. The technique is employed on samples such as peripheral blood lymphocytes, bone marrow aspirates, lymph nodes, formalin-fixed paraffin-embedded tissue, aminocytes, products of conception and buccal mucosal cells.

Limitations of Microarray Analysis Technique

The technique can detect copy number changes. Microarray analysis has certain limitations. It cannot detect chromosomal rearrangements, balanced translocations, insertions and inversions. It also cannot analyze segmental duplication and repetitive sequences. Low level of mosaicism may not be detectable. Loss of heterozygosity (LOH) is demonstrated only by SNP-based platforms.

IN SITU HYBRIDIZATION, CHROMOGENIC *IN SITU* HYBRIDIZATION AND FLUORESCENCE *IN SITU* HYBRIDIZATION (FISH)

IN SITU HYBRIDIZATION: OVERVIEW

In situ hybridization (ISH) is a gold standard technique for localizing specific nucleic acid targets within fixed tissues and cells to obtain information about gene expression and genetic loci.

- Basic principle of *in situ* hybridization is similar to that of blot hybridization, in which the nucleic acid probe is created by labeling DNA strand complimentary to a gene of interest with fluorescent radioactive tag.
- DNA specimen is denatured *in situ* or isolated and then transferred to a membrane slide. DNA specimen is now incubated with the labeled probe at a specific temperature determined by the type of probe used. Excess of probe is then washed away to produce an image by using an appropriate detection method.
- Clinical applications of DNA hybridization techniques are Southern blot DNA mutational analysis, comparative genomic hybridization (CGH) and fluorescence *in situ* hybridization (FISH) for detection of gene amplification rearrangements and chromosomal translocations.

APPLICATIONS OF *IN SITU* HYBRIDIZATION

Prenatal Test during Pregnancy

Birth defects occur as a result of genetic disorders caused by mutations in one or more genes, chromosomal aneuploidy or environmental factors during

gestational period. Cytogenetic disorders occur in women older than 35 years.

- Women with high-risk pregnancies undergo prenatal diagnosis through amniocentesis for cytogenetic analysis of fetal cells for detection of chromosomal abnormalities in Down syndrome (trisomy 21), the number of chromosomes by karyotyping, a time-consuming diagnostic test.
- Currently, most laboratories perform rapid diagnostic tests for aneuploidy such as fluorescence *in situ* hybridization (FISH) as a part of a combination test with conventional cytogenetic analysis for prenatal diagnosis. In addition to FISH, other modern diagnostic techniques include multi-color primed *in situ* labeling (multi-PRINS), quantitative fluorescence polymerase chain reaction (QF-PCR) and multiplex ligation-dependent probe amplification (MLPA).

Pharmacogenomics

Pharmacogenomics is the branch of genetics concerned with determining the likely response of an individual to therapeutic drug. For example, the enzyme CYP2C19 takes part in metabolism of several therapeutic drugs, such as the anti-clotting drug clopidogrel, into their active forms. Some patients possess polymorphisms in specific places on 2C19 gene that make poor metabolizers of those drugs. Clinicians can test for these polymorphisms by modern diagnostic techniques, and find out whether the drugs would be fully effective for that patient.

CHROMOGENIC *IN SITU* HYBRIDIZATION: OVERVIEW

In present scenario, there are two basic methods to visualize RNA and DNA targets fluorescence *in situ* hybridization and chromogenic *in situ* hybridization.

- Chromogenic *in situ* hybridization (CISH) is a cytogenetic diagnostic technique that combines the chromogenic signal detection method of immunohistochemistry (IHC) techniques with *in situ* hybridization. Both CISH and FISH are useful for very distinct applications. These are used to detect the presence or absence of specific regions of DNA.
- Both CISH and FISH use a labeled target specific probe that is hybridized with the sample. The instrumentation used in CISH and FISH to visualize the sample is different for each method.
- However, CISH is much more practical in diagnostic laboratories, because it uses bright-field microscopes rather than more expensive and complicated fluorescence microscopes used in FISH.

DNA PROBE DESIGN

Probe design for CISH as well as FISH is very similar with differences only in labeling and detection. FISH is generally labeled with a variety of different fluorescent tags analyzed under a fluorescence microscope. On the other hand, CISH probe is labeled with biotin or digoxigenin and analyzed by using a bright-field microscope after treatment steps have been applied. Differences and advantages of FISH and CISH are highlighted (Table 14.88).

FLUORESCENCE *IN SITU* HYBRIDIZATION: OVERVIEW

Fluorescence *in situ* hybridization (FISH) is a technique that hybridizes DNA nucleic acid probe to a target chromosomal-specific DNA sequence of interest contained within cell nucleus. FISH technique permits identification of both structural and numeric

Table 14.88 Comparison of fluorescence *in situ* hybridization (FISH) and chromogenic *in situ* hybridization (CISH)

Parameters	Fluorescence *in situ* Hybridization	Chromogenic *in situ* Hybridization
Instrument/visualization method	▪ Epifluorescence or confocal microscope ▪ Probe labeled with fluorescent tag	▪ Bright field microscope ▪ Probe labeled with biotin or digoxigenin
Primary advantage	▪ Visualization of multiple targets in the same sample ▪ FISH is not routinely used by pathologists	▪ Ability to view the CISH signal and tissue morphology simultaneously ▪ Pathologists are familiar with IHC signals
Primary application	Gene expression and cytogenetics	Molecular pathology diagnostics
FISH versus CISH signal	Fluorescence signals can fade within several weeks	Chromogenic reaction is permanent
Morphologic analysis	Morphology is not always easy to analyze	Morphology is easy to analyze
Recording of results	Results of FISH have to be recorded with an expensive CCD camera	Regular slide storage is done

aberrations characteristics of certain hematopoietic and nonhematopoietic cancers in many clinical settings (Table 14.89).

- FISH technique can be performed on nondividing (interphase) cells on air-dried or formalin-fixed specimens. It can detect molecular abnormalities in cancers with low proliferative rates such as multiple myeloma. This technique detects aneusomies/deletions, gene amplification and chromosomal translocations.
- On the other hand, conventional cytogenetic analysis has ability to evaluate entire genome for detection of numerical and structural chromosomal abnormalities. Conventional cytogenetic analysis lacks sensitivity to detect mutations such as deletions, amplifications, and single base substitutions.
- A variety of specimen types can be analyzed using FISH. The intact cells are attached to slide using standard cytogenetic methods. It allows one to look at multiple genomic changes within a single cell, without destruction of the cellular morphology.
- DNA probe is a nucleic acid that can be labeled with a marker which hybridizes to another nucleic acid on the basis of base complementarity allowing identification and quantitation. Various types of labeling are used—direct and indirect, radioactive (^{32}P, ^{35}S, ^{14}C, ^{3}H), fluorescent (FISH) and biotinylated (avidin-streptavidin).

Pathology Pearls: Methods of Fluorescence *in situ* Hybridization

- **Direct FISH method:** Fluorescent dye binds directly to DNA probe using polymerase enzymes and labeled nucleoside triphosphates.
- **Indirect FISH method:** DNA probe is tagged with a hapten (biotin/digoxigenin) and detected by antibody tagged with fluorescent dye, which gives easy amplification of signal.
- **Multicolor FISH method:** Multicolor FISH can provide colorized information relative to chromosome rearrangements, especially useful in specimens where chromosome preparations are less than optimal for standard cytogenetic banding analysis.

FISH TECHNIQUE METHODOLOGY

Sample is fixed in Carnoy's fixative (3:1 methanol and glacial acetic acid) on the slide. Denaturation is done by formamide at 42°C. Nucleic acid hybridization involves interaction of DNA probe and target DNA.

- Nucleic acid hybridization is the formation of a duplex between two complementary DNA sequences.
- Annealing is another term used to describe the hybridization of two complementary molecules. Post-hybridization washings are carried out.

Table 14.89 Diagnostic tests by FISH technique to detect various disorders

Diagnostic Tests	Disorders
Prenatal testing	▪ Trisomy 13, 18, 21 ▪ XY aneusomies
Microdeletion syndromes	▪ Cri du chat (5p) ▪ Prader-Willi/Angelman (15q) ▪ DiGeorge syndrome
Transplant pathology	▪ XY FISH on sex mismatched organ transplant ▪ Disease relapse using known genetic alterations in primary tumor
Oncology (diagnostic, predictive and prognostic markers of hematopoietic and nonhematopoietic cancers)	▪ Chromosome aneusomies ▪ Gene locus/locus deletions ▪ Gene amplifications ▪ Translocations

- DNA probe is labeled with a colored fluorescent molecule, which remains attached to the DNA during the hybridization process. The fluorescent molecule emits a particular color when viewed through a fluorescence microscope in the darkroom that is equipped with the appropriate filter sets. Fluorescence *in situ* hybridization (FISH) technique is shown in Figs 14.25 and 14.26.

Advantages and Limitations of FISH Technique

Specimen Type Applicable of FISH Technique

Fluorescence *in situ* hybridization (FISH) technique is applicable to various specimens including cytology smears, buccal smears, fresh/frozen specimens and formalin-fixed paraffin-embedded (FFPE) tissue specimens. Specimen analyzed by fluorescence *in situ* hybridization technique is given in Table 14.90.

FISH Versus Cytogenetic and Other Molecular Techniques

Fluorescence *in situ* hybridization (FISH) technique can be performed on nondividing (interphase) cells on air-dried or formalin-fixed specimens. It detects molecular abnormalities in malignant neoplasms with low proliferation rates such as multiple myeloma. FISH technique detects deletions, gains, chromosomal translocations and amplifications.

- FISH is more sensitive and quicker than conventional karyotyping, which provides targeted approach for molecular cytogenetic alterations, which have been identified by various global techniques such as classic cytogenetics, loss of heterozygosity (LOH), screening, comparative genomic hybridization (CGH), array CGH (aCGH), single-nucleotide polymorphism (SNP) array and gene expression profiling.

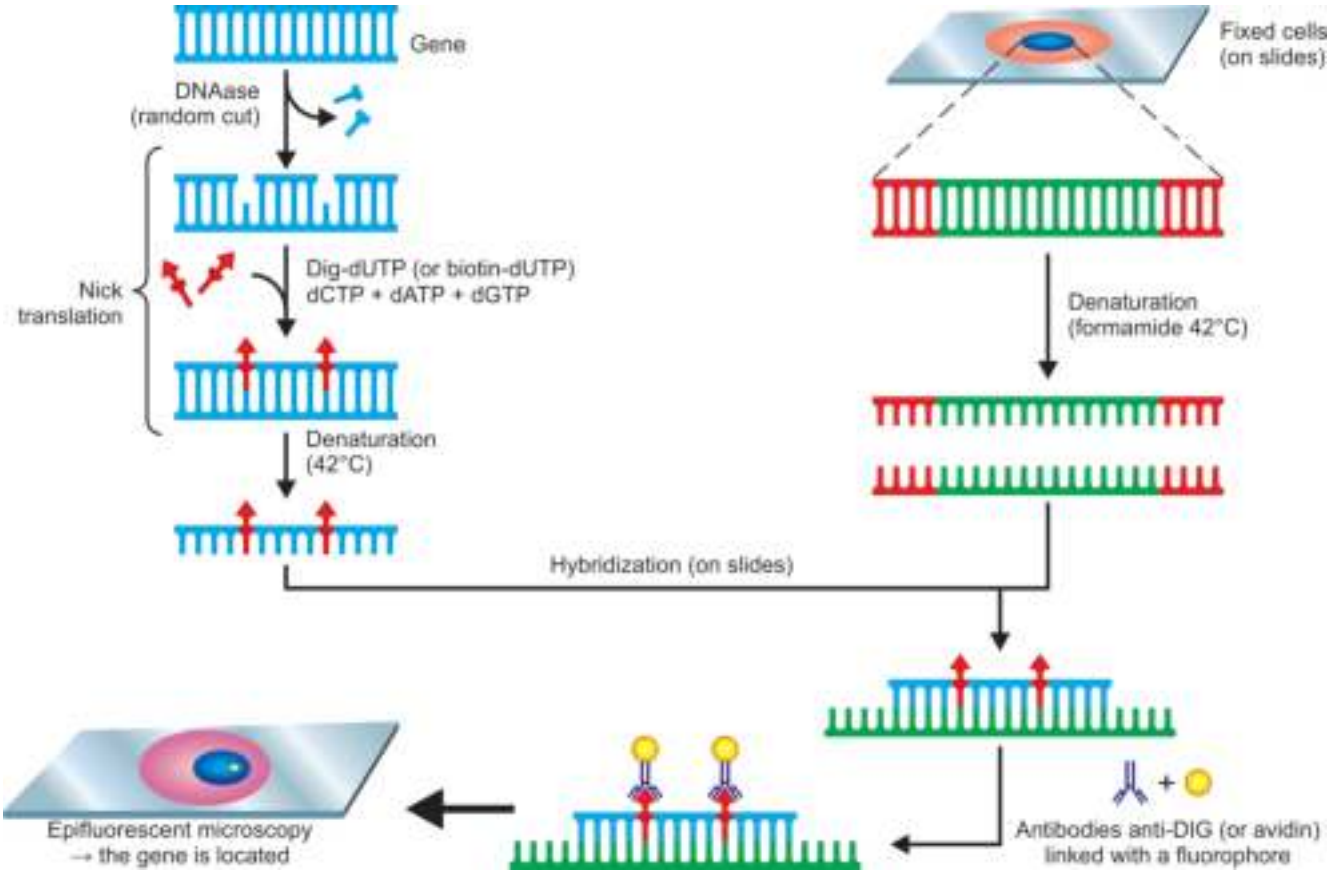

Fig. 14.25: Fluorescence *in situ* hybridization (FISH) technique.

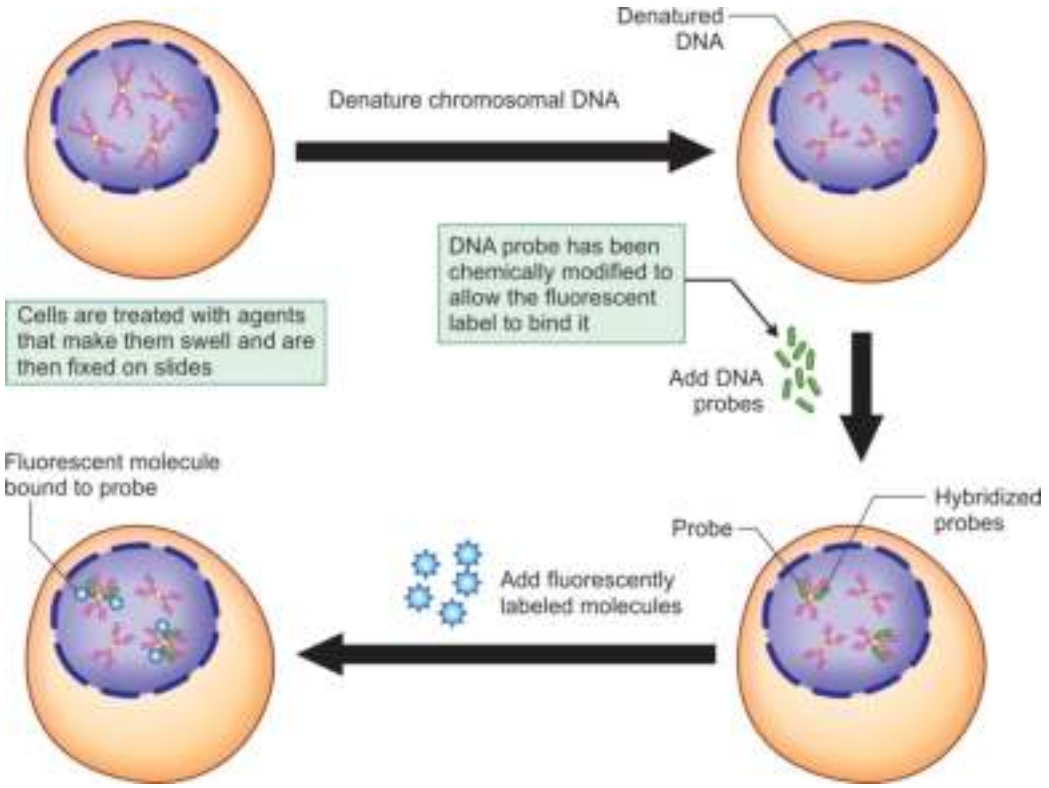

Fig. 14.26: Fluorescence *in situ* hybridization (FISH) technique.

Table 14.90 Specimens analyzed by fluorescence *in situ* hybridization technique

Categories	Characteristics
Peripheral blood and bone marrow aspirate	Rapid analysis required
Cytology specimens	▪ Body fluids, urine, pleural effusions ▪ Intraoperative cytology smears ▪ Cell culture preparations
Buccal smears	Used for sex determination
Fresh/frozen tissue	Fresh/frozen tissue analysis
Formalin fixed paraffin-embedded (FFPE) tissues	▪ Thin sections obtained (4–6 µm) ▪ Disaggregated nuclei ▪ Archived unstained sections ▪ Previously stained sections (e.g. negative immunohistochemistry control)

- Minimal residual disease or early recurrences are better detected by polymerase chain reaction (PCR).

Tissue Microarray—FISH Technique

Tissue microarray—FISH technology has advantage over multiple specimen paraffin blocks tissue microarrays, which is constructed from hundreds of 0.6–2.0 nm neoplastic, non-neoplastic and tissue cores of interest. The tissue microarray—FISH technique reduces data acquisition time, probe, reagents and storage space requirement space. Tissue microarray—FISH technique is excellent for validation of new DNA probe, proficiency testing and quality control.

Disadvantages and Pitfalls of FISH Technique

Artifacts due to underestimation of copy number, aneuploidy or hyperploidy, autofluorescence and partial hybridization failure make interpretation difficult. Signal fading is another disadvantage. Minimal residual disease or early recurrences are better detected by polymerase chain reaction (PCR). Permanent record is not possible unless chromogenic *in situ* hybridization (CISH) is used.

DEVELOPMENT OF DNA PROBES

Centromere Enumerating Probe (CEP)

Initially developed centromere enumerating DNA probes remain ideal for detection of gains and losses of whole chromosomes such as monosomy, trisomy and other polysomies.

A Whole Chromosome Paint Probe

A whole chromosome paint probe (WCP) consists of a cocktail of DNA fragments that targets all the nonrepetitive DNA sequences of an entire chromosome. As WCP covers large region, it produces a diffuse signal in interphase nuclei. WCP probe is not often used in interphase FISH technique, primarily utilized in advanced cytogenetic applications.

Locus Specific Identifier (LSI) Probe (Most Versatile)

Locus specific identifier (LSI) probe targets distinct chromosomal regions of interest, which utilizes single copy rather than repetitive DNA sequences. Assortment of locus specific is now commercially available. Various cloning vectors such as bacterial artificial chromosomes (BACs), P1-derived artificial chromosomes (PACs) and yeast artificial chromosomes (YACs) are important sources of development of probes used in FISH technique.

CLINICAL APPLICATIONS OF FISH TECHNIQUE

Clinical applications of FISH technique include detection of chromosomal microdeletion, gene arrangements, breakpoint mapping of chromosomes and interphase chromosome. Clinical applications of FISH technique in detection of cancer associated genetic alterations are given in Table 14.91.

- **Aneusomies and deletions:** Aneusomies represent gains or losses of whole chromosomes. Deletions refer to losses of distinct chromosomal regions, varying in size from loss of a specific gene or portion of a gene to entire chromosomal arm.
- **Gene amplifications:** Gene amplification occurs in one of two patterns demonstrated by FISH technique. Presence of amplified gene on extrachromosomal segments is known as double minutes and is demonstrated numerous individual signal by FISH technique.
  - Gene amplification consisting of numerous contiguously arranged gene copies within single chromosomal region gives abnormal globular signals by FISH technique. HER2/neu amplification is demonstrated in breast carcinoma in 20–35%. Herceptin administration is beneficial in breast carcinoma patients with HER2/neu positivity.

Table 14.91 Clinical applications of FISH technique in detection of cancer-associated genetic alterations

Systems Involved	Malignant Neoplasms	Genetic Alterations	Diagnostic/Predictive/Prognostic Significance
Aneusomes and deletions			
Nervous system	▪ Glioblastoma multiforme ▪ Oligodendroglioma ▪ Medulloblastoma ▪ Meningioma ▪ Malignant peripheral nerve sheath tumor	▪ + 7, –10 ▪ 1p– with 19q– ▪ 17q–, 17q+ (i17q) ▪ NF2 (22q–) ▪ NF1 (17q–)	▪ Diagnostic significance ▪ Diagnostic/predictive/prognostic significance ▪ Diagnostic significance ▪ Diagnostic significance ▪ Diagnostic significance
Hematologic system	▪ Chronic lymphocytic leukemia ▪ Leukemia/myelodysplastic syndrome ▪ Multiple myeloma	▪ 13q–, 11q–, 17q– ▪ + 8, + 12; –5, –7 ▪ RB1 (–13q), TP53 (17p–)	▪ Diagnostic/prognostic significance ▪ Diagnostic/prognostic significance ▪ Diagnostic significance
Respiratory system	Lung carcinoma	+ 17p, 7, or 17; 9q–	Diagnostic significance
Urogenital system	Urothelial carcinoma	+ 3 , 7 or 17; 9p–	Diagnostic significance
Soft tissue	▪ Malignant rhabdoid tumor ▪ Atypical rhabdoid tumor	INI1/Hsnf5 (22q–)	▪ Diagnostic significance ▪ Diagnostic significance
Gene amplifications			
Nervous system	▪ Glioblastoma multiforme ▪ Medulloblastoma ▪ Neuroblastoma	▪ EGFR ▪ c-Myc ▪ N-Myc	▪ Diagnostic significance ▪ Diagnostic/prognostic significance ▪ Diagnostic/prognostic significance
Breast	Breast carcinoma	HER2/neu	Diagnostic/predictive significance
Gastrointestinal tract	Gastric carcinoma	HER2/neu	Diagnostic/predictive significance
Chromosomal translocation			
Soft tissue	▪ Synovial sarcoma ▪ Alveolar rhabdomyosarcoma ▪ Desmoplastic round cell tumor ▪ Myxoid round cell liposarcoma ▪ Inflammatory myoblastic tumor (IMT)	▪ SYT-SSX, SYT-BA* ▪ PAX3-FKHR, FKHR-BA* ▪ EWS-WT1, EWS-BA* ▪ CHOP-BA* ▪ ALK-TPM3, ALK-TPM4, ALK-CARS, ALK-BA*	▪ Diagnostic significance ▪ Diagnostic significance ▪ Diagnostic significance ▪ Diagnostic significance ▪ Diagnostic/prognostic significance
Skeletal system	Ewing's sarcoma/primitive neuro-ectodermal tumors	EWS-FLI1, EWS-BA	Diagnostic significance
Hematologic lymphoid system	▪ Acute myelogenous leukemia ▪ Acute lymphoblastic leukemia ▪ Chronic myelogenous leukemia ▪ Myeloid and lymphoid neoplasms with eosinophilia ▪ Multiple myeloma ▪ Burkitt's lymphoma ▪ Follicular lymphoma ▪ Mantle cell lymphoma ▪ Anaplastic large cell lymphoma ▪ MALT lymphoma ▪ BCL, unclassified with features in between diffuse large B cell lymphoma and Burkitt's lymphoma	▪ AML1-ETO, CBFB-BA, PML-RARA, RARA-BA*, MLL-BA, BCR-ABL ▪ TEL-AML1, BCR-ABL, MLL-BA ▪ BCR-ABL ▪ PDGFRA, PGDFRB, FGFR1, FIP1L1-PDGFRA IGH-CCND1, IGH-FGFR3 ▪ IGH-BA* ▪ Myc-OGH, Myc-BA ▪ IGH-BCL-2 ▪ IGH-CCND1 ▪ ALK-BA* ▪ AP12-MALT1, IGH-MALT1, MALT1-BA* ▪ IGH-BCL-2, Myc-IGH, Myc-BA*	▪ Diagnostic/predictive/prognostic significance ▪ Diagnostic/predictive/prognostic significance ▪ Diagnostic/predictive significance ▪ Diagnostic minimal residual disease/predictive/prognostic significance ▪ Diagnostic significance ▪ Diagnostic significance ▪ Diagnostic significance ▪ Diagnostic significance ▪ Diagnostic/predictive/prognostic significance ▪ Diagnostic significance ▪ Diagnostic significance

**BA: Break apart*

- N-Myc and c-Myc amplifications have been demonstrated in neuroblastoma.

- **Chromosomal translocations:** Tumor-associated chromosomal translocations demonstrated by FISH technique are useful diagnostic aid in primitive appearing hematopoietic and soft tissue malignancies. Reliable DNA probes are commercially available for most common translocations. Three types of strategies are employed to demonstrate chromosomal translocations as given in Table 14.92.

DEVELOPMENT OF FISH TEST FOR CLINICAL USE

Development on the frequencies of various translocations and breakpoints, FISH-F, FISH-BA, FISH-ES, D-FISH or combination of strategies can be designated. Newly developed FISH technique is useful to demonstrate cytogenetic abnormalities such as chromosomal gain or loss, deletion of gene or locus, gene amplification and translocation, diagnostic, prognostic and predictive response or lack of response to patient therapy.

Table 14.92 Comparison among three types of strategies to demonstrate translocations

Parameters	FISH-F Technique	FISH-BA Technique	FISH-ES Technique
Probe used	Two loci-specific probes with different fluors (color tags) targeting two different partners (BCR on 22q and ABL on 9q)	Two probes localizing just proximal and distal to one of two breakpoints of interest (c-Myc at chromosome 8q24 can fuse with IGH at 14q32 in Burkitt's lymphoma)	One large probe that spans a breakpoint region demonstrated in minimal residual disease in patients with chronic myelogenous leukemia

ENZYME-LINKED IMMUNOSORBENT ASSAY TECHNIQUE

ENZYME-LINKED IMMUNOSORBENT ASSAY TECHNIQUE: OVERVIEW

Enzyme-linked immunosorbent assay (ELISA) technique is a sensitive microtiter plate-based immunoassay technique, also called solid-phase enzyme immunoassay as it employs an enzyme-linked antigen or antibody as a marker for the detection of specific protein (antigen or antibody).

- ELISA technique is used to assess the presence of specific protein (antigen or antibody) in the given sample and its quantification. Antigen–antibody reaction is immune-mediated reaction.
- Enzyme used in ELISA technique acts on colorless substrate and converts into colored (chromogenic) product. Color intensity of the colored product generated by enzyme is analysed.

PRINCIPLE

In ELISA technique, an enzyme conjugated with an immunoglobulin reacts with a colorless substrate to generate colored chromogenic product. A number of enzymes employed for ELISA include alkaline phosphatase, horseradish peroxidase, and β-galactosidase. Signals are developed by the action of hydrolyzing enzyme on chromogenic substrate and the optical density analyzed by microplate reader. General procedure of ELISA technique is shown in Fig. 14.27. Clinical applications of ELISA technique are given in Table 14.93.

ELISA TECHNIQUE DATA INTERPRETATION

ELISA technique yields three different types of data output.

- **ELISA technique quantitative data:** ELISA technique data can be interpreted in comparison to a standard curve (a serial dilution of a known, purified antigen) in order to precisely calculate the concentration of antigen in various samples.
- **ELISA technique qualitative data:** ELISA technique can also be used to achieve a yes or no answer indicating whether a particular antigen is present in a sample, as compared to a blank well containing no antigen or an unrelated control antigen.
- **ELISA technique semiquantitative data:** ELISA technique can be used to compare the relative levels of antigen in assay samples, since the intensity of signal will vary directly with antigen concentration.

TYPES OF ENZYME-LINKED IMMUNOSORBENT ASSAY (ELISA) TECHNIQUE

There are various types of ELISA techniques such as direct, indirect, sandwich, competitive and noncompetitive are shown in Fig. 14.28.

Direct ELISA Technique

Direct ELISA technique uses directly labeling antibody itself. Sample of antigen is applied to the surface, often in the well of a microtiter plate. The antigen is fixed to the surface to render it immobile. The plate well and other surfaces are then coated with a blocking buffer.

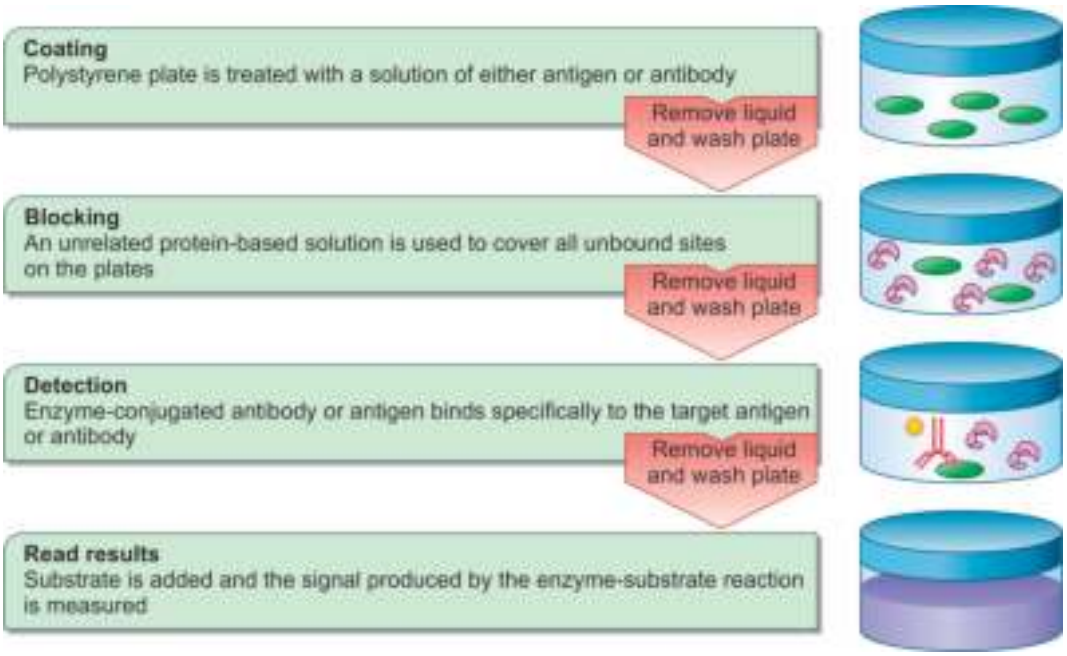

Fig. 14.27: General procedure of ELISA technique.

Table 14.93 Clinical applications of ELISA technique

Sample	Disease
Serum immunoglobulin concentrations	Clinical settings
Serum markers	Hepatitis B virus infection
Blood hormones	Pregnant women
Blood sample for antibody to infectious agents	▪ Human immunodeficiency virus ▪ Mycobacterium tubercle bacilli ▪ *Treponema pallidum* infection (syphilis) ▪ *Vibrio cholerae* (cholera) ▪ Bird flu ▪ Lyme disease ▪ Pernicious anemia ▪ Toxoplasmosis ▪ Varicella-zoster virus (chickenpox)
Feces	Rotavirus

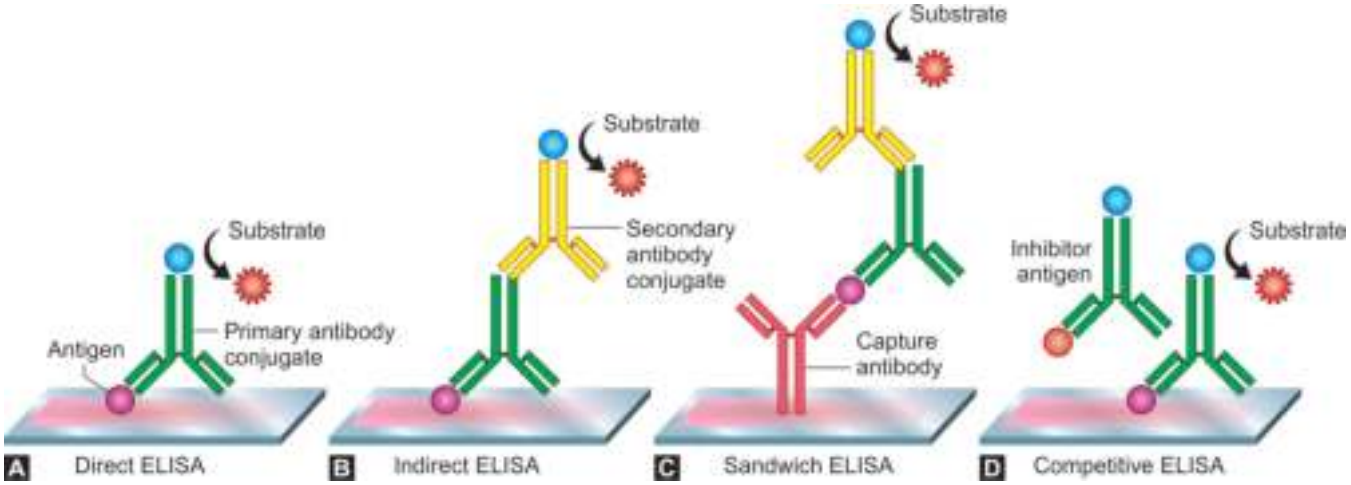

Fig. 14.28: Types of ELISA technique.

Antibody labeled by an enzyme (detecting antibody) is usually diluted in buffer and applied to the microtiter plate for binding to the antigen coated on plate.

Indirect ELISA Technique

Indirect ELISA technique detects the presence of antibody in a sample. The protein antigen to be tested is added to each well of ELISA microtiter plate; where it is given time to adhere to the plastic through charge interactions.

- Primary antibody present in the sample binds to the antigen after addition of sample.
- The solution is washed to remove unbound antibodies. Enzyme conjugated secondary antibodies are added to the solution. The substrate for enzyme is added to quantify the primary antibody through color change.
- The concentration of primary antibody present in the serum directly correlates with the intensity of the color. Procedure of indirect ELISA technique is shown in Fig. 14.29.
- A wide variety of labeled secondary antibodies is now available commercially. The indirect ELISA technique is versatile because many primary antibodies can be prepared in one species and the same labeled secondary antibody can be used for detection. Maximum immunoreactivity of the primary antibody is retained because it is not labeled. Sensitivity is increased because each primary antibody contains several epitopes that can bind with the labeled secondary antibody, permitting for signal amplification.
- Indirect ELISA technique, cross reactivity may occur with the secondary antibody resulting in nonspecific signal. An extra incubation step is required in the procedure. Comparison between direct ELISA and indirect ELISA technique is given in Table 14.94.

Sandwich ELISA Technique

In sandwich ELISA technique, microtiter plate is coated with antibody to detect specific antigen. Any nonspecific binding sites on the surface are blocked by using bovine serum albumin.

- Antigen-containing sample is applied to the microtiter plate. Unbound antigen is removed by washing.

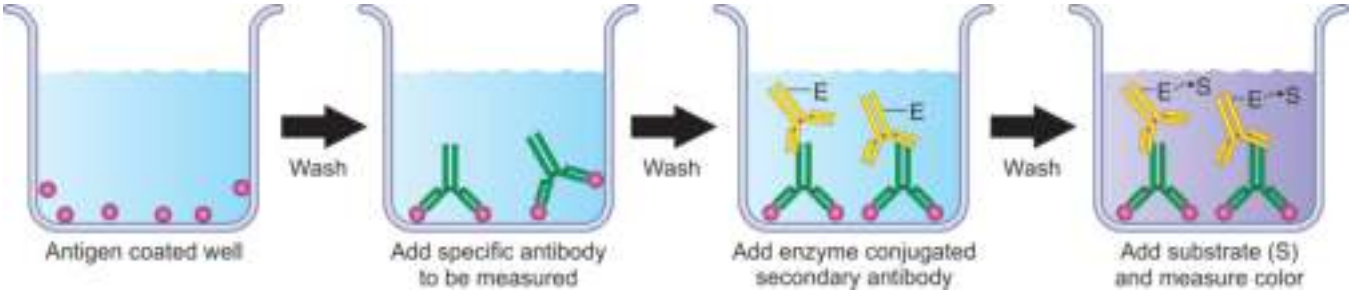

Fig. 14.29: Procedure of indirect ELISA.

Table 14.94 Comparison between direct ELISA and indirect ELISA technique

ELISA Technique	Direct ELISA Technique	Indirect ELISA Technique
Advantages	▪ Quick as only one antibody and fewer steps are used ▪ Cross reactivity of secondary antibody is eliminated	▪ A wide variety of labeled secondary antibodies is available commercially ▪ Maximum immunoreactivity of the primary antibody is retained because it is not labeled ▪ Increased sensitivity allowing signal amplification, as each primary antibody contains many epitopes bound by labeled secondary antibody ▪ Different visualization markers can be used with the same primary antibody
Disadvantages	▪ Immunoreactivity of primary antibody may be adversely affected by labeling with enzymes or tags ▪ Minimal signal amplification occurs ▪ Labeling primary antibody for each specific ELISA system is time-consuming and expensive	▪ Cross reactivity might occur with secondary antibody resulting in nonspecific signals ▪ Extra incubation step is required in the procedure

- Enzyme-linked primary antibodies are applied as detection antibodies, which also bind specifically to the antigen. Then the unbound antibody-enzyme conjugates are removed by washing.
- A chemical substance is added, which is converted by the enzyme into a colored product, absorbency of which is analyzed to determine the presence and quantity of antigen. Sandwich ELISA technique is shown in Fig. 14.30.

Advantages

Sandwich ELISA is highly-specific technique, in which antigen/analysate is specially captured and detected. It is suitable for complex (or crude/impure) samples as the antigen does not require purification prior to measurement. Sandwich ELISA technique is flexible and sensitive, by which both direct and indirect detection ELISA methods can be used.

Competitive ELISA Technique

Competitive ELISA technique is highly sensitive technique even when the specific detecting antibody is present in relatively small amounts.

- The technique depends on the competitive reaction between the sample antigen and antigen bound to the wells of microtiter plate with the primary antibody.
- Antigen and antibody are labeled with an enzyme and allowed to compete with unlabeled ones (in patient's serum) for binding to the same target.
- Hydrolysis signal from antigen–antibody complex (enzyme-labeled) is measured. Antigen or antibody in serum is then calculated.
- There is no need to remove the excess/unbound antigen or antibody from the reaction plate or tubes. Concentration of color is inversely proportional to the amount of antigen presents in the sample. Competitive enzyme-linked immuosorbent assay (ELISA) technique is shown in Fig. 14.31.

Noncompetitive ELISA Technique

In noncompetitive ELISA technique excess/unbound antigen or antibody must be removed before every step of reactions. It can be of various types—direct ELISA technique, indirect ELISA technique, sandwich ELISA technique and antibody capture ELISA technique (similar to sandwich ELISA technique but in first step, anti-IgM or IgG is coated on the plate and then antibodies in patient serum are allowed to capture in next step).

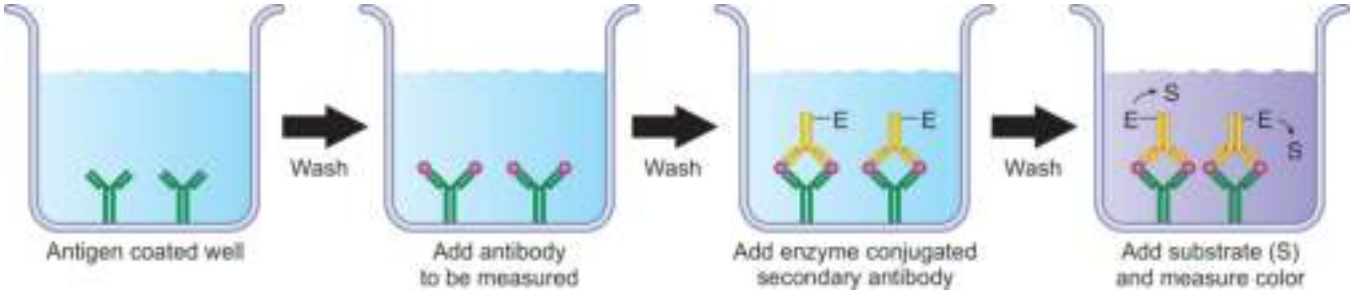

Fig. 14.30: Sandwich enzyme-linked immunosorbent assay (ELISA) technique.

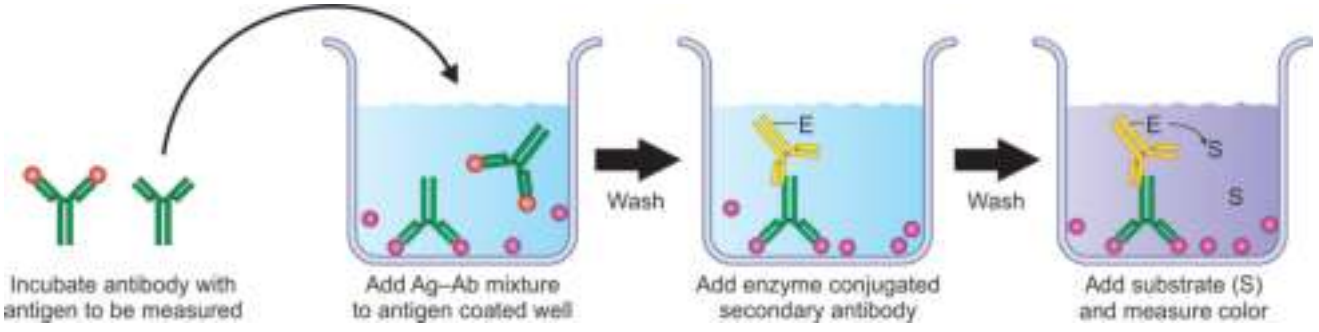

Fig. 14.31: Competitive enzyme-linked immunosorbent assay (ELISA) technique.

DNA SEQUENCING METHODS

DNA sequencing methods are used to determine diagnosis, prognosis, the detection of minimal residual disease, and the diagnosis of hereditary predisposition to cancer. Molecular profiling of malignant tumors by cDNA arrays can determine expression of large segments of the genome at once and can be useful in molecular stratification of otherwise identical tumors for the purpose of treatment. DNA sequencing methods are used for detection of gene mutations as given in Table 14.95. Techniques used to analyze DNA, RNA and proteins are given in Table 14.96. Next generation DNA sequencing is shown in Fig. 14.32.

POLYMERASE CHAIN REACTION TECHNIQUE

Most molecular tests performed in surgical pathology focus on somatic or acquired DNA variations in the cells of the disease process, which provide information of diagnostic, prognostic and predictive indicators. Polymerase chain reaction (PCR) is quick, reliable and sensitive technique, which has become a central diagnostic tool in clinical molecular genetic testing.

Pathology Pearls: Polymerase Chain Reaction Technique

Polymerase chain reaction (PCR) technique is used to amplify single or a few copies of a piece of DNA to generate thousands to millions of copies of a particular DNA sequence.

Methodology

Polymerase chain reaction (PCR) technique involves amplification of a target sequence of DNA using 3 and 5 DNA primers. After 25 cycles 10^7 copies of target DNA are produced.

Clinical Applications

- Polymerase chain reaction (PCR) is a diagnostic technique to detect genetic and acquired disorders.
- PCR technique detects direct DNA sequences in forensic medicine, circulating tumor or microorganisms, e.g. Myocobacterium tubercle bacilli, *Helicobacter pylori, Treponema pallidum*, hepatitis C virus, Epstein-Barr virus and *Toxoplasma gondii.*
- PCR technique detects paternal assay.
- PCR technique detects BCR-ABL translocation in chronic myelogenous leukemia, clonal assay in lymphomas, DNA mismatch repair (microsatellite sequence) in hereditary nonpolyposis colorectal cancer (HNPCC), and detection of EWS/FLI-1 fusion gene in Ewing sarcoma.
- RT-PCR, DNA hybridization *in situ* or Southern blot techniques are used to detect certain chromosomal translocations.

SPECIMENS REQUIRED

Nucleic acids are used for molecular testing by polymerase chain reaction (PCR). Specimen requirements are dictated by the disease process.

- Sources of nucleic acids are peripheral blood, bone marrow aspirate, fresh or frozen tissue stored at –200° to –700°C, formalin-fixed paraffin-embedded tissue (FFPE), cytology specimens, and enriched population of cells from flow cytometry.
- Transport of these specimens on ice reduces cell lysis, minimizes nuclease activity and reduces nucleic acid degradation. Peripheral blood and bone marrow aspirate are added anticoagulants. Samples obtained for DNA sequencing by polymerase chain reaction technique are given in Table 14.97.

Table 14.95 DNA sequencing methods are used for detection of gene mutations

Technique	Principle	Type of Gene Mutation Detection
Cytogenetic analysis	Unique visual appearance of various chromosomes	Numerical structural abnormalities in chromosomes
Fluorescence *in situ* hybridization (FISH) technique	Hybridization to chromosomes with fluorescent labeled probes	Numerical structural abnormalities in chromosomes
Southern blot technique	Hybridization with genomic probe or cDNA probe after digestion of high molecular DNA	Detection of large deletion, insertion, rearrangement
Polymerase chain reaction (PCR) technique	Amplification of DNA	Expansion of triplet repeats, variable number of tandem repeats (VNTR), gene rearrangement, translocation
Reverse transcriptase PCR (RT-PCR) technique	Reverse transcription, amplification of DNA segment, absence or reduction of mRNA transcription	To analyze the expression level of targeted genes
DNA sequencing technique	Direct sequencing of PCR products. Sequencing of DNA segment cloned into plasmid vectors	Point mutation, small deletions and insertions
Restriction fragment length polymorphism (RFLP) technique	Detection of altered restriction pattern of genome: DNA Southern blot or PCR products	Point mutation, small deletions and insertions

Table 14.96 Techniques used to analyze DNA, RNA and proteins

Technique	Sample Analyzed	Gel Used	Purpose
Southern blot technique	DNA	Yes	Detection of DNA changes
Northern blot technique	RNA	Yes	Analysis of mRNA amount and size
Western blot technique	Protein	Yes	Analysis of protein content
Allele specific oligonucleotides technique	DNA	No	Detection of DNA mutations
Microarray technique	RNA or cDNA	No	Measurement of many mRNA at one time
ELISA technique	Protein or antibodies	No	Detection of proteins (antigens) or antibodies

Next generation sequencing (NGS) of DNA by illumina genome analyzer sequencing process

- Next generation sequencing of DNA is a technology for determining the nucleic acid sequence in DNA (adenine, guanine, cytosine and thymine) and RNA (adenine, cytosine, uracil and guanine) to study genetic variation associated with genetic diseases and other diseases.
- Next generation sequencing of DNA has three steps: (a) library preparation (DNA fragmentation, adaptor ligation *in vitro*, sequencing), (b) clonal amplification (emulsion PCR and bridge PCR) and (c) cyclic array sequencing (sequencing by ligation and sequencing by synthesis).
- Methods for next generation sequencing of DNA include: massively parallel signature sequencing, Riche 454 pyrosequencing, reversible terminator sequencing, oligonucleotide ligation detection sequencing, Ion Torrent sequencing, illumina sequencing and single-molecule real-time sequencing.

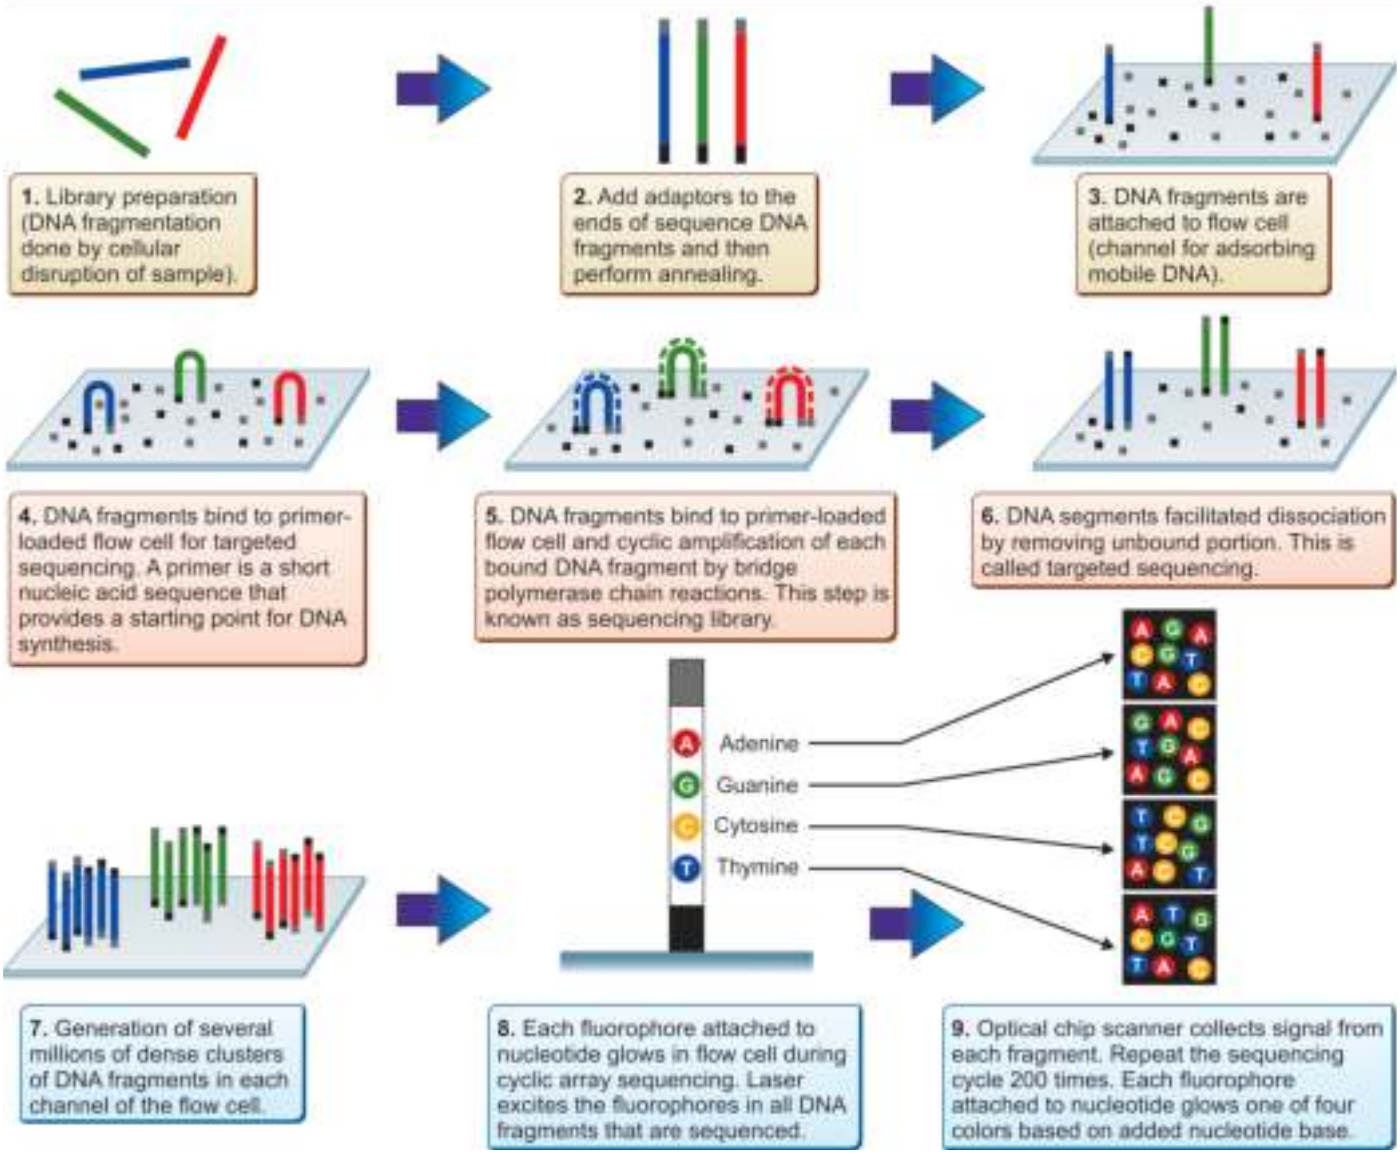

Fig. 14.32: Next-generation sequencing of DNA.

Table 14.97 Samples obtained for DNA sequencing by polymerase chain reaction technique

Prenatal/Postnatal Period and Cancer Genetic Sampling	Sample
Prenatal period	▪ Amniotic fluid ▪ Chorionic villus (fresh or formalin-fixed) ▪ Fetal cord blood
Postnatal period	▪ Peripheral blood ▪ Product of conception (fresh or formalin-fixed) ▪ Skin biopsy (fresh or formalin-fixed)
Cancer cytogenetic sampling	▪ Bone marrow ▪ Lymph node ▪ Peripheral blood ▪ Core biopsy ▪ Solid tumor ▪ Pleural effusion

Tissue Microdissection Method

Microdissection enables the targeted collection of cells or tissues from slide-mounted cytologic specimens or frozen or formalin-fixed paraffin-embedded (FFPE) tissue sections. After that, sample tissues may be treated for extraction of nucleic acids or protein. Microdissection method is carried out by dissecting microtome (simplest method) and laser capture microdissection (LCM) requiring a specialized microscopy. It is primarily a research application but also is useful in surgical pathology practice.

Nucleic Acid Extraction Method

Extraction of nucleic acids from pathologic samples involves cell lysis followed by selective DNA or RNA isolation and a quantitative or qualitative assessment. Pathologic samples used for molecular analysis include tissue samples (fresh or formalin-fixed paraffin-embedded, i.e. FFPE); body fluids (amniotic fluid, saliva, stools, urine); buccal and cervical scrapes; fine needle aspirates; peripheral blood; cell cultures and hair root.

DNA Extraction Methods

Classic DNA extraction methods are time-consuming (about 3 days) and require relatively large quantities of tissues (100 mg to 1 g).

- Numerous DNA extraction kits are now available that use glass-fiber filters that selectively bind DNA after tissue treatments with protease and chaotropic buffers (which disrupt protein and DNA secondary structures).
- With DNA extraction kits, pure DNA recovery from diverse pathologic samples is possible within several hours.
- Automated DNA extraction platforms are available for the processing of multiple patient samples.

RNA Extraction Methods

Classic RNA extraction methods cause rapid homogenization of large quantities of fresh tissues in protease and guanidinium thiocyanate solution to denature ubiquitous endogenous RNases. Current methods allow relatively rapid (1 day) recovery of RNA, again after tissue homogenization in chaotropic guanidinium salt solution that leaves RNA contained in an aqueous phase and protein and DNA in an organic phase.

DNA and RNA Extraction Preservation

DNA and RNA extraction from fresh tissue specimens gives high-integrity nucleic acids. Next best option is preservation of extracted nucleic acids from tissues in liquid nitrogen (commercially available storage reagents, e.g. RNA later, ambion).

- DNA and RNA extracts from FFPE block tissues tend to be degraded with block age. The concentration and purity of extracted nucleic acids are assessed spectrophotometrically (NanoDrop spectrophotometer).
- Nucleic acid integrity can be estimated by comparing nucleic acid fragment size against a molecular weight ladder after agarose gel electrophoresis.

Nucleic Acids Storage

Nucleic acids are generally stored at 4°C for assays performed within 1 week to 1 month of extraction and in aliquots at 20°C or 80°C for long-term storage. Repeated freeze-thawing may lead to DNA degradation. RNA is more labile than DNA and is susceptible to degradation by RNases. RNA is stored at 20°C for short-term use and at 80°C or under liquid nitrogen for long-term use.

PCR TECHNIQUE METHODOLOGY

Polymerase chain reaction technique generates thousands to millions of copies of a particular sequence. It is currently used in biomedical research laboratories for the diagnosis of hereditary and infectious diseases. Essential ingredients of polymerase chain reaction are given in Table 14.98. It is a method for the *in vitro* amplification of DNA involving automated cycles of denaturation, annealing, and extension or synthesis performed in a thermocycler.

Basic Steps of Polymerase Chain Reaction Technique

Basic steps of polymerase chain reaction (PCR) technique are denaturation, annealing and extension (Figs 14.33 and 14.34).

Table 14.98 Essential ingredients of polymerase chain reaction (PCR) technique

Essential Ingredients	Comments
Buffer	▪ pH is typically maintained using a Tris-HCl-based buffer ▪ Other ingredients include KCl (aid primer template annealing), bovine serum albumin (BSA) and nonionic detergents (aid Taq DNA polymerase enzyme stability)
DNase or RNase free pure water	Final PCR reaction volumes vary from 10 to 50 μl
Magnesium cations (Mg^{2++})	Stabilizes the interaction between the oligonucleotide primer, template DNA and Taq DNA polymerase enzyme
dNTP (deoxyribonucleoside triphosphate)	–
Oligonucleotide primers	18–25 bases in length
Template DNA	Sample amount in a reaction can range from 1 ng to 1 μg
Thermostable DNA polymerase enzymes	Taq DNA polymerase extracted from *Thermus aquaticus* isolated from a hot-springs dwelling bacterium of the Deinococcus–Thermus phylum

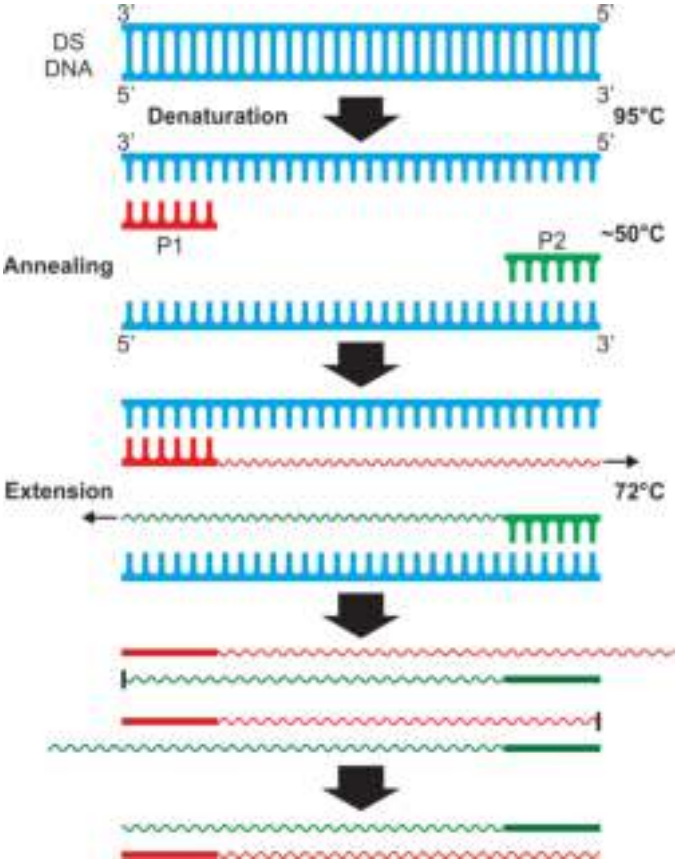

Fig. 14.33: Polymerase chain reaction shows denaturation, annealing and extension.

- **Denaturation step:** Sample specimen DNA of extracted is rendered single-stranded by heating to 94°–98°C.
- **Annealing step:** In annealing step, oligonucleotide primers hybridize with the target sequences. The annealing temperature depends on deoxyribonucleoside triphosphate (dNTP) composition of the primers and temperature in the range of 40°–60°C.
- **Extension step:** The extension step (72°C) leads to DNA synthesis (5′→3′) by thermostable DNA polymerase of new DNA strand. DNA amplification is accomplished by repetitive cycle (30–50 times) of the denaturation, annealing, and extension steps. The time period for each of the denaturation, annealing and extension steps can vary from 10 seconds to >1 minute, which depends on reaction volume size, amplicon base composition and length, thermostable DNA polymerase activity (about 1000 bp are extended per minute) and hardware specifications.

CLINICAL APPLICATIONS OF POLYMERASE CHAIN REACTION TECHNIQUE

Analysis of Molecular Genetic Alterations in Various Disorders

Polymerase chain reaction technique is performed to detect genetic disorders, BCR-ABL translocation in chronic myelogenous leukemia (CML), detection of EWS/FLI-1 fusion gene in Ewing sarcoma, hereditary nonpolyposis colorectal cancer (HNPCC) mutation analysis and detection of circulating tumor or pathogen. Molecular techniques used in nonhematologic and hematologic malignancies are shown in Figs 14.35 and 14.36. Polymerase chain reaction (PCR) technique variations are given in Table 14.99.

NUCLEIC ACID SIGNAL AMPLIFICATION TECHNOLOGY

Previously described techniques directly amplify target nucleic acid sequences to threshold of detection. Alternative strategy is to employ amplification technology at the level of detection, where a non-amplified nucleic acid is targeted using a probe and an amplified signal is generated from the probe.

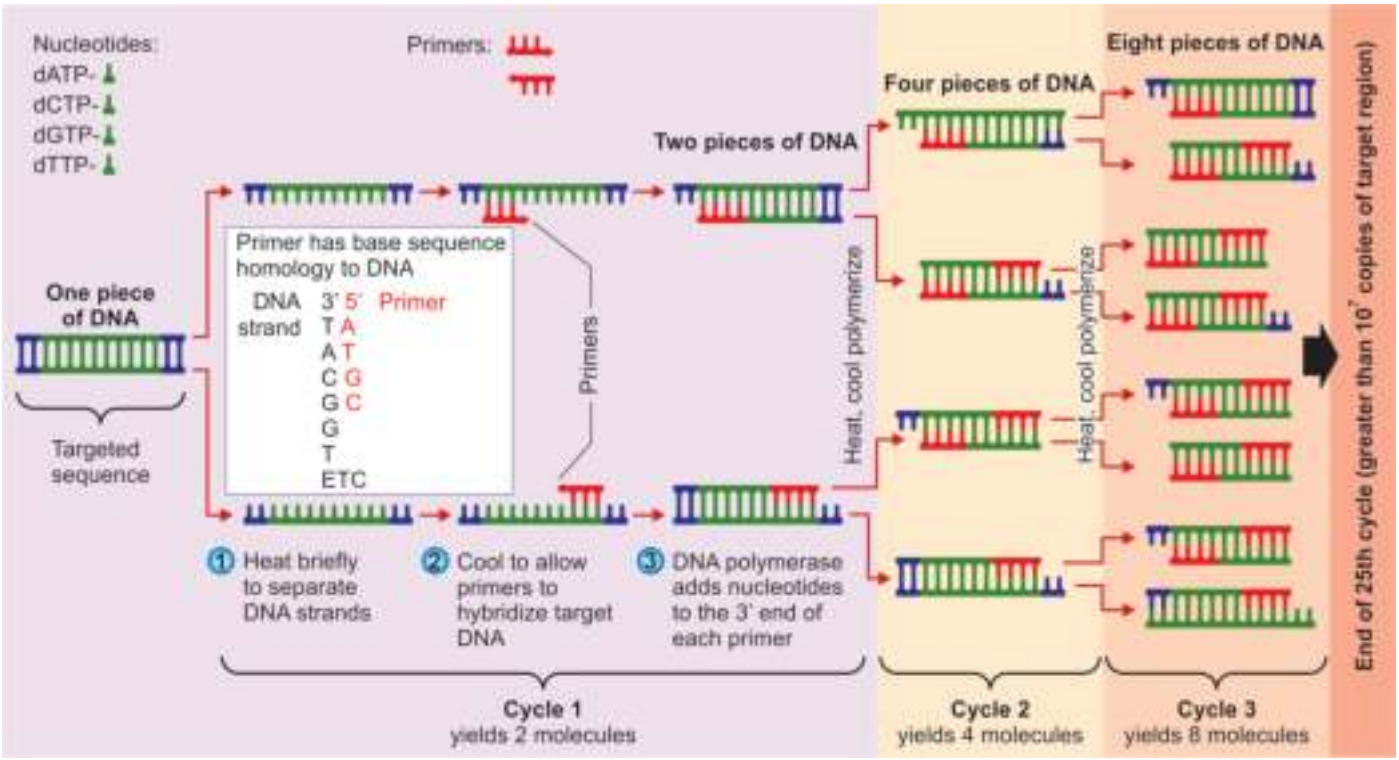

Fig. 14.34: Basic steps in polymerase chain reaction (PCR).

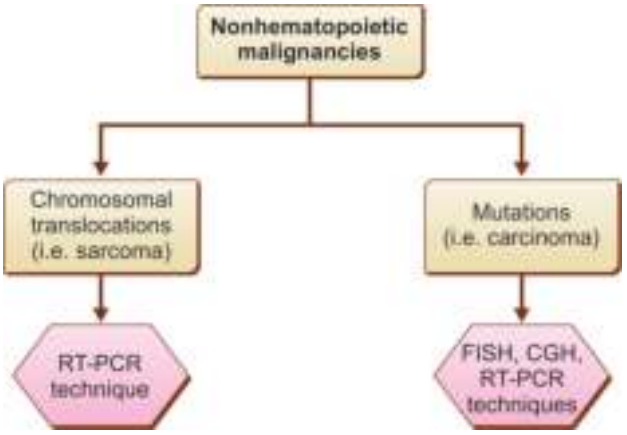

Fig. 14.35: Molecular techniques used in nonhematologic malignancies.

Nucleic acid amplification methods are given in Table 14.100.

Signal amplification techniques are less susceptible to false positive data and used in multiple ligation-dependent probe amplification (MLPA) and hybrid capture (Table 14.101).

WESTERN BLOTTING TECHNIQUE

Western blotting technique is widely used in molecular biology to identify specific antibodies in patient's blood and tissue samples by using a probe. A probe used is an antibody raised against that particular protein. Western blotting works on the principle of gel electrophoresis. Proteins are separated based on sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE). Gel electrophoresis is commonly used for separating proteins on the basis of size, shape and charge. In gel electrophoresis, protein of sample is separated according to molecular weight. Western blot technique is shown in Fig. 14.37.

SDS-PAGE Protocol

Sodium dodecyl-sulfate polyacrylamide gel electrophoresis (SDH-PAGE) is commonly used to obtain high resolution separation of complex mixture of proteins. Sample loading is done into the wells of gel electrophoresis equipment containing buffers.

Pathology Pearls: Blotting Techniques

- Blotting is a method of transferring proteins, DNA or RNA onto a carrier such as nitrocellulose membrane or polyvinylidene difluoride (PVDF) or nylon membrane.
- Western blotting technique is used to detect proteins.
- Southern blotting technique is used to detect RNA.
- Northern blotting technique is used to detect DNA.

SOUTHERN BLOT TECHNIQUE

Southern blot technique is used to detect specific DNA sequence in samples, which was developed by

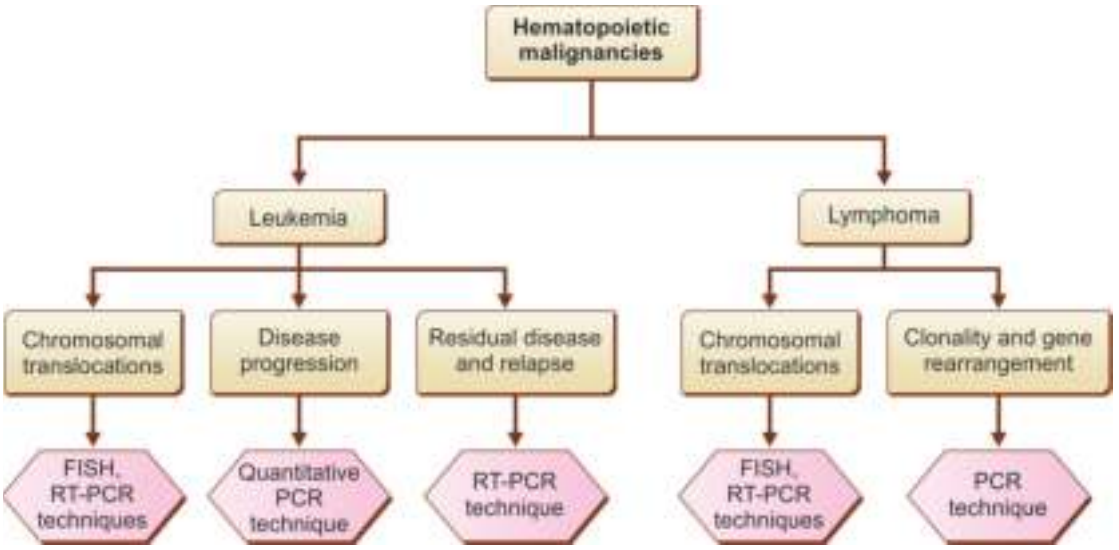

Fig. 14.36: Molecular techniques used in hematologic malignancies.

Table 14.99 Polymerase chain reaction (PCR) technique variations

PCR Technique Variations	Comments
Multiplex PCR technique	Simultaneous detection of more than one target by use of multiple primer pair sets
Consensus PCR technique	Used to amplify single target that has variable sequences or multiple targets that have similar (common) sequences
Degenerate PCR technique	Also used in the amplification of variable sequence target
Nested PCR technique	Used for improved PCR sensitivity and specificity
Reverse transcription PCR (RT-PCR) technique	For investigation of RNA expression through PCR, first step is conversion of total RNA or mRNA into single-stranded complementary DNA (cDNA) as thermostable DNA polymerases require DNA as a substrate
Real-time quantitative PCR (qPCR) technique	Used for the accurate quantification of DNA or RNA and cDNA target in a sample. Note: In standard PCR/end-point PCR, final product is obtained after 30–50 cycles. Although end-point PCR can be semiquantitative, it is essentially a qualitative assay
Allele-specific PCR (AS-PCR) technique	Allows direct detection of any point mutation in human DNA by analyzing PCR products in an ethidium bromide stained agarose or polyacrylamide gel
PCR amplification of specific alleles (PASA) technique	Generally applicable technique for detection of known point mutations, small deletions, insertions and polymorphisms
Long and accurate PCR (LA-PCR) technique	Allows the amplification of sequences 5–>20 kb in length
Amplification refractory mutation system (ARMS) technique	Simple method for detecting any mutation involving single base change, uses sequence-specific primers that allow amplification of test DNA only when the target allele is contained within the sample

Table 14.100 Nucleic acids amplification methods

Amplification Methods	Description	Applications
Transcription-mediated amplification (TMA) technique	Amplification of RNA targets, including species-specific rRNA sequences	Detection of *Chlamydia trachomatis, Neisseria gonorrhoeae, Mycobacterium tuberculosis* and hepatitis C virus (HCV)
Nucleic acid sequence-based amplification (NASBA) technique	Isothermal amplification of a DNA or RNA target, identical to TMA but uses a separate RNase H enzyme and fluorescence resonance energy transfer (FRET) based detection technology	Detection of CMV and human immunodeficiency virus (HIV) RNA
Strand displacement amplification (SDA) technique	Requires a DNA polymerase that has strand displacement activity	Detection of *Chlamydia trachomatis, Neisseria gonorrhoeae*, and *Legionella pneumophila*
Ligase chain reaction (LCR) technique	Involves cycles of DNA denaturation and annealing and uses a thermostable DNA ligase	Detection of *Chlamydia trachomatis* and *Neisseria gonorrhoeae*

Table 14.101 Signal amplification techniques

Techniques	Description	Applications
Multiple ligation-dependent probe amplification (MLPA)	Involves ligation of two oligonucleotides hybridized immediately adjacent to each other at the target of interest. The ligation product is then amplified by PCR	Detection of familial cancers (BRCA1 and BRCA2 testing in breast cancer, colon polyposis (APC), retinoblastoma, Wilms' tumor); prenatal and postnatal screening; syndromes (Turner and Klinefelter syndromes)
Hybrid capture	Involves an *in vitro* solution hybridization of a target DNA sequence with an RNA probe, followed by a signal amplification step	Screening of 13 high-risk HPV genotypes (16, 18, 31, 33, etc.); detection and quantitation of CMV, *Chlamydia trachomatis, Neisseria gonorrhoeae,* HBV and herpes simplex virus (HSV)

Dr EM Southern in 1975 as a method for transferring DNA out of an agarose slab gel onto solid support like nitrocellulose or nylon membrane.

- Cellular DNA is digested by using restriction endonucleases to cut genomic DNA into different sized fragments.
- Gel electrophoresis is now used to separate DNA fragments. Alkaline buffer is used for denaturing DNA to ssDNA. Digested DNA is then transferred to nitrocellulose membrane.
- Complementary probe is now hybridized to the nitrocellulose membrane to detect specific gene of interest by labeling with radioactive or fluorescent dye.
- Southern blot technique requires relatively large quantity of high molecular weight DNA. Southern blotting technique is shown in Fig. 14.38A to F.

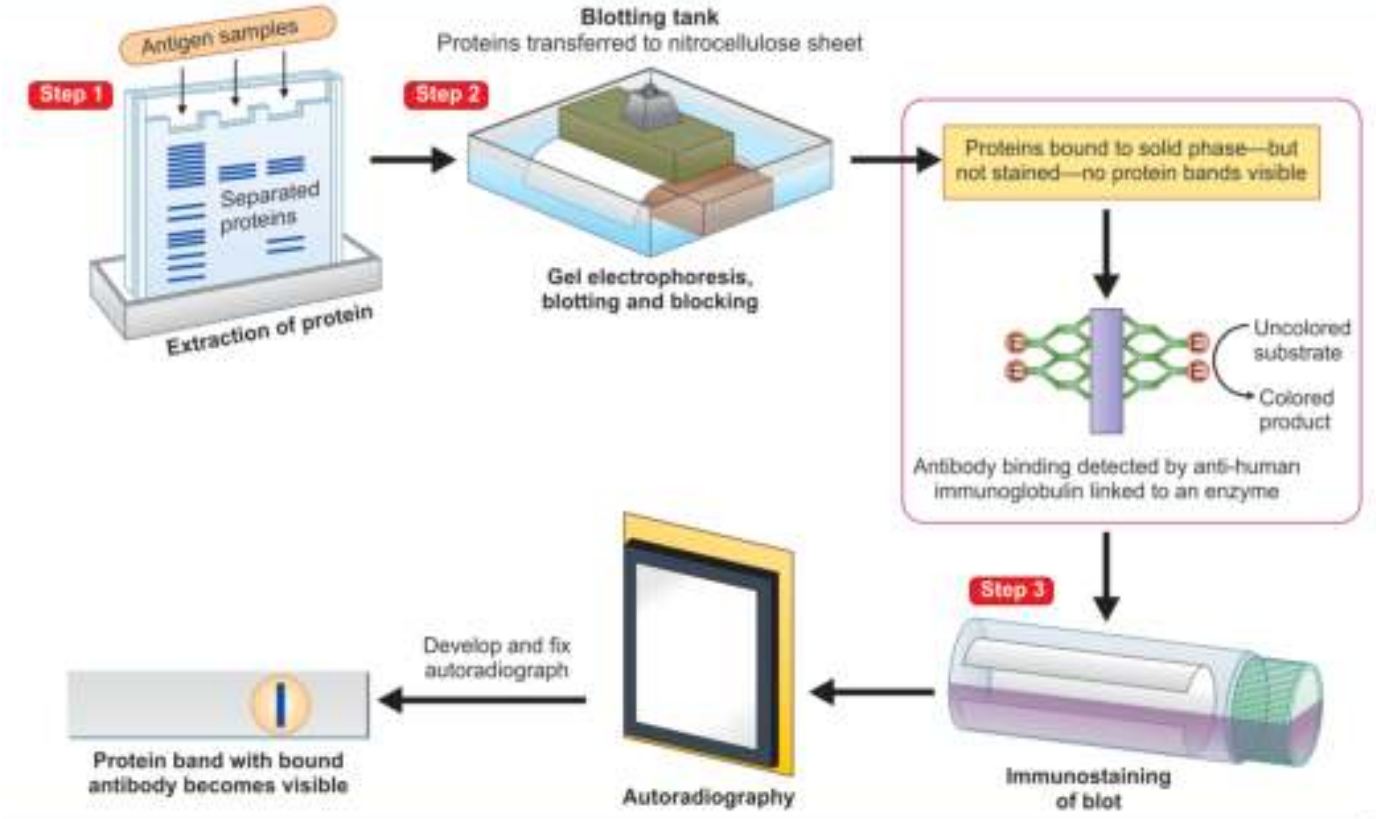
APPLICATIONS OF SOUTHERN BLOT TECHNIQUE

Southern blot technique can be used to detect chromosomal rearrangements, DNA amplifications, deletions and loss of heterozygosity. It can be used in combination with polymerase chain reaction (PCR) technique. Southern blotting technique is mostly used in restriction fragment length polymorphism (RFLP) analysis.

Pathology Pearls: Clinical Applications of Southern Blot Technique

- Autosomal dominant cerebellar ataxia evaluation
- Myotonic dystrophy evaluation
- Epstein-Barr virus clonality assay
- Beckwith-Wiedemann syndrome
- Fragile X syndrome evaluation
- Hemophilia A analysis for inversion, deletion, and carrier
- Ig gene rearrangement detection in B cell lymphoma and minimal residual disease
- T cell receptor gene rearrangement in T cell lymphoma
- MLH1, MSH2, MSH6 deletion/duplication screening
- Partial Duchenne muscular dystrophy (DMD) deletion/duplication assay
- Huntington disease (trinucleotide repeat)
- Sickle cell disease (noncoding repeats or satellite DNA sequence variations).

- Southern blot technique has advantages over polymerase chain reaction (PCR) technique when available sequence data are insufficient to design PCR primers specific to the site of a chromosomal rearrangement. Comparison between PCR and Southern blot technique is given in Table 14.102.
- Southern blot technique requires large quantities of DNA. It is a time-consuming process.



NORTHERN BLOT TECHNIQUE

Northern blot technique is used to analyze special sequences of messenger RNA (mRNA). Messenger RNA (mRNA) constitutes up to 5% of the total cellular RNA. RNA molecules are separated by electrophoresis and transferred to nitrocellulose membrane. RNA molecules are now identified by specific hybridization probe.

- **Northern blot technique methodology:** Extracted mRNA is denatured with formaldehyde or glyoxal to prevent the formation of secondary RNA structures.
  - RNA digestion into smaller fragments is not required as native mRNA fragment sizes range from about 300–12,000 nucleotide base pairs (average size is 1,000–3,000 nucleotide base pairs).
  - After agarose gel electrophoresis, RNA is transferred to membrane by capillary, vacuum, or electrotransfer process, and then the membrane is hybridized with a labeled probe to the gene target.
  - The resulting data indicates whether a gene is overexpressed or underexpressed or if an abnormally sized transcript is expressed.
- **Disadvantages of Northern blot technique:** Northern blotting is time-consuming technique, which requires relatively large amounts of high-integrity RNA and requires a high level of laboratory skill. Differences between Southern blotting and Northern blotting techniques are given in Table 14.103.
- **Clinical applications of Northern blot technique:** Northern blot technique is used to compare the expression of normal tissue versus malignant

Western blot (immunoblotting) technique: Basic goal

- Western blot technique is used to separate the blood proteins and detect the specific proteins (HIV antibodies that indicate HIV infection).
- Labeled antibody against particular protein is used to identify the desired protein.
- Western blot technique is used to confirm a positive ELISA test, and the combined tests are 99.9% accurate.
- A positive Western blot test confirms an HIV infection. A negative Western blot test indicates ELISA test as false positive.
- Calorimetric, chemiluminescence and fluorescence techniques are used to visualize a Western blot.
- As the antibodies only bind to the protein of interest, only one band should be visible.
- Thickness of the band corresponds to the amount of protein present.

Step 1. Extraction of protein from cell (called tissue separation)

- Cell lysate is most common sample used in Western blot test.
- Protein is extracted from mechanical or chemical induced lysis of cell.
- Protease inhibitor is added to prevent denaturing of protein.
- Protein concentration is determined by spectroscopy.

Step 2. Gel electrophoresis, blotting and blocking

- **Gel electrophoresis:** The sample is loaded in well of SDS-PAGE sodium dodecyl sulfate-polyacrylamide gel electrophoresis. Proteins are negatively charged, so they move toward positive (anode) pole as the electric current is applied.
- **Blotting:** The nitrocellular membrane is placed on the gel. Proteins are transferred to nitrocellular paper by capillary action.
- **Blocking:** Blocking is very important step in Western blot test, as it prevents antibodies from binding to the membrane before adding the primary antibody. Blocking is often made with 5% bovine serum albumin (BSA) or casein to reduce the background.

Step 3. Treatment with primary and secondary antibodies; and suitable substrate

- Proteins bound to solid phase are not stained, hence no protein band is visible.
- The primary antibody is specific to the desired protein so it forms antigen–antibody complex.
- The secondary antibody is enzyme labeled (e.g. alkaline phosphatase or horseradish) and against primary antibody so it can bind with antigen–antibody complex.
- The mixture is incubated with specific substrate to visualize the enzyme action. The enzyme converts the substrate to give visible colored product, so band of color can be visualized in the membrane.
- Western blotting is also a quantitative test to determine the amount of protein in the sample.

Fig. 14.37: The Western blot (sometimes called the protein immunoblot), or Western blotting is a widely used analytic technique in molecular biology and immunogenetics to detect specific proteins in a sample of tissue extract or homogenate. The sample undergoes protein denaturation, followed by gel electrophoresis.

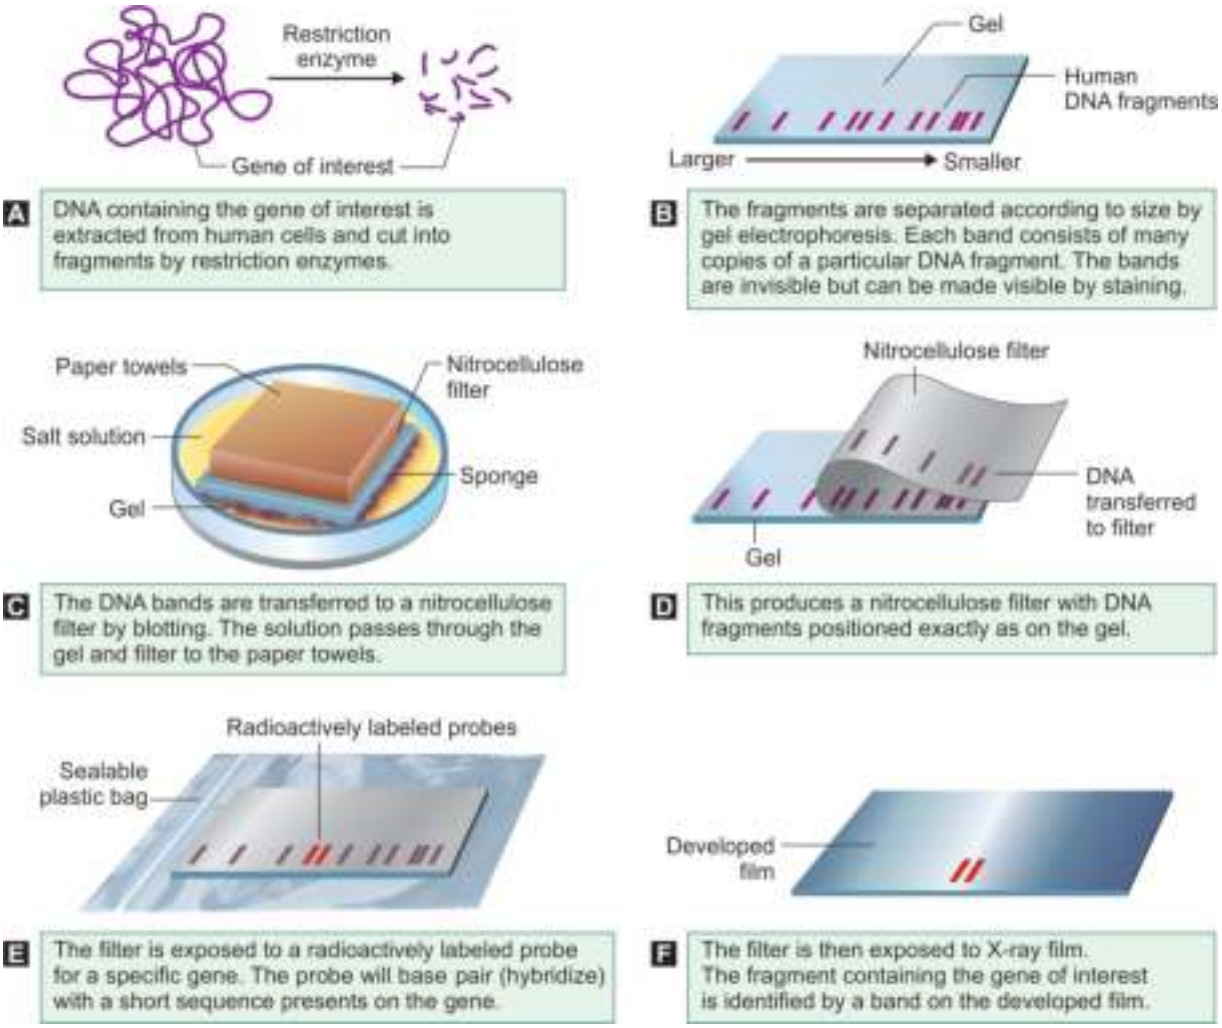


Fig. 14.38A to F: Southern blotting technique.

Table 14.102 Comparison between polymerase chain reaction (PCR) technique and Southern blot technique

Features	Polymerase Chain Reaction (PCR) Technique	Southern Blot Technique
DNA amount	≤1 µg	At least 30 µg per probe
Restriction enzyme digestion	Not needed	Required
DNA quality and size	Can be severely degraded and 100–300 bp DNA	High quality DNA and at least 20 kb
Gel electrophoresis	Polyacrylamide gel required	Agarose gel required
Detection methods	Fluorescence dye, silver stain, chemiluminescence radioactivity	Usually radioactivity, less often chemiluminescence
Time	1–2 days	1–2 weeks
False negative results	Common for B cell lymphomas, but uncommon in T cell lymphomas	Rare
Sensitivity	1 cell per 1000 cells	1–5% of total DNA

tumors and identification of potential oncogenes. This technique provides prognostic information via expression of profiling.

Northern blot technique is also used to study pathogenesis of disease by analyzing specific messenger RNA (mRNA) levels in tissues.

Table 14.103 Differences between Southern blotting and Northern blotting techniques

Features	Southern Blotting Technique	Northern Blotting Technique
Naming of blotting	Named after inventor Dr EM Southern	It is a misnomer
Separation	DNA	RNA
Denaturation step	Required	Not required
Membrane used	Nitrocellulose filter membrane	Aminobenzyloxymethyl filter paper
Hybridization	DNA-DNA	RNA-DNA

TISSUE MICROARRAY (TMA) TECHNIQUE

TISSUE MICROARRAY TECHNIQUE: OVERVIEW

Tissue microarray (TMA) technique involves cylindrical tissue core needle biopsies of multiple tissues constructed in the same paraffin-embedded tissue block by inserting tissue core from the donor's block and inserted into recipient's block.

- Tissue microarray is a new technique used to analyze several hundred tissues, especially tumor samples on single slide by *in situ* technology.
- Difficulty with paraffin-embedded tissue relates to antigenic changes in proteins and mRNA degradation induced by the fixation and embedding processes.
- Tissue microarray (TMA) technique allows rapid visualization of morphology and molecular targets (DNA/RNA/protein) in thousand's of tissue specimens at a time, which correlates gene and protein expression patterns in intact tissues with clinical outcomes. Tissue microarray technique is shown in Fig. 14.39.

TISSUE MICROARRAY METHODOLOGY

Selection of Donor's Block

Primary donor paraffin-embedded cylindrical tissue block may be obtained from surgical pathology, autopsy or research material. Ideally donor block should contain 2–3 mm thickness of target tissue to permit large number of histologic sections (usually 100–300 sections) from it. A morphologically representative area of interest within the donor block is identified under light microscope using hematoxylin and eosin stained section on a glass slide as a guide.

Creation of New Paraffin-embedded Tissue Block

Cylindrical tissue cores are removed from the donor and inserted into a recipient paraffin-embedded tissue block. Using a precise spacing pattern, tissues can be inserted at high density, with up to 1,000 tissue cores in single paraffin-embedded tissue block.

Cutting Section from Tissue Block

Sections from tissue block that are cut with a microtome are placed onto standard glass slides that can be used or *in situ* analysis. Depending on the overall depth of tissue remaining in the donor blocks, tissue arrays can generate between 100 and 500 sections.

Recording of Source Tissue Data

Recording of source tissue data comprises clinical history, metastatic disease, staging, treatment history, tumor gross description such as size, shape, infiltration of margins and core tissue.

Tissue Processing

Marked slide and paraffin wax block are transferred to the person who will make the array. Then the core biopsies from selected tissue are taken either manually or by automated arrays. In tissue microarray (TMA) technique, cylindrical tissue cores are taken with intercore space of 0.8 mm. This TMA core size just fills the field of 40X objective. The core thickness should be 2–3 mm uniformly, if this is variable some sections of the block face will have empty spaces.

TISSUE MICROARRAY DESIGN

The cylindrical tissue cores are placed in X-Y axis positioning. While scoring TMA microscopically, it is easy to loose place when >10 cores in either axis. In such cases, sub-arrays of 5 rows and 5 columns can be made with empty spaces between arrays. Histologic sections/blocks can be stored for 70 years at room temperature as antigenicity of most tissues stored in paraffin wax is retained. However, RNA *in situ* hybridization (ISH) sections can be stored up to 1 year are best.

Cutting Sections from Tissue Block

Most tissue microarray (TMA) technique, cylindrical tissue cores are slip fit into recipient block holes without any bonding material between tissue cores and wax.

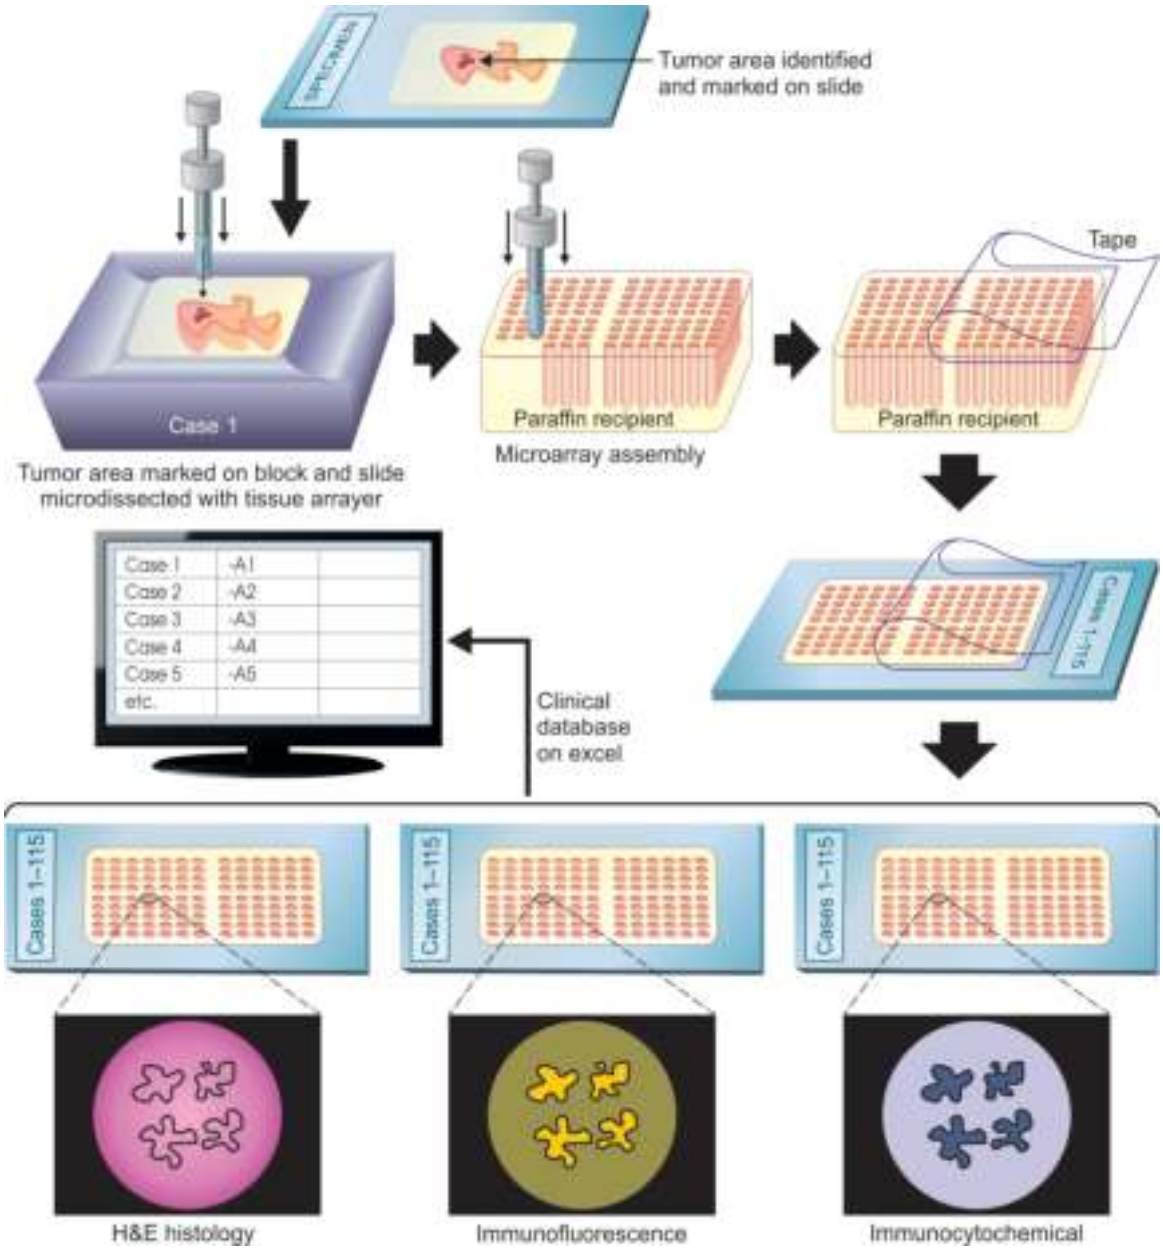

Fig. 14.39: Tissue microarray technique.

Thus, sections cut from block face have nothing to hold tissue cores in place. Ideally melting temperature and hardness of donor and recipient block's paraffin wax should match.

Hematoxylin and Eosin Staining

Hematoxylin and eosin stain permits visualization of morphology of area of interest from different donor blocks in one slide. Also since morphology of tissues may change with more sections from the TMA; 1st and every 50th section of TMA block may be stained with hematoxylin and eosin (H&E) to monitor morphology and representability of the specimens.

Analysis of Tissue Sections

Once constructed, tissue microarrays can be used with a wide range of techniques including histochemical staining, immunohistochemical/immunofluorescent staining or *in situ* hybridization for either DNA or mRNA.

Image Capturing

Regular bright field microscope can be used for analysis and scoring TMA slides, which can image 8–10 slides on single run in each of bright field, dark field and 3-color fluorescent mode if needed and view them simultaneously. It can also do morphometric analysis of these images.

APPLICATIONS OF TISSUE MICROARRAY TECHNIQUE

Tissue microarray (TMA) is an emerging diagnostic technique tool for research which has high throughput, uniform reaction conditions and experimental uniformity. TMA does not destroy the original block for diagnosis and economizes the use of reagents.

- TMA also facilitates data recording and linking to clinical data. Main application of TMA is understanding of tumor biology.
- There are different types of TMAs: multi tumor TMA, progression TMA and prognostic TMA.
  - In multi-tumor TMA, samples obtained from multiple tumors are analyzed for role of newly identified genes in normal and neoplastic tissues.
  - Progression TMA is used to study molecular changes in different stages of one particular tumor type.
  - Prognostic TMA comprises samples from tumors with available clinical follow-up data.

Surgical Pathology: Molecular Diagnostic Techniques in Clinical Practice
Immunohistochemistry Technique
Immunohistochemistry technique measures the detection of protein antigens. One IHC experiment can give quantitative (fluorescence intensity value) and semiquantitative (pathologist's score) data.
Fluorescence *in situ* Hybridization (FISH) Technique
FISH is used for analysis of genetic alterations. A single hybridization provides visualization of specific gene change in up to 1,000 tissues.
mRNA *in situ* Hybridization Technique
This detects mRNA transcripts in multiple different tissues.
DNA Microarray Technique
DNA microarray technique can be used along with TMA to generate information regarding DNA in different solid tissue cancers.

HIGH-PERFORMANCE LIQUID CHROMATOGRAPHY

HIGH-PERFORMANCE LIQUID CHROMATOGRAPHY TECHNIQUE

Main function of high-performance liquid chromatography (HPLC) is to separate, identify, quantify and purify nonvolatile and thermally stable components in the target sample.

PRINCIPLE OF HIGH-PERFORMANCE LIQUID CHROMATOGRAPHY

The principle of separation in normal phase mode and reverse phase mode is adsorption in chromatography column of high-performance liquid chromatography (HPLC). The component, which has less affinity towards the stationary phase travels faster. The component which has same affinity towards the stationary phase, the components are separated.

COMPONENTS OF HPLC

HPLC has various components: mobile phase solvent reservoir, degasser, high-pressure pump, injector system, reversed-phase column compartment, detector, data processor and waste collection.

- Mobile phase solvent reservoir is delivery system that introduces the sample under pressure with the help of high-pressure pump from one or several reservoirs and flows through the column at a constant rate.
- A degasser is required to remove dissolved air and other gases from the solvent in the mobile phase.
- Column compartment controls the temperature of the column, if required.
- After leaving the column, the individual substances are detected by a suitable detector and passed on as a signal to the HPLC software on the computer.
- At the end of this operation, a chromatogram in the HPLC software on the computer is obtained.
- The chromatogram allows identification and quantification of the different substances. Waste is collected from the liquid.

TYPES OF HPLC

High-performance liquid chromatography (HPLC) types are based on: (a) modes of chromatography (normal mode HPLC or reverse mode HPLC), (b) principle of separation technique (adsorption HPLC, ion exchange HPLC, size exclusion, i.e. gel permeation HPLC and affinity HPLC), (c) elution technique (isocratic separation HPLC and gradient separation HPLC), and (d) purpose of separation technique (analytic HPLC and preparative HPLC).

- Ion exchange high-performance liquid chromatography is based on an exchange of ions between charged stationary surface and ions of the opposite charge in the mobile phase.

- Schematic representation of HPLC functioning, separation, identification, and quantification of substances in biological fluids, newborn screening by high-performance liquid chromatography–mass spectroscopy to analyze blood sample are shown in Figs 14.40 to 14.43.

SEPARATION OF COMPONENTS IN TARGET SAMPLE IN HPLC

Modes of separation in high-performance liquid chromatography (HPLC) include normal phase chromatography, reverse phase chromatography, reverse phase ion exchange chromatography and size exclusion chromatography.

- Normal phase chromatography is generally used for separation of nonpolar compounds. On the other hand, reverse phase chromatography is used for separation of polar compounds.
- In ion exchange chromatography, the stationary phase contains ionic groups, which interacts with the ionic groups of the sample molecules. This method is suitable for the separation of charged molecules only. Ion pair chromatography may be used for the separation of ionic compounds. Strong acids and basic compounds may be separated by reverse phase chromatography by forming ion pairs with suitable counter ions.

PRESSURE PUMP COMPONENT IN HPLC

The pressure pump is one of the most important components of HPLC, since its performance directly affects retention time, reproducibility and detector sensitivity.

- Various types of pressure pumps can be used in HPLC: displacement pump, reciprocating pump and pneumatic or constant pressure pump. Displacement pressure pump produces a flow that tends to be independent of viscosity and back pressure and also is pulse free out but possesses limited capacity (250 ml).
- Reciprocating pressure pump has small internal volume and its high output pressure at constant flow rates but it produces pulsed flow.
- Pneumatic or constant pressure pump has small internal limited capacity, and flow rate depends on viscosity and column back pressure.

SAMPLE INJECTION SYSTEM COMPONENT IN HPLC

Sample injection system component includes loop injection, valve injection and column injection. A fixed

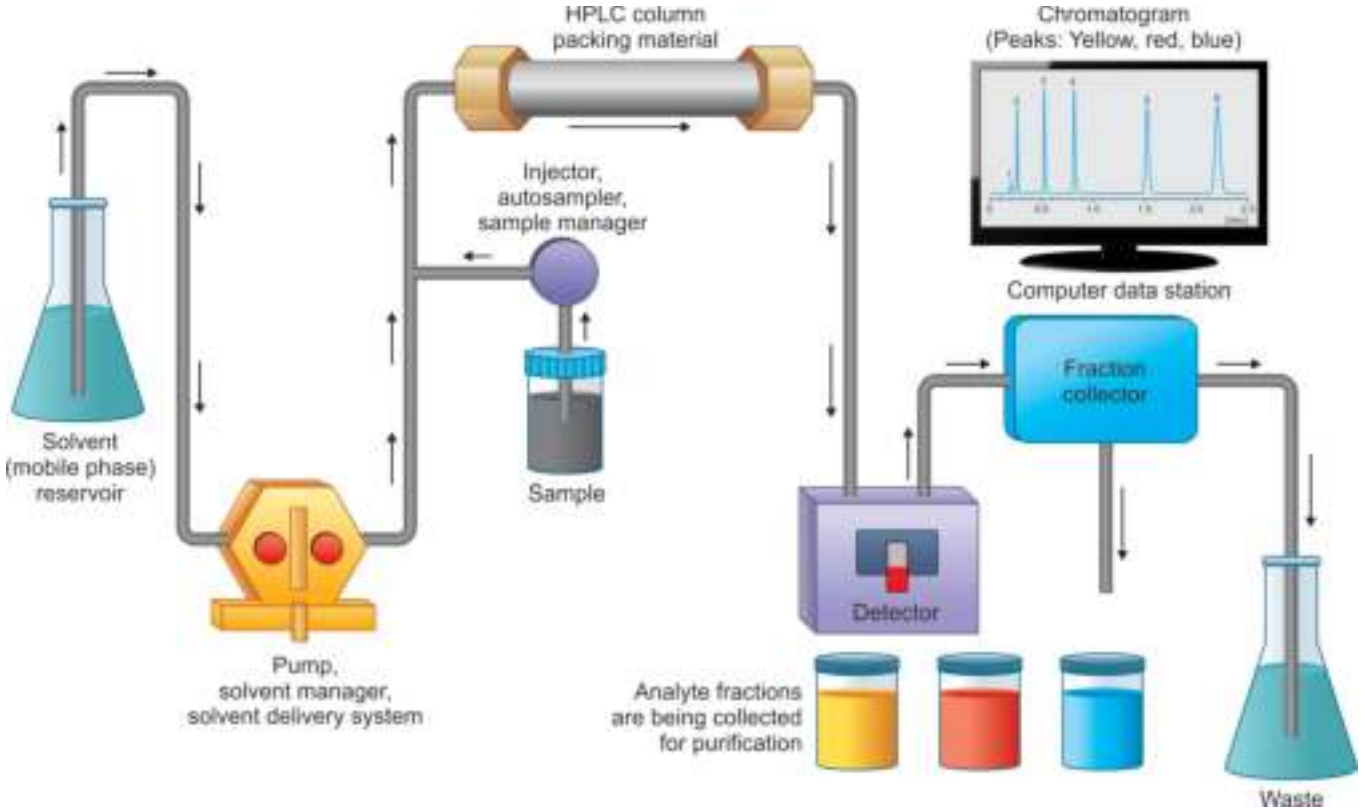

Fig. 14.40: Schematic representation of high-performance liquid chromatography functioning.

Chromatography technique for separation, identification, and quantitation of substances in biologic fluids

- Chromatography is an analytic laboratory technique commonly used for separating a mixture of chemical substances into individual components so that individual components such as proteins, peptides, nucleic acids and polynucleotides can be thoroughly analyzed in biologic fluids. Biologic fluid sample is extracted to remove extraneous molecules.
- Chromatography techniques include gas chromatography, high-performance liquid chromatography (ion exchange, paper, thin layer and gel chromatography), and affinity chromatography.
- Biologic fluid sample is injected into instrument with column chromatography.
- Low-molecular weight compounds in biologic fluid analysis require chemical derivation to increase volatility in gas phase by gas chromatography.
- High-molecular weight compounds in biologic fluid analysis is done by high-performance liquid chromatography (HPLC).

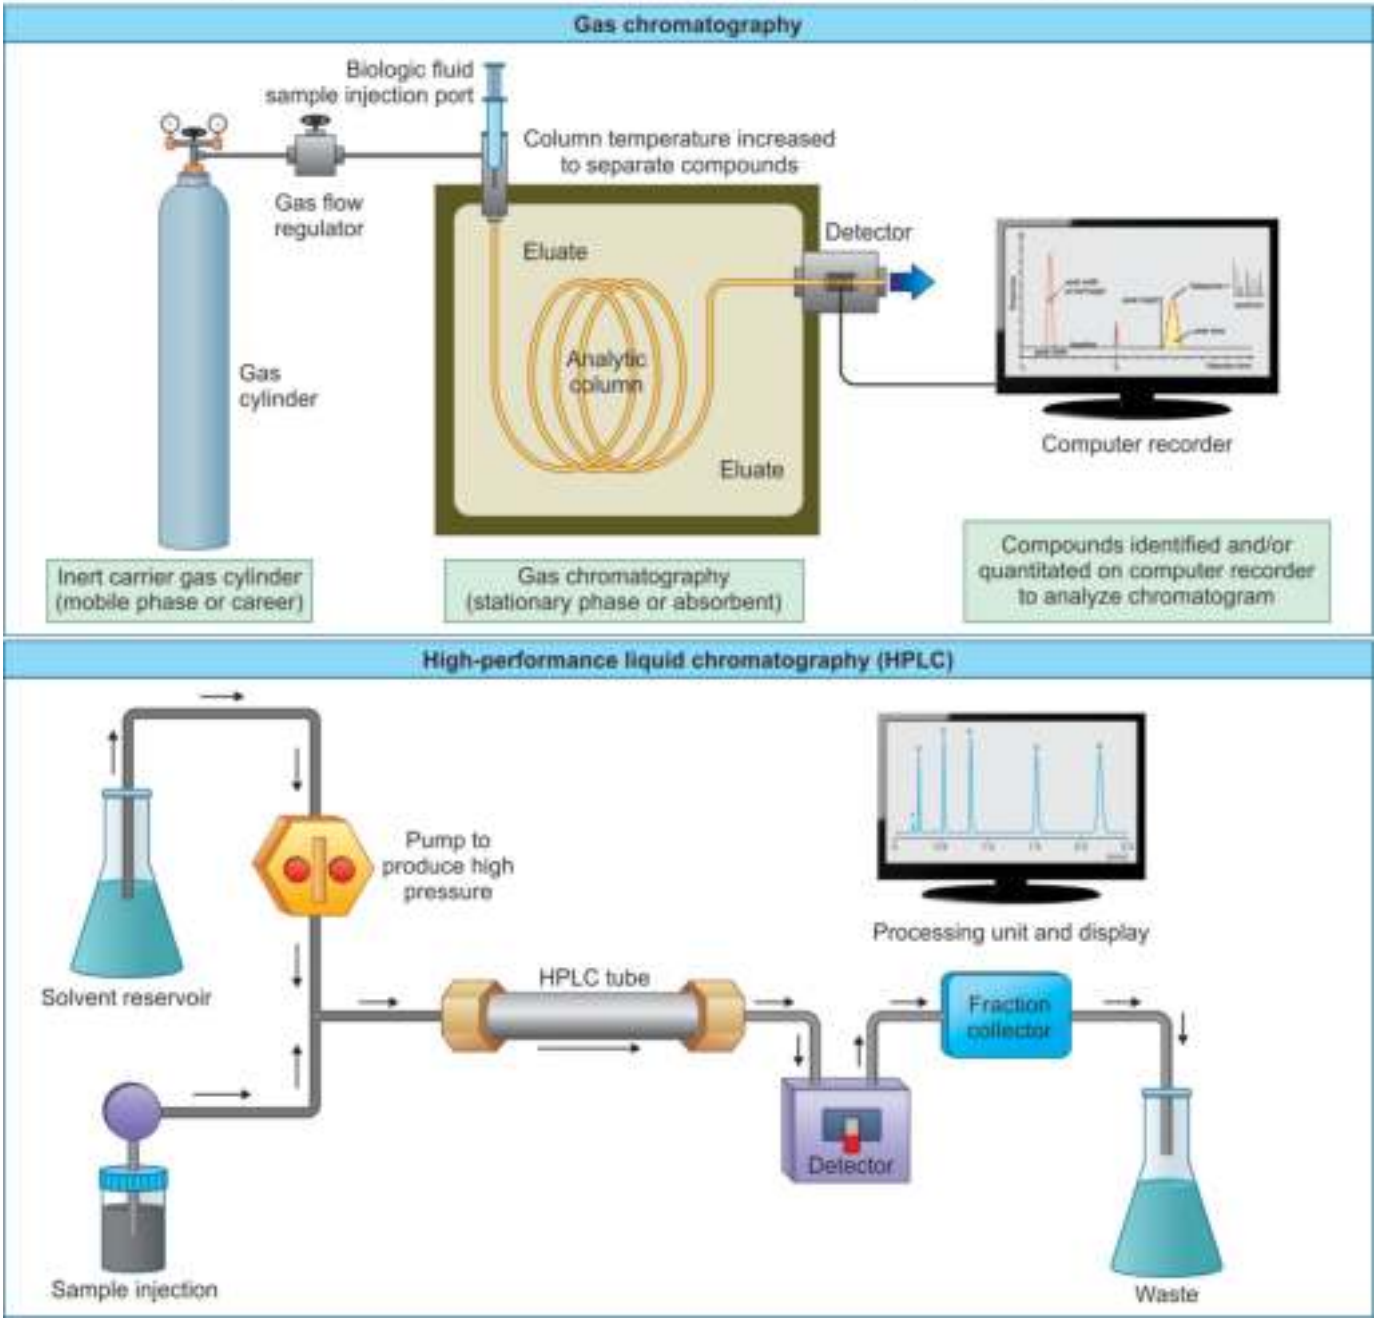

Fig. 14.41: Schematic representation of high-performance liquid chromatography (HPLC) for separation, identification, and quantification of substances in biological fluids.

Rapid analysis of newborn screening to detect early disease using liquid chromatography–mass spectrometry (LC–MS) technique

- **Principle:** Liquid chromatography–mass spectrometry (LC–MS) is a powerful analytic technique used for separation, identification and quantification of both unknown compounds as well as to elucidate the structure and chemical properties of different molecules. After 24 hours of life, heal of newborn is punctured to obtain whole blood which is spotted onto a special card and processed in the central laboratory. Extraction of molecular compounds of interest from a portion of the blood spot and separated by liquid chromatography and then analyzed by mass spectrometry.
- **Purpose:** LC–MS is performed for screening newborn babies blood samples and analyzing and detecting early disease and prevention with respect to disorders of amino acid metabolism and other congenital disorders.
- **LC–MS in clinical practice:** LC–MS is performed to diagnose early diseases: (a) hemoglobin disorders (sickle cell, hemoglobin sickle cell disease, β-thalassemia), (b) metabolic [phenylketonuria, methylmalonic acidemia, maple syrup urine disease (MSUD), tyrosinemia, citrullinemia, medium chain acyl-CoA dehydrogenase (MCAD) deficiency], (c) endocrine disorders (congenital hypothyroidism, congenital adrenal hyperplasia), and (d) rare disorders (galactosemia, cystic fibrosis, severe combined immunodeficiency, Pompe disease, mucopolysaccharidosis type 1, spinal muscle atrophy, X-linked adrenoleukodystrophy, biotinidase deficiency).

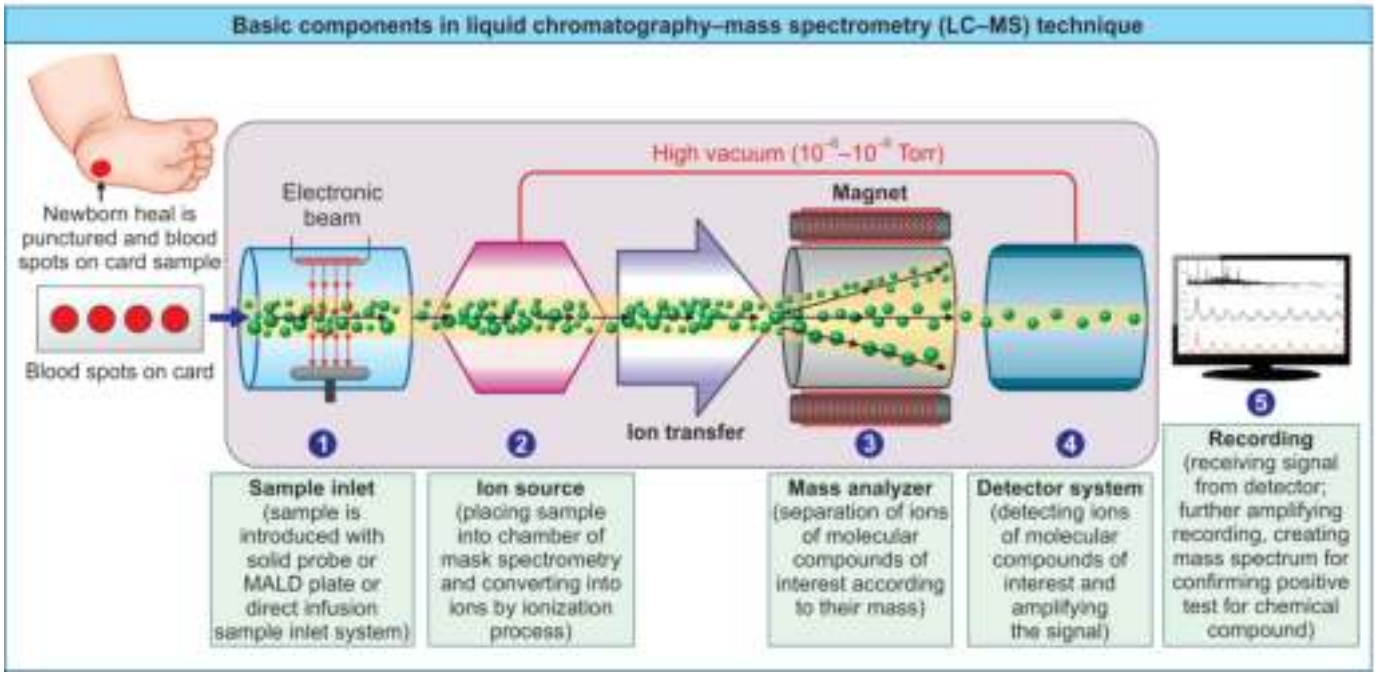

Fig. 14.42: Schematic representation of newborn screening by high-performance liquid chromatography (HPLC)–mass spectroscopy to analyze blood sample.

amount of volume is introduced by making use of fixed volume loop injection. Injection valve and column valve can introduce variable volume of sample.

COLUMNS COMPONENT IN HPLC

Columns are the main component of high-performance liquid chromatography (HPLC), because the columns are responsible for the separation of the sample components. The sample passes through the columns with the mobile phase and separates its components when sample comes out from the columns. The material filled in the HPLC columns is known as stationary phase. There are different types of chromatography columns on the basis of their composition and method of separation, which include: normal phase columns, reverse phase columns, ion exchange columns and size exclusion columns.

DETECTOR COMPONENT IN HPLC

The function of detector component in high-performance liquid chromatography (HPLC) is to monitor the mobile phase as it merges from the columns. Solute property detector responds to a physical property of the solute which is not exhibited by pure mobile phase, e.g. ultraviolet absorbance, fluorescence diffusion current.

- Bulky property detector compares overall changes in physically property of the mobile phase with and without an eluting solute, e.g. refractive index, dielectric constant or density.
- Types of detectors in high-performance liquid chromatography (HPLC) include: ultraviolet/visible detector, photodiode array detector, fluorescence detector, electrochemical detector, refractive index detector, evaporative light scattering detector and mass spectroscopy.

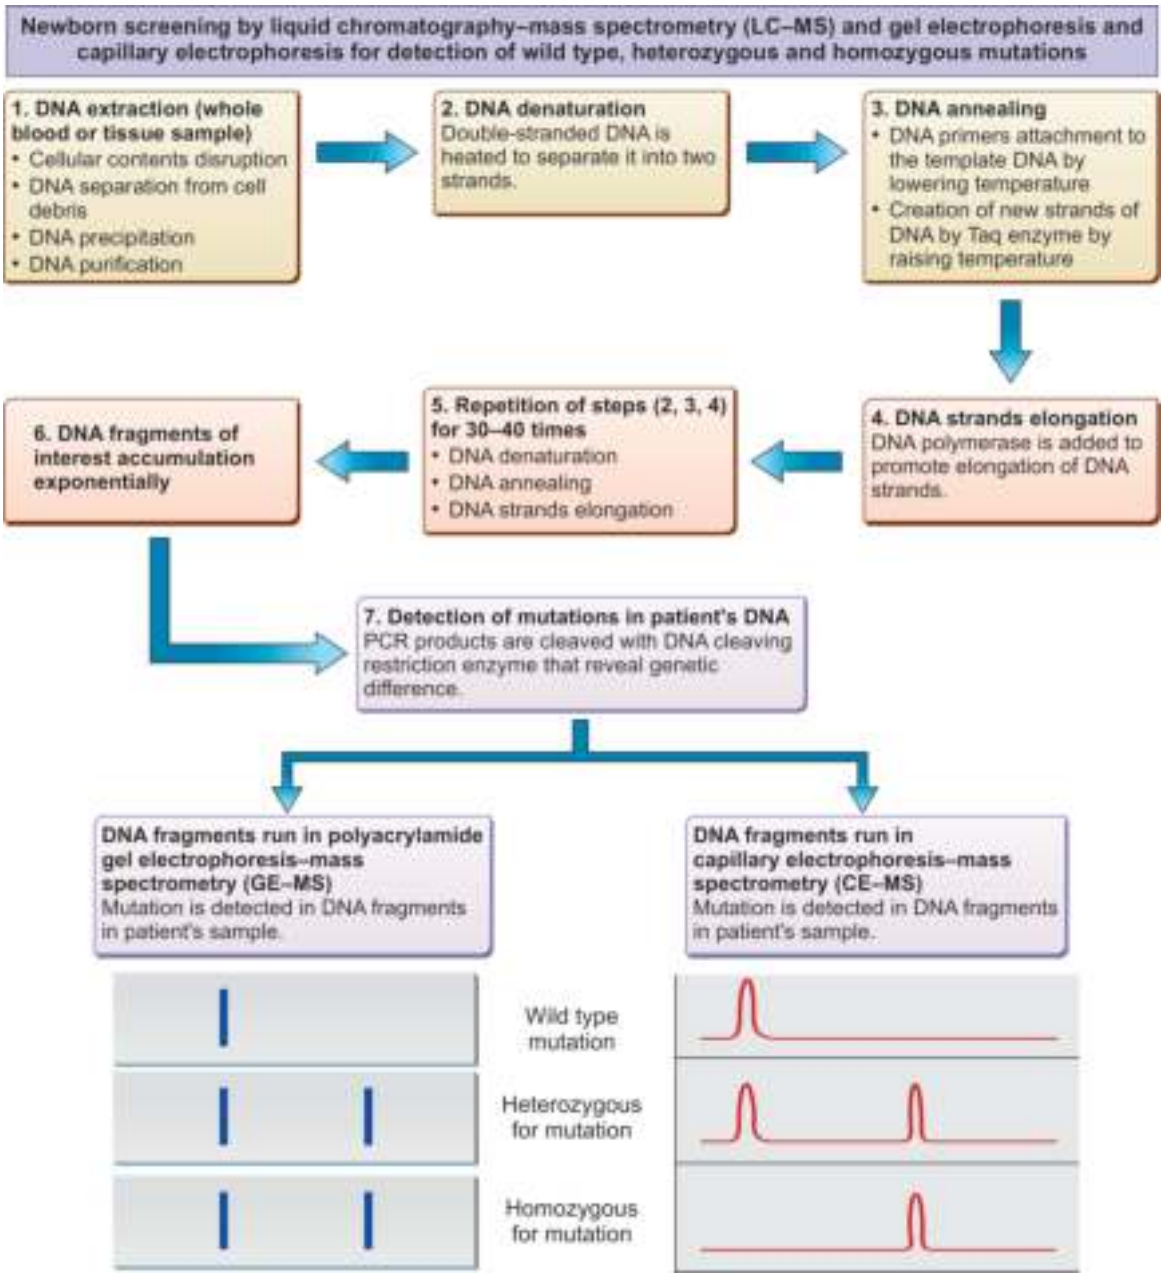

Fig. 14.43: Schematic representation of high-performance liquid chromatography–mass spectroscopy for detection of mutations in DNA by using polyacrylamide gel and capillary electrophoresis.

VALIDATION OF HPLC

Validation is the procedure, which proves that high-performance liquid chromatography technique yields the expected results with reliability, adequate precision and accuracy. Validity parameters include specificity, linearity, range, accuracy, precision, limit of detection, limit of quantitation and robustness.

ADVANTAGES OF HPLC

High-performance liquid chromatography is ideally suited for separation and identification of proteins, amino acids, nucleic acids, hydrocarbons, carbohydrates, pharmaceuticals, environmental (monitoring of water pollution), forensic science (drug in biological samples), pesticides, pigments, antibiotics, steroids and other organic substances.

DISADVANTAGES OF HPLC

Cost of high-performance liquid chromatography (HPLC) equipment and reagents is more. Overall HPLC has more advantages than electrophoresis technique and routinely performed in many laboratories.

APPLICATIONS OF HPLC

High-performance liquid chromatography (HPLC) can be performed on very small venous sample to estimate quantity of normal and abnormal hemoglobins.

- Different hemoglobins have different affinity for the stationary phase. Hemoglobins possess strong positive charge and have higher affinity for stationary phase and appear in the elute later than other hemoglobins. Retention time is the time taken by normal and variant hemoglobins to appear in the eluate.
- Cation exchange high-performance liquid chromatography (CE-HPLC) technique achieves good separation and quantitation of HbF and HbA_2 in addition to screening for variant hemoglobins along thalassemia. A cut-off level of HbA_2 >4% predicts the majority of carriers of classic β-thalassemia.
- Thalassemia and thalassemic hemoglobinopathies pose serious health problem leading to severe morbidity and mortality in Indian population. Detection of asymptomatic carriers of thalassemia major by reliable laboratory methods is the cornerstone of prevention of this serious health problems.
- Genetic studies are indicated to confirm borderline thalassemia cases and to detect silent carriers of β-thalassemia, α-thalassemia, and area and novel variants in routine clinical practice.
- High-performance liquid chromatography coupled with electrospray mass spectroscopy (HPL-MS) is widely used for neonatal screening for metabolic disorders, quantitative determination of therapeutic immunosuppressive drugs in biological fluids, and toxicological investigations.
- High-performance liquid chromatography is used to test water samples to analyze pollution in lakes and rivers. Ion exchange chromatography is more effective in the separation of macromolecules such as nucleic acids and proteins.
- High-performance liquid chromatography (HPLC) is widely used in industrial and scientific applications such as pharmaceutical, environmental, forensic science and chemicals agents.

HEMOGLOBIN ELECTROPHORESIS AND GEL ELECTROPHORESIS TECHNIQUES

HEMOGLOBIN ELECTROPHORESIS TECHNIQUE

Hemoglobin electrophoresis is a diagnostic tool to measure different types of hemoglobin in the blood in suspected disorder associated with abnormal hemoglobin sickle cell anemia and thalassemia. Hemoglobin electrophoresis technique is used to analyze HbA, HbA_2, HbF, HbS, HbC and HbE.

PRINCIPLE

The principle of hemoglobin electrophoresis technique is that when proteins are exposed to charge gradient, they separate from each other by forming bands that separate toward one end or the other end in the electric field. The hemoglobins are separated on variety of supporting media on the basis of electric charge differences.

- The commonly used mediums in electrophoresis technique are cellulose acetate membrane, starch gel, agarose gel, citrate agar gel and filter paper.
- Cellulose acetate hemoglobin electrophoresis is performed at alkaline pH of 8.2–8.6.
- Citrate agar or agarose gel hemoglobin electrophoresis is done in acidic pH of 6.0–6.2. HPLC is rapidly taking its place in many laboratories. Principle of hemoglobin electrophoresis technique is shown in Fig. 14.44.

BLOOD SAMPLING

Blood transfusions within the previous 12 weeks may alter test results. Hemoglobin electrophoresis is done on venous blood samples taken in anticoagulant EDTA container. Red blood cell hemolysate is prepared using a lysing reagent (Na_4 EDTA and KCN).

TYPES OF HEMOGLOBIN ELECTROPHORESIS TECHNIQUES

Cellulose acetate hemoglobin electrophoresis at pH 6.8 is the method of choice in most clinical laboratories. In this technique, there is overlapping of bands of hemoglobins S, D, G and Lepore. Agar gel hemoglobin electrophoresis using citrate buffer at pH 6.0 is useful in supplementing technique that helps in getting separate hemoglobin S band (Fig. 14.45A and B).

Cellulose Acetate Hemoglobin Electrophoresis Technique (pH 8.6)

Cellulose acetate hemoglobin electrophoresis is the primary screening technique used to detect variant of abnormal hemoglobins. The major portion of normal adult Hb is HbA. In addition, up to 3.5% HbA_2 is normally present, along with <2% HbF. The more common mutant Hbs are S, C, E, D, G, and Lepore.

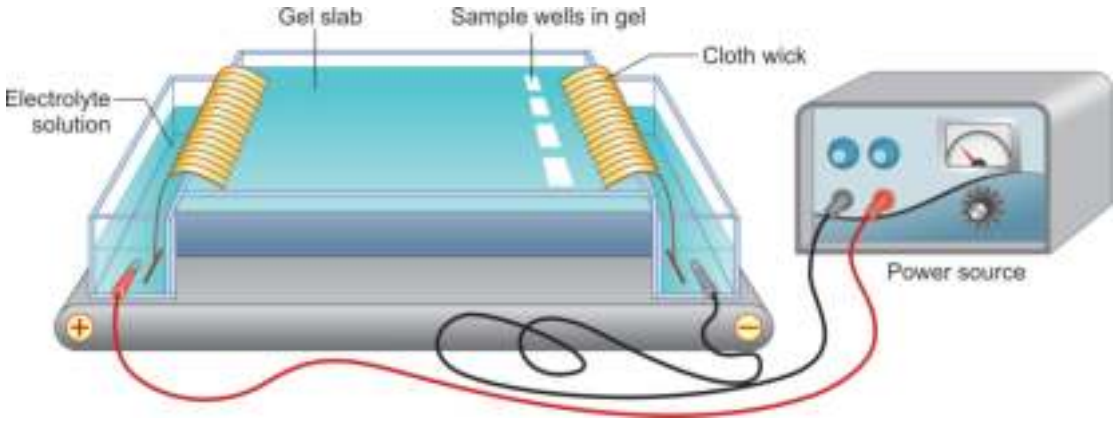

Fig. 14.44: Principle of hemoglobin electrophoresis technique.

Principle

In an alkaline pH (8.2–8.6), Hb is a negatively charged molecule and will migrate toward the anode (+). The various Hbs move at different rates depending on their net negative charge in cellulose acetate hemoglobin electrophoresis.

Methodology

The red blood cell hemolysate (red blood cell membranes are destroyed to free the Hb molecules for testing) is placed in a cellulose acetate membrane, which is positioned in an electrophoresis tray with the inoculated red blood cell hemolysate near the cathode (–).

- One end of the cellulose acetate strip is immersed in the buffer (pH 8.2–8.6) on the cathode side and the other end is placed in the buffer on the anode (+) side. An electric current of specific voltage is allowed to run for timed period. During electrophoresis, the hemoglobin molecules migrate toward the anode because of their negative charge.
- The difference in the net charge of the hemoglobin molecule determines its mobility and manifests its self by the speed with which it migrates to the anode (+) pole.
- The cellulose acetate membrane is then stained in order to color of the proteins (Hbs). By noting the distance, each Hb has migrated and comparing this distance with the migration distance of known controls, the types of hemoglobins may be identified. Example of the fast moving hemoglobin is Hb Bart and the two fastest hemoglobin variants include HbH and I, while HbC is the slowest common Hb. Cellulose acetate hemoglobin electrophoresis at pH 8.6 is shown in Fig. 14.46.

Citrate Agar Hemoglobin Electrophoresis Technique (pH 6)

Citrate agar hemoglobin electrophoresis technique separates hemoglobin fractions that migrate together

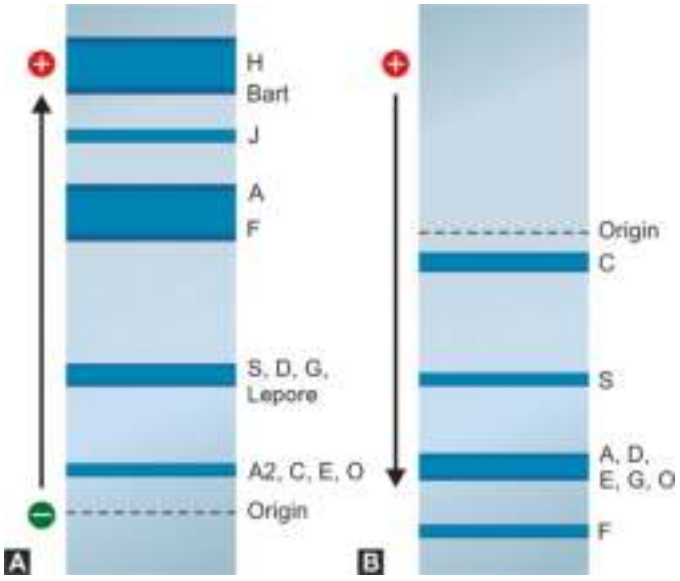

Fig. 14.45: (A) Schematic representation of electrophoretic mobility of normal and abnormal hemoglobins on cellulose acetate at pH 8.6, (B) agar gel at pH 6.

on cellulose acetate agar. All hemoglobin specimens that show an abnormal electrophoretic pattern in alkaline media (cellulose acetate agar) should undergo electrophoresis on an acid citrate agar. Citrate agar hemoglobin electrophoresis technique is used to confirm variant Hbs and further differentiates HbS from HbD and G and HbC from HbE, O_{Arab}, and C_{Harlem}. The procedure should not be used as a screening procedure because many abnormal hemoglobins migrate with HbA.

INTERPRETATION OF HEMOGLOBIN ELECTROPHORESIS

Each of the major hemoglobin types has an electrical charge of a different degree. Hemoglobin electrophoresis separates and measures normal and abnormal

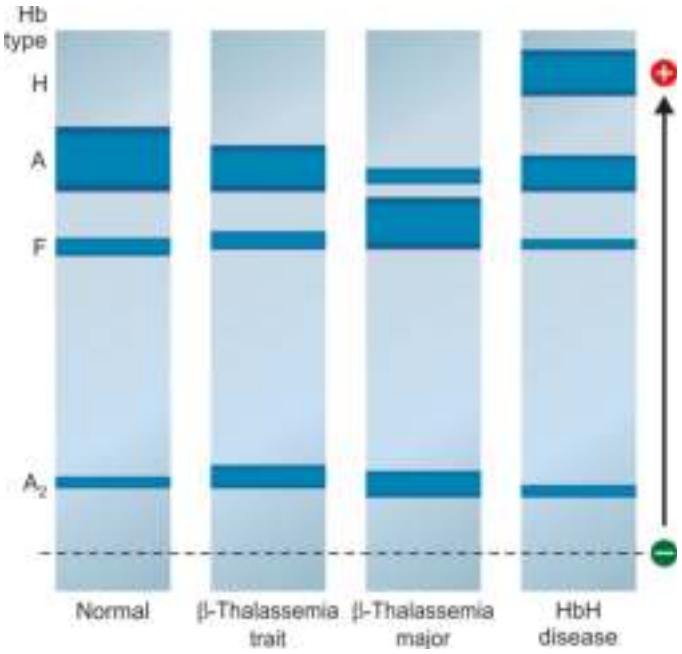

Fig. 14.46: Cellulose acetate hemoglobin electrophoresis at pH 8.6.

hemoglobins. The components then move away from each other at different rates, and when separated from a series of distinctly pigmented bands, which are then compared with those of a normal sample.

- Each pigmented band is further assessed as a percentage of total hemoglobin, thus indicating the severity of any hemoglobin abnormality.
- Hemoglobin electrophoresis technique detects many different types, the most common being HbA_1, HbA_2, HbF, HbS, and HbC.
- Normal reference values of hemoglobins can vary by laboratory, but are generally within the following ranges.

Hemoglobin Electrophoresis Patterns

In normal adults, HbA_1 is the major component of hemoglobin in the normal red blood cell. HbA_2 is a minor component of normal hemoglobin, comprising approximately 2–3% of the total. In children, HbF is the major hemoglobin component in the fetus, but usually exists only in minimal quantities in the normal adult. Levels of HbF >2% in patients over three years of age are considered abnormal. Hemoglobin electrophoresis pattern in normal persons and hemoglobin disorders is given in Tables 14.104 and 14.105.

Table 14.104 Hemoglobin electrophoresis pattern in normal persons

Hemoglobin Type	Hemoglobin Percentage
Adults	
HbA_1	95–98%
HbA_2	2–3%
HbF	0.8–2.0%
HbS	0%
HbC	0%
Children	
HbF (newborn)	50–80%
HbF (6 months age)	8%
HbF (>6 months age)	1–2%

Table 14.105 Hemoglobin electrophoresis pattern in hemoglobin disorders

Hemoglobin	Hemoglobin Disorder	Hemoglobin Percentage
HbA_2	▪ β-Thalassemia ▪ HbH disease	▪ 4.00–5.8% ▪ <2%
HbF	▪ β-Thalassemia major ▪ β-Thalassemia minor ▪ Homozygous hereditary persistence of fetal hemoglobin ▪ Heterozygous hereditary persistence of fetal hemoglobin ▪ Heterozygous HbS	▪ 10–90% ▪ 2–5% ▪ 100% ▪ 5–35% ▪ 15%
HbS	Sickle cell disease (homozygous)	70–98%
HbC	Hemoglobin C disease (homozygous)	90–98%

GEL ELECTROPHORESIS TECHNIQUE

Gel electrophoresis is a technique used to separate DNA fragments or other macromolecules, such as RNA and proteins depending on their size.

- DNA samples are loaded into the pocket like wells at one end of gel, and an electric current is passed to pull them through the gel. Gel is made out of polysaccharide called agarose. Based on their size and charge, the molecules travel through gel in different directions at different speeds, allowing them to be separated from one another.
- DNA fragments are negatively charged; therefore, they move towards the positive electrode. Small fragments of DNA move through the gel faster than large ones.
- Because DNA and RNA are negatively charged molecules, they move towards the positive electrode.
- Proteins however, are not negatively charged, thus when one desires to separate proteins using gel electrophoresis, they must first mix the proteins with a detergent called sodium dodecyl sulphate,

Table 14.106 Various types of gel electrophoresis

Electrophoresis Types	Comments
Agarose gel electrophoresis	▪ Agarose composed of multiple linked repeat units of disaccharide agarobiose (d-galactose and 3, 6-anhydro-l-galactose) is manufactured from seaweed such as Rhodophyta ▪ *Applications:* Analysis of end-point PCR or RT-PCR assays; analysis of restriction fragment length polymorphism (RFLP) assays; routinely used in molecular biology for the analysis of recombinant DNA experiments and can also be used for the purification of probes for ISH
Polyacrylamide gel electrophoresis (PAGE)	▪ Polyacrylamide is produced from monomers of acrylamide in a reaction initiated by free radicals generated by reduction of ammonium persulfate; higher the concentration of acrylamide, the finer the resolution of DNA fragments ▪ The advantage of polyacrylamide over agarose is that size differences at the base-pair level can be distinguished ▪ *Applications:* End-point PCR fragment analysis where fragment size differences are slight; for sequencing assays and for microsatellite marker-based assays using autoradiography or fluorescence-labeled fragments
Pulsed-field gel electrophoresis (PFGE)	▪ Used for improved resolution (accomplished by alternating the direction of the electrical field) of high molecular weight DNA ▪ *Applications:* Identification of microorganism strains such as *Escherichia coli* O157:H7, *Salmonella*, *Shigella*, *Listeria*, or *Campylobacter* species; evaluation of autosomal dominant ataxia
Capillary gel electrophoresis	▪ It supports automated DNA sequencing and fragment analyses ▪ *Applications:* Widely used for DNA sequencing and microsatellite assay

which makes the proteins unfold into linear shape and coats them with a negative charge, thus allows them to migrate toward the positive end of the gel and be separated.

- Finally, after the DNA, RNA, or protein macromolecules have been separated using gel electrophoresis, gel is stained with dyes and observed as bands representing molecules of different sizes can be observed.
- Each band contains a large number of DNA fragments of the same size that have travelled as a group to the same position. A single DNA fragment will not be visible by itself on gel electrophoresis.
- By comparing the bands in a sample to the DNA ladder, one can determine their approximate sizes. For example, the bright band on the gel above will be roughly 700 nucleotide base pairs in size. Various types of gel electrophoresis are given in Table 14.106.

Hematoxylin and Eosin (H&E) Stain in Diagnostic Surgical Pathology

Hematoxylin and eosin (H&E) is the standard stain for histologic examination of human tissues in surgical pathology. Hematoxylin is a positively charged (cation) basic dye, which stains nucleus giving basophilic (blue color) appearance. Eosin is a negatively charged (anionic) acidic dye, which stains cytoplasm giving eosinophilic (red/pink) appearance. Cells may have affinity for both basic dye and acidic dye, which exhibit amphophilic (purple) appearance. Hematoxylin itself has no staining properties not until it has been oxidized and combined with mordant such as aluminum alum. Sequential application of hematoxylin and eosin dyes to the histologic sections results in nuclei being stained blue, and cytoplasm and extracellular matrix pink. Hematoxylin and eosin-stained tissue sections are examined under light microscope. Combined H&E stains are vital for distinguishing many tissues and for making a tentative diagnosis of malignancy.

- **True nuclear inclusions and pseudoinclusions:** Abnormal substances in the nuclei that can be observed by light microscopy are referred to nuclear inclusions and pseudoinclusions. Their presence can aid in the diagnosis of some disease entities and tumor types.
  - **True nuclear inclusions:** True nuclear inclusions consist of material that is foreign to the nucleus and completely contained within the nucleus. True nuclear inclusions are continuous with the cytoplasm and consist of cytoplasmic organelles, such as the endoplasmic reticulum, Golgi apparatus and secretory granules. Immunoreactivity of true nuclear inclusions are same as that of the cytoplasm. True nuclear inclusions are classically caused by viral infections. Basophilic nuclear inclusions are diagnostic of acinic cell carcinoma and malakoplakia (Michaelis-Gutmann bodies).

- **Nuclear pseudoinclusions:** Nuclear pseudoinclusions are formed by invagination of cytoplasm into nucleus and delimited by the nuclear membrane in cytologic and histologic tissue sections. Tumors with pseudoinclusions include papillary thyroid carcinoma, hyalinizing trabecular adenoma of thyroid, pituitary adenoma, meningioma, hepatocellular carcinoma, paraganglioma, pheochromocytoma, melanoma, ductal hyperplasia of breast and inspissated surfactant in lung adenocarcinoma. Nuclear pseudoinclusions can be observed in Arias Stella reaction. Nuclear pseudoinclusions are found in benign and malignant melanocytic tumors. The presence of nuclear pseudoinclusions is not a reliable criterion for differentiating melanoma from benign melanocytic lesions, although it is useful in distinguishing melanocytic from non-melanocytic tumors.

- **Inclusion bodies:** Inclusion bodies are tiny aggregates of specific type of protein within the cytoplasm or nucleus of neurons observed. Amyotrophic lateral sclerosis adversely affects motor neurons. Inclusion body myositis adversely affect skeletal muscle cells. Dementia with Lewy bodies adversely affect central nervous system.
  - **Inclusion bodies in skeletal muscles:** Inclusion bodies of aggregations of multiple proteins are also observed in skeletal muscle cells affected by inclusion body skeletal myositis and hereditary inclusion body skeletal myopathy.
  - **Inclusion bodies in neurons:** Inclusion bodies in neurons in the form of misfolded proteins may be accumulated in the cytoplasm or nucleus in the setting of neurodegenerative diseases including Lewy bodies in Lewy body dementias and Parkinson's disease, neuroserpin inclusion bodies called 'Collins bodies' in familial encephalopathy and Huntington's disease, and Papp-Lantos bodies in multiple system atrophy.
  - **Viral inclusion bodies:** Viral inclusion bodies can be cytoplasmic and nuclear eosinophilic (acidophilic), nuclear basophilic. Examples of intracytoplasmic eosinophilic (acidophilic) viral inclusion bodies are Negri bodies in rabies, Henderson-Patterson bodies in molluscum contagiosum, and Guarnieri bodies in variola (smallpox). Examples of intranuclear eosinophilic (acidophilic) viral inclusion bodies are Cowdry bodies type A in herpes simplex viral infection, Cowdry bodies type B in adenovirus viral infection, Torres bodies in yellow fever, and Warthin-Finkeldey bodies in measles and HIV/AIDS. Intranuclear basophilic viral inclusion bodies in cytomegalovirus infection giving 'Owl eye appearance'.
- **Intracellular inclusions not bound by membranes:** Intracellular inclusions are stored nutrients (glycogen in liver, lipids, and proteins), secretory products and pigment granules. Crystalline inclusions are found in Sertoli cells and Leydig cells of human tissues. Intracellular yellow or brown material may include bile, hemosiderin, lipofuscin, melanin pigment chromoblastomycosis.
- **Extracellular matrix inclusions:** Amyloid, monoclonal immunoglobulin deposits, collagen, basement-like material, fibrin, tubular myelin figures (lamellar bodies in lungs), and crystals (such as Charcot-Leydon crystals and crystalloids within the lumens of neoplastic acinic of prostatic carcinoma) and are present in extracellular compartment of tissue.

LEARNING OBJECTIVES

ANATOMY AND PHYSIOLOGY OF BLOOD VESSELS

ARTERIOSCLEROSIS: HISTOLOGIC VARIANTS

ATHEROSCLEROSIS
- Locations of atherosclerosis
- Major and minor risk factors
- Pathogenesis of atherosclerosis
- Complications of atherosclerosis
- Consequences and clinical manifestations of atherosclerosis
- Therapeutics for atherosclerosis

ANEURYSMS
- Aneurysms: overview
- Aneurysms: causes
  - Atherosclerotic aneurysms
  - Syphilitic (luteic) aneurysms
  - Aortic dissecting hematoma
  - Berry aneurysm
  - Mycotic aneurysm
  - Aneurysm of sinus of Valsalva
  - Arteriovenous fistula
  - Capillary microaneurysm

VASCULITIS
- Vasculitis: overview
- Large vessel vasculitides
- Medium vessel vasculitides
- Small vessel vasculitides

VENOUS SYSTEM
- Varicose veins
- Deep vein thrombosis (thrombophlebitis)
- Thoracic vena cava syndrome

LYMPHATIC SYSTEM
- Acute lymphangitis
- Lymphedema
- Chylous effusion

NEOPLASTIC DISORDERS OF BLOOD VESSELS
- Reactive vascular proliferation
- Capillary hemangioma
- Cavernous hemangioma
- Kaposi sarcoma
- Angiosarcoma

HYPERTENSION
- Hypertension: overview
  - Determinants of hypertension
- Essential (primary) hypertension
- Secondary hypertension
- Vascular changes in hypertension
  - Vascular changes in benign hypertension
  - Vascular changes in malignant hypertension
- Complications of hypertension

ANATOMY AND PHYSIOLOGY OF BLOOD VESSELS

Arteries are blood vessels responsible for carrying oxygen-rich blood from the heart to the body. Veins are blood vessels that carry blood low in oxygen from the body back to the heart for oxygenation.

- Large or elastic arteries, e.g. aorta, innominate arteries, subclavian arteries, origin of common carotid arteries and origin of pulmonary arteries.
- Medium-sized/muscular arteries, e.g. radial artery, renal artery and mesenteric artery.
- Small-sized arterioles <2 mm are present within substance of tissues and organs (peripheral resistance vessels). Arterioles consist of three layers: tunica intima, tunica media and tunica adventitia.
- Arterioles transport blood from heart, maintain blood pressure and regulate peripheral resistance through vasoconstriction and vasodilation.
- Capillaries participate in exchange of gases and nutrients between blood and interstitial tissue.
- Venules transport blood from capillary beds toward the heart.
- Vein is composed of tunica intima, thinner tunica media and tunica adventitia. Its lumen is larger than arteries. Veins participate in transport of blood from venules to the heart (Table 15.1).
- Lymphatic system consists of lymphatic vessels, lymphoid organs and lymphoid tissues.

Table 15.1 The structure and function of blood vessels

Blood Vessel	Structure	Function
Artery	▪ Tunica intima, thick tunica media and tunica adventitia ▪ Contractility and elasticity	▪ Transports blood from heart ▪ Maintenance of blood pressure
Arteriole	▪ Tunica intima, tunica media and tunica adventitia ▪ Lumen smaller than artery	▪ Transports blood from heart and maintenance of blood pressure ▪ Regulation of peripheral resistance through vasoconstriction and vasodilation
Capillary	Microscopic size vessel with single-layered endothelium	Exchange of gases and nutrients between blood and interstitial tissue
Venule	Tunica intima, tunica media and tunica adventitia and gradually enlarge as reaching near the heart	Transports blood from capillary beds toward the heart
Vein	▪ Tunica intima, tunica media and tunica adventitia with larger lumen than artery ▪ Presence of valve aids in the unidirectional blood flow towards the heart	Transports blood from venules to the heart
Lymphatic system	Consists of lymphatics, lymph nodes and lymphoid tissues	▪ Maintains fluid levels in our body tissues ▪ Functions as immune system

ARTERIOSCLEROSIS: HISTOLOGIC VARIANTS

Arteriosclerosis is defined as thickening and loss of elasticity (hardening) of arterial walls. It is responsible for morbidity and mortality due to narrowing and weakening of arteries. There are three histologic variants of arteriosclerosis (e.g. Mönckeberg's arteriosclerosis, arteriolosclerosis and atheromatous plaque) described as under.

MÖNCKEBERG'S ARTERIOSCLEROSIS

Mönckeberg's arteriosclerosis is age-related clinically insignificant entity seen in >50 years of age. Calcium is deposited in the media of arteries in a ring-like fashion resulting in stiff pipe stem arteries. Blood vessels are often palpable.

- Calcium deposition in arteries can be demonstrated on radiological examination. This form of Mönckeberg's arteriosclerosis may coexist with atheromatous plaque, but it is distinct and unrelated to it (Fig. 15.1).
- Mönckeberg's arteriosclerosis involves the media of medium-sized muscular arteries, i.e. radial, ulnar, femoral and uterine arteries.
- These calcific deposits do not encroach the lumen of blood vessels; hence blood supply to tissues is not impaired.

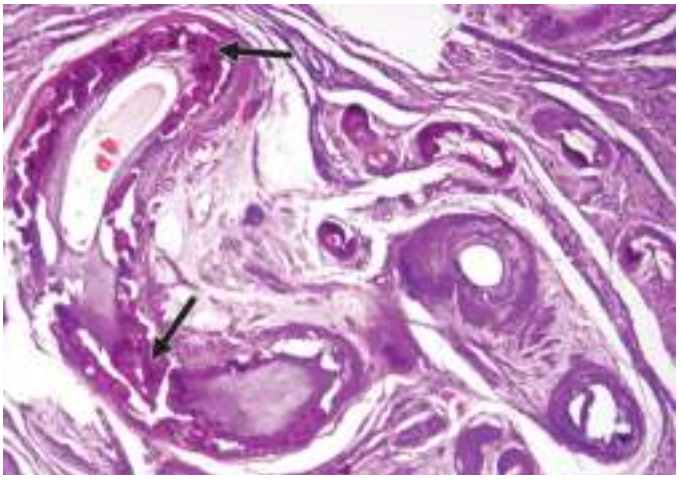

Fig. 15.1: Mönckeberg's arteriosclerosis shows calcium deposition in the media of blood vessels (arrows).

ARTERIOLOSCLEROSIS

Arteriolosclerosis is characterized by thickening of the walls of small arteries and arterioles that narrows the lumen and can lead to ischemia or insufficient blood flow to organs. Hyaline arteriolosclerosis is usually associated with benign hypertension, normotensive elderly persons and diabetes mellitus. Renal arterioles involvement in benign hypertension and malignant

hypertension are known as benign nephrosclerosis malignant hypertension respectively. Renal arterioles in malignant hypertension exhibit two histologic patterns: hyperplastic arteriolosclerosis and fibrinoid necrosis (necrotizing arteriolitis).

HYALINE ARTERIOLOSCLEROSIS

Hyaline arteriolosclerosis is characterized by thickening of the arterioles due to the accumulation of homogenous hyaline material in their walls in the kidneys of patients who have diabetes mellitus or benign arterial hypertension. Hyaline material in arterioles stains eosinophilic pink in hematoxylin and eosin-stained tissue sections. The increased intraluminal pressure in benign hypertension imposed on the arteriolar walls drives proteins and get deposited into the subintimal region of arterioles and occlude the lumen leading to progressive organ atrophy (Fig. 15.2).

HYPERPLASTIC ARTERIOLOSCLEROSIS

Hyperplastic arteriolosclerosis is characterized by thickening of the wall of arterioles due to proliferation of smooth cells arranged in concentric laminated pattern exhibiting an '**onion-skin pattern**'. There is subsequent marked narrowing of the lumen of arterioles. These changes represent an adaptive response of arterioles to severe (malignant) hypertension and progressive systemic sclerosis. Hyperplastic arteriolosclerosis may be accompanied by damage to arterioles known as fibrinoid necrosis (Fig. 15.3).

FIBRINOID NECROSIS OF ARTERIOLES

Fibrinoid necrosis of arterioles is most often associated with malignant hypertension with diastolic blood pressure >120 mm Hg and immune complex vasculitis that can lead to bleeding and organ damage throughout the body. Histologic examination reveals arterioles exhibiting intraluminal deposition of fibrinoid material, vascular necrosis, inflammation, focal hemorrhage and narrow and fixed lumen (Fig. 15.4).

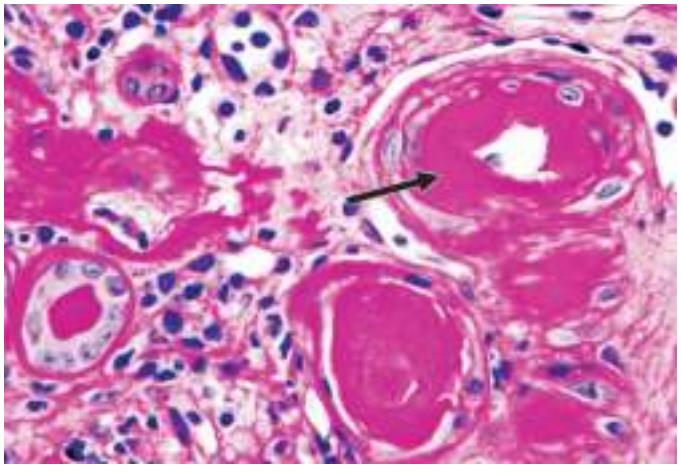

Fig. 15.2: Hyaline arteriolosclerosis (arrow) (400X).

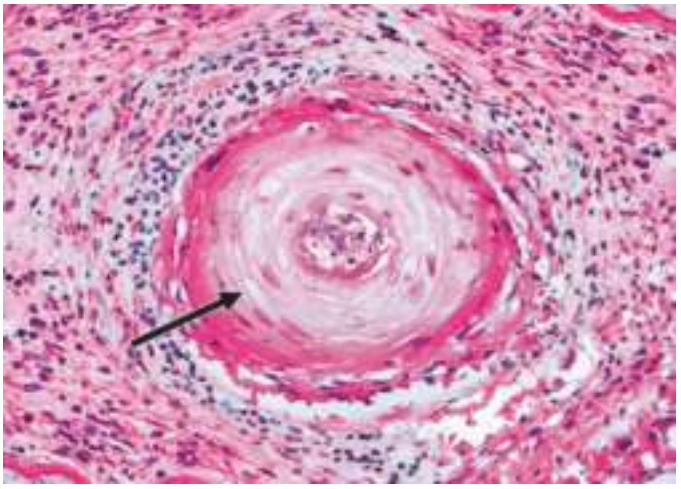

Fig. 15.3: Hyperplastic arteriolosclerosis—blood vessel shows proliferation of intimal and smooth muscle cells arranged in concentric laminated pattern exhibiting an onion-skin pattern (arrow) (400X).

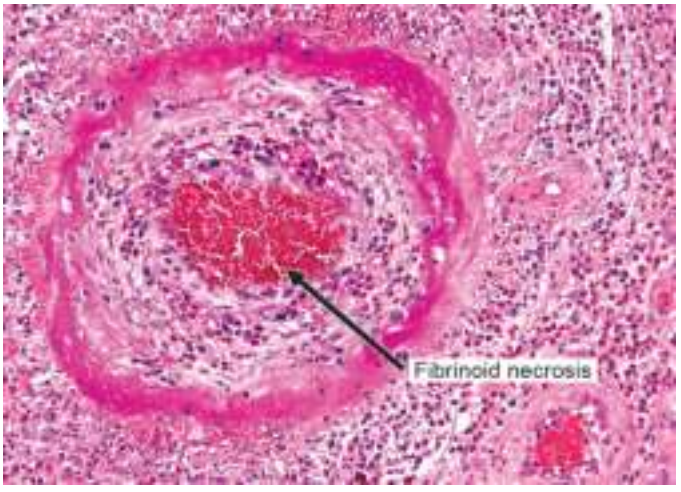

Fig. 15.4: Fibrinoid necrosis. Malignant hypertension leads to fibrinoid necrosis of small arteries as shown here. The damage to the arteries leads to formation of pink fibrin, hence the term fibrinoid (arrow) (400X).

ATHEROMATOUS PLAQUE

Atherosclerosis is a progressive thickening and hardening of medium and large elastic arteries as a result of lipid deposition on their intima. Atheromatous plaques are most often eccentrically located in the arterial lumen as a result of vascular hemodynamic stress at branching points and posterior wall of the abdominal aorta.

ATHEROSCLEROSIS

Atherosclerosis is hardening and narrowing of arteries caused by the deposition of lipids, cholesterol, calcium, and other substances in the innermost layer of endothelium of the large- and medium-sized arteries. Risk factors include hyperlipidemia, hypertension, diabetes mellitus, tobacco smoking, obesity, lack of exercise and diet high in saturated fat. Atheromatous lesions are frequently found in the aorta and in large aortic branches, which may cause partially or total blockage of blood flow through the arteries supplying vital body organs (i.e. heart, brain, kidneys) and lower extremities. Patient may develop angina pectoris, myocardial infarct, cerebral stroke, renal infarct and peripheral vascular disease.

Clinical Pearls: Atheromatous Plaque

- Atherosclerosis occurs due to focal accumulation of lipid in the intima of the large elastic and medium size arteries with inflammation and fibrosis forming atheromatous plaques. It causes luminal narrowing, associated with ischemia in the heart, brain, intestine, lower extremities and kidneys. Atheromatous plaque rupture with superimposed thrombosis causes acute tissue ischemia and infarction.
- Acute myocardial infarction, cerebral stroke and peripheral vascular disease are the main causes of morbidity and mortality in developed countries.
- Overtime, atheroma undergoes changes resulting in complicated plaque. Occlusive atheroma occludes most of the artery's lumen leading to tissue/organ ischemia. On the other hand, in ruptured atheroma, fissures of the fibrous cap and defects of the endothelial lining cause thrombosis and embolism. The formation of an occlusive thrombus over a ruptured atheromatous plaque in coronary arteries is the most important cause of myocardial infarction. Removal of the thrombus by coronary angioplasty or administration of tissue plasminogen activator (tPA) may save the patient's life.
- Clinical management of atherosclerosis is based on minimizing risk factors. Hypertension is controlled by antihypertensive medication (e.g. diuretics, β-blockers), HMG-CoA reductase inhibitors (statins-lipid lowering agents), anticoagulants, i.e. 75 mg aspirin daily to minimize thrombotic risk; and lifestyle advice (e.g. stopping tobacco smoking, healthier diet and increasing exercise).

LOCATIONS OF ATHEROSCLEROSIS

Atheromatous plaques formed in the large and medium size arteries include abdominal aorta, proximal region of coronary arteries, carotid arteries, vertebral arteries (circle of Willis), iliac arteries, popliteal artery, anterior tibial artery, posterior tibial artery, and renal artery. Arteries of the upper extremities and internal mammary artery are always spared. This is the reason that internal mammary artery is used as graft in coronary artery bypass surgery. Depending on the duration of ischemia to tissues/organs, main clinical syndromes caused by atheromatous plaque are given in Table 15.2. Locations of atheromatous plaques in order of frequency and clinical manifestations are shown in Fig. 15.5.

Table 15.2 Main clinical syndromes caused by atheromatous plaque

Atheromatous Plaque Location and Clinical Manifestations	
Ischemic Heart Disease (Coronary Arteries Involved)	
▪ Angina pectoris (intermittent ischemia)	▪ Heart failure
▪ Myocardial infarction (acute ischemia)	▪ Chronic ischemic heart disease
▪ Sudden cardiac death (SCD)	
Cerebrovascular Disorders (Internal Carotid and Middle Cerebral Artery Involved)	
▪ Transient cerebral ischemic attacks (transient ischemia)	▪ Dementia (arteriopathic)
▪ Cerebral stroke/infarction (acute ischemia)	
Mesenteric Vascular Disease (Celiac, Superior and Inferior Mesenteric Artery Involved)	
▪ Intestinal infarction/gangrene intestine (acute ischemia)	▪ Mesenteric claudication also known as abdominal angina (intermittent ischemia)
Peripheral Vascular Disease (Popliteal, Anterior Tibial and Posterior Tibial Artery Involved)	
▪ Intermittent claudication (intermittent ischemia)	▪ Gangrene foot (acute ischemia)
Renovascular Diseases (Extrarenal or Intrarenal, Renal Artery Involved)	
▪ Hypertension	▪ Renal failure
Aneurysm (Abdominal Aorta)	
Abdominal aortic aneurysm associated with rupture	

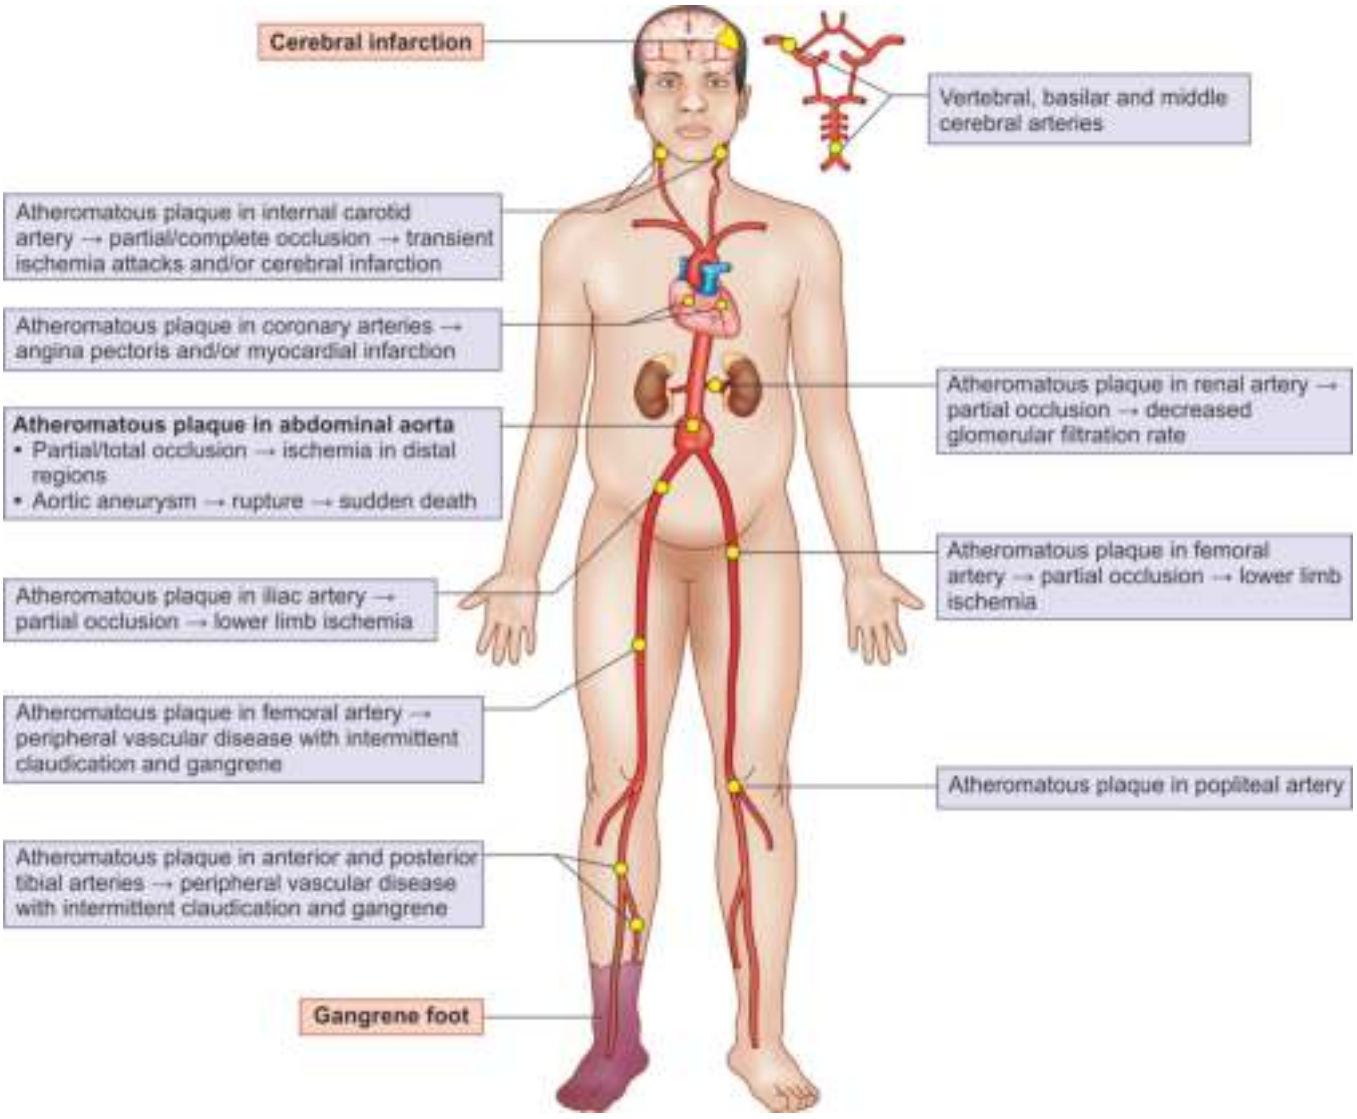

Fig. 15.5: Locations of atheromatous plaques in order of frequency and clinical manifestations.

MAJOR AND MINOR RISK FACTORS

Major modifiable risk factors for atherosclerosis include hyperlipidemia, hypertension, tobacco smoking and diabetes mellitus; and nonmodifiable factors are increasing age, male gender, family history of atherosclerosis and genetic abnormalities (ApoA1, ApoE, hepatic lipase and LDL receptor). Minor risk factors include obesity, stress type A personality, thrombophilia, high intake of carbohydrates, homocysteinemia, racial factors and infectious agents. Major and minor risk factors for atherosclerosis are given in Table 15.3.

HYPERLIPIDEMIA

Disorders of the lipid metabolism play major role in the pathogenesis of atherosclerosis and coronary artery disease. A clear-cut relationship is evident between elevated serum cholesterol and myocardial infarction. At the tissue level, cholesterol deposits occur in areas of endothelial cell damage in atheromatous plaques. Normally, cholesterol is a vital structural component of cell membranes and a source of steroid hormone. Cholesterol and triglycerides are the most important lipids in the study and management of coronary artery disease. Increased LDLs and IDLs are directly related to the risk for atherosclerosis. On the other hand, increased HDL exerts protective effect of risk for atherosclerosis by removing cholesterol from the tissues.

Major Lipoprotein Classes

Lipids are soluble in nonpolar solvents, such as ether and chloroform; but relatively insoluble in polar solvents such as water. Thus, triglycerides and cholesterol circulate in plasma as a part of watersoluble lipoproteins. The lipoproteins act as lipid shuttle, which transport cholesterol through the blood stream. Apolipoproteins

Table 15.3 Major and minor risk factors for atherosclerosis

Risk Factors	Comments
Major modifiable risk factors	
Hyperlipidemia	Diet high in saturated fats, diabetes mellitus, hypothyroidism, hepatic metabolic syndrome and nephrotic syndrome (hyperlipidemia controlled by diet and lipid lowering drugs)
Hypertension	Persistent high blood pressure
Diabetes mellitus	Fasting sugar >126 mg/dl, random blood sugar >200 mg/dl (advanced glycosylated end products atherogenic)
Tobacco smoking	Tobacco smoking injures vascular endothelium, causes deranged lipid profile (increased LDL, decreased HDL) and promotes aggregation of platelets in the intima of atheromatous plaque
Sedentary lifestyle	Accelerates atherosclerosis (prevented by regular exercise)
Major nonmodifiable risk factors	
Increasing age	Aging process results in loss of elasticity of blood vessels (peak incidence at 60 years in men and >70 years in women)
Male gender	Men (>55 years) are more affected than women (>45 years), high estrogen and HDL are antiatherogenic influence in premenopausal women
Family history of premature atherosclerosis	Premature atherosclerosis incidence in children
Genetic abnormalities	▪ ApoA1 mutation: Severe atherosclerosis ▪ ApoE mutation: Premature atherosclerosis ▪ Hepatic lipase deficiency: Premature atherosclerosis ▪ LDL receptor mutation: Premature atherosclerosis by inhibiting cholesterol uptake by liver
Minor risk factors	
Obesity	Obesity is most important risk factor for atherosclerosis
Stress type A personality	Incidence is more in these persons
Factors affecting thrombosis	Factor V Leiden, prothrombin G20210A mutation, antithrombin III deficiency, protein C deficiency, protein S deficiency, activated protein C resistance
High intake of carbohydrates	Accelerates atherosclerosis
Homocysteinemia	>100 µmol/L
Racial factors	White population is more affected than Black persons
Infectious agents	*Chlamydia pneumoniae*, *Helicobacter pylori*, herpesvirus, cytomegalovirus promote atherosclerosis

(Apo) are the protein moiety of lipoproteins. Four major lipoprotein classes have been identified based on the buoyant density of the lipid particles: chylomicron (**CM**), very lowdensity lipoprotein (**VLDL**), lowdensity lipoprotein (**LDL**) and highdensity lipoprotein (**HDL**). Several minor lipoproteins have been identified such as intermediatedensity lipoproteins and lipoprotein-a, i.e. Lp-a. LDL and intermediate-density lipoproteins (**IDLs**) are bad cholesterol and directly related to the risk of atherosclerosis. Major classes of human plasma lipoproteins are given in Table 15.4 and Fig.15.6. Relative concentration of lipoprotein fractions is analyzed as clinical predictors for development of atherosclerosis. Ideally, the ratio between LDL cholesterol to HDL cholesterol should be 4:1. Desirable lipid profile is given in Table 15.5.

Table 15.4 Major classes of human plasma lipoproteins

Lipid Particle	Major Apolipoproteins
Chylomicrons	ApoA-1, ApoA-IV, ApoC-1, ApoC-II, ApoC-IIIE
VLDL	ApoB-100, ApoC-I, ApoC-II, ApoC-IIIE
IDL	ApoB, ApoE1.006–1.019
LDL	ApoB-100
HDL2	ApoA-II, ApoA-I, ApoE
HDL3	ApoA-II, ApoA-I, ApoE
La(a)	ApoB-100, Apo(a)

Exogenous and Endogenous Transport Pathways

Exogenous and endogenous pathways for triglyceride and cholesterol transport are shown in Fig. 15.7.

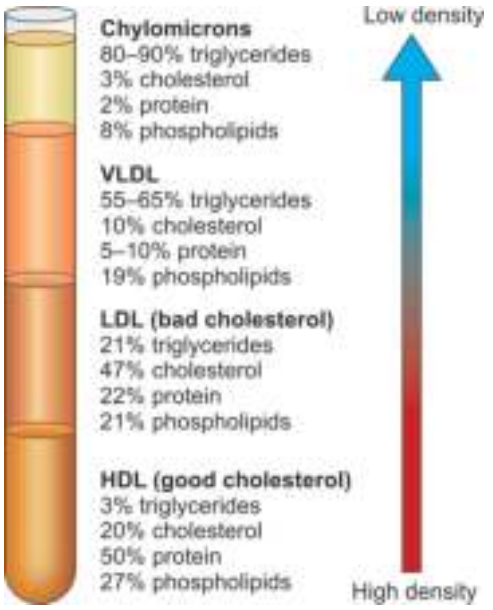

Fig. 15.6: Major classes of human plasma lipoproteins. Lipoproteins are named on their protein content, which is measured in density. These include chylomicrons, VLDL, LDL and HDL. Lipids are less dense than proteins. As the proportion of triglyceride decreases, the density increases.

Table 15.5 Desirable lipid profile

Parameters	Lipid Fraction Range
▪ Cholesterol	<200 mg/dl
▪ Triglyceride	<150 mg/dl
▪ LDL	<100 mg/dl
▪ HDL	>60 mg/dl
▪ Ratio of LDL cholesterol to HDL cholesterol	4:1

- **Exogenous pathway for triglyceride and cholesterol transport:** In the exogenous pathway, cholesterol and fatty acids from food are absorbed through intestinal mucosa. Fatty acid chains are linked to glycerol to form triglycerides. Cholesterol and triglycerides are packaged into chylomicrons and returned via the lymph into the blood circulation. The lipids are coupled to proteins by enzymes. The ester bonds holding the fatty acids in glycerides are split by lipoprotein lipase in the capillaries of adipose tissue and skeletal muscles. Now the fatty acids are removed, leaving cholesterol-rich lipoprotein remnants. These lipoprotein remnants bind to special remnant receptors and are taken up by hepatocytes.
- **Endogenous pathway for triglyceride and cholesterol transport:** The cholesterol of the lipoprotein remnant is either secreted into the intestine, largely as bile

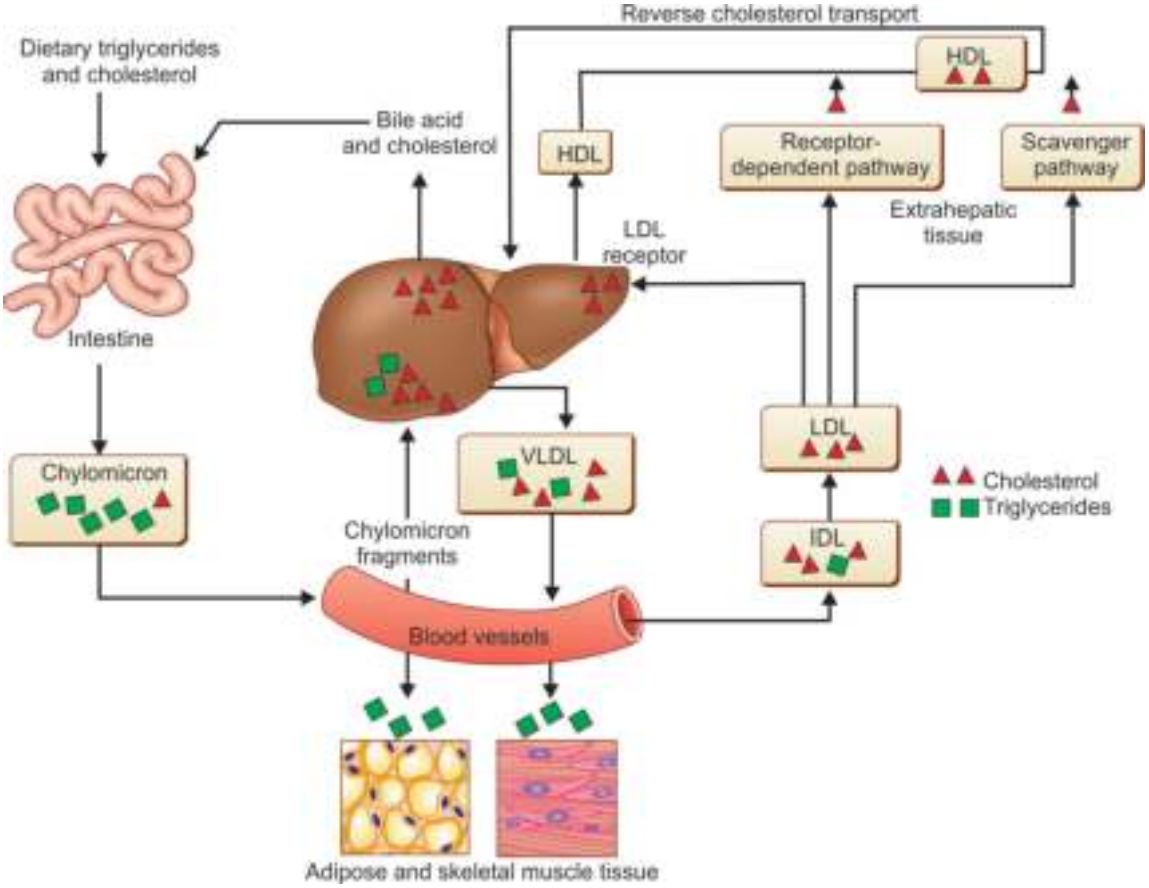

Fig. 15.7: Exogenous and endogenous pathways for triglyceride and cholesterol transport.

acids, or packaged as very low-density lipoprotein (VLDL) particles, which are then secreted into the blood circulation. This is the first step in the endogenous pathway for lipid transport. In adipose tissue or skeletal muscles, the triglyceride is removed from VLDLs with the help of lipoprotein lipase. The intermediate density lipoprotein (IDL) particles remain in the blood circulation. Some IDLs are immediately taken up by hepatocytes via the mediation of LDL receptor for ApoB/ApoE. The remaining IDLs in the blood circulation bind to the hepatocytes and other cells, and are removed from the blood circulation. HDLs take up cholesterol from the cells. The cholesterol is now esterified by the enzyme lecithin cholesterol acyltransferase, after which the esters are transferred to LDLs and then taken up by the cells. Classification of total LDL cholesterol in children with targeting fasting screening in children over age two years with family history of dyslipidemia or premature coronary artery disease is given in Table 15.6.

Apolipoproteins (Apo) and Dyslipoproteinemias

Apolipoproteins (Apo) constitute the major protein moiety of lipoproteins. These are commonly referred by using the nomenclature introduced in 1971. Apolipoproteins, their major sites of synthesis and functions are given in Table 15.7.

Familial Hypercholesterolemia

Familial hypercholesterolemia is inherited autosomal disorder, that causes LDL (bad) cholesterol level to be

Table 15.6 Classification of total LDL cholesterol in children with targeting fasting screening in children over age two years with family history of dyslipidemia and premature coronary artery disease

Category	Total Cholesterol	LDL Cholesterol
Acceptable	>170 mg/dl	<110 mg/dl
Borderline	171–199 mg/dl	111–129 mg/dl
High	≥200 mg/dl	≥130 mg/dl

Table 15.7 Apolipoproteins, their major sites of synthesis and functions

Apolipoprotein	Major Density Class	Chromosome	Major Sites of Synthesis	Functions in Lipoprotein Metabolism
ApoAI	HDL	11	Liver, intestine	Activation of lecithin: Cholesterol acyltransferase
ApoAII	HDL	1	Liver, intestine	Unknown
ApoAIV	Chylomicrons	11	Intestine	Unknown
ApoB-100	VLDL, IDL, LDL	2	Liver	Binds to LDL receptor
ApoB-48	Chylomicrons, VLDL, IDL	2	Intestine	Unknown
ApoCI	Chylomicrons, VLDL, HDL	19	Liver	Activation of lecithin: Cholesterol acyltransferase
ApoCII	Chylomicrons, VLDL, HDL	19	Liver	Activation of lipoprotein lipase
ApoCIII	Chylomicrons	11	Liver	Inhibition of lipoprotein uptake by the liver
ApoD	HDL	3	Unknown	Cholesteryl ester exchange protein
ApoE	Chylomicrons, VLDL, HDL	19	Liver, macrophage	Binds to E receptor
ApoF	VLDL	12	–	Transport and/or esterification of cholesterol
ApoH	VLDL	17	–	Encoded by APOH gene and function is to bind cardiolipin
ApoJ	HDL	8	–	Encoded by CLU gene on chromosome 8, regulates cholesteryl ester transfer protein (CETP)
ApoL	HDL	22	–	May be linked to reverse cholesterol transport
ApoM	Chylomicrons, VLDL, LDL, HDL	6	–	May be linked to reverse cholesterol transport
ApoO	HDL, LDL, VLDL	X	–	Homologue to plasminogen, may be prothrombotic, bound to ApoB-100 by disulfide bond
Apo(a)	Lp(a)	6	–	Carries cholesterol load has role in wound healing

LDL: Low density lipoprotein; IDL: Intermediate density lipoprotein; HDL: High density lipoprotein.

very high. The condition begins at birth and can cause myocardial infarction at an early age. The defect makes the body unable to remove LDL from the blood. It results in a high level of LDL in the blood circulation, which is deposited in the large elastic and medium size arteries. These blood vessels show atheromatous plaques in the intima encroaching lumen.

- Mutations of ApoA1, ApoE and LDL receptor; and hepatic lipase deficiency leads to hypercholesterolemia. Cholesterol gets deposited in the intima of large elastic and medium size arteries.
- Normally, LDL receptors are cell surface proteins, which regulate plasma cholesterol by mediating endocytosis and recycling of apolipoprotein E. Capillary lipoprotein lipase participates in degradation of lipids.
- Gene mutations of apolipoproteins lead to defective assembly of lipid with apolipoprotein. Defective LDL receptors lead to defective internalization of lipids. Defective capillary lipoprotein lipase leads to defective degradation of lipids. Net result of defective degradation of lipids is hypercholesterolemia.
- High level of cholesterol in the blood is endocytosed by tissue macrophages in the large elastic and medium size arteries; and under skin resulting in atherosclerosis and xanthomas respectively. Molecular defects of dyslipoproteinemias and pathologic features are given in Table 15.8. Serum lipids and dyslipoproteinemias are given in Table 15.9.

Table 15.8 Molecular defects of dyslipoproteinemias and pathologic features

Defects in Apolipoprotein, Enzymes and Receptors	Genetic Defect	Pathologic Features
Apolipoprotein defects		
ApoAI deficiency	ApoAI cutting or rearrangements (11q23)	▪ HDL absence ▪ Severe atherosclerosis
ApoAI variant deficiency	ApoAI point mutation (11q23)	▪ Reduced HDL level ▪ Severe atherosclerosis
ApoB-100 and ApoB-48 deficiency	Microsomal triglyceride protein mutation (4q22–24)	▪ Hemolytic anemia ▪ Mild ataxia, malabsorption ▪ Visual disturbance ▪ Absence of atherosclerosis
ApoB-100 deficiency	Mutation (2p24)	▪ Mild ataxia ▪ Malabsorption ▪ Absence of atherosclerosis
ApoCII deficiency	ApoCII mutation (19q13.2)	▪ Type I hyperlipidemia ▪ Severe hypertriglyceridemia ▪ Variable atherosclerosis
ApoE variant deficiency	ApoE mutation (19q13.2)	▪ Type III hyperlipidemia ▪ Elevated hypertriglyceridemia ▪ Premature atherosclerosis
Enzyme defects		
Lipoprotein lipase deficiency	Lipoprotein lipase mutation (8p22)	▪ Type I hyperlipidemia ▪ Hypertriglyceridemia ▪ Minimal atherosclerosis
Hepatic lipase deficiency	Hepatic lipase mutation (8p21–23)	▪ Elevated IHD and HDL levels ▪ Severe atherosclerosis
Lecithin: Cholesterol acyltransferase (LACT) deficiency	LCAT mutation (16q22.1)	▪ Mild hypertriglyceridemia ▪ Reduced HDL ▪ Variable atherosclerosis ▪ Corneal opacities
Receptor defect		
Familial hypercholesterolemia	LDL receptor mutation (19p13.2)	▪ Type II hyperlipidemia with severe elevation of LDL ▪ Premature atherosclerosis

LDL: Low density lipoprotein; IDL: Intermediate density lipoprotein; HDL: High density lipoprotein.

Table 15.9 Serum lipids and dyslipoproteinemias

Most useful lipid and lipoprotein testing are done by enzymatic analysis
Low-density lipoprotein cholesterol can be analyzed after fasting. It is currently considered the most important value in assessing risk for ischemic heart disease and directing therapy
Lipid profile currently recommended for initial screening in persons includes total cholesterol, low density lipoproteins, high density lipoproteins and triglycerides. Testing should be repeated at least once every five years
Other tests, including apolipoprotein levels and lipoprotein subclasses, may prove valuable in fine-tuning risk assessment and evaluating response to therapy
New guidelines enhance the perceived atherosclerotic plaque risk due to diabetes mellitus and support aggressive intervention in patients suffering from diabetes mellitus and metabolic syndrome

Acquired Hypercholesterolemia

Foods rich in cholesterol, saturated fat and *trans*-fats can raise blood cholesterol. Foods rich in fat include cheese, egg yolk, fried and processed food, pastries and red meat. High intake of these dietary products is associated with atherosclerosis.

- On the other hand, unsaturated fatty acids in ground nut consist of double bond with low melting point, hence less stable and not deposited in the arteries and under skin. Hypercholesterolemia can occur in the settings of diabetes mellitus, hypothyroidism and nephrotic syndrome. Progesterone therapy increases plasma levels of LDL, cholesterol and triglyceride and decreases HDL level.

Clinical Pearls: Lipid Lowering Drugs (Statins) in Hypercholesterolemia

- Diet regulation and administration of lipid lowering drugs have beneficial effect on reducing the risk for development of atherosclerosis in large elastic and medium size arteries supplying organs/tissues. Intake of omega-3 fatty acid derived from fish oil is beneficial to lower plasma cholesterol levels.
- Statins are lipid lowering drugs, which inhibit HMG-CoA reductase, which is rate-limiting enzyme in hepatic biosynthesis of cholesterol.
- Regular exercise, weight loss, intake of ethanol and estrogen intake increase HDL and decrease LDL cholesterol.

HYPERTENSION

Uncontrolled blood pressure is a major risk factor for atheromatous plaque. Persistent high systolic blood pressure over 160 mm Hg increases the risk for myocardial infarction and cerebral stroke. The use of antihypertensive drugs has significantly decreased the risk for myocardial infarction and cerebral stroke.

- Hypertension enhances the severity of atherosclerotic plaques further supports a role for hemodynamic disturbances inducing several factors in the development of atherosclerotic plaques.
- Hemodynamic forces induce gene expression patterns in the endothelial cells that promote atherosclerosis, e.g. endothelin, platelet endothelial cell adhesion molecule 1 (PECAM-1), FGF2, tissue factor and plasminogen activator.

DIABETES MELLITUS

Both type 1 and type 2 diabetes mellitus are powerful and independent risk factors for coronary artery disease, cerebral strokes and peripheral vascular disease. Atherosclerosis accounts for virtually 80% of all deaths among diabetic patients. Microvascular complications include retinopathy, nephropathy and neuropathy.

- Prolonged exposure to hyperglycemia induces a large number of alterations at cellular levels of vascular tissue that potentially accelerates atherosclerotic process.
- Increased plasma glucose combines with apolipoproteins and other proteins to form Schiff base (reversible reaction by controlling plasma glucose). Schiff base is converted to early glycosylated end products and then to advanced glycosylated end products. Glycosylation is a process affecting circulating lipoproteins and protein component of the vasculature. Advanced glycosylated end products play important role in the pathogenesis of atherosclerosis. Glycosylated LDL is less susceptible to oxidation and thus delivers cholesterol to vasculature.
- Human studies have elucidated major mechanisms that encompass most of the pathologic alterations in diabetic vasculature. Nonenzymatic glycosylation of proteins and lipids can interfere with normal function by disrupting molecular conformation, alter enzymatic activity and interfere with receptor recognition. In addition, glycosylated proteins interact with specific receptors present on all the cells in atherosclerotic plaque, including endothelial cells, monocyte-derived macrophages and smooth muscle cells. The interaction of glycosylated proteins with their receptors leads to induction of oxidative stress and proinflammatory responses. Protein kinase C (PKC) activation leads to subsequent alterations in expression of growth factors.

Clinical Pearls: Glycosylated Hemoglobin (HbA1C) Analysis

- Glycosylated hemoglobin (HbA1C) is a form of hemoglobin that is covalently bound to glucose. Hemoglobin is exposed to glucose in the blood and both are bound together through the glycosylation process.

- HbA1C is a measure of the β-N-1-deoxy fructosyl component of hemoglobin.
- Glycosylated hemoglobin is tested to monitor the long-term diabetes mellitus to assess average blood sugar over the past 2–4 months.
- Normal range for HbA1C is <6%; and 6–6.4% in prediabetics. An HbA1C of 6.5 is recommended as the cut off point for diagnosing diabetes mellitus.

TOBACCO SMOKING

Tobacco smoking is an important major risk factor for atherosclerosis. Tobacco smoke contains tar, polycyclic aromatic hydrocarbons, nicotine, phenol, nitrosamines, nitrogen oxide and carbon monoxide. Prolonged tobacco smoking doubles the death rate from ischemic heart disease. Tobacco smoke causes endothelial dysfunction, deranged lipids (increased LDL and decreased HDL), increase adhesiveness and activation of platelets.

INFECTIONS AND ATHEROSCLEROSIS

Serological and epidemiological studies suggest that some infectious agents such as *Chlamydia pneumoniae*, cytomegalovirus, *Helicobacter pylori*, herpesvirus may participate in the pathogenesis of atherosclerosis. DNA obtained from these infectious agents has been demonstrated in atheromatous plaque, but the nature of their association is obscure.

HOMOCYSTEINEMIA

Homocysteinemia is rare autosomal recessive disorder caused by mutation in gene encoding homocysteine synthase. The disorder enhances formation of premature and severe atheromatous plaque. Raised plasma homocysteine level is an independent risk factor for atheromatous plaque.

- Homocysteine has toxic effects on endothelial cells resulting in impairment of several antithrombotic mechanisms in endothelial cells.
- Homocysteine inhibits thrombomodulin on the surface of endothelial cells, antithrombin III binding activity of heparan sulphate proteoglycans and binding of tissue plasminogen activator, which accelerates atherosclerosis.

FAMILIAL GENETIC ALTERATIONS

Family history is the most important independent factor for atherosclerosis. Familial hypercholesterolemia is well established risk factor for atherosclerosis and ischemic heart disease. Familial clustering of diabetes mellitus and hypertension may predispose to premature atherosclerosis.

GENDER PREDILECTION

Premenopausal women are relatively protected against atherosclerosis due to increased estrogens compared with age-matched men. Estrogens have antiatherogenic properties. Postmenopausal women are more prone to develop atherosclerosis as a result of decreased circulating estrogens.

INFLAMMATION DURING ATHEROGENESIS

Inflammation is present during all stages of atherogenesis. It is linked with atheromatous plaque formation and its disruption. C-reactive protein is increased in disrupted atheromatous plaque. It is an acute phase reactant synthesized in the liver. Its expression is enhanced by IL-6 cytokine. Increased plasma level of C-reactive protein is an independent risk factor for coronary artery disease, sudden cardiac death, cerebral stroke and peripheral arterial disease.

Clinical Pearls: C-Reactive Protein Analysis

- Estimation of C-reactive protein synthesized by liver is an important marker in inflammation and disrupted atheromatous plaque with superimposed thrombosis.
- C-reactive protein level is increased in patients with disrupted atheromatous plaque with superimposed thrombosis in acute myocardial infarction, cerebral stroke and peripheral vascular disease.

PATHOGENESIS OF ATHEROSCLEROSIS

Over the years, many theories have been proposed to explain the pathogenesis of atherosclerosis. With the new knowledge from experimental and clinical observations, a comprehensive description of the pathogenesis of atheroma formation, evolution and clinical features of the atheromatous plaques vary from patient to patient.

- Virchow in 1952 stated that atherosclerosis occurs due to low-grade inflammation of blood vessels. Imbibing of lipids from the blood causes proliferation of the intimal cells. Rokitansky in 1852 stated that incorporation of small thrombus results in formation of atheromatous plaque.
- According to monoclonal hypothesis, atherosclerosis was suggested as a neoplastic lesion due to monoclonal proliferation of smooth muscle cells as a result of alterations in lipoproteins. Response to injury hypothesis is most widely accepted. Injury to intima results in dysfunctional endothelium. Lipids and monocytes from blood reach subintimal region through dysfunctional endothelium. Lipid accumulation in the macrophages, synthesis of cytokines and migration of smooth muscle cells lead to formation of atheromatous plaque.

- Atherosclerosis progresses through endothelial injury and dysfunction, accumulation of lipoproteins, monocyte adhesion to endothelium and transmigration into intima, platelet adhesion and activation, growth factors synthesized by endothelium, macrophages, smooth muscle cells and T cells; smooth muscle proliferation and synthesis of extracellular matrix (ECM) and lipid accumulation. Pathogenesis of atheromatous plaque and its complications is shown in Fig. 15.8.

CHRONIC INJURY TO VASCULAR ENDOTHELIUM

Hyperlipidemia, sustained hypertension, tobacco smoking, diabetes mellitus, homocysteinemia, hemodynamic disturbances at ostia, branching points, reactive oxygen species and infectious agents cause chronic endothelial injury of large elastic and medium size arteries resulting in dysfunctional endothelium.

- The dysfunctional endothelium is more permeable to lipoproteins and monocytes. Hyperlipidemia can

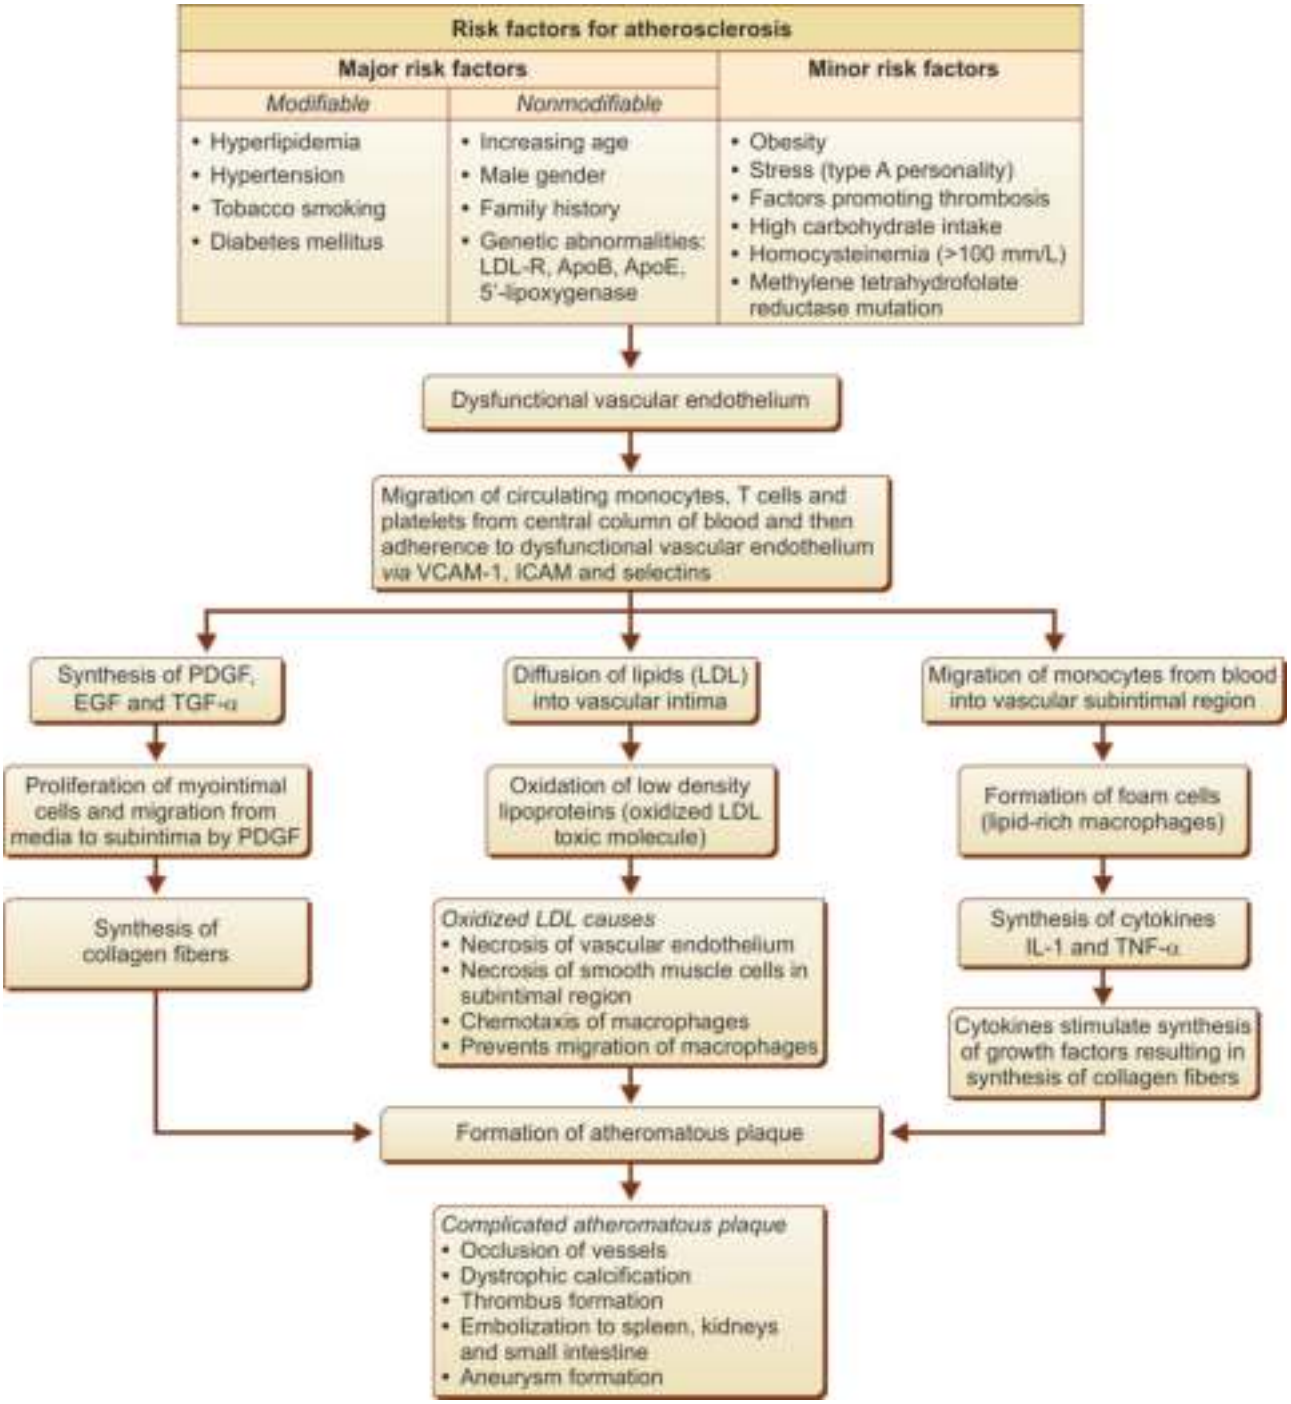

Fig. 15.8: Pathogenesis of atheromatous plaque and its complications.

directly impair endothelial function. Lipids increase production of reactive oxygen species, which decay nitrous oxide (vasodilator). Lipids also increase local shear and stress.

- However, hemodynamic disturbances and hypercholesterolemia are the most important causes of dysfunctional endothelium.
- Hemodynamic disturbances occur at the ostia of exiting blood vessels, branching points and along the posterior wall of the abdominal aorta. Laminar blood flow induces superoxide dismutase antioxidant, which gives protection against atherosclerosis.

ADHERENCE OF BLOOD CELLS TO DYSFUNCTIONAL VASCULAR ENDOTHELIUM

At the sites susceptible to development of atheromatous plaque, expression of proinflammatory genes leads to synthesis of cell adhesion molecules such as vascular cell surface adhesion molecule 1 (VCAM-1) and intercellular adhesion molecule 1 (ICAM-1), which recruit monocytes into the vessel wall. However, stress and shear also induce gene expression and synthesis of antiatherogenic agents such as nitrous oxide (vasodilator) and plasminogen activator inhibitor 1 (PAI-1).

HEMODYNAMIC FORCES

Hypertension enhances the severity of atherosclerotic plaques further supports a role for hemodynamic forces induce several factors in the development of atherosclerotic plaques. Hemodynamic forces induce gene expression and synthesis of endothelin, fibroblast growth factor 2, tissue factor and plasminogen activator in the endothelial cells, which promote atherosclerosis.

INFLUX OF MONOCYTES

Monocyte-macrophage recruitment is one of the early events in the development of atheromatous plaque. It is orchestrated through a multistep process involving adhesion, transmigration and chemotaxis. Adhesion of monocytes–macrophages is regulated by cell surface adhesion molecules including VCAM-1, ICAM-1, E-selectin, P-selectin and several chemokines such as monocyte chemotactic protein 1 (MCP-1) and macrophage colony stimulating factor (M-CSF). Transmigration involves platelet endothelial cell adhesion molecule 1 (PECAM-1). Chemokines (MCP-1 and M-CSF) participate in recruitment of additional monocytes in blood vessel wall.

INFLUX OF LIPIDS AND OXIDIZED LDL MOLECULE

Lipid accumulation depends on disruption of integrity of the endothelial barrier through inter-endothelial gaps and endothelial dysfunction. Dysfunctional endothelium is caused by hypercholesterolemia, abnormal laminar flow, reactive oxygen species, cytokine-induced inflammation, advanced glycosylated end products in diabetes mellitus and homocysteinemia.

- Platelet synthesizes malondialdehyde enzyme that acts on the LDL molecule, which gets converted to modified LDL molecule. LDL carries lipids into the intima. Modified LDL molecule enters the subintimal region. Oxygen reactive species synthesized by macrophages and dysfunctional endothelium participate in the oxidation of LDL molecule to form oxidized LDL molecule.
- Oxidized LDL activates cell surface adhesion molecules. Macrophages can adhere to activated endothelial cells and transmigrate between endothelial cells into the intima, carrying lipids with them.

Uptake of Oxidized LDL Molecule by Macrophages

Monocyte-derived macrophages express receptors such as β-VLDL receptors and scavenger receptors, which bind modified LDL molecule. Lipid laden macrophages are known as foam cells. Smooth muscle cells also imbibe LDL molecules. Some of foamy macrophages laden with lipid undergo necrosis and release lipids in extracellular compartment. Alterations in extracellular matrix proteoglycans synthesized by smooth muscle cells in the intima also render these sites prone to lipid accumulation. Reduced egression of lipids out of artery also promotes accumulation of lipid. Accumulation of cholesterol in foam cells leads to mitochondrial dysfunction, apoptosis, necrosis and release of cellular proteases, inflammatory cytokines and prothrombotic molecules.

Toxic Effects of Oxidized LDL Molecules

Oxidized LDL molecules imbibed by macrophages and smooth muscle cells play important role in the pathogenesis of atheromatous plaque.

- Oxidized LDL molecules cause necrosis of foamy macrophages, smooth muscle cells and endothelium. Oxidized LDL molecules participate in the recruitment of additional monocyte-derived macrophages with the help of monocyte-binding protein synthesized by endothelium; and also inhibit egression of macrophages.
- LDL molecules also participate in migration of smooth muscle cells from media to subintimal region. Role of oxidized low-density lipoproteins in the pathogenesis of atheromatous plaque is shown in Fig. 15.9.
- The nuclear factor-κB (NF-κB) pathway is an important signal transduction system that participates in

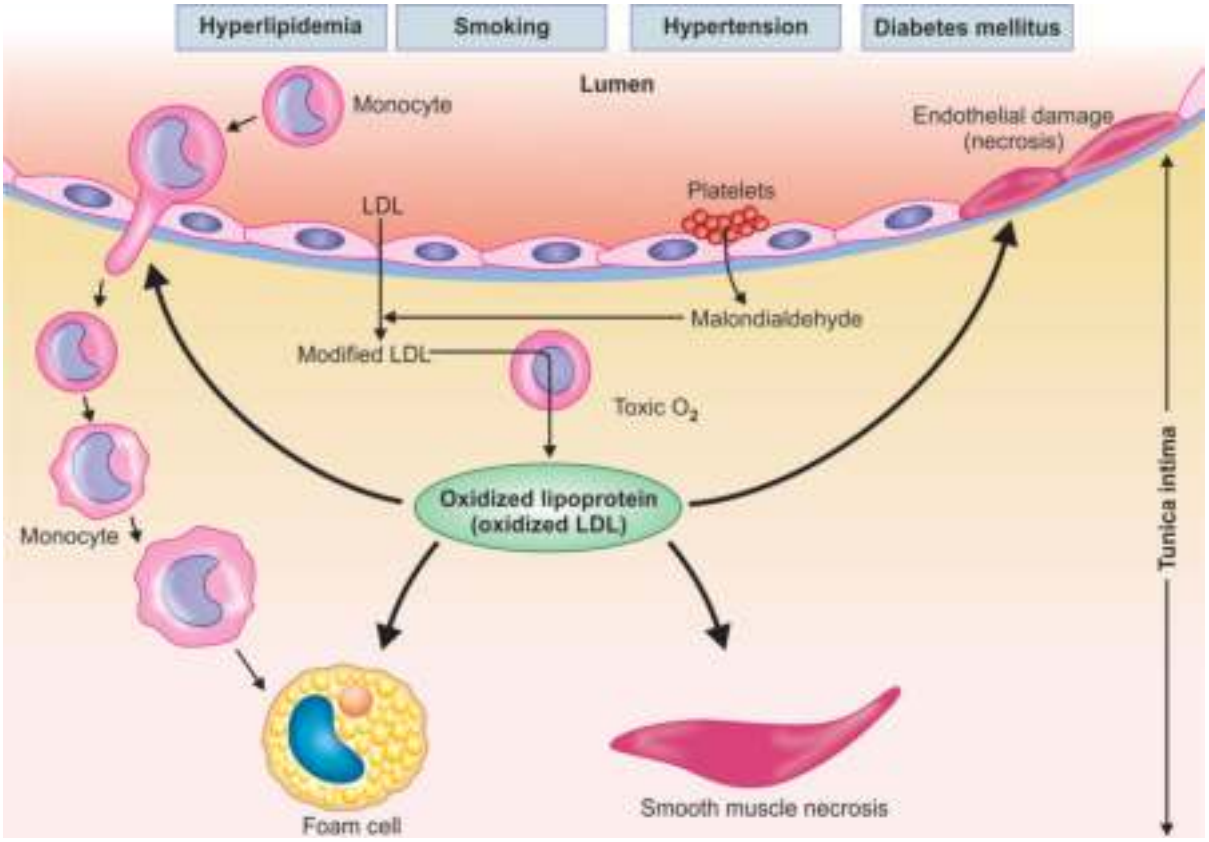

Fig. 15.9: Role of oxidized low-density lipoproteins in the pathogenesis of atheromatous plaque. Oxidized LDL causes necrosis of the endothelial and smooth muscle cells; migration and proliferation of smooth muscle cells; chemotaxis of monocyte-derived macrophages, and inhibition of egress of monocyte derived macrophages.

atheromatous plaque growth and progression. It also enhances recruitment of leukocytes, synthesis of cytokines and remodeling of extracellular matrix in atheromatous plaque.

ROLE OF GROWTH FACTORS AND CYTOKINES

There are cellular interactions in the progression of the atheromatous plaque. Endothelium, platelets, macrophages, T cells and smooth muscle cells synthesize

Table 15.10 Cytokines, growth factors and other molecules synthesized by endothelial cells, platelets, macrophages, T cells and smooth muscle cells

Cells	Growth Factors
Endothelial cells	PDGF, FGF-β, IL-1, TGF-β, PGI_2, IGF-1,NO, OxLDL, TF, TFPI
Platelet	PDGF, EGF, TGF-β, TxA_2, IGF-1, thrombin
Macrophages	PDGF, FGF, HB-EGF, TGF-β,TNF-α, IL-1, PGF, oxidized LDL, MMP/TMP, TF, TFPI
T cells	IFN-γ, TGF-β, TNF-α, IL-1
Smooth muscle cells	▪ Growth factors and cytokines ▪ PDGF, FGF, IGF-1, IL-1, M-CSF, TGF-β, TNF-α, PGE, HB-EGF, MCP-1, GM-CSF, TF, TFPI
Synthesis of other products	Collagen fibers, proteoglycans, MMP/TIMP

PDGF: Platelet derived growth factor; FGF-β: Fibroblastic growth factor β; FGF: Fibroblastic growth factor; IL-1: Interleukin 1; PGI_2: Prostaglandin I_2; PGE: Prostaglandin E; IGF-1: Insulin growth factor 1; NO: Nitric oxide; TFPI: Tissue factor pathway inhibitor; EGF/TGF-β: Epidermal growth factor/transforming growth factor β; TXA_2: Thromboxane A_2; TNF-α: Tumor necrosis factor-α; HB-EGF: Heparin binding epidermal growth factor; TF: Tissue factor; IFN-γ: Interferon γ; MMP/TMP: Matrix metalloproteinase/tissue metalloproteinase; MCP-1: Monocyte chemotactic protein 1; GM-CSF: Granulocyte/monocyte-colony stimulating factors; M-CSF: Macrophage colony stimulating factor; PGF: Placental growth factor; Oxidized LDL: Oxidized low density lipoproteins.

a variety of cytokines, growth factors and other molecules, which act on smooth muscle cells. The cellular interactions promote the proliferation of smooth muscle cells. Cytokines, growth factors and other molecules synthesized by endothelial cells, platelets, macrophages, T cells and smooth muscle cells are given in Table 15.10.

Source of Growth Factors

- **Macrophages:** Activated macrophages synthesize various growth factors such as PDGF, FGF, HB-EGF, TGF-β, TNF-α, IL-1, PGF, oxidized LDL, MMP/TMP, TF and TFPI. These also synthesize collagen fibers, proteoglycans, MMP/TIMP. PDGF, EGF and TGF-β induce migration and proliferation of smooth muscle cells in the subintimal region; and synthesis of extracellular matrix proteins such as collagen, elastin and proteoglycans.
- **Smooth muscle cells:** Activated smooth muscle cells synthesize PDGF, FGF, IGF-1, IL-1, M-CSF, TGF-β, TNF-α, PGE, HB-EGF, MCP-1, GM-CSF, TF and TFPI. PDGF has autocrine action.
- **Platelets:** Platelets synthesize PDGF, EGF, TGF-β, TXA_2, IGF-1 and thrombin. Thrombin stimulates protease activated receptors, which send signal for migration and proliferation of smooth muscle cells; and synthesis of extracellular matrix. PDGF, EGF, TGF-β induce migration and proliferation of smooth muscle cells in the subintimal region; and synthesis of extracellular matrix proteins such as collagen, elastin and proteoglycans.
- **T cells:** T cells synthesize IFN-γ, TGF-β, TNF-α and IL-1. TNF-α and IL-1 cytokines increase the expression of cell surface adhesion molecules on dysfunctional endothelium. These cytokines also participate in migration and proliferation of smooth muscle cells in subintimal region; and formation of new blood vessels in the atheromatous plaque. Cytokines IFN-γ, TGF-β and IL-1 activate macrophages, which synthesize matrix metalloproteinases (MMPs). Metalloproteinases cause degradation of collagen fibers in the atheromatous plaque.
- **Endothelial cells:** Activated endothelium PDGF, FGF-β, IL-1, TGF-β, PGI_2, IGF-1, NO, OxLDL, TF and TFPI. PDGF and TGF-β participate in migration and proliferation of smooth muscle cells beneath intima.

ROLE OF SMOOTH MUSCLE CELLS (SMCs)

Smooth muscle cells are quiescent (qSMCs) in the normal arterial wall. The qSMCs exhibit differentiated contractile phenotype. These are derived embryonically from the progenitor mesenchymal cells and neural crest cells. Progenitor smooth muscle cells (pSMCs) are derived from the hematopoietic stem cells in the bone marrow.

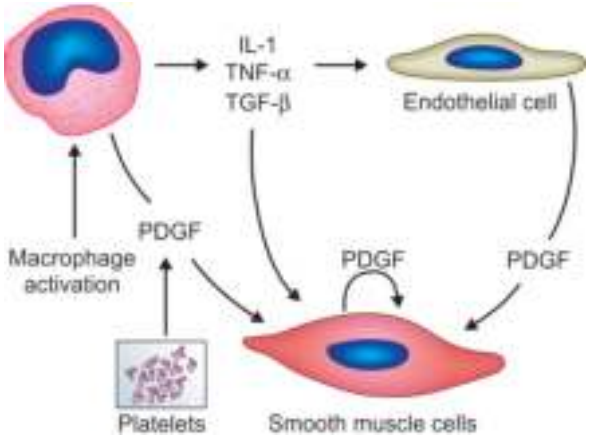

Fig. 15.10: Cellular interactions in the progression of atheromatous plaque that promote proliferation of smooth muscle cells.

- The qSMCs are activated by lipids, cytokines, chemokines and other chemical mediators synthesized by macrophages and endothelial cells through paracrine pathways in the atheromatous plaque. Activated smooth muscle cells (aSMCs) participate in repair and remodeling of the atherosclerotic lesion. Activated smooth muscle cells migrate, proliferate and synthesize extracellular matrix, and can accumulate lipids and become foam cells in the atheromatous lesion.
- Endothelial progenitor cells (EPCs) derived from mesenchymal stem cells in the bone marrow may replenish SMCs in the vasculature, especially during a response to endothelial injury. The aSMCs interact with endothelial cells (ECs) and macrophages directly or indirectly to regulate atheromatous plaque growth. Cellular interactions in the progression of atheromatous plaque that promote proliferation of smooth muscle cells are shown in Fig. 15.10.

SYNTHESIS OF EXTRACELLULAR MATRIX

The nuclear factor-κB (NF-κB) pathway is an important signal transduction system that participates in growth and progression and remodeling of extracellular matrix in atheromatous plaque. Smooth muscle cells participate in synthesis of extracellular matrix, i.e. collagen fibers, proteoglycans, metalloproteinases (MMPs) and tissue inhibitors of metalloproteinases (TIMPs). Extracellular matrix subsequently produces fibrotic atherosclerotic plaque. Synthesis of connective tissue determines the stiffness of the blood vessels and further progression of atheromatous plaque.

THROMBUS FORMATION

Thrombus formation in atheromatous plaque induces fibrin generation. Fibrin stimulates protease activated receptors, which transmit signal for migration and proliferation of smooth muscles, and synthesis of extracellular matrix.

MORPHOLOGY OF ATHEROSCLEROSIS

Grossly recognizable atherosclerosis begins as a fatty streak and progresses to an atheroma and then fibroatheroma. Histology of atherosclerosis shows three components of fibroatheroma: fibrous cap, cellular layer and necrotic care.

COMPLICATIONS OF ATHEROSCLEROSIS

Complications of atherosclerosis include acute occlusion of vessel lumen, chronic narrowing of vessel lumen, bleeding in atheromatous plaque, mural thrombus formation, embolism, aneurysm, dystrophic calcification and restenosis of blood vessel involved.

Pathology Pearls: Gross Morphology and Histologic Features of Atheromatous Plaque

Morphologic Features of Fibroatheroma

- **Fatty streak:** Fatty streak is characterized by intimal accumulation of foam cells (lipid filled macrophages). It may represent as the initial precursor of atherosclerosis. However, all fatty streaks are not precursor of atherosclerosis. Virtually, these are present in thoracic aorta of children by the age of 10 years. These lesions are not sufficiently raised to cause any significant blood flow obstruction. Fatty streaks are multiple, minute, yellow elongated slightly raised streaks measuring ≥1.0 cm in length and 0.1 cm in diameter in thoracic aorta of infants and children. Fatty streaks are also demonstrated in the coronary arteries.
- **Atheroma:** Atheroma is characterized by intimal collection of foam cells and extracellular lipid resulting in restriction of the circulation and risk for thrombosis. Atheromatous plaques are white yellow, raised usually eccentric lesion, measuring 0.3–1.5 cm or more in size encroaching vascular lumen.
- **Fibroatheroma:** Atheroma with development of a fibrous cap is called fibroatheroma. Lesion is yellow to white elevated above intima measuring 0.3–1.5 cm or more in size protruding toward the vascular lumen (Figs 15.11 and 15.12).

Histologic Features of Fibroatheroma

There are three main components of a fibroatheroma: Fibrous cap, atheroma core and shoulder. Components of atheromatous plaque is shown in Fig. 15.13A to C and Table 15.11. Comparison of fatty streak and atheromatous plaque is given in Table 15.12. Pathophysiologic events and consequences of atherosclerotic are given in Table 15.13. Complications of atheromatous plaque are shown in Fig. 15.14.

- **Fibrous cap:** The thick fibrous separates the vessel lumen from the central core of fibroatheroma. It is more stable and less likely to develop complications such as hemorrhage and rupture. The fibrous cap is composed of smooth muscle cells and extracellular matrix (e.g. collagen). Fibrous is composed of smooth muscle cells, foam cells, fibrin, and extracellular matrix such as collagen, elastin, glycosaminoglycans and proteoglycans. The endothelium over the fibrous cap appears intact.
- **Central core and shoulder of atheromatous plaque:** Central core of the atheroma contains cholesterol and cholesterol esters, lipid-filled macrophages (foam cells), necrotic smooth muscle cell debris and calcium. The shoulder of the atheromatous plaque is located at the junction of normal intima near the fibroatheroma lesion. It contains macrophages, leukocytes including T cells and newly formed blood vessels.

Fig. 15.11: Autopsy finding in a long-standing diabetes mellitus. Abdominal aorta demonstrates severe atherosclerosis and a mural thrombus. (*Courtesy*: Dr. Sujata Kanetkar, Professor and Head of Pathology, Krishna Institute of Medical Sciences, Karad, Maharashtra.)

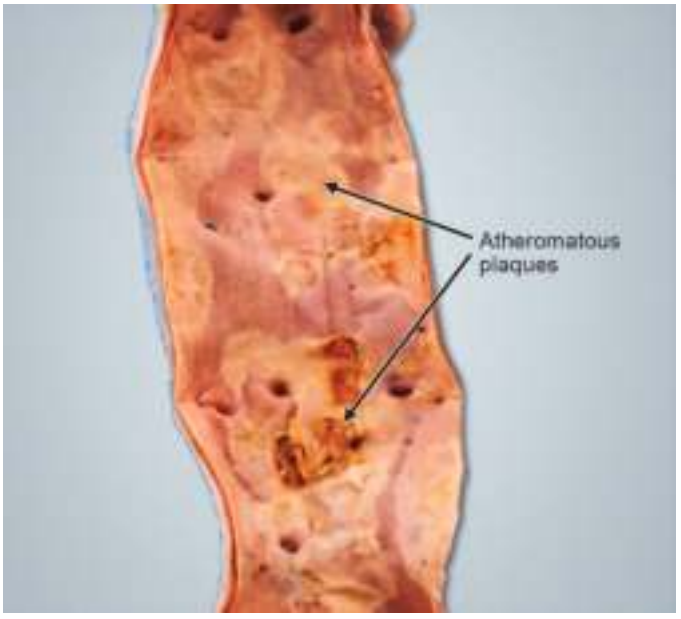

Fig. 15.12: Atheromatous plaques in abdominal aorta. Multiple atheromatous plaques of various sizes are demonstrated in the abdominal aorta. Ostia of the small branches arising from the abdominal aorta show narrowing due to deposition of lipid.

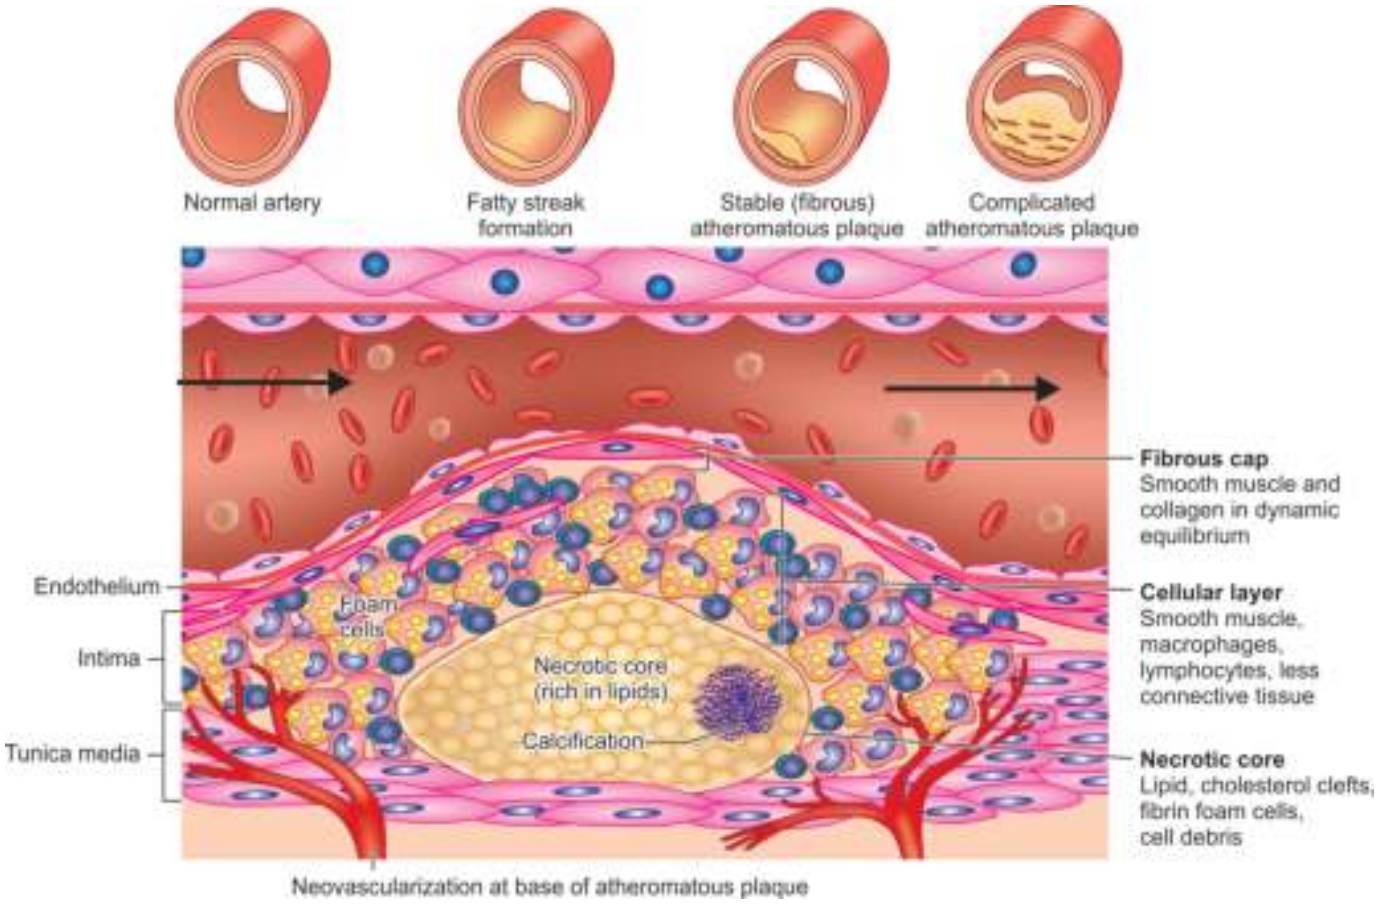

Fig. 15.13A: Evolution of the atheromatous plaque. It shows normal blood vessel, development of fatty streaks, stable fibrous plaque and complicated atheromatous plaque. Atheromatous plaque consists of fibrous cap, central core and shoulder. The thick fibrous cap is more stable and less likely to develop complications such as hemorrhage and rupture. The fibrous cap is composed of smooth muscle cells and extracellular matrix (e.g. collagen). Central core of the lesion contains cholesterol and cholesterol esters, lipid-filled macrophages (foam cells), necrotic smooth muscle cell debris and calcium.

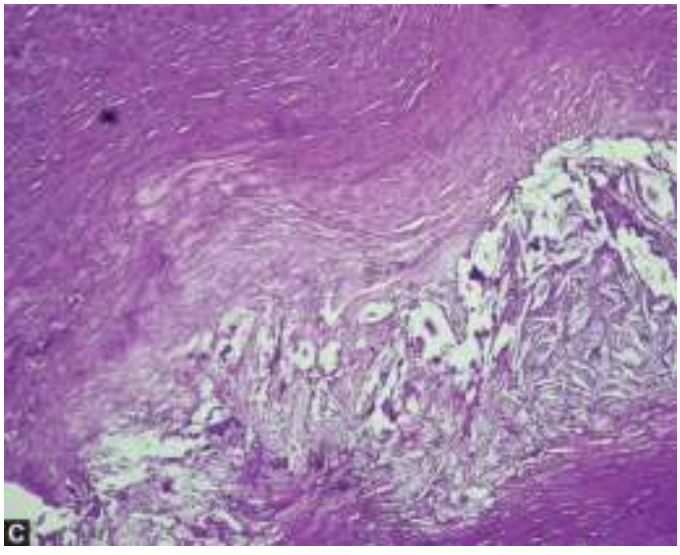

Fig. 15.13B and C: Evolution of the atheromatous plaque. (B) Gross morphology of abdominal aorta shows atheromatous plaque, (C) atheromatous plaque is initially covered by endothelium. Area between the blood vessel lumen and necrotic central core, termed the fibrous cap, contains smooth muscle cells, macrophages, T cells, lipid laden foam cells and connective tissue components. Cholesterol crystals are present within the fibrous tissue and the necrotic areas. It is worth mentioning that newly formed blood vessels are fragile, which may rupture and resulting in acute expansion of the atheromatous plaque due to intraplaque hemorrhage (40X).

Table 15.11 Components of atheromatous plaque

Cellular Component	Extracellular Matrix Component	Lipid Component
▪ Endothelial cells ▪ Smooth muscle cells ▪ Macrophages ▪ Foam cells ▪ Paltelets ▪ Mast cells ▪ T cells ▪ B cells ▪ Neutrophils	▪ Collagen fibers ▪ Elastin ▪ Proteoglycans ▪ Glycoproteins ▪ Proteolytic enzymes (MMPs)* ▪ Tissue inhibitors of MMPs	▪ Lipids (cholesterol and cholesterol esters) ▪ Lipoproteins

**MMPs: Matrix metalloproteinases*

Table 15.12 Comparison of fatty streak and atheromatous plaque

Features	Fatty Streak	Atheromatous Plaque
Age group	Children	Older age group
Composition	Fatty streak is characterized by intimal accumulation of foam cells (lipid filled macrophages), lipid accumulation mainly intracellular, small amount in extracellular compartment	Central core of the atheromatous plaque contains lipid accumulation mainly in the extracellular region
Gross morphology	Fatty streaks are multiple, minute, yellow elongated slightly raised streaks measuring 1.0 cm in length and 0.1 cm in diameter in thoracic aorta of infants and children, and not encroaching lumen	Atheromatous plaques are white yellow, raised usually eccentric lesion, measuring 0.3–1.5 cm or more in size encroaching lumen
Vasculature involved	Thoracic aorta and coronary arteries	Large- and medium-sized blood vessels such as abdominal aorta, coronary arteries, internal carotid artery, middle cerebral artery, celiac artery, superior mesenteric artery, inferior mesenteric artery, popliteal artery, anterior tibial artery, posterior artery, renal artery
Geographic distribution	May be demonstrated in clinical normal persons	Developing and developed countries
Complications	No complication	Atheromatous plaque may occlude lumen, bleeding in plaque, mural thrombus, embolism, aneurysm, calcification
Clinical consequences	Not affecting blood flow in vessels	Patient may develop clinical manifestations related to heart (angina, myocardial infarction, sudden cardiac death, heart failure), brain (transient ischemic attacks, cerebral infarction), intestine (gangrene intestine), lower leg (gangrene foot)

Table 15.13 Pathophysiologic events and consequences of atherosclerotic plaque

Pathophysiologic Events	Consequences
Acute occlusion of artery secondary to atheromatous plaque rupture/thrombosis	End organ/tissue infarction such as myocardial infarction, cerebral stroke, gangrene intestine, gangrene foot
Progressive lumen narrowing of vessel in atherosclerosis	Chronic ischemic heart disease
Erosion/replacement of media by atheromatous plaque with loss of tensile strength	Aneurysm especially abdominal aorta
Dislodgment of thrombus in atheromatous plaque and or release of the highly thrombogenic components of the central core of atheroma	Thromboembolism, atheroembolism

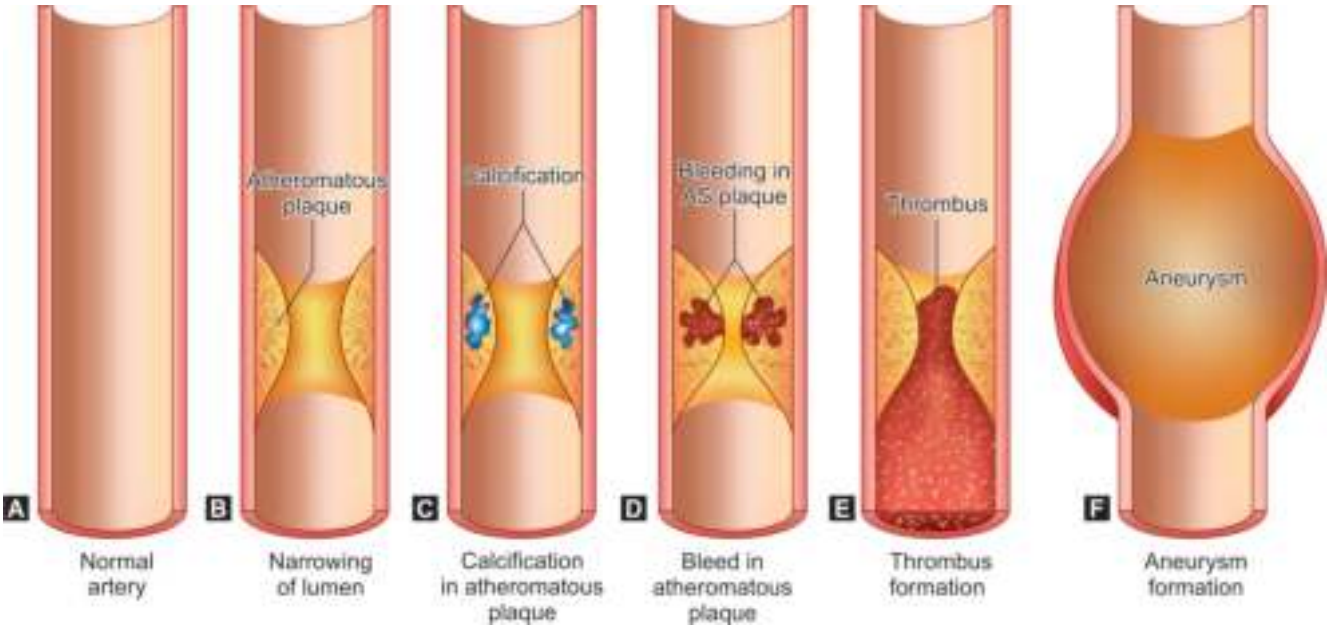

Fig. 15.14: Complications of atheromatous plaque. It shows a normal blood vessel, narrowing of blood vessel as a result of atheromatous plaque and its complications such as dystrophic calcification, bleed into the atheromatous plaque, thrombus formation and aneurysm.

ACUTE OCCLUSION OF THE VESSEL LUMEN

Thrombosis on an atheromatous plaque can abruptly occlude medium size artery resulting in ischemic necrosis (infarction) of the tissue supplied by that blood vessel. Patient may present with myocardial infarction, cerebral stroke or gangrene of the intestine or gangrene of lower extremities. Some occlusive thrombi can be dissolved therapeutically by thrombolytic agents (streptokinase and tissue plasminogen activator) that can activate fibrinolytic activity of blood.

CHRONIC NARROWING OF THE VESSEL LUMEN

As an atheromatous plaque grows, it may cause narrowing of the vascular lumen, progressively reducing the blood flow to the tissue/organ supplied by that artery. Chronic ischemia of the affected tissue leads to atrophy of the organ. For example, unilateral renal artery stenosis results in renal atrophy. Stenosis of the mesenteric artery causes intestinal gangrene. Stenosed blood vessel in a case of diabetes mellitus may result in peripheral vascular disease.

HEMORRHAGE INTO ATHEROMATOUS PLAQUE

The initial stage is associated with formation of new vasa vasorum in areas of subsequent atheromatous plaque. The overall appearance of these vasa vasorum newly formed blood vessels is fairly disorganized. In the progression stage, there is extension of adventitial new blood vessels to the media and eventually into the enlarging atheromatous plaque. Eventually, most advanced atheromatous plaques are fairly neovascularized. Moreover, neovascularization seems to characterize the active atheromatous plaque rather than calcified inactive atheromatous plaque. Newly formed small blood vessels within atheromatous plaque may rupture resulting in sudden enlargement of the atheromatous plaque and impairment of the blood supply to the tissue or organ.

ATHEROMATOUS PLAQUE DISRUPTION

Vasoconstriction can potentiate disruption of atheromatous plaque. Vasoconstriction at the site of atheromatous plaque is stimulated by circulating adrenergic agonists, platelet adhesions, activation and secretion; endothelial dysfunction with impaired synthesis of endothelial derived vasodilator nitric oxide and endothelin; and the synthesis of inflammatory mediators from perivascular inflammatory cells.

MURAL THROMBUS FORMATION

Mural thrombus results from turbulent blood flow around atheromatous plaque, where it protrudes into the vessel lumen and creates reduced luminal blood flow or stasis. The disturbance in blood flow also causes damage to the endothelial lining, which may become dysfunctional or locally ulcerated, and hence patient no longer has thromboresistant endothelial surface.

- Thrombi most often form at the sites of erosion and fissuring on the surface of the fibrous cap of atheromatous plaque. Mural thrombi located in

the more proximal region of a coronary artery may embolize to more distal sites in the blood vessel.

- Thrombotic vascular occlusion may manifest as myocardial infarction (coronary arteries), cerebral stroke (internal carotid and middle cerebral artery), gangrene intestinal loop (celiac trunk, superior mesentery and inferior mesenteric artery) and gangrene limb (popliteal, anterior tibial and posterior tibial arteries).

THROMBOEMBOLISM

A thrombus formed over an atheromatous plaque may detach and lodge as an embolus in the distal blood vessel. Thus, embolization from a thrombus in an abdominal aortic atherosclerotic aneurysm may cause sudden occlusion of blood vessels supplying distal tissues/organs. Ulceration of an atheromatous plaque may become dislodged and produce so-called cholesterol crystal emboli, which look like needle-shaped cholesterol clefts in the affected tissues/organs, most often in the kidney.

ANEURYSM FORMATION

Complicated atheromatous plaque may extend into the media of large elastic arteries and weaken their walls resulting in aneurysm formation in abdominal aorta. The reduced elastin of the large elastic artery promotes thinning and ballooning of the vessel wall, while matrix metalloproteinases (MMPs) synthesized by macrophages and smooth muscle cells cause of breakdown collagen fibers.

- Such aneurysms contain mural thrombi, which may embolize to distant organs. Sudden rupture of the abdominal aneurysm has fatal outcome.
- The abdominal aortic aneurysms may be saccular, fusiform or cylindrical in shape, which may be demonstrated by ultrasonography and MRI. Patient presents with pulsatile mass abdomen, pressure exerted by aneurysm related symptoms, rupture into the cavities and thromboembolism.

DYSTROPHIC CALCIFICATION

Dystrophic calcification involving osteochondrocytic differentiation occurs in the central areas of necrosis in the atheromatous plaque. Oxidized lipids and inflammatory cytokines enhance vascular calcification.

- Dystrophic calcification in the vasculature depends on mineral deposition and resorption, which are regulated by osteoblast-like cells and osteoclast-like cells present in the vessel wall. Several transcriptional factors including RUNX2, MSX2, osterix and SOX9 promote development of osteoblast-like cells.
- Dystrophic calcification of atheromatous plaque may undergo vasospasm, which results in rupture of the atheromatous plaque.

RESTENOSIS OF CORONARY ARTERIES

Percutaneous transluminal coronary angioplasty (PTCA) is an important treatment in stenosed epicardial coronary artery disease as a result of atheromatous plaque. With a catheter-based approach, coronary arteries are inflated by a balloon catheter to dilate stenotic coronary artery, so that blood flow to the heart may be restored.

- Ballooning of coronary arteries causes endothelial damage and tear in the atheromatous plaque and media. Restenosis of coronary arteries may occur within 3–6 months in 30–40% of cases.
- Restenosis of coronary arteries occurs as a result of intimal hyperplasia, smooth muscle cell proliferation, extracelluar matrix deposition with or without organized thrombus on the luminal surface.
- Restenosis of coronary arteries is treated by using stents coated with biocompatibility polymers and biologically active agents. Drug-eluting stents with antiproliferative agents inhibit cell cycle progression and thus inhibit over proliferation of smooth muscle cells in the blood vessel.

CONSEQUENCES AND CLINICAL MANIFESTATIONS OF ATHEROSCLEROSIS

Consequences and clinical manifestations of atherosclerosis include cardiac manifestations (angina pectoris, myocardial infarction, sudden cardiac death, heart failure and chronic ischemic disease), brain manifestations (transient ischemic attacks, cerebral infarction), gangrene intestine, peripheral vascular disease and hypertension.

CARDIOVASCULAR MANIFESTATIONS

Angina pectoris is the most important manifestation of myocardial ischemia due to coronary artery disease. Coronary angiography revolutionized the diagnosis and management of coronary artery disease. Some persons present with chest pain, nausea, fatigue, shortness of breath, sweating and dizziness.

- Complicated atheromatous plaque involving >75% of vessel lumen can cause myocardial infarction and sudden cardiac death.
- Survivors may develop heart failure and chronic ischemic heart disease. Abdominal aorta below the origin of renal arteries is the most common site for atherosclerosis. Atheromatous plaque can undergo aneurysm formation in abdominal aorta that may rupture with fatal outcome.

CEREBROVASCULAR DISEASES

Internal carotid artery and circle of Willis are the most important sites of atheromatous plaque. Patient presents with transient ischemic attacks as a result of partial blockage of these vessels by atheromatous plaques. Complete occlusion of blood vessels supplying brain results in cerebral stroke/infarction. Clinical manifestations depend on the deprivation of blood supply to brain.

PERIPHERAL VASCULAR DISEASE

Popliteal, anterior tibial and posterior tibial arteries are sites of atheromatous plaque. Depending on the encroachment of lumen of the arteries, there may be partial or complete blockage. Partial blockage in the supplying blood vessels presents with intermittent claudication, i.e. cramps and pain in the leg. Complete occlusion of peripheral blood vessels presents with gangrene foot.

BOWEL ISCHEMIC NECROSIS (GANGRENE)

Celiac trunk, superior and inferior arteries are most sites for atherosclerosis. Complete occlusion of blood supply results in necrosis in the watershed regions of intestine. It is serious condition that can have fatal outcome. Patient presents with pain, tenderness and cramp in abdomen, passage of bright red or maroon blood in stool, nausea and diarrhea.

RENAL HYPERTENSION

Renal artery is also site for atherosclerosis. Decreased in blood supply to kidney activates renin-angiotensin-aldosterone system. Angiotensinogen synthesized by liver is converted to angiotensin II in lungs. Angiotensin II causes vasoconstriction and thus increases the peripheral resistance. Angiotensin II activates adrenal cortex to synthesize increased aldosterone production, that helps in the absorption of sodium and water in the kidney. Increased peripheral resistance and expansion of blood volume lead to renal hypertension.

THERAPEUTICS FOR ATHEROSCLEROSIS

HMG-CoA reductase inhibitors (statins lipid lowering agents) administration reduces cholesterol level by inhibiting cholesterol synthesis by liver. It is essential to treat the underlying major risk factors for atherosclerosis such as hyperlipidemia, hypertension, and diabetes mellitus. Daily intake of 75 mg aspirin minimizes thrombotic risk. Change of lifestyle advice, i.e. stopping tobacco smoking, healthier diet and increasing exercise also minimizes risk for atherosclerosis.

Clinical Pearls: Management of Atheromatous Plaque

- Major risk factors for atheromatous plaque include hyperlipidemia, hypertension, diabetes mellitus and tobacco smoking. It is essential to treat the underlying major risk factor. Patient is put on antihypertensive drugs, e.g. β-blockers and diuretics to control hypertension. Diabetes mellitus should be treated to maintain normal blood sugar level.
- Clinical management of atherosclerosis is based on minimizing its risk factors: hypertension is controlled by antihypertensive medication (e.g. diuretics, β-blockers), HMG-CoA reductase inhibitors, i.e. statins as lipid lowering agents, anticoagulants, i.e. 75 mg aspirin daily to minimize thrombotic risk; and lifestyle advice (e.g. stopping tobacco smoking, healthier diet and increasing exercise).
- Regular exercise reduces the risk of development of atheromatous plaque by maintaining elasticity of arteries and increasing high-density lipoproteins also reduces risk of development of diabetes mellitus and hypertension.
- HMG-CoA reductase inhibitors (statins-lipid lowering agents), i.e. administration reduces cholesterol level by inhibiting cholesterol synthesis by liver. HMG-CoA reductase (or 3-hydroxy-3-methyl-glutaryl-coenzyme A reductase abbreviated as HMGCR) is the rate-limiting enzyme for cholesterol biosynthesis by liver. Normally, this enzyme is suppressed by cholesterol derived from the internalization and degradation of low density lipoproteins (LDL) via the LDL receptors. Competitive inhibitors of the HMG-CoA reductase induce the expression of LDL receptors in the liver, which in turn increases the catabolism of plasma LDL and lowers the plasma concentration of cholesterol, an important determinant of atherosclerosis.

ANEURYSMS

ANEURYSMS: OVERVIEW

Aneurysms are localized, abnormal permanent dilatation of cardiovascular tree that results from weakening of the wall of large elastic and medium size artery. Aneurysm can erode adjacent structures and cause pressure symptoms, pain, edema, rupture resulting in hypotensive shock and gangrene. The most important cause of aneurysm is an atheromatous plaque in the abdominal aorta. However, any abnormality that weakens the vessel media may predispose to an aneurysm.

Most common sites of aortic aneurysms and their etiology are given in Table 15.14.

Table 15.14 Most common sites of aortic aneurysms and their etiology

Site of Aneurysm	Etiology
Ascending aorta	Hypertension, syphilis
Descending aorta especially below the origin of renal arteries	Atherosclerosis
Aortic arch of aorta	Atherosclerosis
Popliteal artery	Atherosclerosis

Aneurysm is more common in splenic artery than hepatic artery.

Aneurysms may be congenital or acquired. These may be true or false. False aneurysm occurs due to trauma to intima and media. Aneurysms may take various shapes, i.e. saccular, fusiform, cylindrical, berry aneurysms, racemose/cirsoid (scalp), serpentine (torturous), arteriovenous fistula, and dissecting hematoma. Various shapes of aneurysm are described as under:

- **Saccular aneurysm:** It most often occurs in abdominal or thoracic aorta. The aortic wall bulges like a rounded sac-like structure. It throbs and pushes against surrounding structures. Mural thrombus is most often found within aneurysmal sac of saccular aneurysm.
- **Fusiform aneurysm:** It is most common type of aortic aneurysm assuming round and more tubular shape. The aorta is widened like a sausage for a few inches.
- **Cylindrical aneurysm:** Aortic aneurysm assumes cylindrical shape due to atherosclerosis (Figs 15.15 and 15.16).
- **Berry aneurysm:** It is small aneurysm located in the arteries of brain.
- **Dissecting hematoma:** It is not a true aneurysm and least common, but most painful type of aortic damage. Increased blood pressure and weakened wall split the layers of the aorta between the tunica intima (inner-most) and the tunica media (muscular layer). It is possible to have a dissecting hematoma of aorta without aneurysm.
- **Racemose/cirsoid aneurysm:** It is most often seen in scalp.
- **Serpentine aneurysm:** Aneurysm may assume serpentine (torturous) shape.
- **Arteriovenous fistula:** Arteriovenous fistula is formed secondary to trauma. Arteriovenous (AV) fistulas are abnormal communications (direct shunt) between arteries and veins.

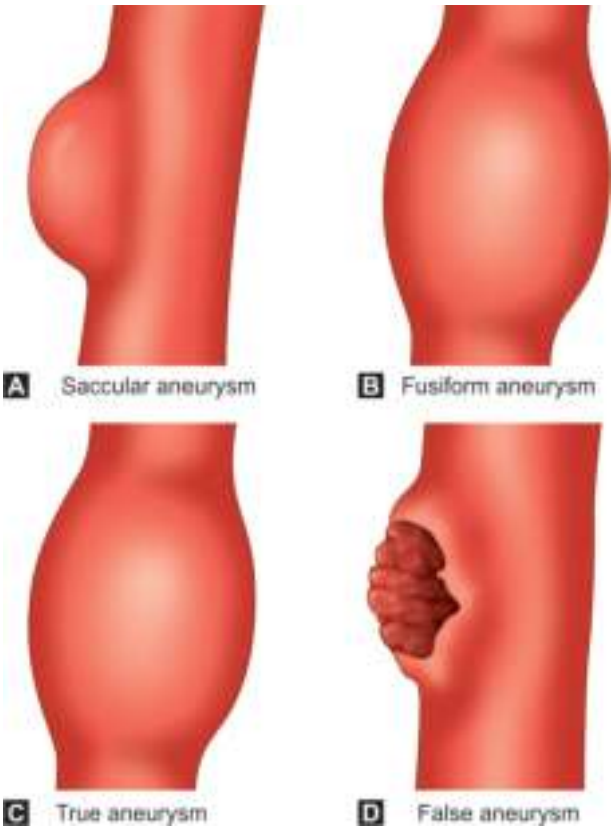

Fig. 15.15A to D: Shape of aneurysms.

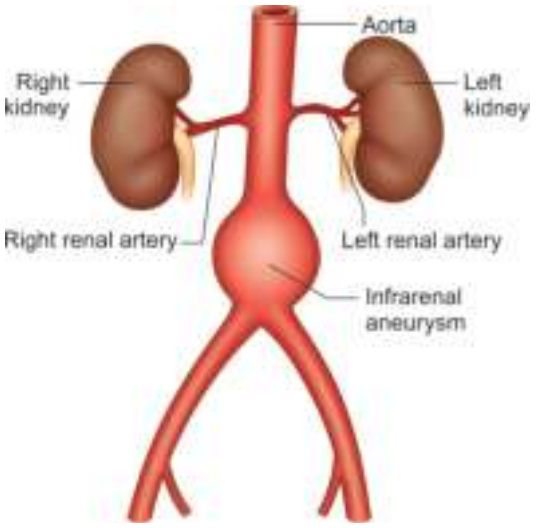

Fig. 15.16: Aneurysm in abdominal aorta due to atheromatous plaque.

ANEURYSMS: CAUSES

Several risk factors participate in the development of aneurysms, which include atheromatous plaques, smoking, congenital weakness of arterial wall (Marfan's syndrome or Ehlers-Danlos syndrome), inflammation (bacterial endocarditis), untreated syphilis and trauma.

ATHEROSCLEROTIC ANEURYSMS

Most important cause of aneurysm is an atheromatous plaque in the abdominal aorta. Major risk factors include hyperlipidemia, hypertension, diabetes mellitus and tobacco smoking. Males are more affected than females above 50 years of age.

Locations and Morphology

Atherosclerotic aneurysms occur in descending order, i.e. abdominal aorta below the origin of renal arteries (most common site), common iliac arteries and rarely aortic arch, which may take any shape, i.e. fusiform, cylindrical or saccular. Most abdominal aortic atherosclerotic aneurysms are fusiform in shape extending to involve common iliac arteries. Femoral or popliteal aneurysms are relatively uncommon.

Clinical Features

Patient presents with lower abdominal pain and dull backache, pulsatile abdominal mass, pressure symptoms, massive retroperitoneal hemorrhage and thromboembolism.

Imaging Technique

Atherosclerotic aneurysms are diagnosed by imaging techniques such as ultrasonography and MRI.

Blood Biochemistry

Serum C-reactive protein (CRP) is increased in patients with disrupted atheromatous plaques.

SYPHILITIC (LUTEIC) ANEURYSMS

Syphilitic (luteic) aneurysm is associated with tertiary syphilis. It typically affects the ascending arch of thoracic aorta resulting in dilatation and aortic valve insufficiency (Fig. 15.17).

Fig. 15.17: Syphilitic aneurysm of the arch of aorta. The aortic wall shows thickening and numerous wrinkled whitish plaques on the intimal surface. Patient may die due to rupture of the aneurysm (arrow).

Pathophysiology

Syphilitic aortitis shows obliterative endarteritis and periarteritis of the vasa vasorum.

- Vasa vasorum penetrate the outer- and middle-third of the aorta. In syphilitic aortitis, the vasa vasorum are surrounded by lymphocytes, plasma cells, and macrophages.
- Obliteration of the vasa vasorum causes focal necrosis, scarring of the media, and calcification, which results in disruption and disorganization of the elastic lamellae of aortic arch. Differences between atherosclerotic aneurysm and sphilitic aortitis are given in Table 15.15.

Table 15.15 Differences between atherosclerotic aneurysm and syphilitic aortitis

Parameters	Atherosclerotic Aneurysm	Syphilitic Aortitis
Etiology	▪ Hyperlipidemia ▪ Diabetes mellitus ▪ Hypertension ▪ Tobacco smoking	*Treponema pallidum* (tertiary syphilis)
Age group	More common >50 years	Young >20 years
Sex predilection	Males > females	Males and females equally affected
Site of blood vessel involved	Abdominal aorta below origin of renal arteries	Aortic arch of thoracic aorta
Morphology	Fibrofatty plaques measuring 0.3–1.5 cm in blood vessel affecting lumen	Obliterative endarteritis of vasa vasorum leads to necrosis of aortic media. Healing lesion in aorta gives tree bark appearance in intima due to fibrosis
Consequences	▪ Ulceration of atheromatous plaque ▪ Thrombus formation ▪ Embolism ▪ Dystrophic calcification ▪ Pressure symptoms on surrounding structures ▪ Atherosclerotic aneurysm rupture leads to fatal outcome	▪ Superior mediastinal compression ▪ Bronchial obstruction ▪ Aortic valve incompetence ▪ Massive cardiomegaly occurs known as cor bovinum ▪ Vertebral compression ▪ Recurrent laryngeal nerve paralysis of left site

Surgical Pathology: Syphilitic Aortitis

Gross Morphology

- The inner surface of the affected thoracic aorta shows a typical tree bark appearance as a result of fibrosis.
- Intima shows gray white, and gelatinous lesion.

Light Microscopy

- In cardiovascular syphilis, the vasa vasorum of the aortic arch show dense chronic inflammatory infiltrate mainly confined to the adventitia and the media.
- Obliterative endarteritis leads to infiltration by chronic inflammatory cells and replacement of the elastic layer muscle fibers by fibrous tissue causing the aortic wall to undergo weakening and dilatation due to inflammation of the wall of the ascending thoracic aorta, the coronary artery orifices narrowing and aortic valve incompetence.
- Aortic valve incompetence and coronary artery stenosis occur due to mesoarteritis of the proximal portion of the aorta and ischemic fibrosis of myocardium.
- Aortic arch is the most common site for syphilitic aneurysm.
- Tertiary syphilis may also involve other large elastic arteries and cerebral arteries.

Clinical Manifestations

- **Blood vessels involved:** *Treponema pallidum* involves aortic arch (most common) and abdominal aorta (less common).
- **Bronchial obstruction:** Syphilitic aneurysm may cause superior mediastinal compression and bronchial obstruction.
- **Hoarseness of voice:** Syphilitic aneurysm can cause paralysis of left recurrent laryngeal nerve, which is a branch of vagus nerve and found inferior to the aortic arch.
- **Vertebral erosion:** Syphilitic aneurysm may lead to painful vertebral erosion.
- **Cor bovinum:** Syphilitic aneurysm may cause aortic valve incompetence resulting in massive cardiomegaly known as '**cor bovinum**' (most common). Auscultation reveals '**Austin Flint murmur**' due to excessive blood dropping back from incompetent aortic valve onto the anterior mitral valve leaflet during diastole. This finding indicates the need for aortic valve replacement (Fig. 15.18).

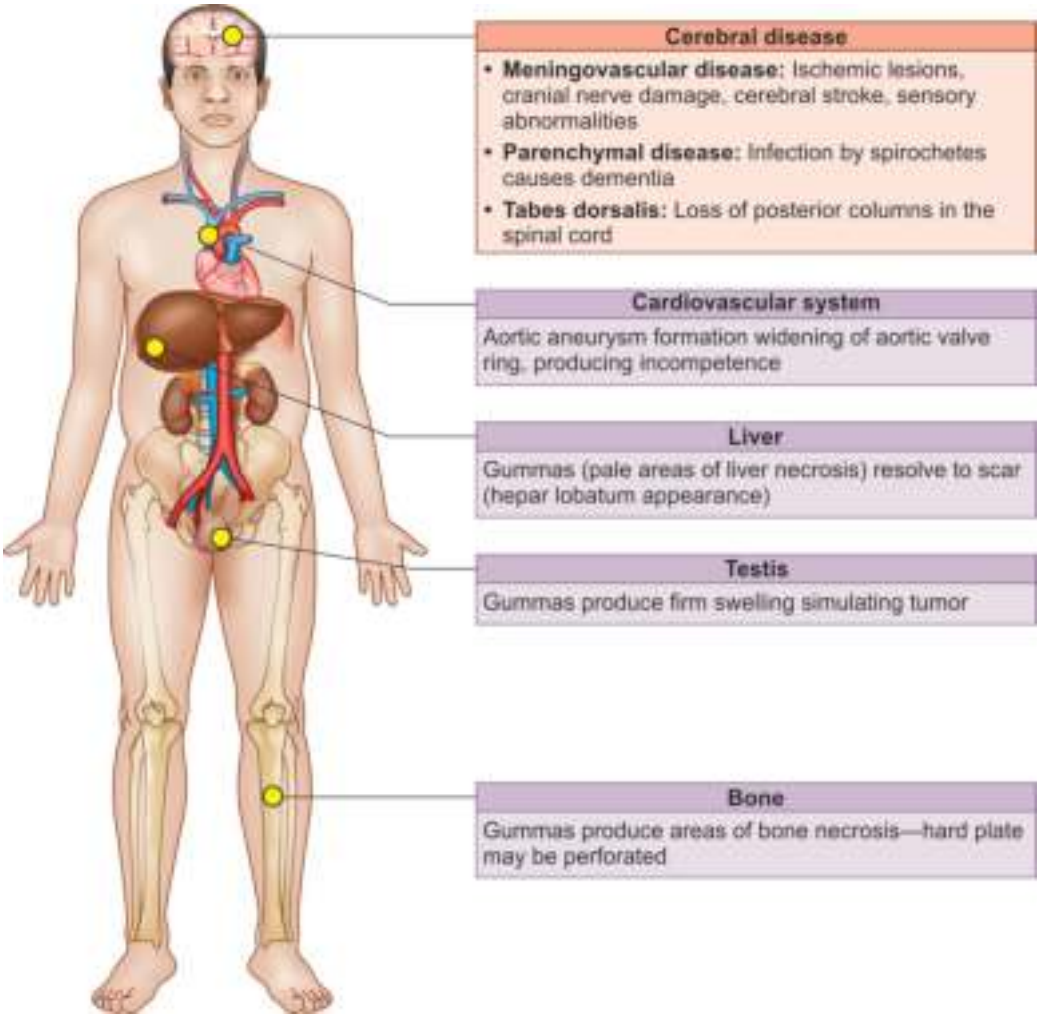

Fig. 15.18: Organs involved in tertiary syphilis.

AORTIC DISSECTING HEMATOMA

Aortic dissecting hematoma is associated with hypertension or diseases affecting the vascular media, most notably Marfan's syndrome (Figs 15.19 to 15.21).

Locations

Aortic dissecting hematoma usually occurs due to longitudinal tear in thoracic aorta and major branches; within 10 cm of the aortic valve.

- According to Stanford classification of aortic dissecting hematoma, type A involves either ascending thoracic aorta only or both ascending and descending thoracic aorta (most common and worst type); and type B affects descending thoracic aorta only usually distal to origin of left subclavian artery.
- According to DeBakey classification of aortic dissecting hematoma, type 1 involves ascending thoracic aorta and rest of aorta, type 2 affects ascending thoracic aorta only; and type 3 arises after ascending thoracic aorta. Blood dissects aorta under arterial pressure through the weakness of its wall.

Risk Factors

- **Hypertension:** It is the single most important factor responsible for aortic dissecting hematoma.
- **Atheromatous plaques:** Severe atheromatous plaque in abdominal aorta weakens aortic wall and produces aortic dissecting hematoma.
- **Traumatic injury:** Trauma to chest may cause tear in aorta.
- **Pregnancy:** Accumulation of proteoglycans rich extracellular matrix in aorta and increased blood volume weaken aortic wall in pregnant women.

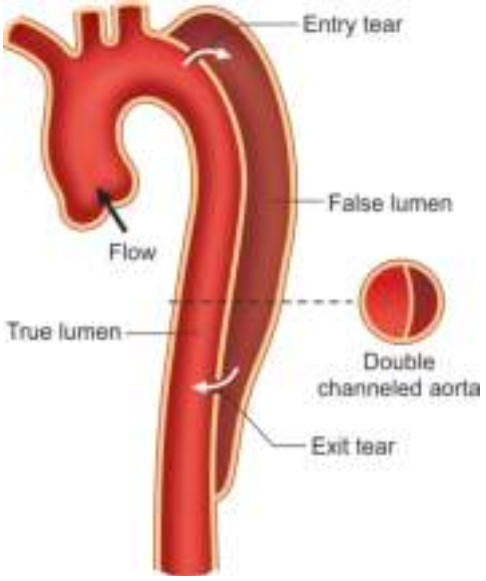

Fig. 15.19: Dissecting hematoma. Illustration shows splitting of aortic intima, entry of blood in false lumen and forming double barrel aorta.

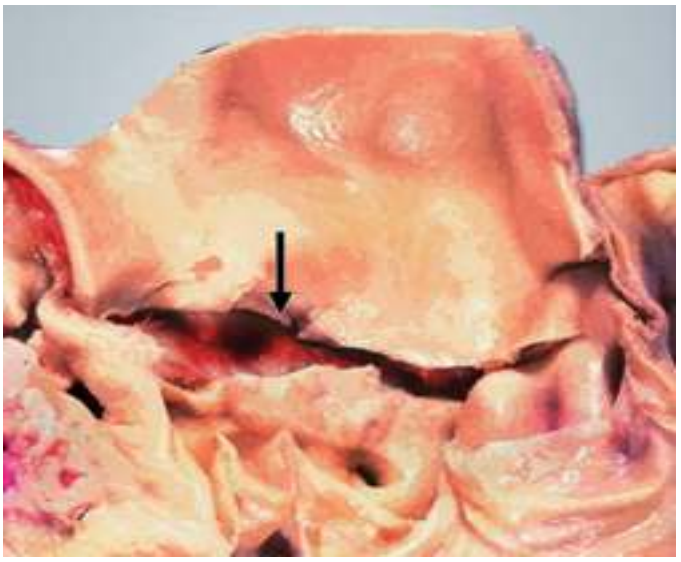

Fig. 15.20: This aortic dissection occurred just above the aortic root. The tear extends across the aorta. Hemopericardium with tamponade occurred within minutes of this event (arrow).

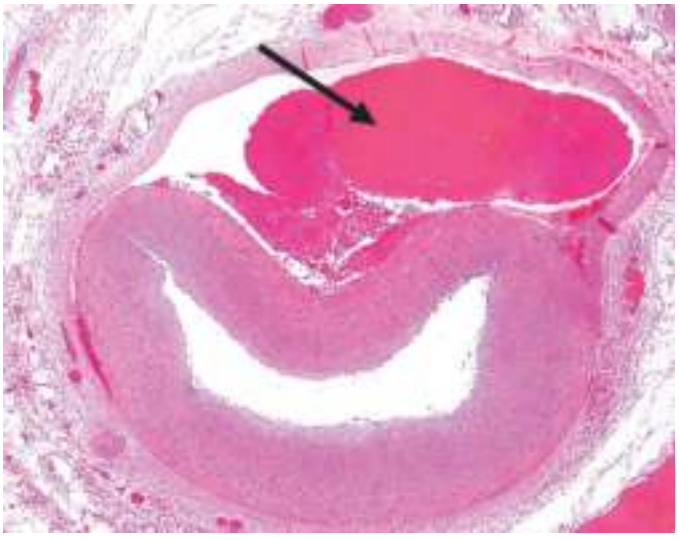

Fig. 15.21: Aortic dissection. It shows dissection extending into the muscular wall. Blood dissecting up around the great vessels can close off the carotids. Blood can dissect down to the coronaries and shut them off (arrow).

- **Marfan's syndrome:** It is an autosomal dominant disorder caused by missense mutations of the fibrillin gene 1 (FGN 1) located on chromosome 15. Fibrillin is a family of connective tissue proteins analogous to the collagen fibers. Defective cross-linkage collagen fibers weaken aortic wall. Mucin stain of the wall of the aorta demonstrates cystic medial necrosis.
- **Ehlers-Danlos syndrome:** Genetic defect in the synthesis of procollagen fibers in Ehlers-Danlos syndrome weakens the aortic wall. Mutation of lysyl hydroxylase gene is demonstrated in patient with Ehlers-Danlos syndrome.

- **Advancing age:** Blood vessels may undergo myxoid degeneration in advancing age.
- **Copper deficiency:** Copper is cofactor in lysyl oxidase, which takes part in collagen synthesis. Its deficiency leads to defective collagen synthesis which weakens the blood vessel.
- **Coarctation of aorta (wall stress):** It may result in aortic tear.

Pathologic Effects

Aortic dissecting hematoma may egress proximally and distally. It can cause vascular occlusion of branches arising from thoracic arch (i.e. loss of peripheral pulses), hemopericardium (i.e. retrograde spread), formation of second arterial lumen within the media (double-barreled aorta) and external rupture (retroperitoneal and mediastinal hemorrhage).

Clinical Features

- **Retrosternal pain:** Patient presents with severe tearing retrosternal chest pain often radiating to the back, which may be clinically confused with acute myocardial infarction. Abnormal electrocardiogram, increased serum troponin I and serum myocardial enzymes such as CK-MB and LDH indicate acute myocardial infarction (AMI).
- **Absence of pulse in subclavian artery:** There is absence of pulse due to compression of the subclavian artery.
- **Cerebral stroke:** It occurs due to carotid artery dissection.
- **Cardiac tamponade:** Aortic dissection resulting in cardiac tamponade has fatal outcome.

Imaging Techniques

The mediastinum is often widened and demonstrated by radiographic examination. Retrograde arteriography is a gold standard diagnostic tool.

BERRY ANEURYSM

The most common site of berry aneurysm is between the anterior communicating and the anterior cerebral arteries in the circle of Willis. These are not present at birth.

Shape of Aneurysm

Berry aneurysm develops as saccular lesions (1.0–1.5 cm) at site of congenital defects in smooth muscle distribution at a branch point of the arterial wall. It occurs in 10–15% of patients with adult polycystic kidney disease.

Risk Factors

Risk factors for berry aneurysm include hemodynamic stress, hypertension and coarctation of aorta.

Clinical Features

Rupture of berry aneurysm is the most common cause of subarachnoid hemorrhage. Patient presents with history of severe headache, nuchal rigidity from irritation of the meninges.

MYCOTIC ANEURYSM

Mycotic aneurysm occurs in the root of aortic arch and its descending branches, due to direct extension from aortic valve endocarditis.

Clinical Features

Emboli from infective endocarditis may involve cerebral blood vessels resulting in hemorrhage into the basal ganglia and extending into the subarachnoid space.

ANEURYSM OF SINUS OF VALSALVA

Aneurysm of sinus of Valsalva occurs due to lack of continuity between aortic media and fibrous ring of aortic valve resulting in thin paper-like aneurysm. It may be congenital or acquired.

Clinical Features

Patient presents with chest pain, heart failure, coarse cardiac murmur and thrill bounding pulse with fatal outcome. Arteriography establishes the diagnosis of aneurysm of sinus of Valsalva.

ARTERIOVENOUS FISTULA

Arteriovenous fistulas are often secondary to trauma. Arteriovenous (AV) fistulas are abnormal communications (direct shunt) between arteries and veins. Arteriography with thorostat dye establishes the diagnosis.

Etiology and Locations

Penetrating knife injury is the most common cause of arteriovenous fistula. Most common sites are scalp, arm and leg vessels. Veins are arterialized.

Clinical Features

Patient develops increased circumference of the limbs. There is presence of bruits and thrills. Large arteriovenous fistulas reduce systemic resistance and bypass the microcirculation, hence increasing venous return to the heart and producing high output cardiac failure.

CAPILLARY MICROANEURYSM

Capillary microaneurysm is also known as Charcot-Bouchard aneurysm. It is formed in intracerebral capillaries due to hypertension and diabetes mellitus.

Clinical Features

Patient may present with cerebral hemorrhage due to hypertension or retinal hemorrhage due to diabetic retinopathy. Table 15.16 shows clinical effects of aneurysms.

Table 15.16 Clinical effects of aneurysms

Types	Site and Mechanism	Clinical Effects
Atherosclerotic aneurysm	Thinning and fibrous replacement of media affecting lower abdominal aorta and iliac arteries	▪ Pulsatile abdominal mass ▪ Lower limb ischemia ▪ Rupture with massive retroperitoneal hemorrhage
Aortic dissection	Aortic and major branches	▪ Loss of peripheral pulses (e.g. radial artery) ▪ Hemopericardium ▪ External rupture (retroperitoneal hemorrhage)
Berry aneurysm	▪ Congenital defect(s) in elastic lamina/media ▪ Circle of Willis	Subarachnoid hemorrhage
Microaneurysms (Charcot-Bouchard)	Intracerebral capillaries	Intracerebral hemorrhage associated with hypertension
Syphilitic aneurysm	Inflammatory destruction of media and fibrous replacement affecting ascending arch of aorta	Aortic valve incompetence
Mycotic (infective) aneurysm	▪ Destruction of wall by root of aorta (direct extension from aortic valve endocarditis) ▪ Any vessel	Thrombus or rupture causing cerebral infarction or hemorrhage

VASCULITIS

VASCULITIS: OVERVIEW

Vasculitis is usually immune-mediated disorder, which affects arteries, arterioles, capillaries or venules that involves multi-systems with a predilection for highly vascular tissue such as skin, renal glomerulus, synovium and eye. Classification of the vasculitides is described in Table 15.17.

ETIOLOGICAL CLASSIFICATION

- **Immune-mediated vasculitis:** It is mediated by immune complex formation and complement

Table 15.17 Classification of the vasculitides

Examples	Diagnostic Features	Light Microscopy	Clinical Features
Large vessel vasculitides			
Giant cell (temporal) arteritis	**Three of five diagnostic criteria:** Age >50 years, recent localized headache, temporal artery tenderness, ESR 50 mm/hour and biopsy temporal artery shows vasculitis	Transmural granulomatous inflammation and giant cells	Recent localized headache, temporal artery tenderness
Takayasu arteritis (pulseless disease)	Aortic arch, carotid, subclavian arteries (most common), pulmonary arteries and abdominal aorta involved in men (50%), and in women under 30 years (>90%)	Granulomatous inflammation	Absence of pulse in carotid, radial or ulnar arteries, and visual disturbances

Contd...

Table 15.17 Classification of the vasculitides (*Contd...*)

Examples	Diagnostic Features	Light Microscopy	Clinical Features
Medium vessel vasculitides			
Polyarteritis nodosa	Necrotizing vasculitis weakens wall, aneurysm formation resulting in rupture associated with HBV (30–40%), intravenous amphetamines, sulfonamides and penicillin	Necrotizing vasculitis of medium- or small-sized arteries, segmental involvement with partial circumferential not associated with glomerulonephritis	Renal artery (85%), coronaries (75%), hepatic artery (75%), mesenteric arteries (65%), skeletal muscles arteries (40%), cerebral arteries, arteries supplying nerves, pancreas, and eye
Kawasaki disease	Large-, medium-to-small-sized arteries (especially coronaries)	Acute necrotizing vasculitis similar to polyarteritis nodosa	Febrile illness of childhood, self-limited acute vasculitis syndrome associated with mucocutaneous lymph node syndrome
Thromboangiitis obliterans	Tibial and radial arteries in heavy tobacco smokers. Segmental involvement with thrombus formation, sometimes involving nerves and veins of extremities	Vessel shows acute and chronic inflammation	Pain on claudication
Small vessel vasculitides (ANCA positive)			
Wegener's granulomatosis (ANCA positive)	Necrotizing vasculitis of arteries, capillaries and venules due to autoantibodies PR3-antineutrophilic cytoplasmic antibody (c-ANCA) against proteinase 3, MPO-ANCA and perinuclear ANCA (p-ANCA) against myeloperoxidase	Destructive nasal, lung and renal lesions	Clinical features related to organs involved
Microscopic polyangiitis (ANCA positive)	▪ Necrotizing vasculitis of capillaries, venules and arterioles involving glomeruli and lungs ▪ Immune-complex deposits (a few or absent)	Necrotizing vasculitis of glomeruli and lungs	Lung (most common) and renal manifestations
Churg-Strauss syndrome (ANCA positive)	Bronchial asthma, granuloma and eosinophilia	Granulomatous inflammation	Asthmatic attacks as a result of involvement of respiratory tract
Drug-induced small vessel vasculitides involving skin (ANCA positive)	Dermal post-capillary venules inflammation due to administration of penicillin or phenylbutazone	Acute or chronic inflammation	Skin rash 1–3 weeks after the drug therapy
Henoch-Schönlein purpura (ANCA negative)	IgA deposition occurs in vessel of skin often similar to IgA nephropathy. Other antigens may include drugs or foods	Vasculitis	Nephritic syndrome and skin rashes on extensor surfaces of the arms, legs and buttocks, painful joints, gastrointestinal involvement (colicky abdominal tract pain with melena)
Cryoglobulinemia vasculitis (ANCA negative)	Necrotizing vasculitis involving arterioles, capillaries, and venules. Glomeruli and small vessels of skin are involved in elderly population infected with hepatitis C infection. Serum cryoglobulin (IgM) is increased	Necrotizing vasculitis	Purpura of skin, arthralgia, and glomerulonephritis. Renal involvement can be life-threatening

Contd...

Table 15.17 Classification of the vasculitides (*Contd...*)

Examples	Diagnostic Features	Light Microscopy	Clinical Features
Diabetic vascular disease (ANCA negative)	▪ Microangiopathy in uncontrolled diabetes mellitus ▪ Hyperglycemia produce premature atherosclerosis, and microangiopathy resulting to kidneys, nerves and retina	Atheromatous plaque in large- and medium-sized arteries	Gangrene foot, renal failure and blindness
Raynaud's phenomenon (ANCA negative)	Arterial insufficiency of the digital vessels secondary to systemic lupus erythematosus and progressive systemic sclerosis. Raynaud's phenomenon may also occur in thromboangiitis obliterans, Takayasu's arteritis, cryoglobulinemia, ergot poisoning, thoracic outlet syndrome, and cold agglutinin diseases (IgM)	Vasculitis	Extreme cold temperatures and emotional stress may trigger color changes of the fingers from white to blue to red

activation. Examples of vasculitis are polyarteritis nodosa, Wegener's granulomatosis, systemic lupus erythematosus and rheumatoid arthritis. Vasculitis and antineutrophil cytoplasmic antibodies are given in Table 15.18.

- **Infective vasculitis:** It occurs due to bacteria (pyogenic bacteria, *Neisseria meningitidis*, *Neisseria gonorrhoeae*, fungi (Candida, Aspergillus, and Mucormycosis), viruses (HBV, HCV, rubella, herpes zoster), and *Rickettsia rickettsii*.
- **Metabolic disorder:** Diabetic vascular disease occurs in uncontrolled diabetes mellitus.
- **Unknown etiology:** Vasculitis of unknown etiology includes cranial or giant cell (temporal) arteritis, Takayasu's arteritis (pulseless disease), thromboangiitis obliterans (Buerger's disease).

LARGE VESSEL VASCULITIDES

TEMPORAL (CRANIAL/GIANT CELL) ARTERITIS

Temporal (cranial/giant cell) arteritis is the most frequent form of granulomatous vasculitis, which primarily involves branches of the carotid artery, particularly the temporal artery. Involvement of the ophthalmic branch of the external carotid can lead to blindness. Aorta, its major branches and coronaries may also be affected.

Diagnostic Criteria

Three of five diagnostic criteria of temporal arteritis include: Age >50 years, recent localized headache, temporal artery tenderness, ESR 50 mm/hour and biopsy temporal artery showing vasculitis.

Table 15.18 Vasculitis and antineutrophil cytoplasmic antibodies

ANCA (Antineutrophil Cytoplasmic Antibody) Positive	ANCA (Antineutrophil Cytoplasmic Antibody) Negative
Wegener granulomatosis	Temporal arteritis
Microscopic polyarteritis	Takayasu arteritis
Polyarteritis nodosa	Glomerulonephritis
Systemic lupus erythematosus	Henoch-Schönlein purpura*
Idiopathic crescentic arteritis	Connective tissue diseases*
Kawasaki disease	Drug-induced vasculitis*
Churg-Strauss syndrome	

*ANCA (antineutrophil cytoplasmic antibody) rarely positive: *Henoch-Schönlein purpura, connective tissue diseases and drug-induced vasculitis.*

Pathogenesis

Exactly etiology is unknown, but type 4 cell-mediated hypersensitivity mediates this form of vasculitis.

Clinical Features

Patient presents with unilateral headache (most common) or claudication of the jaw, painful, palpable enlarged, tender temporal artery, morning stiffness in the neck and fever. Temporary or permanent impaired vision occurs due to involvement of ophthalmic artery.

Surgical Pathology: Temporal Arteritis
Light Microscopy
▪ Histologic examination of temporal arteritis shows transmural granulomatous inflammation of blood vessel, giant cells, thrombus formation, organization and intimal fibrosis, disrupted elastic lamellae, and marked intimal edema. ▪ Neovascularization in media is a useful indicator of previous inflammation. It can be quite focal, requiring serial sections of a small biopsy.

Laboratory Diagnosis

Elevated erythrocyte sedimentation rate (ESR) (>100 mm/hour) in conjunction with tender temporal artery is highly suggestive of cranial or giant cell arteritis (temporal arteritis).

Treatment

Treatment of patient with temporal arteritis is immediate institution of corticosteroid therapy to prevent blindness.

TAKAYASU ARTERITIS (PULSELESS DISEASE)

Takayasu arteritis involves branches of the aortic arch, i.e. carotid and subclavian arteries, pulmonary arteries and abdominal aorta (50% cases). Disorder is characterized by chronic progressive granulomatous inflammation and stenosis of aortic arch and its branches (carotid, subclavian arteries), resulting in aortic arch syndrome (Fig. 15.22).

Age and Sex Predilection

More than 90% of patients are women under 30 years of age. Takayasu arteritis may affect middle-aged women of Asian descent.

Pathogenesis

Type 4 hypersensitivity reaction is mainly responsible for Takayasu arteritis.

Clinical Features

Patient presents with absence of pulse in carotid, radial and ulnar arteries, visual disturbances, myocardial infarction due to involvement of coronary arteries and hypertension due to involvement of renal artery. Constitutional symptoms include fever, night sweats, malaise, myalgia, arthritis and arthralgia, ocular problems, and painful skin nodules.

Fig. 15.22: Takayasu's arteritis. It is common in Japan with unknown etiology. The aortic wall is thickened. Intima shows thick plaques. The walls of the innominate and common carotid arteries show thickening and narrowing. Consequences of occlusions lead to pulseless disease. Gross morphology and histopathological appearances are identical to syphilitic aortitis (arrow).

Surgical Pathology: Takayasu Arteritis
Gross Morphology
On gross examination, the aorta is thickened, and the intima exhibits focal, raised plaques.
Light Microscopy
Blood vessel shows granulomatous inflammation.

Diagnosis

Arteriography is a diagnostic tool for Takayasu arteritis.

Therapeutic Correlation

Patient with Takayasu arteritis is treated by bypass surgery.

MEDIUM VESSEL VASCULITIDES

POLYARTERITIS NODOSA (PAN)

Polyarteritis nodosa is systemic necrotizing vasculitis of medium- or small-sized arteries with segmental involvement or partial circumferential lesions and associated with glomerulonephritis, which leads to marked destruction of media and internal elastic lamella of arteries resulting in aneurysm formation.

- Small and medium size arteries undergo thrombosis, ulceration and infarction of organs. Affected blood vessel is firm and nodular that gives beaded appearance.
- Pathologic changes at different stages of disease process may show acute, chronic or healing stages.

Pathogenesis

Polyarteritis nodosa is mediated via type 3 immune complex mediated hypersensitivity through antigen–antibody complexes, in which antineutrophilic cytoplasmic autoantibodies are formed resulting in liberation of hydrolytic enzymes, which damage to mediam and small size arteries.

- Hepatitis B virus (30–40%) and intravenous amphetamines play an important role in its pathogenesis.
- Drugs, such as sulfonamides and penicillin, may form immunogenic hapten–protein complexes, which play key role in its pathogenesis.

Clinical Features

Patient presents with clinical manifestations due to involvement of renal arteries (85%), coronary arteries (75%), hepatic artery (75%), mesenteric arteries (65%), and arteries supplying skeletal muscles (40%), brain, nerves, pancreas and eyes (Fig. 15.23 and Table 15.19).

Laboratory Findings

Laboratory findings in polyarteritis nodosa include peripheral neutrophilic leukocytosis and eosinophilia, positive antineutrophil cytoplasmic antibodies with perinuclear staining (p-ANCA), and renal abnormalities (hematuria with RBC casts).

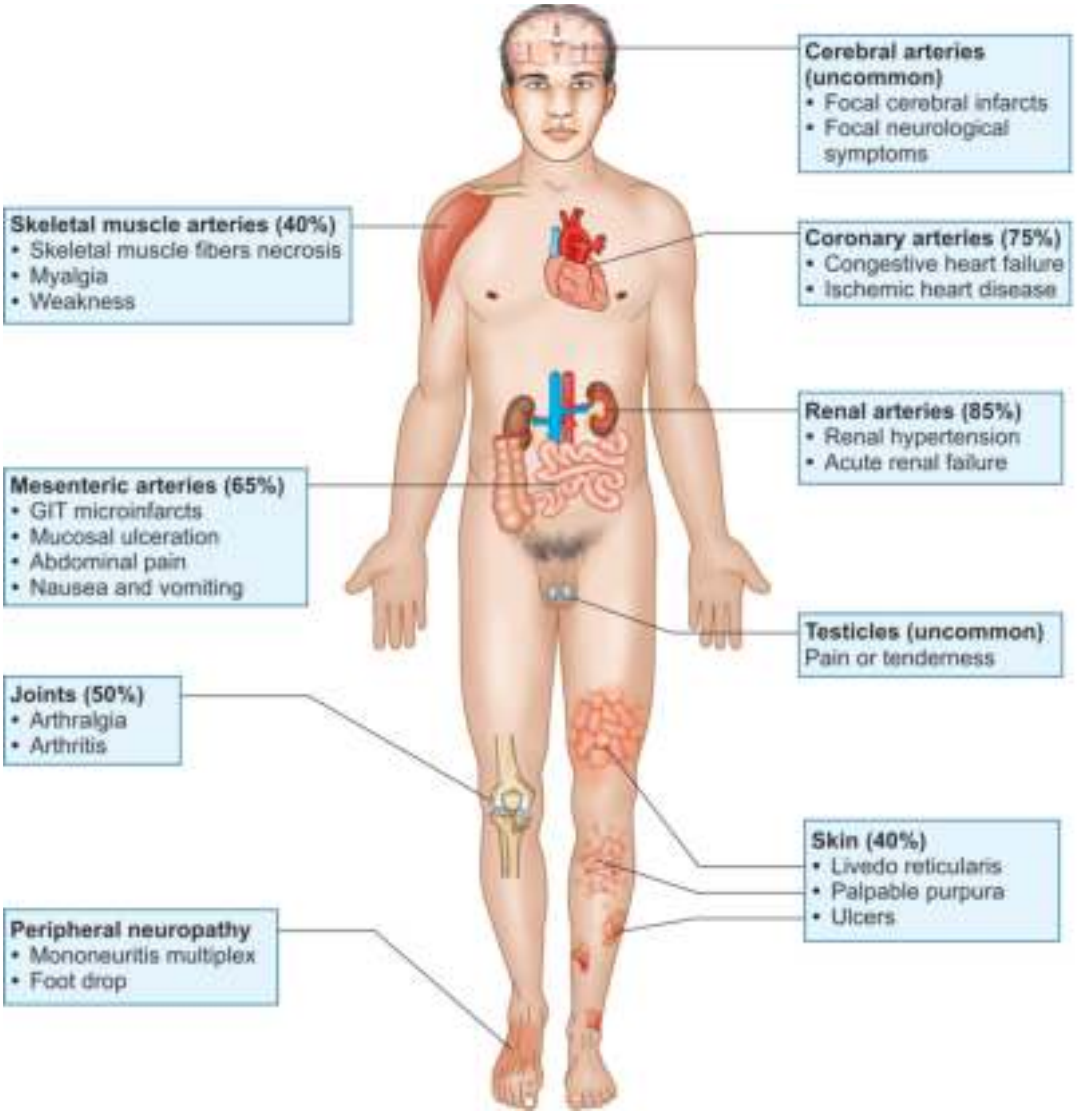

Fig. 15.23: Clinical manifestations of polyarteritis nodosa.

Table 15.19 Clinical manifestations of polyarteritis nodosa

Blood Vessels Affected	Percentage of Cases	Clinical Manifestations
Renal arterioles and glomeruli	85%	▪ Renal hypertension ▪ Acute renal failure due to microinfarcts
Coronary arteries	75%	▪ Ischemic heart disease ▪ Congestive heart failure
Mesenteric arteries	65%	Gut microinfarcts and mucosal ulceration, nausea, vomiting or abdominal pain
Skeletal muscle arteries	40%	Skeletal muscle fibers necrosis resulting in myalgia, weakness, arthralgia or arthritis
Cerebral arteries	Few cases	Focal infarcts with focal neurological symptoms

Diagnosis

Arteriography and biopsy of palpable nodular lesions in the skin and organ are analyzed to establish diagnosis of polyartertis nodosa.

Therapeutic Significance

Untreated polyarteritis nodosa disease is progressive, but most patients improve with corticosteroids and/or cytotoxic drug therapy.

Surgical Pathology: Polyarteritis Nodosa

Light Microscopy

- Lesion shows similar morphology as seen in polyarteritis nodosa, i.e. acute, chronic and fibrosis stages.
- Early lesion shows fibrinoid necrosis with thickening and infiltration of the vessel wall by neutrophils, eosinophils and lymphocytes.
- In mature lesion, vessel occlusion occurs secondary to intimal and mural fibrosis.

KAWASAKI DISEASE

Kawasaki disease is also known as mucocutaneous lymph node syndrome, which involves the coronary arteries. It is an acute febrile self-limited illness of children under the age of 10 years in Japan. Disorder is characterized by acute necrotizing vasculitis of small- and medium-sized vessels.

Clinical Features

Patient presents with fever, desquamating skin rash, mucosal inflammation (conjunctivae, lips, and oral mucosa) and cervical lymphadenopathy. Coronary artery vasculitis results in coronary thrombosis and aneurysm formation associated with fatal outcome.

THROMBOANGIITIS OBLITERANS

Thromboangiitis obliterans also known as Buerger's disease is acute disorder seen in young men especially in Jewish populations.

Blood Vessels Involved

Thromboangiitis obliterans involves arteries of extremities such as tibial, popliteal, and radial, extending to adjacent veins and nerves, i.e. neurovascular compartment.

Pathology

The arteries of the extremities in thromboangiitis obliterans undergo thrombosis resulting in painful gangrenous toes and fingers due to ischemia. Disorder is precipitated by heavy cigarette smoking. Blood vessels show thrombosis and microabscesses formation. Distal gangrene often requires amputation below knee joint.

SMALL VESSEL VASCULITIDES

Immunologic mechanism is responsible for most cases of small vessel vasculitides. Identification of autoantibodies in serum is used in diagnostic evaluation of patients with possible vasculitis.

- **Antineutrophil cytoplasmic antibody (ANCA):** ANCA IgG is formed against antigens, i.e. myeloperoxidase and proteinase 3 present in cytoplasm of neutrophils. Autoantibodies attack on small arteries, arterioles, capillaries and venules resulting in vasculitis. ANCA, i.e. p-ANCA (MPO-ANCA) and c-ANCA (PR3-ANCA) can be demonstrated by enzyme-linked immunosorbent assay (ELISA) and indirect immunofluorescence microscopy.
- **Antineutrophil cytoplasmic autoantibodies (c-ANCA):** Anti-proteinase 3 autoantibodies are formed against proteinase 3 antigen of cytoplasmic component of polymorphonuclear cells leading to subsequent release of hydrolytic enzymes and toxic oxygen-derived free radicals. Immunofluorescence study reveals cytoplasmic pattern, which correlates with anti-proteinase 3 (anti-PR3) antibody. It is more indicative of Wegener's granulomatosis.
- **Perinuclear antineutrophil cytoplasmic autoantibodies (p-ANCA):** Immunofluorescence study reveals perinuclear pattern of staining, which correlates

antimyeloperoxidase antibody (anti-MPO antibody). It strongly suggests microscopic polyarteritis. This pattern may also appear in other vasculitis as well as crescentic glomerulonephritis. Antinuclear antibody test is helpful in diagnosis of autoimmune disorder, i.e. systemic lupus erythematosus.

WEGENER'S GRANULOMATOSIS (ANCA POSITIVE)

Wegener's granulomatosis is a systemic necrotizing granulomatous vasculitis of unknown etiology, which involves respiratory tract such as nose, sinuses and lungs in 90–95% of cases. Patient develops destructive lesions in nasal cavity, lung and kidneys. It mainly affects 50–60 years of age group. Males are more affected than females. Disorder is usually positive for ANCA (Fig. 15.24A—histology and Fig. 15.24B—clinical features).

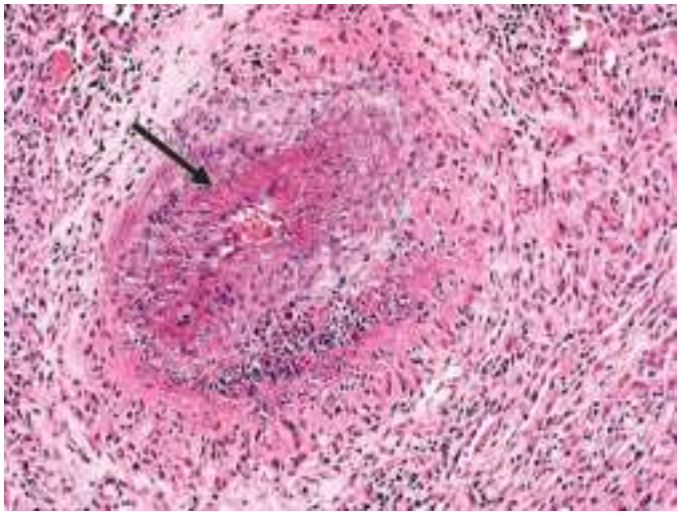

Fig. 15.24A: Wegener's granulomatosis. Blood vessel shows granulomatous inflammation (arrow) (100X).

Etiopathogenesis

Wegener's granulomatosis occurs due to inhalation of some infectious agents. PR3-antineutrophil cytoplasmic antibody (c-ANCA) against proteinase 3, MPO-ANCA and perinuclear ANCA (p-ANCA) autoantibodies against myeloperoxidase are formed. Immune complexes formed are deposited in small vessels of upper and lower respiratory tract, kidneys and other organs resulting in necrotizing vasculitis.

Clinical Features

Many organ systems are involved in Wegener's granulomatosis usually upper and lower respiratory tract (90–95%) and kidneys. Patient develops chronic

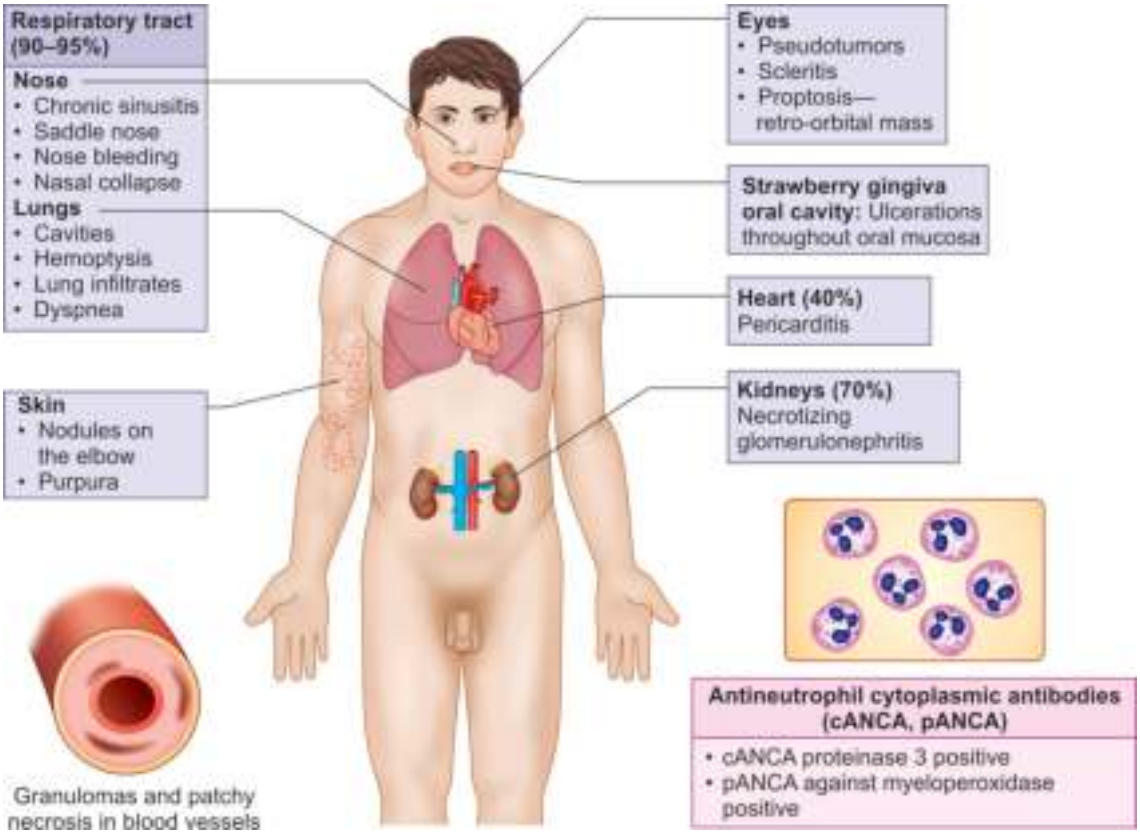

Fig. 15.24B: Clinical features of Wegener's granulomatosis.

Table 15.20 Clinical manifestations of Wegener's granulomatosis

Location	Lesions
Upper respiratory tract	Ulcerative lesions of nose, sinuses and pharynx; chronic sinusitis
Kidney	Chronic necrotizing glomerulonephritis
Lower respiratory tract	Necrotic areas and cavitation in lungs, cough, dyspnea, hemoptysis and chest pain

sinusitis (95%), saddle nose deformity, nasopharyngeal ulcers or pneumonias. Patient may also develop necrotizing glomerulonephritis (70%) resulting in renal failure, arthralgia due to joints involvement (60%), heart (40%), skin, eyes, and ears (Table 15.20).

Chest Radiograph

Chest radiograph may demonstrate bilateral nodular infiltrates or cavitary pulmonary lesions in patients with Wegener's granulomatosis.

Surgical Pathology: Wegener's Granulomatosis

Light Microscopy

- Histologic examination of involved tissue in Wegener's granulomatosis shows fibrinoid necrosis of small arteries and veins, early infiltration by neutrophils, subsequent macrophage cell infiltration, and fibrosis.
- Fibrosis occurs with chronic lesions.
- Granuloma formation with giant cells is prominent.

Treatment

Cyclophosphamide plus corticosteroids are useful in treating these patients. In untreated patients with Wegener's granulomatosis outcome is fatal within one year.

MICROSCOPIC POLYANGIITIS (ANCA POSITIVE)

Microscopic polyangiitis is necrotizing vasculitis involving glomeruli and pulmonary capillaries, which occurs most often in old age. Immune complex deposits may be few or absent.

Surgical Pathology: Microscopic Angiitis

Light Microscopy

- Histologic features are similar to polyarteritis nodosa.
- Early lesion shows fibrinoid necrosis with thickening and infiltration of the vessel wall by acute and chronic inflammatory cells.
- Immune complex deposits in the involved vessels are not common, but may be demonstrated only in a few cases. The p-ANCA is often positive.

CHURG-STRAUSS SYNDROME (ANCA POSITIVE)

Churg-Strauss syndrome is necrotizing vasculitis also known as allergic granulomatous angiitis, which involves pulmonary artery, coronary artery and skin vessels.

Pathogenesis

Types 1, 3, and 4 hypersensitivity reactions contribute to the pathogenesis of this form of vasculitis.

Clinical Features

Patient develops bronchial asthma and peripheral eosinophilia.

DRUG-INDUCED VASCULITIDES INVOLVING SKIN (ANCA POSITIVE)

Administration of penicillin or phenylbutazone causes vasculitis of post-capillary venules of skin.

Pathology

Dermal post-capillary venules show infiltration by polymorphonuclear cells, nuclear dusts due to karyorrhexis of neutrophils and leakage of RBCs leading to purpuric skin rashes. In some cases, blood vessels are mainly infiltrated by lymphocytes.

Clinical Features

Patient develops purpuric skin rash 1–3 weeks after the drug penicillin or phenylbutazone therapy.

HENOCH-SCHÖNLEIN PURPURA (ANCA NEGATIVE)

Henoch-Schönlein purpura (HSP) may be precipitated by exogenous antigens such as drugs, foods, or infectious organisms. HSP can develop after respiratory tract infections with streptococci (β-hemolytic, Lancefield group A) and viruses.

Pathology

IgA deposition occurs in small blood vessels of skin often similar to IgA nephropathy. Various drugs or foods may play role in the pathogenesis of Henoch-Schönlein purpura.

Clinical Features

Patient presents with nephritic syndrome and skin rashes on extensor surfaces of the arms, legs, and buttocks, painful joints, gastrointestinal tract involvement (colicky abdominal pain with melena).

CRYOGLOBULINEMIA VASCULITIS (ANCA NEGATIVE)

Cryoglobulinemia vasculitis is a necrotizing vasculitis, which involves arterioles, capillaries, and venules. Glomeruli and small blood vessels of skin are involved in elderly population infected with hepatitis C.

Clinical Features

Patient presents with purpuric skin rashes, arthralgia, and glomerulonephritis. Renal involvement can be life-threatening.

Laboratory Findings

Serum cryoglobulin (IgM) concentration is increased, that precipitates at 4°C and redissolves at 37°C. Complement C4 is decreased, while C3 is normal.

DIABETIC VASCULAR DISEASE (ANCA NEGATIVE)

In untreated patients with diabetes mellitus, hyperglycemia produces premature atherosclerosis, and microangiopathy involving vessels of kidneys and retina.

Complications

Complications of diabetic vascular disease include gangrene, renal failure and blindness.

Management

Effective control of diabetes reduces the incidence of renal and retinal disease.

RAYNAUD'S PHENOMENON (ANCA NEGATIVE)

Raynaud's phenomenon (ANCA negative) is arterial insufficiency of the digital vessels, which most often affects young healthy women.

Pathogenesis

Raynaud's phenomenon is most often secondary to systemic lupus erythematosus, progressive systemic sclerosis. It may also occur in thromboangiitis obliterans, Takayasu's arteritis, cryoglobulinemia, ergot poisoning, thoracic outlet syndrome, and cold agglutinin disease (IgM).

- Extreme cold temperatures and emotional stress may trigger color changes of the fingers from white to blue to red.
- CREST syndrome (calcinosis, Raynaud phenomenon, esophageal dysmotility, sclerodactyly, and telangiectasia) is a limited variant of progressive systemic sclerosis. It is associated with calcinosis of the fingertips. Patient develops Raynaud's phenomenon, esophageal motility disorder, sclerodactyly, telangiectasia, and a positive anti-centromere antibody.

Clinical Features

Patient presents with recurrent vasospasm of small arteries and arterioles leading to pallor or cyanosis, most often in the fingers and toes.

LYMPHOMATOID GRANULOMATOSIS

Lymphomatoid granulomatosis is a rare granulomatous vasculitis characterized by infiltration by atypical lymphocytoid and plasmacytoid cells.

Blood Vessels Involved

Lymphomatoid granulomatosis most often involves pulmonary vasculature but also has a predilection for vessels of the central nervous system, skin, liver, and kidneys.

Predisposing Factors

Lymphomatoid granulomatosis usually arises in the setting of immunosuppression and infection with Epstein-Barr virus. At present, it is thought to represent B cell neoplasm with an exuberant T cell response.

VENOUS SYSTEM

VARICOSE VEINS

Varicose veins and venous thrombosis together account for 90% of clinical venous disorders. A varicose vein is an enlarged and tortuous blood vessel. Varicose veins may occur in leg, esophagus (esophageal varices), anorectal region (hemorrhoids) and spermatic cord (varicocele).

VARICOSE VEINS IN LEGS

Varicose veins most often affect superficial veins of the lower extremities due to prolonged increased intraluminal pressure and loss of vessel wall support. Superficial varicosities of the leg veins, usually in the saphenous system, are among the most common ailments of humans due to upright posture.

Physiologic State

Superficial saphenous veins drain into deep saphenous veins) via communicating branches.

- Valves prevent blood flow from the deep into the superficial venous system except around the ankles, where blood flow is normally in that direction.

- Muscle contraction in the legs reduces hydrostatic pressure in the veins below the resting pressure, hence increasing the return of blood to the heart.

Pathologic State

- **Predisposing factors:** Prolonged standing in certain occupations, pregnancy, obesity, and inflamed deep vein thrombosis increase the venous pressure up to 10 times of normal resulting in varicose veins. Defective venous wall development is responsible for superficial varicosity in approximately 20% of general population. Individuals with normal veins may develop pedal edema (simple orthostatic edema) during prolonged standing or during journey.
- **Morphology:** Varicose veins are dilated and tortuous. Cut opened affected varicose veins reveal thrombus in lumen. Histologic examination shows variations in thickness as a result of hypertrophy of smooth muscle and subintimal fibrosis. Spotty dystrophic calcification is also demonstrated in varicose veins.
- **Clinical features:** Patient develops venous stasis, congestion, edema, pain, venous thrombosis, stasis dermatitis, ulceration, rupture, poorly healing wounds and superadded infections.

ESOPHAGEAL VARICES

Esophageal varices are dilated and tortuous veins in the submucosa of the lower esophagus in patients with cirrhosis developing portal hypertension. Esophageal varices commonly cause massive upper gastrointestinal hemorrhage (hematemesis—vomiting of blood), requiring emergency care to control hemorrhage and prevent hypovolemic shock.

HEMORRHOIDS

Hemorrhoids are dilatation of veins of the rectum and anal canal, which may occur inside or outside the anal sphincter.

- Hemorrhoids are aggravated by repeated pregnancy, straining at defecation and venous obstruction by rectal tumors.
- Thrombosis of hemorrhoids is exquisitely painful, may result in ulceration. Internal hemorrhoids typically bleed without pain, whereas external hemorrhoids typically cause pain but do not bleed.

VARICOCELE

A varicocele is a varicose dilatation of the veins draining the testis. Normally, veins draining testis and epididymis form the pampiniform plexus resulting in drainage into testicular veins. Left testicular vein directly opens into left renal vein, and the right into the inferior vena cava. A varicocele may develop as a result of poorly functioning valves that are normally found in veins.

Clinical Features

Most patients develop varicocele on the left side due to obstruction of testicular venous drainage due to spread of left-sided renal cell carcinoma into left renal vein. Patient presents with dragging discomfort. On palpation, with patient standing, the varicose plexus feels like a bag of worms.

DEEP VEIN THROMBOSIS (THROMBOPHLEBITIS)

Venous thrombosis occurs most often in the deep veins of the lower extremities due to stasis of venous blood especially in immobilized patients. Inflammation of veins with thrombus formation is known as thrombophlebitis.

PREDISPOSING FACTORS AND LOCATIONS

Cardiac failure, pregnancy, prolonged bed rest, or varicose veins cause venous circulatory stasis, which results in venous thrombus formation in the deep veins of lower extremities.

- Patient with cancers of pancreas, colon, or lung may develop venous thrombosis at one site and then disappear to be followed by thrombosis in other veins, is known as migratory thrombophlebitis (Trousseau sign).
- Pregnant women develop thrombosis in iliofemoral vein (painful white leg). Gravid uterus and hypercoagulable state during pregnancy initiate inflammation of thrombus with painful swelling. It is also known as plegmasia alba dolens.
- Venous thrombi are present in deep veins in the lower extremities below knee joint (most common in 90%); superior saphenous, periprostatic, pelvic (ovarian or uterine) veins.
- Less common sites of venous thrombosis include hepatic veins, renal veins, and dural sinuses.

CLINICAL FEATURES

- Patient presents with pain, tenderness and distal edema. In some cases, forced dorsiflexion of the foot resulting in pain is known as **Homan sign**.
- Deep vein thrombosis is entirely asymptomatic in 50% of affected patients. It is recognized only after thrombus is embolized to lung resulting in pulmonary hemorrhagic infarcts.

THERAPEUTIC CORRELATION

Anticoagulant therapy with heparin and warfarin prevents formation of venous thrombi.

THORACIC VENA CAVA SYNDROME

Superior vena cava syndrome is a collection of clinical signs and symptoms resulting from either partial or complete obstruction of blood flow through the superior vena cava. Thoracic vena cava syndrome occurs due to compression of superior vena cava or inferior vena cava. Depending on the involvement of vena cava, these are categorized into superior or inferior vena cava syndrome.

SUPERIOR VENA CAVA SYNDROME

Superior vena cava obstruction is caused by bronchogenic carcinoma in 90% of cases. Mediastinal lymphoma and cervical rib are less common causes.

Clinical Features

- Patient presents with dusky cyanosis, marked dilatation of veins of the face, arms, and shoulders giving purple discoloration.
- Compression of pulmonary veins may result in respiratory distress.
- Involvement of nerves results in neurologic manifestations.
- Visual disturbances occur due to congestion of retinal veins.
- The jugular veins are visibly distended resulting from raised jugular venous pressure.

INFERIOR VENA CAVA SYNDROME

Inferior vena cava syndrome may be caused by compression of inferior vena cava by a tumor, or propagation of thrombus from the iliofemoral vein, or growing of renal cell carcinoma as well as hepatocellular carcinoma into inferior vena cava, and occasionally into the right atrium.

Clinical Features

Due to obstruction of inferior vena cava, patient presents with marked pedal edema, distension of the superficial collateral veins of the lower abdomen. Involvement of renal vein may result in massive proteinuria.

LYMPHATIC SYSTEM

Lymphatic vessels have an incomplete basement membrane, hence predisposing them to infection and tumor invasion. Drainage of harmful pathogens to regional lymph nodes leads to reactive hyperplasia with enlarged, tender nodes. Lymphatic drainage of tumor emboli first occurs in the subcapsular sinus of draining lymph nodes.

ACUTE LYMPHANGITIS

Acute lymphangitis is inflammation of the lymphatic channels (red streak). It is most commonly secondary to group A β-hemolytic streptococci in majority of cases and *Staphylococcus aureus* to a lesser degree.

- Affected lymphatic channels are dilated and filled with inflammatory exudate, which extends through the wall and produce cellulites or focal abscess.
- Patient presents with painful red streaks in subcutaneous region along the course of inflamed lymphatic channels; and painful lymphadenopathy. Septicemia occurs due to spillage of bacteria into venous system.

LYMPHEDEMA

Lymphedema is an abnormal interstitial collection of lymphatic fluid due to obstruction to lymphatic flow. Increased concentration of proteins in lymphedema gives fibrogenic stimulus resulting in dermal fibrosis in chronic lymphedema. Lymphedema usually occurs due to secondary causes.

LYMPHEDEMA VARIANTS

Lymphedema is a chronic condition that occurs when lymph (also known as lymphatic fluid) pools in a person's legs, arms, hands, feet, or other body parts. Lymphedema is classified into primary and secondary forms.

- **Primary lymphedema:** It occurs due to congenital defect of lymphatic channels. It is known as **Milroy disease** or **heredofamilial lymphedema**. Other form of primary lymphedema is known as **lymphedema praecox** affects females of 10–25 years. Females develop slow onset edema feet extending to trunk resulting in superimposed infection or ulcerations.

- **Secondary lymphedema:** Lymphatic channels can be obstructed by (a) malignant neoplasms, (b) fibrosis resulting in inflammation, filariasis (elephantiasis) or irradiation, and (c) surgical ablation (axillary dissection of radical mastectomy). Breast cancer cells obstructing lymphatic channels produce peau d'orange of the breast in inflammatory carcinoma.

CHYLOUS EFFUSION

Chylous effusion is collection of lymphatic fluid (chylomicrons plus lymphocytes) in a body cavity. It is caused by rupture of obstructed lymphatic channels due to invasion by an infiltrating malignant lymphoma (most common) or trauma.

NEOPLASTIC DISORDERS OF BLOOD VESSELS

Vascular tumors of soft tissues occur in the deep subfascial soft tissue and/or subcutis. Some vascular tumors occurring in the dermis may involve deep soft tissue. Vascular tumors according to recent WHO classification of soft tissue are given in Table 15.21.

Table 15.21 Vascular tumors according to recent WHO classification of soft tissue

Reactive Vascular Endothelial Hyperplasia
▪ Papillary endothelial hyperplasia ▪ Pyogenic granuloma (lobular capillary hemangioma) ▪ Bacillary angiomatosis ▪ Glomeruloid hemangioma
Benign Tumors
▪ Capillary hemangioma ▪ Cavernous hemangioma ▪ Hemangioma of subcutaneous/deep soft tissue ▪ Angiomatosis ▪ Epithelioid hemangioma (angiolymphoid hyperplasia with eosinophilia) ▪ Intramuscular hemangioma ▪ Spindle cell hemangioma ▪ Lymphangioma
Intermediate (Borderline) Malignant Tumors
▪ Kaposiform hemangioendothelioma ▪ Dabska type (papillary intralymphatic angioendothelioma) and retiform hemangioendothelioma ▪ Kaposi sarcoma
Malignant Tumors
▪ Angiosarcoma ▪ Epithelioid hemangioendothelioma

REACTIVE VASCULAR PROLIFERATION

Reactive proliferation of vascular endothelial cells occurs due to infectious or paraneoplastic disorders. Reactive proliferation of vascular endothelial cells occurs in the cutaneous and mucosal regions. Variants of reactive vascular proliferations include papillary vascular endothelial hyperplasia, pyogenic granuloma, bacillary angiomatosis and glomeruloid hemangioma (Table 15.22).

PROGNOSIS AND TREATMENT

Prognosis is excellent in pyogenic granuloma treated by simple surgical excision. Bacillary angiomatosis is treated by antibiotics and correction of immunosuppressive state. Glomeruloid hemangioma is treated by simple surgical excision. It is difficult to treat polyneuropathy, organomegaly, endocrinopathy, monoclonal gammopathy, and skin changes (**POEMS syndrome**).

Table 15.22 Variants of reactive vascular proliferations

Variants	Features
Papillary vascular endothelial hyperplasia	▪ Most common sites are superficial soft tissue of extremities especially thumb, head and neck region ▪ Patient presents with vascular endothelial hyperplasia in the superficial soft tissue of extremities especially thumb, head and neck region
Pyogenic granuloma	▪ Pyogenic granuloma is also known as lobular capillary hemangioma ▪ Most common sites are buccal mucosa and skin. It may affect any age group ▪ Patient presents with ulcerated polypoidal mass on the mucosal surface and skin
Bacillary angiomatosis	▪ Bacillary angiomatosis occurs in HIV positive persons and other immunosuppressive state ▪ Most common sites are mucosal surface and skin in the immunocompromised persons
Glomeruloid hemangioma	▪ Glomeruloid hemangioma occurs in patient with POEMS (polyneuropathy, organomegaly, endocrinopathy, monoclonal gammopathy, and skin changes) syndrome. It occurs in elderly patients without sex predominance ▪ Patient presents with small, red to violaceous papules on proximal extremities and trunk

Surgical Pathology: Reactive Vascular Proliferations
Gross Morphology
Mucosal lesion shows polypoidal small red to blue mass. Skin biopsy shows erythematous lesions.
Light Microscopy
▪ **Papillary vascular endothelial hyperplasia:** Early lesion is composed of ingrowth of vascular endothelial cells into the thrombus with formation of pseudopapillae lined by plump endothelial cells. In the fully developed lesion, proliferation of vascular endothelial cells may create inter-anastomosing vascular channels simulating angiosarcoma. ▪ **Pyogenic granuloma:** It is well circumscribed and lobular lesion inolving large vessel in the central region and peripheral aggregates of well-formed capillaries. Lesion is infiltrated by acute and chronic inflammatory cells. ▪ **Bacillary angiomatosis:** It shows a vaguely lobular pattern. It is composed of capillary-sized vessels lined by endothelial cells. Stroma shows numerous neutrophils, fibrin and Bartonella bacilli demonstrated by Warthin-Starry stain. ▪ **Glomeruloid hemangioma:** It is composed of ectatic small vessels containing intraluminal papillae resembling glomeruli. Endothelial cells are vacuolated and containing eosinophilic proteinaceous material.
Differential Diagnosis
▪ **Pyogenic granuloma:** It should be differentiated from angiosarcoma, Kaposi sarcoma and vascular proliferation seen in other disorders. ▪ **Bacillary angiomatosis:** It should be differentiated from granulation tissue and Kaposi sarcoma. ▪ **Glomeruloid hemangioma:** It should be differentiated from papillary endothelial hyperplasia and Dabska tumor (low grade angiosarcoma).
Immunohistochemistry Technique
Vascular endothelial cells show positivity for CD31, CD34, Fli-1 protein and vWF.

Markers	Expression
▪ CD31	▪ Positive
▪ CD34	▪ Positive
▪ Fli-1 protein	▪ Positive
▪ vWF	▪ Positive

CAPILLARY HEMANGIOMA

Capillary hemangioma is a regressing most common benign neoplasm of vascular endothelial cells either present at birth or during infancy in 15–20% of cases and children. Initially, it grows rapidly followed by stabilization and involution. Familial capillary hemangioma may show abnormality of chromosome 5.

LOCATIONS, AGE AND SEX PREDILECTION

Most common sites of capillary hemangioma are skin and mucosal surface followed by viscera. Large capillary hemangioma in infants on the head and neck region occurs as a part of **PHACES syndrome** (posterior fossa refers to possible abnormal structure in the brain especially cerebellum, hemangiomas of the cervicofacial region, abnormalities of arteries, cardiac and ocular regions). Lumbosacral capillary hemangioma occurs in infants with occult spinal malformations. Capillary hemangioma affects infants and children without sex predominance.

CLINICAL FEATURES

Patient with small superficial capillary hemangioma presents with red macules, usually level with the surface of the skin or slightly elevated (Fig. 15.25). Large capillary hemangioma appears as firm, blue-violet tortuous mass. Some capillary hemangiomas are associated with Sturge-Weber syndrome and von Hippel-Lindau syndrome.

- **Port-wine stain:** It is flat, red or purple benign lesion demonstrated on face of infants. It is composed of large vascular channels frequently interspersed with small capillaries.
- **Sturge-Weber syndrome:** It is characterized by port-wine stain of face, ipsilateral glaucoma, vascular lesions of choroidal tissue and extensive hemangiomatous involvement of meninges. Patient presents with convulsions, mental retardation and retinal detachment.
- **von Hippel-Lindau syndrome:** It is an autosomal dominant disorder characterized by multiple vascular tumors, other tumors and cysts widely scattered in many organ systems.

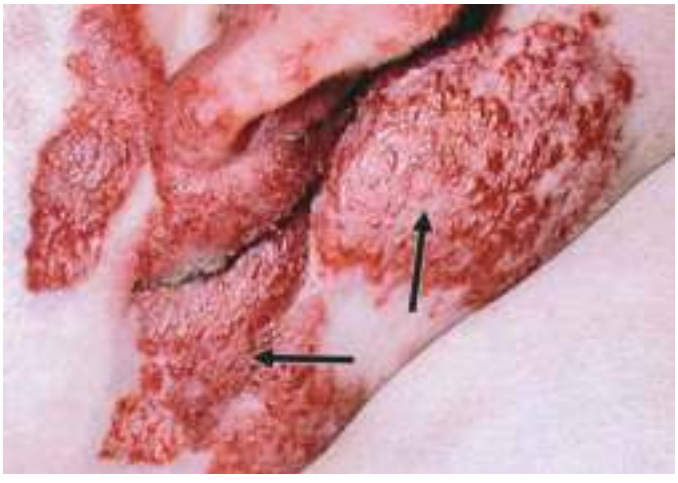

Fig. 15.25: Cutaneous hemangioma. Patient with small superficial hemangioma presents with red macules, usually level with the surface of the skin or slightly elevated (arrows).

PROGNOSIS AND TREATMENT

Treatment of capillary hemangioma depends on the age of patient, size of lesion and location. Large capillary hemangioma is treated by administration of interferon-α or glucocorticoids or both. Unresectable capillary hemangioma is treated by anti-angiogenesis agents.

Surgical Pathology: Capillary Hemangioma

Gross Morphology

- Capillary hemangioma is well circumscribed but lacking capsule. Gross morphology of capillary hemangioma varies depending on its size and location.
- Small-sized capillary hemangioma in the superficial region appears as red macules. Capillary hemangioma located in deep tissues appears as firm and blue violet mass.

Light Microscopy

- Capillary hemangioma is composed of closely packed aggregates of thin-walled capillaries usually filled with blood lined by single layer of bland endothelial cells. Each capillary is surrounded by scant connective tissue stroma.
- The lumen of capillaries may be partially or completely thrombosed and organized (Fig. 25.26).
- Juvenile capillary hemangioma in young children may be highly cellular and appearing solid with lumen formation due to protrusion of plump endothelial cells into the lumen and admixed with large number of pericytic cells. Mitoses may be demonstrated.
- In adults, lumen of capillaries is more obvious due to flattening of endothelial cells. Each capillary is surrounded by scant connective tissue stroma. Old lesions are usually fibrotic.

Differential Diagnosis

Capillary hemangioma should be differentiated from kaposiform hemangioendothelioma (KHE) and pediatric round cell tumors.

Immunohistochemistry Technique

Capillary hemangioma shows positivity for CD31, CD34, Fli-1, vWF and GLUT-1 (glucose transporter protein 1).

Markers	Expression
CD31	Positive
CD34	Positive
Fli-1	Positive
vWF	Positive
GLUT-1	Negative

CAVERNOUS HEMANGIOMA

Cavernous hemangioma is a benign tumor of endothelial origin, which tends to be larger than capillary hemangioma. It never undergoes regression and is less common than capillary hemangioma. Most common site of cavernous hemangioma is deep structures such as liver (most common), pancreas, spleen, placenta and brain. It affects young children with sex predominance.

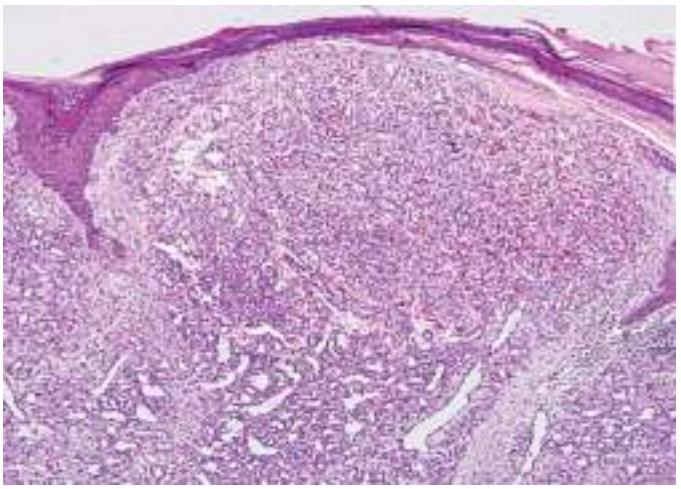

Fig. 15.26: Capillary hemangioma. Capillary hemangioma is composed of closely packed aggregates of thin-walled capillaries usually filled with blood lined by single layer of bland endothelial cells. Each capillary is surrounded by scant connective tissue stroma. The lumen of capillaries may be partially or completely thrombosed and organized (100X).

CLINICAL FEATURES

Cavernous hemangioma located in cutaneous region presents with irregular reddish tumor. Kasabach-Merritt syndrome is characterized by cavernous hemangioma and coagulopathy. Cavernous hemangioma located in skin and gastrointestinal tract has been as 'Blue bleb nevus syndrome'.

TREATMENT

Cavernous hemangioma never undergoes regression. It may produce destruction and compression of surrounding tissue. It does not respond to medicines. Surgical excision of tumor is curative.

Surgical Pathology: Cavernous Hemangioma

Gross Morphology

- Cavernous hemangioma located in skin shows irregular reddish lesion. Tumor located in the deep soft tissue especially in liver shows blue and nonpigmented.
- Cut surface shows sponge-like appearance.

Light Microscopy

- Cavernous hemangioma is composed of large dilated blood-filled inter-anastomosing vascular spaces lined by flattened endothelial cells resembling a sponge. Walls of the vessels are usually fibrotic.
- Thrombosis and calcification are most often demonstrated in the tumor. Thrombosis and recanalization in cavernous hemangioma may produce a sinusoidal pattern.

Differential Diagnosis

Cavernous hemangioma should be differentiated from angiosarcoma, spindle cell hemangioma and capillary hemangioma.

Immunohistochemistry Technique	
Capillary hemangioma shows positivity for CD31, CD34, Fli-1 and vWF. It is negative for GLUT-1 (glucose transporter protein 1).	
Markers	**Expression**
▪ CD31 ▪ CD34 ▪ Fli-1 ▪ vWF ▪ GLUT-1	▪ Positive ▪ Positive ▪ Positive ▪ Positive ▪ Negative

LYMPHANGIOMA

Lymphangiomas are malformations of lymphatic system characterized by formation of thin walled cysts. These can occur anywhere on the skin and mucous membrane.

- Lymphangiomas can be categorized as deep or superficial based on the size and depth of the abnormal lymphatic vessels or congenital or acquired.
- Superficial form of lymphangioma is lymphangioma circumscriptum also known as **lymphangiectasia**.
- Deep forms of lymphangioma include two specific congenital entities: cavernous lymphangioma and cystic hygroma.

LOCATIONS

Lymphangioma in skin is also called **lymphangioma circumscriptum**. Most common sites of cystic lymphangioma are neck, axilla and groin regions. Cavernous lymphangioma most often occurs in the oral cavity, upper trunk region, vulva and conjunctiva. Lymphangioma affects pediatric age group especially during first year of life. It may affect any age group without sex predominance.

PATHOPHYSIOLOGY

Congenital lymphangioma is formed due to the blockage of the lymphatic system during fetal development, though its cause remains unknown.

- Cystic hygromas are associated with genetic disorders including trisomies 13, 18 and 21; Noonan syndrome, Turner syndrome and Down syndrome.
- Acquired lymphangioma circumscriptum occurs in association with chronic lymphedema that leads to disruption of previously normal lymphatic drainage such as surgery, trauma, malignancy and radiation therapy.

CLINICAL FEATURES

Clinically, lymphangioma circumscriptum appears as multiple, grouped or scattered, translucent or hemorrhagic vascular papules.

- Cystic hygromas are lymphatic malformations that are clinically more circumscribed than cavernous lymphangioma and typically occur as cystic lump in the neck, axilla and groin regions. It may extend into the mediastinum in children compress lungs, heart and nerves.
- MRI can be useful in determining the extent of anatomical involvement of cystic hygroma or cavernous lymphangioma.

PROGNOSIS AND TREATMENT

Lymphangioma is not encapsulated tumors. It is treated by surgical excision. Recurrence may occur due to incomplete surgical excision.

Surgical Pathology: Lymphangioma	
Gross Morphology	
Multicystic spongy mass of lymphangioma is not encapsulated and containing watery/milky fluid.	
Light Microscopy	
▪ Lymphangioma is composed of large irregular vascular spaces lined by flattened bland endothelial cells with fibroblastic or collagenous stroma. Surrounding stroma may contain lymphoid aggregates. ▪ Abdominal lymphangioma may show marked inflammatory changes that obscure its lymphatic origin. Histology of cavernous lymphangioma is shown in Fig. 15.27.	
Immunohistochemistry Technique	
Lymphangioma shows positivity for CD31, CD34, D2–40 (podoplanin), PROX1, Fli-1 and CD141.	
Markers	**Expression**
▪ CD31 ▪ CD34 ▪ D2–40 (podoplanin) ▪ PROX1 ▪ Fli-1 ▪ CD141	▪ Positive ▪ Positive ▪ Positive ▪ Positive ▪ Positive ▪ Positive

SPINDLE CELL HEMANGIOMA

Spindle cell hemangioma (SCH) was originally described as spindle cell hemangioendothelioma. Later, it was believed to be low-grade angiosarcoma. Now, it has been reclassified by World Health Organization as spindle cell hemangioma.

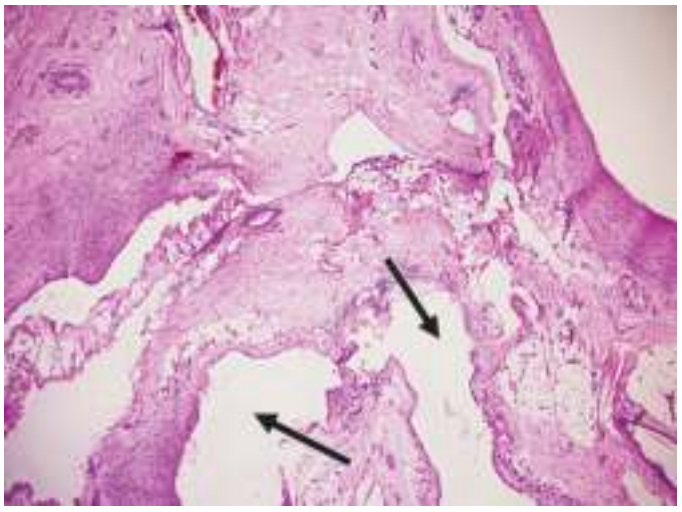

Fig. 15.27: Cavernous lymphangioma. It is composed of large irregular vascular spaces lined by flattened bland endothelial cells with fibroblastic or collagenous stroma (arrows). Surrounding stroma may contain lymphoid aggregates. Abdominal lymphangioma may show marked inflammatory changes that obscure its lymphatic origin (400X).

LOCATIONS

Spindle cell hemangioma is a benign possibly reactive endothelial tumor associated with Maffucci syndrome in 5% of cases. Most common site of spindle cell hemangioma is dermis or subcutis of distal extremities. It affects young adults without sex predominance.

CLINICAL FEATURES

Patient presents with violaceous nodule in dermis or subcutis of distal extremities. Maffucci syndrome is characterized by hemangiomas and endocrinopathies in 5% of cases. Spindle cell hemangioma is treated by surgical excision. It may recur through propagation of along blood vessel.

Surgical Pathology: Spindle Cell Hemangioma

Gross Morphology

Spindle cell hemangioma is small solitary mass in the dermis or cutis.

Light Microscopy

- Spindle cell hemangioma most often shows organizing thrombi, calcification and phleboliths. It is composed of two zones diagnostic of spindle cell hemangioma.
  - First zone shows thin-walled dilated blood vessels, reminiscent of cavernous hemangioma.
  - Second zone shows proliferation of spindle cells with normochromatic nuclei and eosinophilic cytoplasm, creating slit-like vascular spaces and vacuolated epithelioid cells indicating of spindle cell tumor.
- Mitoses and necrosis are not demonstrated in the tumor. Absence of chronic inflammatory cells helps in distinguishing spindle cell hemangioma from Kaposi sarcoma.

Differential Diagnosis

Spindle cell hemangioma should be differentiated from Kaposi sarcoma, kaposiform hemangioendothelioma and angiosarcoma.

Immunohistochemistry Technique

Spindle cell hemangioma shows positivity for CD31, CD34, desmin and smooth muscle actin (SMA).

Markers	Expression
▪ CD31	▪ Positive
▪ CD34	▪ Positive
▪ Desmin	▪ Positive
▪ SMA	▪ Positive

DEEPLY LOCATED HEMANGIOMA INCLUDING ANGIOMATOSIS

Deeply located hemangioma is a benign progressive vascular tumor. Angiomatosis must involve multiple tissue planes or skeletal muscles.

LOCATIONS

Most common sites of deeply located hemangioma are synovium and nerves. Deeply located hemangioma affects any age group without sex predominance. On the other hand, angiomatosis can involve multiple planes (e.g. skin, subcutis, muscle, bone) or multiple skeletal muscles in a contiguous fashion.

CLINICAL FEATURES

Patient presents with large nonspecific lump simulating sarcoma. Deeply located hemangioma and angiomatosis are treated by surgical excision.

Surgical Pathology: Deeply Located Hemangioma including Angiomatosis

Gross Morphology

Gross morphology of deeply located hemangioma depends on the relative proportion of fat, capillary hemangioma and cavernous-like appearance.

Light Microscopy

- Deeply located hemangioma may show histologic features of both capillary and cavernous hemangiomas; and large malformed blood vessels resembling both arteries and veins.
- Deeply located hemangioma in the skeletal muscle most often splays apart the skeletal muscle in a checkerboard pattern and contain adipose tissue. Presence of adipose tissue poses difficulty in determination of surgical margin status.

Differential Diagnosis

Deeply located hemangioma and angiomatosis should be differentiated from epithelioid hemangioendothelioma and epithelioid angiosarcoma.

Immunohistochemistry Technique

Deeply located hemangioma shows positivity for CD31, CD34, Fli-1 and vWF. It is negative for GLUT-1 (glucose transporter protein 1).

Markers	Expression
▪ CD31	▪ Positive
▪ CD34	▪ Positive
▪ Fli-1	▪ Positive
▪ vWF	▪ Positive
▪ GLUT-1	▪ Negative

KAPOSIFORM HEMANGIOENDOTHELIOMA

Kaposiform hemangioendothelioma is an intermediate (borderline) malignant vascular tumor. Kasabach-Merritt syndrome is characterized by kaposiform hemangioendothelioma, thrombocytopenia and hemorrhage. Most common sites are extremities in dermis and cutis; and retroperitoneum. It usually affects in the first year of life.

CLINICAL FEATURES

Patient presents with violaceous plaque in the dermis or subcutis of extremities; and large vascular tumor in the retroperitoneal region.

TREATMENT

Kaposiform hemangioendothelioma is a locally aggressive borderline malignant tumor. Complete excision of the tumor is difficult. There is little risk of metastases to distant organs. **Kasabach-Merritt syndrome** is characterized by kaposiform hemangioendothelioma, thrombocytopenia and hemorrhage resolve with complete excision of the tumor.

Surgical Pathology: Kaposiform Hemangioendothelioma

Gross Morphology

Kaposiform hemangioendothelioma located in the skin appears as large violaceous plaques; and large nodular infiltrative vascular tumor in retroperitoneal region associated with fibrosis.

Light Microscopy

- Tumor is composed of dilated lymphatic channels at the periphery of tumor resembling lymphangioma. It shows crescentic vascular spaces identical to angioma.
- Tumor shows admixture of well-formed capillary-sized vessels resembling angioma; and solid appearing foci with spindled and slit-like vascular spaces simulating Kaposi sarcoma. Glomeruloid foci contain small thrombi.

Differential Diagnosis

Kaposiform hemangioendothelioma should be differentiated from capillary hemangioma and Kaposi sarcoma.

Immunohistochemistry Technique

Kaposiform hemangioendothelioma shows positivity for CD31, CD34, Fli-1 and vWF. It is negative for GLUT-1 (glucose transporter protein 1).

Markers	Expression
▪ CD31	▪ Positive
▪ CD34	▪ Positive
▪ Fli-1	▪ Positive
▪ vWF	▪ Positive
▪ GLUT-1	▪ Negative

DABSKA-TYPE PAPILLARY INTRALYMPHATIC ANGIOENDOTHELIOMA AND RETIFORM HEMANGIOENDOTHELIOMA

Dabska-type papillary intralymphatic angioendothelioma and retiform hemangioendothelioma are vascular tumors of intermediate malignancy defined by the presence of distinctive 'hobnailed' endothelial cells, most likely exhibiting lymphatic endothelial differentiation. Both entities show overlapping histologic features.

- Most common sites are extremities in the dermis and cutis regions; and head and neck regions. Both entities affect infants and young children without sex predominance.
- Patient presents with ill-defined and sometimes violaceous and plaque-like lesions in the extremities; and head and neck regions. Both Dabska-type papillary intralymphatic angioendothelioma and retiform hemangioendothelioma are locally aggressive intermediate malignant vascular tumors. Wide surgical excision of tumor is curative.

Surgical Pathology: Dabska-type Papillary Intralymphatic Angioendothelioma and Retiform Hemangioendothelioma

Gross Morphology

Both Dabska-type papillary intralymphatic angioendothelioma and retiform hemangioendothelioma are ill-defined violaceous lesions.

Light Microscopy

Both Dabska-type papillary intralymphatic angioendothelioma and retiform hemangioendothelioma are composed of distinctive 'hobnailed' endothelial cells with scant cytoplasm and irregular

hyperchromatic nuclei. There is presence of lymphocytic infiltrate and dense fibrosis in the lesions.

- **Dabska-type papillary intralymphatic angioendothelioma:** It is composed of relatively well-formed blood vessels with intraluminal papillae. The intraluminal papillae are composed of hyaline core and 'hobnailed' endothelial cells. There is presence of dilated lymphatic channels near lesion. Few mitoses are demonstrated.
- **Retiform hemangioendothelioma:** It shows infiltrative proliferation of elongated branching blood vessels lined by 'hobnailed' endothelial cells. The intraluminal papillae are composed of hyaline core and 'hobnailed' endothelial cells identical to Dabska-type papillary intralymphatic angioendothelioma. Few mitoses are also demonstrated.

Differential Diagnosis

Dabska-type papillary intralymphatic angioendothelioma and retiform hemangioendothelioma should be differentiated from tumors showing hobnailed endothelial cells and intraluminal papilla, e.g. hemangioma and angiosarcoma.

Immunohistochemistry Technique

Dabska-type papillary intralymphatic angioendothelioma and retiform hemangioendothelioma show positivity for CD31, CD34, Fli-1, D2–40 and VEGFR3. It is negative for vWF.

Markers	Expression
▪ CD31	▪ Positive
▪ CD34	▪ Positive
▪ Fli-1	▪ Positive
▪ D2–40	▪ Positive
▪ VEGFR3	▪ Positive
▪ vWF	▪ Negative

EPITHELIOID HEMANGIOENDOTHELIOMA

Epithelioid hemangioendothelioma is a low-grade malignant vascular tumor of adult life, which is characterized by an 'epithelioid' or histiocytoid' endothelial cells. Tumor arises from small blood vessel in skin, deep soft tissue, bone, lung and liver. It may rarely present as an intravascular neoplasm. It affects children and adults.

- Patient presents with vascular thrombosis and painful lump in superficial or deep soft tissue. Patient with bone lesion presents with asymptomatic osteolytic lesion. Involvement of lung and liver by tumor may be asymptomatic.
- Epithelioid hemangioendothelioma is treated by wide surgical excision. Adjuvant radiotherapy may be in selected cases. Hepatic epithelioid hemangioendothelioma should be treated by liver transplantation.
- Tumor may metastasize to distant sites in 17% of cases with poor prognosis. Classic low-grade and high-grade epithelioid hemangioendotheliomas have risk of local recurrence and distant metastasis.

Surgical Pathology: Epithelioid Hemangioendothelioma

Gross Morphology

Epithelioid hemangioendothelioma neoplasm excised from superficial and deep soft tissue is white, firm and sometimes calcified. Lesion from lung may show thrombosed blood vessel.

Light Microscopy

- Epithelioid hemangioendothelioma is composed of small uniform rounded or slightly spindled eosinophilic endothelial cells with rounded nuclei and prominent cytoplasmic vacuolization. The latter feature probably represents primitive lumen formation by single cell.
- The tumor cells are arranged in small nests or cords or single file-array and only line well-formed vascular channels embedded in dense myxochondroid or myxohyaline matrix. Necrotic debris, hyaline collagen and thrombosed material may be demonstrated within the blood vessel (Fig. 15.28).
- Approximately 30% of epithelioid hemangioendothelioma shows anaplastic features, i.e. high nuclear grade, numerous atypical mitoses and necrosis with aggressive clinical course referred as malignant or high grade epithelioid hemangioendothelioma.

Differential Diagnosis

Epithelioid hemangioendothelioma should be differentiated from epithelioid hemangioma, epithelioid angiosarcoma, and metastatic carcinoma especially lobular carcinoma of breast.

Immunohistochemistry Technique

Epithelioid hemangioendothelioma shows positivity for CD31, CD34, Fli-1, vWF and low molecular weight cytokeratins (low molecular weight) (25%). CD34 positivity is shown in Figs 15.29 and 15.30.

Markers	Expression
▪ CD31	▪ Positive
▪ CD34	▪ Positive
▪ Fli-1	▪ Positive
▪ vWF	▪ Positive
▪ Cytokeratins (LMW)	▪ Positive

KAPOSI SARCOMA

Kaposi sarcoma is a locally aggressive vascular neoplasm. It occurs in the four clinicopathological settings (Table 15.23).

- **Classic Kaposi sarcoma:** It affects elderly males of East European and Mediterranean. Most common site is lower extremities in the subcutaneous region. Disease has indolent course.

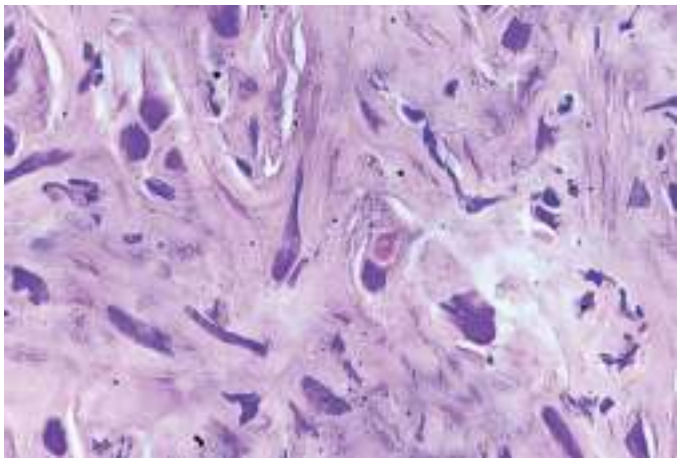

Fig. 15.28: Epithelioid hemangioendothelioma of liver. Tumor is composed of small uniform round and spindled endothelial cells with round nucleus, vacuolated cytoplasm and well-formed vascular channels, arranged in small nests or single file pattern embedded in dense myxochondroid or myxohyaline matrix (400X).

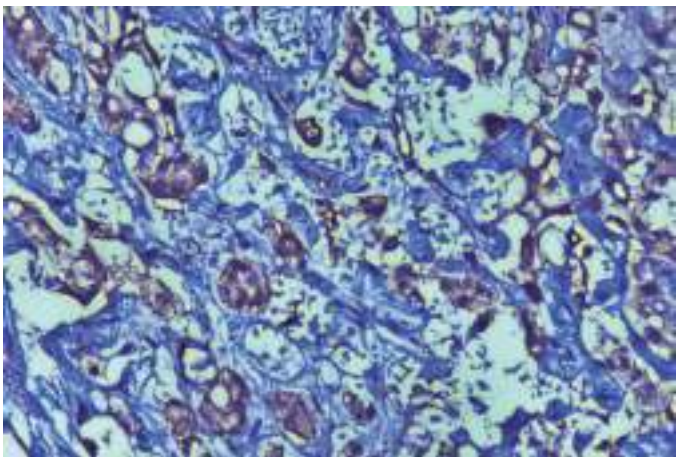

Fig. 15.30: Epithelioid hemangioendothelioma of liver. Vascular endothelial cells of epithelioid hemangioendothelioma of liver demonstrate immunohistochemical marker CD34 positivity (400X). It is a multifocal vascular tumor in liver of childhood most often first year of life.

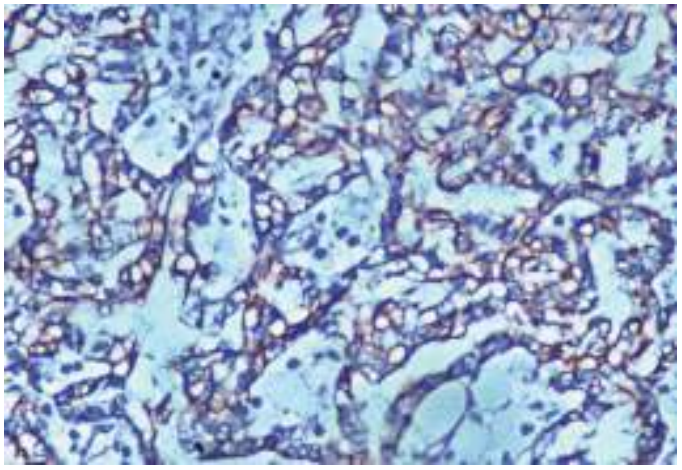

Fig. 15.29: Epithelioid hemangioendothelioma of liver. Vascular endothelial cells of the neoplasm demonstrate immunohistochemical marker CD34 positivity (400X).

- **Endemic (African) Kaposi sarcoma:** It affects young African males. Patient presents with bulky lymphadenopathy and soft tissue tumor. Disease has indolent clinical course in adults; and aggressive clinical course in African children with bulky lymphadenopathy.
- **Iatrogenic Kaposi sarcoma:** It occurs in renal transplantation cases, who develop cutaneous or visceral lesions. Disease has unpredictable clinical course. Lesions resolve on withdrawal of immunosuppressive therapy.
- **Epidemic AIDS-related Kaposi sarcoma:** Most common sites of epidemic AIDS-related Kaposi sarcoma are mucosal surfaces, skin, face, lower extremities, visceral and cutaneous lesions in HIV infected homosexual or bisexual persons.

Table 15.23 Clinicopathological types of Kaposi sarcoma

Kaposi Sarcoma Type	Clinical Groups	Location of Lesion	Clinical Course
Classic Kaposi sarcoma	Elderly males of East European and Mediterranean descent	Skin of lower extremities in the subcutaneous region	Indolent clinical course
Endemic (African) Kaposi sarcoma	Children and middle-aged males from equatorial Africa	Skin of lower extremities; and possibly viscera (bulky lymph nodes in children) and soft tissue tumor	Indolent clinical course in adults; and aggressive clinical course in African children with bulky lymphadenopathy
Iatrogenic Kaposi sarcoma	Immunocompromised persons (e.g. post-renal transplantation patients)	Skin of lower legs; and possibly viscera	Unpredictable clinical course; lesions resolve on withdrawal of immunosuppressive therapy
Epidemic (AIDS related) Kaposi sarcoma	Homosexual or bisexual males with HIV infection	Widespread involvement of skin, face, lower extremities, genitalia; and widespread involvement of viscera (e.g. lungs, lymph nodes, gastrointestinal tract, oral mucosa)	Aggressive clinical course

CLINICAL COURSE

Patient with Kaposi sarcoma presents with cutaneous violaceous patch, plaque, papule, macule or tumor mass. Lymphedema is demonstrated in occasional patient. Involvement of viscera and lymph nodes presents with hemorrhagic mass.

- Kaposi sarcoma is treated by cryotherapy and radiotherapy. Prognosis is good in immunocompetent patients with cutaneous lesions.
- Prognosis is poor in immunocompromised patients without high active antiretroviral therapy (HAART). Prognosis can be improved by administration of antiretroviral HAART and chemotherapy.

Surgical Pathology: Kaposi Sarcoma

Gross Morphology

- Cutaneous lesions in Kaposi sarcoma are variable, i.e. violaceous patch, plaque, papule, macule or tumor mass.
- Visceral and lymph nodes involved in Kaposi sarcoma are large hemorrhagic mass.

Light Microscopy

Histologic features of Kaposi sarcoma are always identical regardless of clinical settings.

- **Patch stage in Kaposi sarcoma:** Tumor is composed of small infiltrative blood vessels lined by endothelial cells surrounding large ectatic blood vessels; dissecting collagen bundles in the upper reticular dermis and infiltrated by lymphocytes and plasma cells.
- **Plaque stage in Kaposi sarcoma:** Tumor is composed of proliferation of relatively bland, vaguely myxoid spindled cells producing slit-like vascular channels showing jagged outlines. There is presence of extravasated red blood cells and extracellular hyaline globule.
- **Papule (nodule) stage in Kaposi sarcoma:** Tumor is well circumscribed cellular nodular polypoidal mass simulating pyogenic granuloma. It is composed of intersecting fascicles of spindle cells with little or without cytologic atypia. Numerous slit spaces contain red blood cells.

Differential Diagnosis

Kaposi sarcoma should be differentiated from acroangiodermatitis, spindle cell hemangioma and spindle cell sarcomas.

Immunohistochemistry Technique

Kaposi sarcoma shows positivity for CD31, CD34, Fli-1, D2–40, VEGFR3 and HHV8 LANA protein (most sensitive marker).

Markers	Expression
CD31	Positive
CD34	Positive
Fli-1	Positive
D2–40	Positive
VEGFR3	Positive
HHV8 LANA protein	Positive

ANGIOSARCOMA

Angiosarcoma is highly malignant tumor showing endothelial differentiation, which affects elderly persons without sex predominance. Characteristics and clinical behavior of angiosarcoma depend on the clinical presentation.

- Angiosarcoma may be caused by radiation, long-standing lymphedema, post-irradiation and in the setting of use of radiocontrast media thorostat, vascular grafts and arteriovenous fistulae. Variants of angiosarcoma based on etiology are given in Table 15.24.
- Cutaneous angiosarcoma presents with violaceous, erythematous plaque and nodule. Angiosarcoma in deep soft tissue presents with hemorrhagic lump. Mammary angiosarcoma presents with rapidly growing mass in the women.
- Patient with angiosarcoma has poor prognosis. Administration of Taxanes chemotherapeutic agents may be of value in cutaneous angiosarcoma related to sun exposed skin.

Surgical Pathology: Angiosarcoma

Gross Morphology

- Gross morphology of angiosarcomas in cutaneous region are variable ranging from erythematous or violaceous plaque or nodule.
- Angiosarcoma in the deep tissue is large hemorrhagic mass.

Light Microscopy

Histologic features of angiosarcoma are variable ranging from well differentiated lesion simulating hemangioma; spindled lesion resembling fibrosarcoma; or epithelioid lesion simulating carcinoma.

- **High-grade angiosarcoma:** Tumor is composed of epithelioid-like endothelial cells with high nuclear grade and sieve-like to solid architectural pattern. Mitoses and necrosis are frequently demonstrated.
- **Well-differentiated angiosarcoma:** Tumor is composed of cells with low nuclear grade lacking mitotic activity and dissecting the adjacent connective tissue.
- **Epithelioid angiosarcoma:** Tumor is composed of epithelioid-like endothelial cells with abundant cytoplasm and uniform high nuclear grade and arranged in sheets. Such lesion is mistaken for carcinoma.

Differential Diagnosis

Angiosarcoma should be differentiated from hemangioma, diffuse angiomatosis, atypical vascular proliferation after radiation, carcinoma, spindle cell carcinoma, melanoma and other spindle cell sarcomas.

Immunohistochemistry Technique	
Angiosarcoma shows positivity for CD31, CD34, Fli-1, vWF, D2–40, VEGFR3 and cytokeratins (low molecular weight) in epithelioid tumors.	
Markers	**Expression**
▪ CD31	▪ Positive (100%)
▪ CD34	▪ Positive (100%)
▪ Fli-1	▪ Positive (100%)
▪ vWF	▪ Positive (100%)
▪ D2–40	▪ Positive (some cases)
▪ VEGFR3	▪ Positive (some cases)
▪ Cytokeratins	▪ Positive (25%)

Table 15.24 Variants of angiosarcoma based on etiology

Variants	Comments
Primary angiosarcoma associated with radiation	Primary angiosarcoma is related to prolonged sun exposure and therapeutic radiation. Elderly patients present with single or multiple lesions in the superficial region of head and neck
Angiosarcoma associated with long-standing lymphedema	Angiosarcoma may arise in the long-standing lymphedema due to Stewart-Treves syndrome, secondary to lymph node dissection and mastectomy performed for breast cancer. Stewart-Treves syndrome is a rare deadly cutaneous angiosarcoma that develops in long-standing chronic lymphedema
Post-irradiation angiosarcoma	Angiosarcoma arises from soft tissue of patient treated by radiation as adjuvant treatment for breast cancer
Angiosarcoma associated with other causes	Angiosarcoma may arise in the setting of use of radiocontrast media thorostat, vascular grafts and arteriovenous fistulae

HYPERTENSION

HYPERTENSION: OVERVIEW

Hypertension is intermittent or sustained elevation of systolic blood pressure >139 mm Hg or diastolic blood pressure >89 mm Hg. It occurs as essential (primary) hypertension or secondary hypertension. Normal blood pressure is <120/80 mm Hg. Optimal blood pressure is <115/80 mm Hg (Table 15.25).

ORGANS DAMAGE

Patient with blood pressure <130–139/80–89 mm Hg is prone to develop hypertension. Hypertension can cause damage to multiple organs such as brain, eyes, cardiovascular system, lungs, kidneys and liver.

ADVERSE EFFECTS

If left untreated, essential hypertension can cause retinal changes, left ventricular hypertrophy, cardiac failure, and benign nephrosclerosis. It can predispose to ischemic heart disease or cerebral stroke.

CLINICAL FEATURES

Patient presents with bruits over abdominal aorta or carotid, renal and femoral arteries, dizziness, confusion, fatigue, blurred vision, nocturia, and edema.

CLASSIFICATION

Hypertension is classified according to etiology and severity described as follows.

Table 15.25 Blood pressure classification by Joint National Committee 7 (JNC-7) and 2017 ACC/AHA hypertension guidelines

Systolic and Diastolic Blood Pressure (mm Hg)	Joint National Committee 7 (JNC-7)	2017 ACC/AHA Hypertension Guidelines
<120 and <80	Normal BP	Normal BP
120–129 and <80	Prehypertension	Elevated BP
130–139 or 80–89	Prehypertension	Stage 1 hypertension
140–159 or 90–99	Stage 1 hypertension	Stage 2 hypertension
>160 or >100	Stage 2 hypertension	Stage 3 hypertension

Etiological Classification

Etiological classification of hypertension is given in Table 15.26.

Essential Hypertension

Essential hypertension is a multifactorial disease of unknown etiology. It accounts for 95% of all diagnosed cases of hypertension.

Secondary Hypertension

Secondary hypertension represents 5% cases of hypertension due to temporary complication of various disorders:

- **Renovascular hypertension:** It occurs due to renal artery stenosis.
- **Endocrinal hypertension:** Primary aldosteronism, Cushing's syndrome, pheochromocytoma, oral contraceptive cause hypertension.
- **Hypertension due to cardiovascular system and blood disorders:** Secondary hypertension can occur due to coarctation of aorta, polyarteritis nodosa, polycythemia vera and excessive blood transfusions.
- **Hypertension due to increased intracranial pressure:** It occurs due to brain tumors, drugs and chemicals, notably amphetamines and steroids (neurologic).

Table 15.26 Etiological classification of hypertension

Primary/Essential Hypertension of Unknown Etiology	
Genetic predisposition (strong familial associations)	▪ Genetic defect of calcium transport increases reactivity of blood vessels to vasoconstrictors ▪ Liddle syndrome, autosomal dominant disorder occurs due to SCNN1B or SCNN1G genes located on chromosome 16 resulting in gain of sodium channel functions and thus hypertension ▪ Syndrome of apparent mineralocorticoids excess increases sodium and water reabsorption and thus hypertension ▪ Glucocorticoid-remediable aldosteronism
Dietary factors	▪ Obesity ▪ High salt intake ▪ Excessive caffeine intake
Humoral factors	Abnormalities in renin-angiotensin-aldosterone system
Neurological factors	Excessive activity of sympathetic nervous system activity
Secondary Hypertension	
Renal parenchymal and vascular disorders	▪ Chronic glomerulonephritis ▪ Chronic pyelonephritis ▪ Polycystic disease of kidney ▪ Renal amyloidosis ▪ Renal artery stenosis
Adrenal gland disorders	▪ Pheochromocytoma ▪ Cushing's syndrome ▪ Conn syndrome (primary hyperaldosteronism) ▪ Congenital adrenal hyperplasia
Other endocrinal disorders	▪ Acromegaly ▪ Thyrotoxicosis ▪ Hyperparathyroidism ▪ Diabetic nephropathy
Cardiovascular disorders	▪ Coarctation of aorta ▪ Arteriovenous fistula
Therapeutic drugs	▪ Oral contraceptive drugs ▪ Anabolic steroids ▪ Corticosteroids ▪ Epinephrine (adrenaline) and related sympathomimetic drugs
Pregnancy associated disorder	Toxemia of pregnancy

Classification of Hypertension According to Severity

Benign Hypertension

Benign hypertension involves diastolic pressure that rises slowly and remains over prolonged period. Untreated cases produce vascular changes in kidneys known as benign nephrosclerosis.

Malignant Hypertension

Malignant hypertension can occur in essential or secondary hypertension, in which diastolic pressure rises quickly over weeks or months. It causes severe damage to circulatory system resulting in cerebral strokes and papilledema. It produces vascular changes (hyperplastic arteriolosclerosis and fibrinoid necrosis) in kidneys known as **malignant nephrosclerosis**.

DETERMINANTS OF HYPERTENSION

Blood pressure depends on the cardiac output and peripheral resistance. Blood pressure may result from increasing the cardiac output or peripheral resistance.

Factors Increasing Cardiac Output

Several factors can affect cardiac output (CO) indirectly by affecting the heart rate (HR) and stroke volume (SV), the primary components of cardiac output determinants often expressed as: CO = HR × SV. Water and sodium retention is regulated by aldosterone and atrial natriuretic factor (ANF). Aldosterone and atrial natriuretic factor/cardionatrin have opposite actions.

- **Aldosterone:** It increases blood volume by enhancing absorption of sodium and water by kidneys. Increased blood volume causes distension of both atria resulting in synthesis of atrial natriuretic factor/cardionatrin by atria.
- **Atrial natriuretic factor/cardionatrin:** It participates in decreasing blood volume by increasing excretion of sodium and water by kidneys. It decreases synthesis of renin and aldosterone. It also decreases venous return.

Factors Affecting Peripheral Resistance

Changes in the arteriolar bed causing increased total peripheral resistance depends on neutral α-adrenergic effect on arterioles, catecholamines and renin-angiotensin-aldosterone system.

- Increased arteriolar thickening by genetic factors and increased arteriolar tone by overactivity of sympathetic nervous system (α-adrenergic effect) lead to increased total arteriolar peripheral resistance.
- Abnormal renin release results in formation of angiotensin II, which constricts the arterioles and increases peripheral blood resistance.

Renin-angiotensin-aldosterone System

Kidneys release renin into the bloodstream. Renin participates in conversion of angiotensinogen to angiotensin I in liver.

- Angiotensin I is converted to angiotensin II (a potent vasoconstrictor) in lungs by angiotensin converting enzyme (ACE). Angiotensin II increases arteriolar peripheral resistance and expansion of blood volume. Angiotensin II causes vasoconstriction resulting to increased peripheral resistance.
- Angiotensin II also stimulates adrenal cortex to synthesize aldosterone, which acts on distal renal tubules resulting in absorption of sodium and water by kidneys, and thus plasma expansion. It also stimulates sympathetic nervous system and thus causes vasoconstriction. It also causes proliferation of smooth muscle cells and thickening (Fig. 15.31).

ESSENTIAL (PRIMARY) HYPERTENSION

Essential hypertension accounts for 95% cases of hypertension, which is of unknown etiology. It represents an interaction of predisposing determinants with a number of exogenous factors such as family history of hypertension, ethnicity (Africans), stress, obesity, smoking, advancing age, sedentary lifestyle, high intake of sodium and saturated fats. Pathogenesis of essential hypertension is discussed below.

- Increased release of vasoconstrictors (e.g. renin, catecholamines and endothelin) in persons result in hypertensive state. In some areas, people salt intake is more thus prone to essential hypertension.
- Obese persons under stress and strain are more prone to develop essential hypertension.

GENETIC DEFECT OF CALCIUM TRANSPORT

Genetic defect of calcium transport in vascular smooth muscle cells leads to increased intracellular concentration of calcium, myosin phosphorylation and ATP production. It leads to increased reactivity of blood vessels to vasoconstrictors and hypertrophy of vascular smooth muscle cells resulting in increased peripheral resistance and essential hypertension.

LIDDLE SYNDROME

Liddle syndrome is an autosomal dominant disorder due to gene mutation on chromosome 16.

- Liddle syndrome is characterized by sustained activation of sodium channels (gain of function), which results in increased absorption of sodium and water at distal convoluted renal tubules independent of action due to mineralocorticoids.

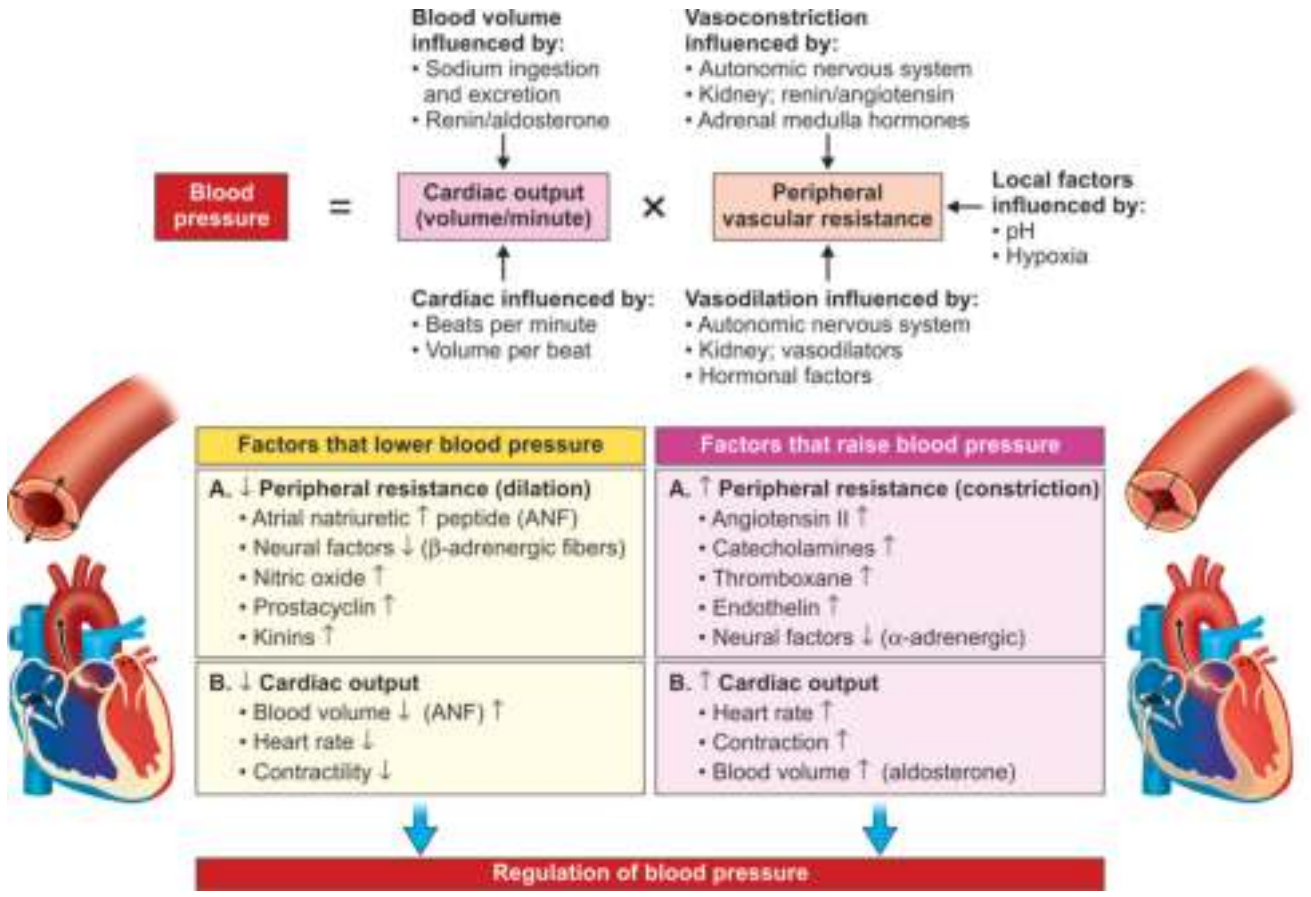

Fig. 15.31: The regulation of blood pressure. Blood pressure is a product of cardiac output (volume of blood flow) and peripheral vascular resistance. Multiple factors influence blood pressure.

- There is expansion of blood volume and thus hypertension. Nephrons are structurally normal.

SYNDROME OF APPARENT MINERALOCORTICOIDS EXCESS (AME)

- **Physiologic state:** Cortisol has weak mineralocorticoids activity. 11β-hydroxysteroid dehydrogenase converts cortisol into cortisone in tubules.
- **Pathologic state:** Gene mutation controlling this 11β-hydroxysteroid dehydrogenase results in accumulation of cortisol, which leads to expansion of blood volume due to sodium and water retention and thus hypertension. Licorice containing glycyrrhetinic acid also inhibits 11β-hydroxysteroid dehydrogenase, thus causes hypertension.

GLUCOCORTICOID-REMEDIABLE ALDOSTERONISM

Glucocorticoid-remediable aldosteronism (GRA) is an autosomal dominant disorder, which causes hypertension.

- **Physiologic state:** Aldosterone synthetase gene and 11β-hydroxylase gene are present on chromosome 8. Aldosterone synthetase acts on zona glomerulosa of adrenal glands to synthesize aldosterone hormones. 11β-hydroxylase gene controls the synthesis of cortisol by zona fasciculata of adrenal glands.
- **Pathologic state:** Mutations of aldosterone synthetase gene and 11β-hydroxylase gene present on chromosome 8 form hybrid genes resulting in ectopic production of aldosterone by zona fasciculata of adrenal cortex. It leads to expansion of blood volume and thus hypertension.

SECONDARY HYPERTENSION

Secondary hypertension accounts for 5% cases of all diagnosed cases of hypertension. Differentiating features of secondary hypertension are given in Table 15.27.

RENOVASCULAR HYPERTENSION

Renovascular hypertension is most important cause of secondary hypertension as a result of increased plasma renin activity. Renal arteriogram reveals narrowing of the ostia of renal arteries due to atherosclerosis. Renal parenchymal diseases and renal artery stenosis result

Table 15.27 Differentiating features of secondary hypertension

Disorder	Specific Clinical and Laboratory Findings
Renal artery stenosis	Bruit
Pheochromocytoma	Episodic hypertension
Conn syndrome	Hypokalemia
Cushing syndrome	▪ Buffalo hump ▪ Truncal obesity ▪ Striae
Coarctation of aorta	Blood pressure elevated in upper extremities than lower extremities
Congenital adrenal hyperplasia	Hirsutism

Investigate secondary causes of hypertension in young <30 or >60 years of age, who fail to control blood pressure within three mediations.

in secondary hypertension. Renal artery stenosis occurs due to atherosclerosis, giant cell arteritis and Takayasu arteritis.

Pathogenesis

- Renovascular hypertension occurs through stimulation of the renin-angiotensin-aldosterone system. Juxtaglomerular cells respond to decreased vascular tone by secreting renin, which facilitates the conversion of angiotensinogen to angiotensin I in liver, which is further converted to angiotensin II in lungs by angiotensin converting enzyme.
- Angiotensin II promotes hypertension by acting both as a vasoconstrictor and as inactivator of aldosterone secretion. Aldosterone promotes sodium and water retention (Fig. 15.32).

Clinical Features

Patient presents with severe uncontrollable hypertension, epigastric bruit (e.g. sound is due to turbulence of blood flow through the narrow renal artery).

ROLE OF HORMONES

Testosterone and estrogens stimulate renin-angiotensin system resulting in expansion of blood volume and vasoconstriction.

- Testosterone and estrogens also increase plasma insulin level, which enhances the synthesis of catecholamines, which increases peripheral resistance and thus secondary hypertension. Insulin increases the peripheral resistance by vasoconstriction of blood vessels and thus secondary hypertension.
- Increased plasma insulin stimulates smooth muscle cells proliferation thus increase peripheral resistance and thus hypertension.

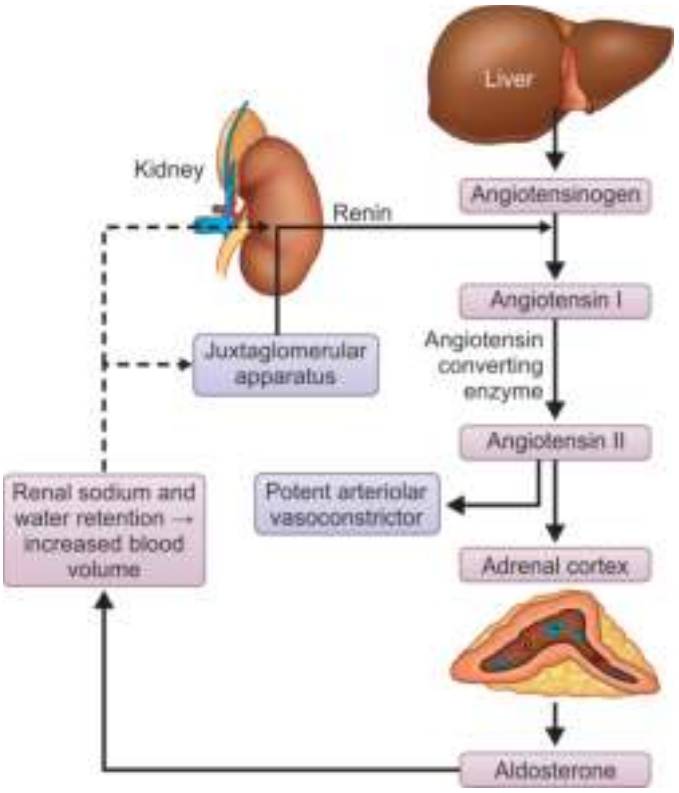

Fig. 15.32: Renin-angiotensin-aldosterone system role in renovascular hypertension.

ENDOCRINE SYSTEM DISORDERS

Endocrine system disorders such as Conn syndrome, pheochromocytoma, or acromegaly, represent the next most common cause. Conn syndrome is an endocrine disorder most commonly caused by an adrenal cortical adenoma or bilateral adrenal hyperplasia. Aldosterone secreted by the adrenal cortical tumor causes secondary hypertension, hypernatremia, and hypokalemia.

CARDIOVASCULAR SYSTEM DISORDERS

Coarctation of aorta is a frequent cause of hypertension limited to the upper extremities. Blood pressure in both arms and one leg must be determined; a pressure difference of >20 mm Hg in favor of the arms may be considered evidence of coarctation of aorta.

TOXEMIA OF PREGNANCY

Pre-eclampsia refers to the triad of hypertension, proteinuria, and edema, complicating third trimester of pregnancy. When these features are complicated by convulsions, the term eclampsia is applied. Early-onset toxemia of pregnancy is attributed to abnormal superficial implantation of placenta resulting in diminished blood supply to the placenta. Late-onset disease occurs due to which release of vasoactive substances lead to endothelial damage. Immunofluorescence microscopy

reveals nonspecific deposits of IgG, IgM and fibrin in renal blood vessels.

Surgical Pathology: Toxemia of Pregnancy

Light Microscopy

- Histopathologic examination of renal biopsy reveals diffuse uniform enlargement of glomeruli and the endothelial cells are swollen (endotheliosis), an appearance that results in an apparently bloodless glomerular tuft.
- Patient blood pressure returns to normal in postpartum period.

Clinical Features

Patient presents with hypertension, proteinuria, and edema usually in the third trimester. Pre-eclampsia is defined as the development of hypertension with proteinuria and generalized edema after 20 weeks gestation. Eclampsia is diagnosed when seizures occur in the setting of pre-eclampsia.

CNS DISORDERS

Hypertension occurs due to increased intracranial pressure due to brain tumors, drugs and chemicals, notably amphetamines and steroids (neurologic).

VASCULAR CHANGES IN HYPERTENSION

VASCULAR CHANGES IN BENIGN HYPERTENSION

Hypertensive nephrosclerosis is identified in 15% of patients with benign hypertension. Even mild-to-moderate hypertension causes benign nephrosclerosis.

- Due to benign hypertension, patient develops increased permeability of vessels resulting into deposition of plasma proteins in subintimal regions of blood vessels. Lumen of the blood vessels is decreased leading to ischemic changes in organs.
- Vascular changes in benign hypertension include hyaline arteriosclerosis and reduplication of elastic lamina. Similar changes are also seen in elderly persons (normal and hypertensive) and diabetes mellitus. Renal changes in benign hypertension are known as benign nephrosclerosis.

Clinical Pearls: Vascular Changes in Benign Hypertension

Gross Morphology

- In benign nephrosclerosis, kidneys are symmetrically reduced in size due to ischemia.
- External surface of the kidneys is finely granular giving grain leather-like appearance.
- V-shaped infarcts may be seen due to occlusion of medium-sized renal vessels.
- On cut section, cortex is thinned out.

Light Microscopy

- In benign nephrosclerosis, renal arterioles exhibit concentric hyaline thickening of the wall with narrowing of lumen.
- It shows tubular atrophy, interstitial fibrosis replacing nephrons and lymphocytic infiltration.

VASCULAR CHANGES IN MALIGNANT HYPERTENSION

Malignant hypertension refers to a severely elevated blood pressure (diastolic blood pressure >130 mm Hg), which results in rapidly progressive vascular disease. It most often occurs in young African-American males. Malignant hypertension affects the brain (cerebral stroke), heart (left ventricular hypertrophy and failure), kidney (renal failure) and retina (focal retinal hemorrhages and papilledema). It can be a complication of either essential (primary) or secondary hypertension (Table 15.28).

Histologic Changes in Blood Vessels

Malignant hypertension causes necrotizing arteriolitis and glomerulitis with fibrinoid necrosis and hyperplastic arteriolosclerosis giving onion skin appearance.

Consequence

Poor perfusion of the kidneys stimulates the release of renin, which serves to elevate systemic blood pressure even further by activation of renin-angiotensin-aldosterone system resulting in renovascular hypertension.

Clinical Pearls: Vascular Changes in Malignant Hypertension

Gross Morphology

Renal changes in malignant hypertension are known as malignant nephroscleosis. Renal arterioles and glomeruli rupture, resulting in '**flea-bitten kidney**', multiple pinpoint petechial hemorrhages on the external surface of kidney.

Light Microscopy

Renal tubules are atrophic. Tubules contain eosinophilic material known as thyroidization of tubules. There is tubular loss in relation to sclerosed glomeruli present. Renal arterioles show fibrinoid necrosis and hyperplastic arteriolosclerosis exhibiting 'onion skin appearance'. Patients develop chronic renal failure with manifestations of uremia.

- **Hyperplastic arteriolosclerosis:** Acute vascular injury in malignant hypertension is followed by smooth muscle proliferation with an increase in concentric layers of smooth muscle cells that yield the so-called 'onion skin appearance'. Smooth muscle hyperplasia occurs as a result of growth factors derived from platelets and inflammatory cells at the site of vascular injury.

- **Fibrinoid necrosis:** Malignant hypertension injures endothelial cells and causes increased vascular permeability, which leads to the insudation of plasma proteins into the vessel wall. Severe endothelial injury causes intravascular coagulation and rupture of blood vessels. Lumen becomes narrow and fixed resulting into ischemia. This morphologic change in renal arterioles is known as fibrinoid necrosis.

Clinical Features

Patient with malignant hypertension develops renal failure and vascular stress that may cause myocardial infarction, congestive heart failure, or cerebral stroke, and increased intracranial pressure, which often produces symptoms such as seizures, headache, nausea, vomiting, visual impairment, and coma.

Physical Examination

Blood pressure is very high >160/≥200 mm Hg, pounding heartbeat on auscultation and bulging optic disc papilledema on fundus examination.

COMPLICATIONS OF HYPERTENSION

- Hypertension is most often called **silent killer**. Initially, patient presents with shortness of breath after mild exercise, headache or dizziness, swelling of the ankles during daytime, excessive sweating and anxiety.
- Long-standing hypertension causes organs damage resulting in coronary artery disease, cerebral stroke, congestive heart failure, end stage renal disease and peripheral vascular disease. These complications may be prevented by treating hypertensive patients by salt restriction, exercise, vasodilators, calcium channel blockers, ACE inhibitors, angiotensin blockers, diuretics, β-blockers and α-blockers (Table 15.29 and Fig. 15.33).

CEREBRAL HEMORRHAGE

Patient may develop cerebral hemorrhages in basal ganglia especially putamen—thalamus region (65%), pons (15%) and cerebellum (10%). Cerebral stroke is common in persons with berry aneurysms undergoing rupture due to hypertension. Cerebral thrombus or embolism may also cause cerebral stroke (Fig. 15.34).

RETINOPATHY

Chronic hypertension results in narrowing of retinal arterioles and hemorrhages in retina producing papilledema giving '**cotton wool spots**' appearance on fundus examination (Fig. 15.35A and B).

Table 15.28 Features of benign and malignant hypertension

Parameters	Benign Hypertension	Malignant Hypertension
Incidence	Very common incidence	Rare incidence
Age group	Begins in <45 years of age and progresses	Young adults of 25–35 years
Sex distribution	Females > males	Male and female equally affected
Etiology	Majority of cases suffers from primary/essential hypertension	Majority of cases develop malignant hypertension due to renal disease, however, a few cases develop in long-standing primary/essential hypertension
Hypertension progression	Very slow progression over many years	Rapid progression within months to one or two years
Blood pressure range	Very slow rise of blood pressure with diastolic blood pressure ranging 90–120 mm Hg	Rapid rise of blood pressure with diastolic blood pressure ≥120 mm Hg
Injury to blood vessels	Mild to moderate injury to blood vessels	Severe injury to blood vessels
Large elastic and medium size arteries involvement	Potentiates slow formation of atheromatous plaque and accelerates arteriosclerosis	Potentiates formation of atheromatous plaque and accelerates arteriosclerosis
Arteriolar changes	Hyaline arteriolar thickening with narrowing of arteriolar lumen and reduplication of elastic lamina	Fibrinoid necrosis of vascular endothelium with occlusion of lumen by thrombus in vessels of kidney and other abdominal viscera
Pathogenesis of arteriolar changes	Benign hypertension increases endothelial permeability of arterioles resulting in deposition of plasma proteins beneath vascular intima and thus ischemia of tissue	Malignant hypertension causes severe damage to vascular endothelium of arterioles resulting in intravascular coagulation and fibrinoid necrosis with fixed vascular lumen

Table 15.29 Complications and systemic effects of hypertension

Parameters	Benign Hypertension	Malignant Hypertension
Blood pressure range and progression		
Blood pressure range	Very slow rise of blood pressure with diastolic blood pressure ranging 90–120 mm Hg	Rapid rise of blood pressure with diastolic blood pressure ≥120 mm Hg
Hypertension progression	Very slow over many years in <45 years of age and progresses	Rapid progression within months to one or two years in young adults of 25–35 years
Cardiovascular manifestations		
Injury to blood vessels	Mild to moderate injury to blood vessels	Severe injury to blood vessels
Large elastic and medium size arteries involvement	▪ Potentiates formation of atheromatous plaque and accelerates arteriosclerosis ▪ Dissection hematoma (low-risk)	▪ Potentiates formation of atheromatous plaque and accelerates arteriosclerosis ▪ Dissection hematoma (high-risk)
Pathogenesis of arteriolar changes	Benign hypertension increases endothelial permeability of arterioles resulting in deposition of plasma proteins beneath vascular intima and thus ischemia of tissue	Malignant hypertension causes severe damage to arteriolar endothelium resulting in intravascular coagulation and fibrinoid necrosis with fixed vascular lumen
Arteriolar morphologic changes	Hyaline arteriolar thickening with narrowing of arteriolar lumen and reduplication of elastic lamina	Fibrinoid necrosis of vascular endothelium with occlusion of lumen by thrombus in vessels of kidney and other abdominal viscera
Cardiac manifestations	▪ Concentric left ventricular hypertrophy (ventricle wall thickness more than 2 cm) ▪ Compensatory left atrium enlargement results in atrial fibrillation ▪ Increased susceptibility to spontaneous cardiac arrhythmias, heart failure, fibrinous pericarditis and ischemic heart disease in 60% of cases ▪ Histology shows myofiber disarray with myocyte hypertrophy and enlarged; box car' nuclei in the background of increased interstitial fibrosis	▪ Concentric left ventricular hypertrophy (ventricle wall thickness more than 2 cm) ▪ Compensatory left atrium enlargement results in atrial fibrillation ▪ Increased susceptibility to spontaneous cardiac arrhythmias, heart failure, fibrinous pericarditis and ischemic heart disease in 60% of cases ▪ Histology shows myofiber disarray with myocyte hypertrophy and enlarged; boxcar nuclei in the background of increased interstitial fibrosis
Brain and retinal manifestations		
Brain	Cerebral hemorrhages and thrombus in basal ganglion (putamen), thalamus, cerebellum	Encephalopathy (fits and loss of consciousness) due to cerebral edema, cerebral hemorrhages and midline shift
Retinal changes on fundus examination	Cotton wool exudates on fundus examination due to ischemia and infarction; and associated with retinal vein thrombosis	Cotton wool exudates on fundus examination due to ischemia and infarction; and associated with retinal vein thrombosis
Renal manifestations		
Renal morphological changes	▪ Benign nephrosclerosis (not usually serious complication) ▪ Grain leather appearance on external surface of kidneys due to ↓ renal blood supply with decrease in thickness of renal cortex and medulla	▪ Malignant nephrosclerosis (serious complications) ▪ Flea bitten appearance due to rupture of renal arterioles, and vascular lumen is narrow and fixed
Pulmonary manifestations		
Lungs	Pulmonary congestion and edema	Pulmonary congestion and edema
Liver changes		
Liver	Chronic venous congestion of liver and nutmeg appearance on cut surface, central veins are dilated congested and later on resulting in cardiac cirrhosis	Rupture of central veins of liver

Patient develops peripheral pitting edema around ankle joints in long-standing case of hypertension.

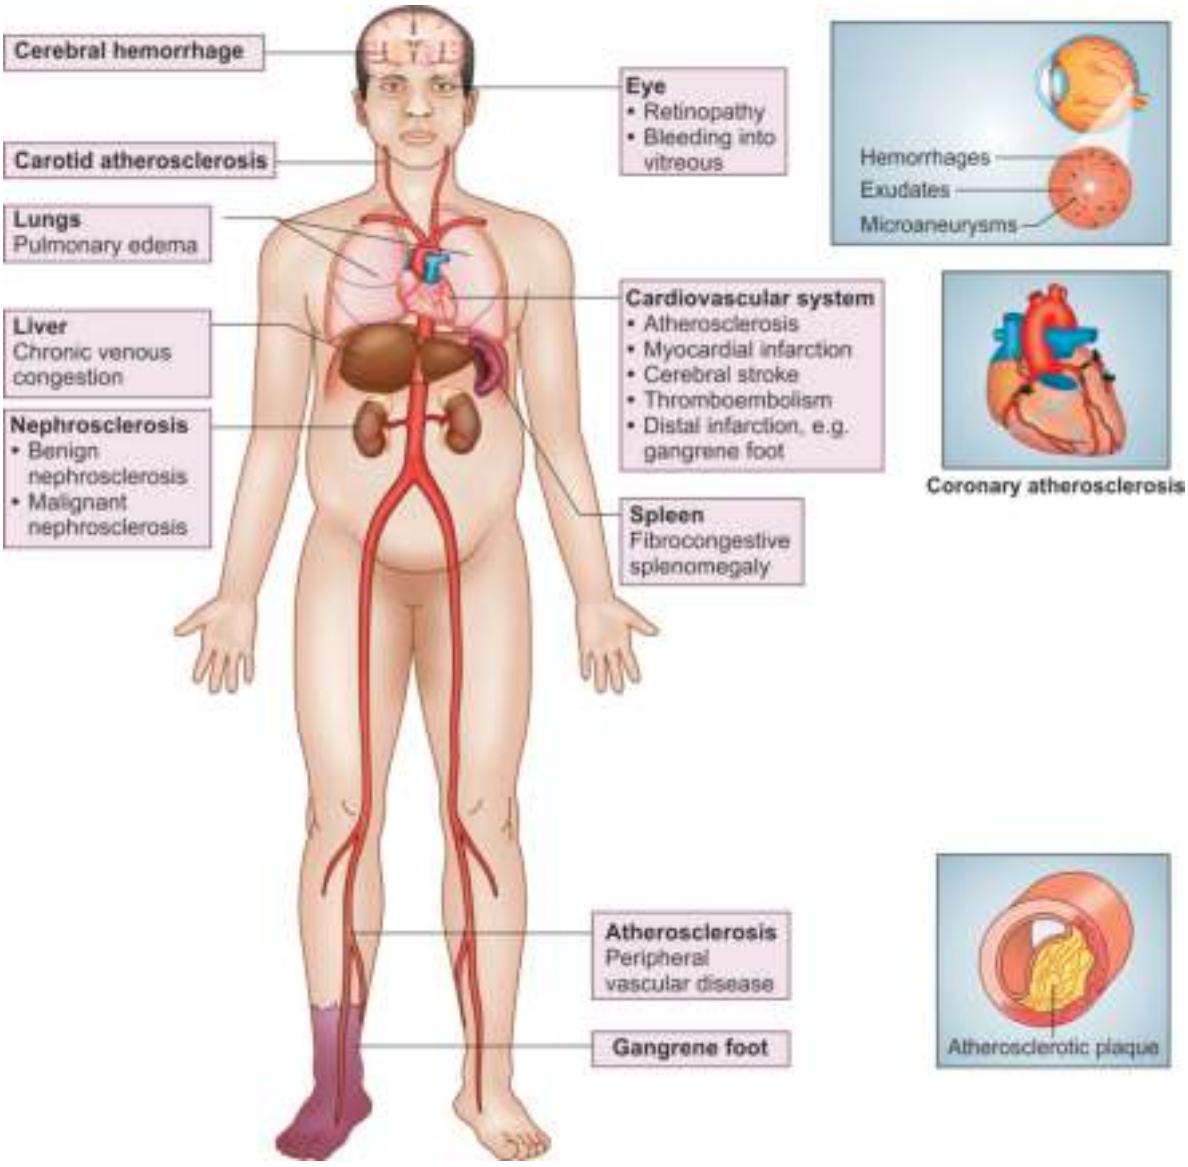

Fig. 15.33: Complications of hypertension. Hypertension is a major risk factor for atherosclerosis.

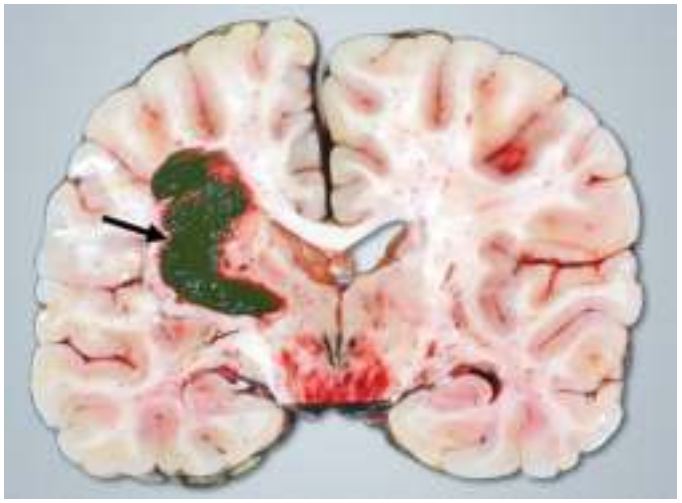

Fig. 15.34: Hemorrhages involving the basal ganglia area (the putamen in particular) tend to be nontraumatic.

CARDIOVASCULAR MANIFESTATIONS

- **Concentric cardiac hypertrophy:** Uncontrolled hypertension results in marked concentric cardiac hypertrophy of left ventricle with decrease in size of left ventricular chamber (Fig. 15.36).
- **Dissecting hematoma (aortic dissection):** Uncontrolled hypertension may tear the intima of aorta. Blood enters and dissects aortic media. External rupture results in massive hemorrhage into the pericardial cavity. Retrograde rupture results in massive hemorrhage into the pericardial cavity. Rarely, internal rupture dissects the aortic wall and reopens at distal region producing '**double-channeled aorta**' (Fig. 15.37).
- **Atherosclerosis:** Chronic hypertension is a major risk factor for atherosclerosis in large elastic and

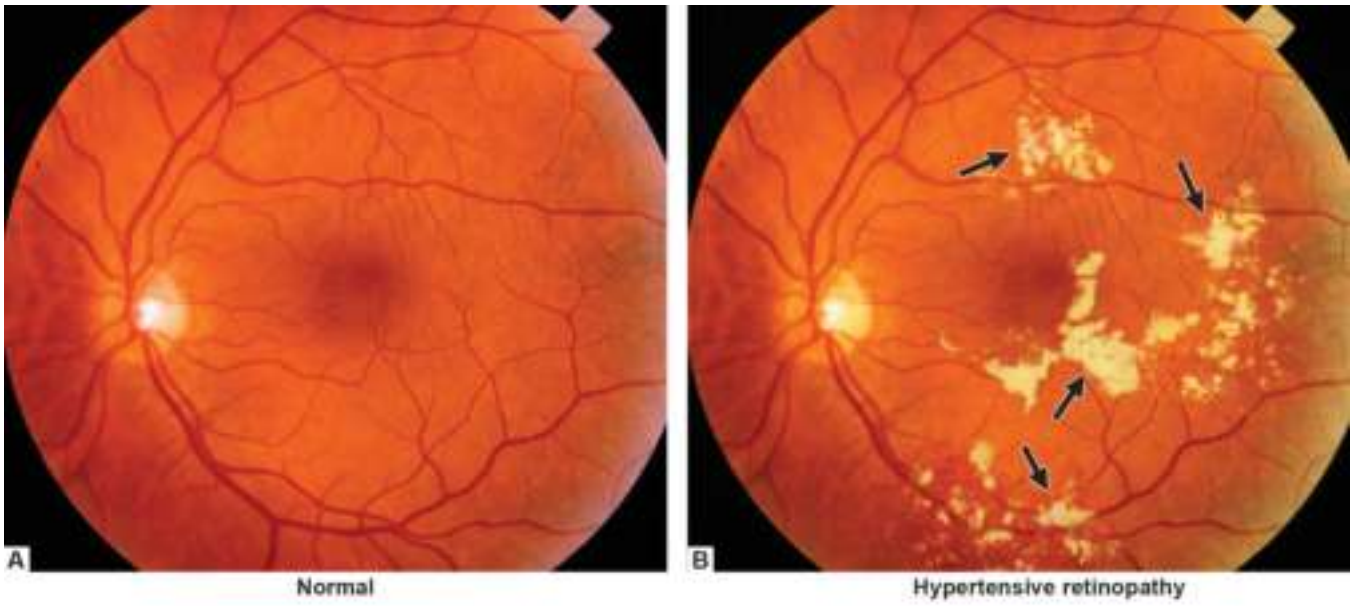

Fig. 15.35A and B: Hypertensive retinopathy. There is arteriolar narrowing and cotton wool spots (arrows). Additional findings can include hemorrhages into the nerve fiber layer and papilledema.

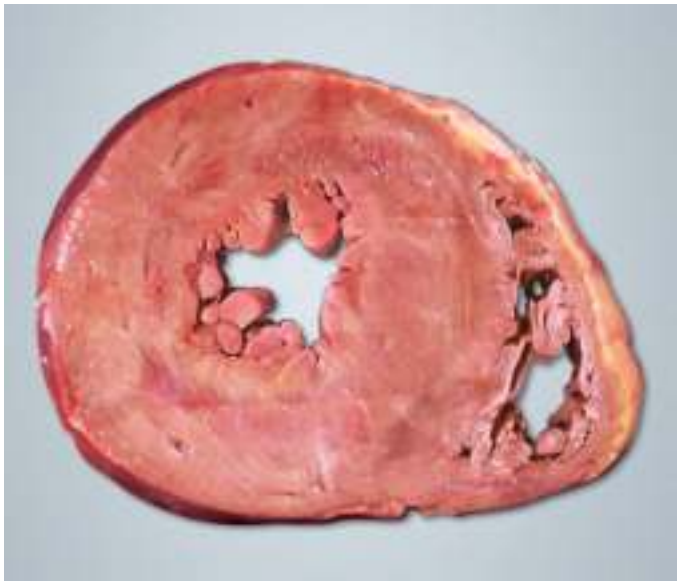

Fig. 15.36: The left ventricle is markedly thickened in this patient with severe hypertension that was untreated for many years. The myocardial fibers have undergone hypertrophy.

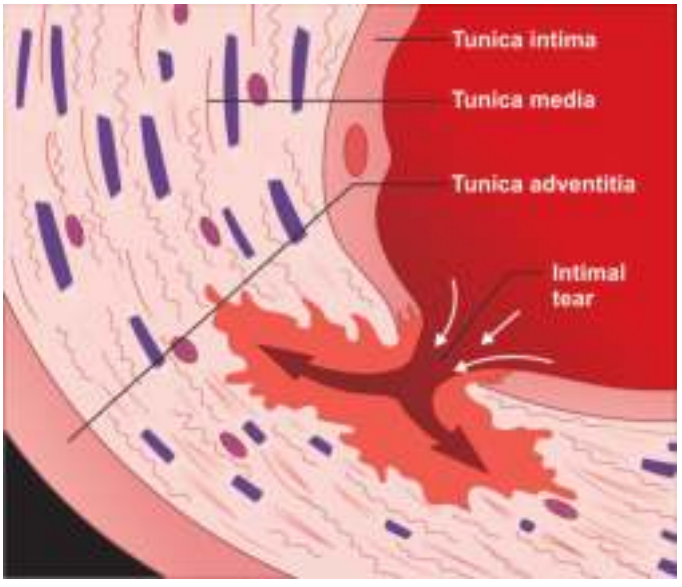

Fig. 15.37: This aortic dissection occurred in patient with uncontrolled hypertension.

medium-sized arteries. Atheromatous plaques consist of central core of lipids covered by fibrous cap, ulceration, thrombus formation, embolism, bleeding into atherosclerotic plaque due to rupture of new vessels formed, calcification and aneurysm. Atheromatous plaques in coronary arteries may cause angina, acute myocardial infarction or chronic ischemic disease (Fig. 15.38).

- **Fibrinous pericarditis:** Chronic hypertension results in deposition of fibrin between visceral and parietal layers of pericardium known as fibrinous pericarditis. Keeping apart of pericardial layers gives bread and butter appearance. On auscultation, friction rub is appreciated. It is worth mentioning that fibrinous pericarditis may also occur in acute myocardial infarction and chronic renal failure.

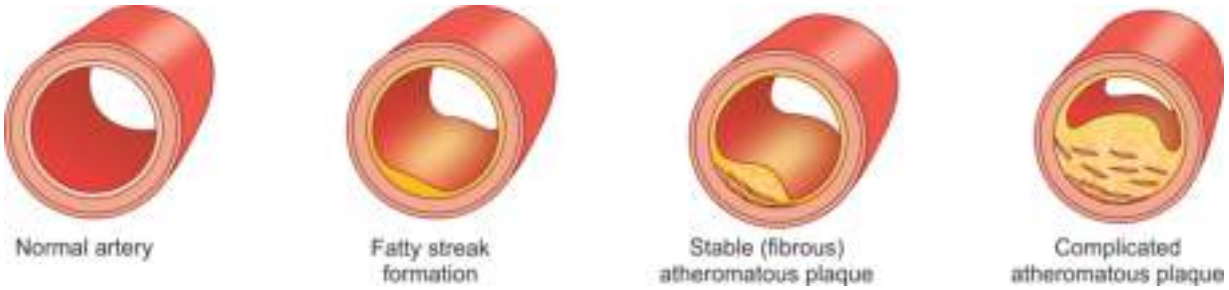

Fig. 15.38: Atheromatous plaques. Uncontrolled hypertension is major risk factor for atherosclerotic plaques in large elastic and medium-sized arteries.

PULMONARY MANIFESTATIONS

Uncontrolled hypertension leads to pulmonary edema. Lungs show passive congestion in alveolar capillaries resulting in accumulation of fluid in the alveoli exhibiting slightly floccular pink material along with 'heart failure cells' (Fig. 15.39A and B).

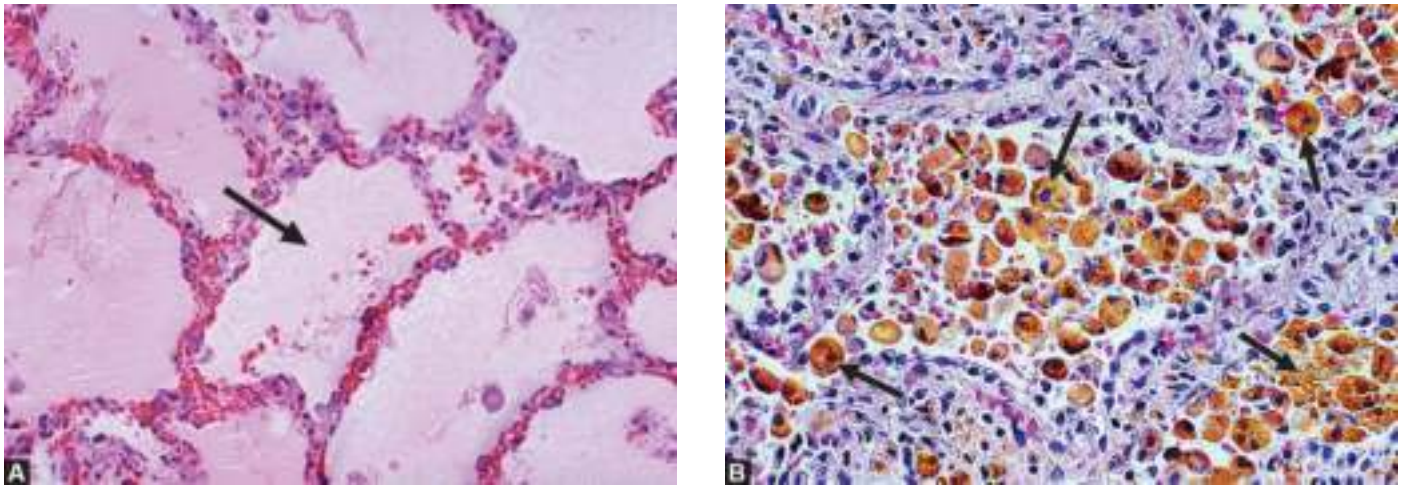

Fig. 15.39: Pulmonary edema. (A) The alveoli in this lung are filled with a smooth to slightly floccular pink material. Alveolar capillaries congested (arrow) (400X), (B) pulmonary edema with heart failure cells (arrows).

Fig. 15.40: Chronic venous congestion in liver. Cut surface shows nutmeg appearance (arrows). The dark red conjusted regions represent accumulation of RBCs in centrilobular regions.

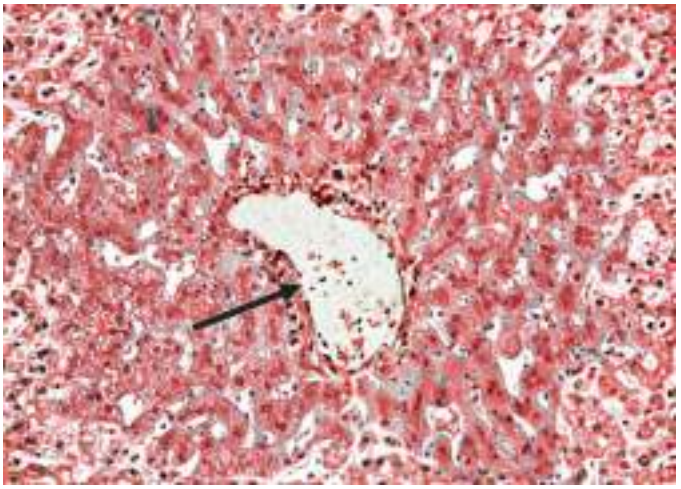

Fig. 15.41: Central venous congestion. Microscopically, the nutmeg pattern results from congestion around the central veins, as seen here (arrow). This is usually due to a right-sided heart failure.

PERIPHERAL PITTING EDEMA

High blood pressure forces fluid out of the capillaries into the interstitial tissues results in pitting type of edema in the dependent parts especially ankles.

RENAL MANIFESTATIONS

- Depending on severity of hypertension, patient may develop benign nephrosclerosis (hyaline arteriolosclerosis with grain leather surface) or malignant nephrosclerosis (flea-bitten kidneys).
- Decreased renal blood supply causes increased renin synthesis by juxtaglomerular apparatus resulting in activation of angiotensin-aldosterone system. Angiotensin II increases peripheral resistance and stimulates aldosterone synthesis. Aldosterone acts on distal tubules and enhances sodium and water retention. These changes further increase the blood pressure.

LIVER MANIFESTATIONS

In long-standing uncontrolled hypertension, patient may also develop right-sided heart failure. Jugular venous pressure is increased.

- Liver shows chronic passive congestion of sinusoids, atrophy of hepatocytes, dilatation of central veins and ischemic changes in zone 3 of liver lobule.
- Long-standing case of chronic venous congestion may develop cirrhosis, known as **cardiac cirrhosis** (Fig. 15.40). Long-standing chronic passive congestion of liver leads to bridging fibrosis in extreme cases resulting in cardiac cirrhosis (Fig. 15.41).

Heart

Vinay Kamal, Anubhav and Vigyat

LEARNING OBJECTIVES

THE NORMAL HEART

ISCHEMIC HEART DISEASE

- Ischemic heart disease: overview
- Angina pectoris
- Myocardial infarction
- Chronic ischemic heart disease

RHEUMATIC FEVER AND RHEUMATIC HEART DISEASE

- Rheumatic fever and rheumatic heart disease: overview
  - Pathogenesis
  - Aschoff's nodule
  - Jones diagnostic criteria
- Laboratory diagnosis
- Management

DISORDERS OF MYOCARDIUM

- Myocarditis
- Cardiomyopathies

DISORDERS OF ENDOCARDIUM

- Endocardium and endocarditis: overview
- Infective endocarditis
- Endocarditis in prosthetic valves
- Endocarditis in intravenous drug abuse
- Libman-Sacks endocarditis
- Nonbacterial thrombotic endocarditis
- Endocarditis in rheumatic heart disease
- Right-sided endocarditis in carcinoid syndrome

DISORDERS OF CARDIAC VALVES

- Cardiac valvular disorders: overview
- Mitral valve stenosis
- Mitral valve insufficiency/regurgitation
- Mitral valve prolapse
- Aortic valve stenosis
- Aortic valve insufficiency/regurgitation
- Calcific aortic stenosis
- Tricuspid valve insufficiency
- Pulmonic valve stenosis
- Carcinoid heart disease

DISORDERS OF PERICARDIUM

- Anatomy and physiology
- Pericardial effusion
- Hydropericardium
- Hemopericardium
- Cardiac tamponade
- Pericarditis: overview
- Acute pericarditis
- Chronic pericarditis

CARDIAC HYPERTROPHY AND HEART FAILURE

- Cardiac hypertrophy
- Heart failure
  - Left-sided heart failure
  - Right-sided heart failure

NEOPLASTIC DISORDERS OF HEART

- Neoplasms: classification
- Atrial myxoma
- Cardiac rhabdomyoma

CONGENITAL HEART DISEASES AND BLOOD VESSEL MALFORMATIONS

- Atrial septal defects
- Ventricular septal defects
- Patent ductus arteriosus
- Coarctation of the aorta
- Tetralogy of Fallot
- Truncus arteriosus communis
- Malformations of CVS

THE NORMAL HEART

ANATOMY AND PHYSIOLOGY

Normal heart weighs 300–350 g (male) and 250–300 g (female). Heart has a critical weight of 500 g termed cor bovinum in tertiary syphilis. Normal left ventricular thickness is 1.2–1.5 cm and 0.3–0.5 cm in the right ventricle measured at the base of papillary muscles. Heart is composed of three layers: epicardium, myocardium and endocardium. Pericardium comprises serous and visceral layers of pericardium.

Histology: Normal Myocardium

Light Microscopy

- Normal myocardium is composed of functional syncytium of myocardial fibers with centrally placed nuclei.
- Numerous capillaries are present in the interstitial tissue between myocardial fibers.

CARDIAC VALVES

Heart consists of atrioventricular valves (mitral and tricuspid). The cardiac valves comprise an annulus,

leaflets, chordae tendineae and papillary muscles. The semilunar valves of aorta and pulmonary artery have three cusps, which meet at commissures.

BLOOD SUPPLY OF HEART

Both coronary arteries are arising from root of aorta, which supply blood to heart during diastole. The principal veins of heart are cardiac vein and the coronary sinus. Most abundant blood supply goes to the myocardium of the left ventricle. Site of myocardial infarct depends on level of occlusion in coronary arteries.

Left Coronary Artery

Left coronary artery divides into left anterior descending (LAD) and left circumflex artery (LCA). Occlusion of left coronary artery at origin site causes produces massive anterolateral acute myocardial infarction.

- **Left anterior descending branch of left coronary artery (LAD):** LAD runs in anterior interventricular sulcus and supplies anterior portion of left ventricle including apex, anterior two-thirds of the interventricular septum, and adjacent area of right ventricle. Stenosis of LAD leads to infarction of anterior part of the left ventricle along with anterior two-thirds of the interventricular septum in 40–50% of cases.
- **Left circumflex artery (LCA):** LCA runs in coronal sulcus is a transverse groove present between the atria and ventricles. It supplies blood to the lateral free wall of the left ventricle. Stenosis of LCA leads to infarction in the lateral wall of the left ventricle in 15–20% of cases.

Right Coronary Artery

- Right coronary artery runs in posterior interventricular sulcus. It nourishes the entire right ventricle, posteroinferior wall of the left ventricle including the posteromedial papillary muscle, and posterior one-third of the interventricular septum. It also supplies 90% of the blood to the SA node (sinoatrial node) and AV node (atrioventricular node).
- Stenosis of right coronary artery causes infarction in the right ventricle, posteroinferior wall of left ventricle, along with posterior one-third of the interventricular septum in 30–40% of cases.

CONDUCTION SYSTEM OF HEART

The conduction system is composed of specialized myocytes, with fewer intercalated discs and higher glycogen content. The conduction system is demonstrated by Masson trichrome, Verhoeff-van Gieson, and Alcian blue histochemical stains.

Sinoatrial Node

Sinoatrial (SA) node measures 0.3 mm and located in the upper right atrial wall near the opening of the superior vena cava. It initiates cardiac action potential at a velocity of 0.3 m/second, which sets basic pace for heart rate and conduction throughout both atria. It possesses high concentration of sodium ions in the extracellular fluid and negative charge inside the nodal fibers.

Atrioventricular Node or Node of Tawara

Atrioventricular (AV) node is located in posterior wall of right atrium along the lower part of interatrial septum, which receives action potential from SA node.

Bundle of His and its Branches

Bundle of His is located in superior portion of interventricular septum and divides into left and right branches, which receives action potential from atrioventricular (AV) node and passes to myofibers through left and right bundle branches.

Conduction Myofibers (Purkinje Fibers)

Purkinje fibers are located in ventricular septum, which extend out to the papillary muscles and lateral walls of ventricles. Purkinje fibers receive action potential from bundle of His and its branches and pass them to ventricular myocardium.

ISCHEMIC HEART DISEASE

ISCHEMIC HEART DISEASE: OVERVIEW

Ischemic heart disease (IHD) is a condition in which there is an inadequate supply of oxygenated blood to the myocardium. It typically occurs when there is an imbalance between myocardial oxygen supply and its demand.

- The most common cause of ischemic heart disease is atheromatous plaque formed in the epicardial artery/arteries, sufficient to cause a regional reduction in myocardial oxygenated blood flow and inadequate perfusion of the myocardium supplied by the involved coronary artery.
- Depending on the extent of involvement of coronary artery/arteries, patient may present with angina pectoris (stable, unstable or Prinzmetal variants), myocardial infarction, sudden cardiac death, and chronic IHD with congestive heart failure.

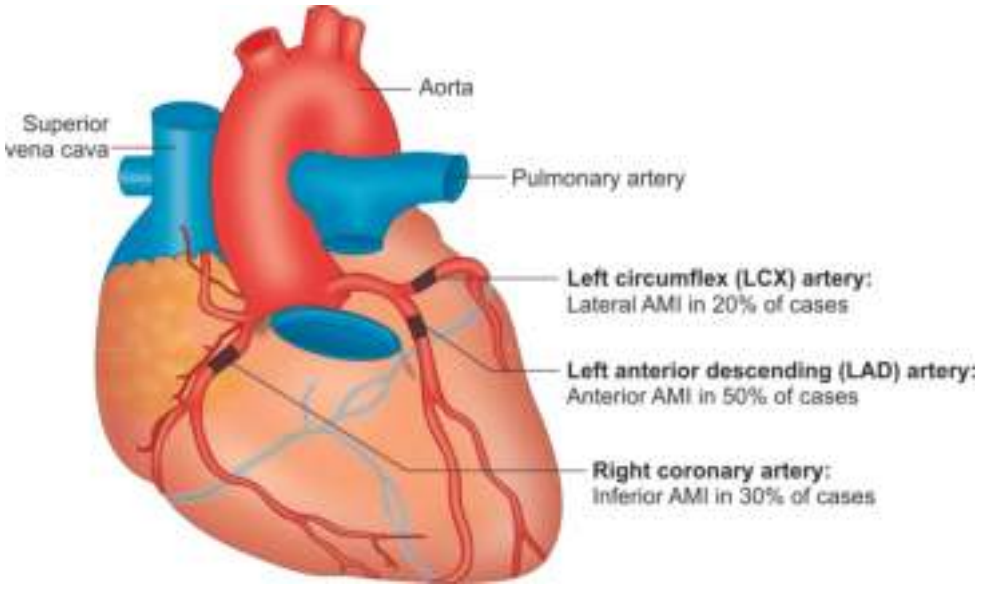

Fig. 16.1: Locations of blockage in the coronary arteries: Left anterior descending artery (50%), right coronary artery (30%) and left circumflex artery (20%).

- Acute coronary syndrome comprises angina pectoris, myocardial infarction and sudden cardiac death.
- Atherosclerosis in epicardial coronary artery is the most important cause of ischemic heart disease.
- Atherosclerosis develops at different rates in different segments of the coronary arteries resulting in segmental reduction in cross-sectional area.
- The coronary arteries involved due to atherosclerosis in descending order include anterior descending branch of left coronary artery (50%) especially in the proximal region, right coronary artery (30%) and circumflex branch of left coronary artery (20%).
- Locations of blockage in the coronary arteries due to atherosclerosis are shown in Fig. 16.1.

RISK FACTORS

Risk factors for atherosclerosis include major modifiable risk factors (hyperlipidemia, hypertension, diabetes mellitus, tobacco smoking), nonmodifiable risk factors (increasing age, male gender, family history of premature atherosclerosis, genetic abnormalities in LDL receptors, ApoA1, ApoAE, hepatic lipase); and minor risk factors (obesity, type A personality, factors affecting thrombosis, high carbohydrate diet, homocysteinemia, infectious agents).

- Approximately 25% of patients either succumb to terminal ventricular arrhythmias and sudden cardiac death prior to reaching hospital or suffer from a similar event in the critical coronary care unit.
- Myocardial ischemia can also occur in left ventricular hypertrophy due to aortic stenosis.
- A reduction in oxygen-carrying capacity in the blood due to severe anemia, presence of carboxyhemoglobin may lower the threshold for myocardial ischemia in patients with moderate coronary obstruction induced by atheromatous plaque. Risk factors for atherosclerosis are given in Table 16.1.

Table 16.1 Risk factors for atherosclerosis

Modifiable Major Risk Factors	Nonmodifiable Major Risk Factors	Minor Risk Factors
▪ Hyperlipidemia ▪ Hypertension ▪ Diabetes mellitus ▪ Tobacco smoking	▪ Increasing age ▪ Male gender ▪ Family history of premature atherosclerosis ▪ Genetic abnormalities (e.g. LDL receptor, ApoA1, ApoB, ApoE, 5-lipoxygenase, hepatic lipase deficiency)	▪ Obesity ▪ Stress (type A personality) ▪ Factors affecting thrombosis (thrombophilia) ▪ High intake of carbohydrate ▪ Homocysteinemia >100 µmol/L ▪ Infectious agents (*Chlamydia pneumoniae*, *Helicobacter pylori*, herpesvirus, cytomegalovirus promote atherosclerosis)

CONSEQUENCE OF MYOCARDIAL ISCHEMIA

During episodes of inadequate perfusion caused by coronary atherosclerosis, myocardial tissue oxygen tension falls, which results in transient disturbances of the mechanical, biochemical and electrical functions of the myocardium. During myocardial ischemia, regional disturbances of ventricular contractility cause segmental hypokinesia, akinesis or dyskinesis in severe cases, which can reduce myocardial pump function. Abrupt development of severe myocardial ischemia due to subtotal or total occlusion of coronary arteries is associated with instantaneous failure of normal cardiac muscle contraction and relaxation. Poor perfusion of the myocardium leads to left ventricular failure. Involvement of papillary muscle causes mitral valve regurgitation.

INCIDENCE OF CORONARY ARTERY DISEASE IN PRESENT SCENARIO

Incidence of ischemic heart disease is decreasing due to various diagnostic and therapeutic advances availability in coronary care units in the present scenario. Diagnostic advances include 12-lead electrocardiogram, coronary angiography, two-dimensional echocardiography, radionuclide scanning, serum cardiac biomarkers (cardiac troponins and enzymes).

- Therapeutic advances include revascularization procedures such as percutaneous coronary artery angioplasty, intracoronary stents and coronary artery bypass graft (CABG) and thrombolytic therapy.
- Modification of major risk factors by treating diabetes mellitus, hypertension, hyperlipidemia (statins lipid lowering agents) and stoppage of tobacco smoking and prophylactic use aspirin reduce the risk of coronary artery disease.
- Diagnostic and therapeutic advances in reducing incidence of coronary artery disease are given in Table 16.2. Revascularization procedures to re-establish coronary artery blood flow to myocardium are given in Table 16.3. 12-lead electrocardiogram (ECG) is given in Table 16.4.

Table 16.2 Diagnostic and therapeutic advances in reducing incidence of coronary artery disease

Advances	Comments
Diagnostic advances	
Coronary artery angiography	Detection of blockage in coronary arteries
12-lead electrocardiogram	Diagnostic in majority of cases
2-dimensional echocardiography	Detection of motion of cardiac chambers
Radionuclide scanning	Detect location of infarct region
Serum cardiac troponins	Defining evidence of myocardial injury
Serum CK-MB isoenzyme	Diagnostic serum cardiac biomarker in myocardial infarction
Revascularization procedures	
Thrombolytic agent therapy (streptokinase or tissue plasminogen activator)	Administered to lyse recently formed thrombus to re-establish blood flow to myocardium
Percutaneous coronary angioplasty	Balloon angioplasty used to vasodilate stenosed coronary artery
Intracoronary stenting	Stents put in the coronary arteries to re-establish blood flow to myocardium, drawback is trauma to myocardium
Coronary artery bypass graft	Internal mammary artery preferred over saphenous vein due to longer life for 5–10 years

Table 16.3 Revascularization procedures to re-establish coronary artery blood flow to myocardium

Revascularization Procedures	Comments
Coronary angioplasty	▪ Coronary angioplasty, also known as balloon angioplasty and percutaneous angioplasty is a minimally invasive endovascular procedure to dilate obstructed coronary artery ▪ A deflated balloon is attached to the catheter and passed over a guidewire into the stenosed coronary artery and then inflated to the fixed size. The balloon forces expansion the blood vessel to re-establish blood flow. Stent can be inserted at the time of ballooning to ensure the blood vessel remains open, and the balloon then deflated and withdrawn ▪ Risks and complications of coronary angioplasty include embolization, hematoma formation in the vessel and arterial rupture from overinflation of balloon ▪ Contraindications of coronary angioplasty include calcified vessel hematoma or a bypass origin

Contd...

Table 16.3 Revascularization procedures to re-establish coronary artery blood flow to myocardium (*Contd...*)

Revascularization Procedures	Comments
Coronary artery bypass grafting (CABG)	▪ Coronary artery bypass grafting is a major surgical operation, where patient's blocked coronary artery with atheromatous plaque is bypassed with harvested arterial or venous conduits ▪ As we know internal mammary arteries are always spared of atheromatous plaque. Therefore, internal mammary graft having longer life is preferred over saphenous vein graft ▪ Saphenous vein graft undergoes adaptive arterialization with development of atheromatous plaque in a span of 5–10 years ▪ Atheromatous plaque formed in saphenous vein graft is indistinguishable from that formed in the native coronary arteries, a process referred to as restenosis of the graft
Thrombolytic agents administration	Administration of thrombolytic agents such as streptokinase or tissue plasminogen activator (tPA) cause lysis of recently formed thrombus to re-establish the coronary blood flow and reduce further myocardial damage

Table 16.4 12-lead electrocardiogram (ECG)

In a 12-lead electrocardiogram (ECG), leads II, III and aVF demonstrate activity from the inferior cardiac wall, while leads I, aVL, V_5 and V_6 reflect activity of the lateral cardiac wall. Leads V_1–V_6 represent the anterior cardiac wall. Changes in the axis of the ECG can indicate conduction blockage or right ventricular hypertrophy. Increasing amplitude of electrical impulses is indicative of cardiac hypertrophy. P wave results from atrial contraction. QRS complex is produced by septal conduction and ventricular contraction. T wave is caused by repolarization of the ventricle

- **ST-segment elevation:** It is indicative of acute myocardial ischemia in myocardial infarction and Prinzmetal angina
- **ST segment depression:** It is indicative of stable and unstable angina
- **Q wave appearance:** It is usually indicative of transmural myocardial infarct
- **Non-Q wave myocardial infarcts:** These are indicative of subendocardial infarcts

ANGINA PECTORIS

Angina pectoris is episodic chest pain caused by inadequate oxygenation of the myocardium. Three variants of angina pectoris include: stable, unstable and Prinzmetal angina. Comparison of stable angina, unstable crescendo angina and Prinzmetal variant angina is given in Table 16.5. Management of angina pectoris is given in Table 16.6.

STABLE ANGINA

Stable angina is most common form of angina pectoris and predictable, which occurs at a fixed level of exercise.

- Due to severe atheromatous plaque in coronary arteries with reduction in cross sectional area by 70% and luminal diameter <1 mm in epicardial arteries (fixed stenosis) and decreased blood flow are not able to meet out the metabolic demand of myocardium during exercise.

Table 16.5 Comparison of stable angina, unstable crescendo angina and Prinzmetal variant angina

Characteristics	Stable Angina	Unstable Crescendo Angina (also known as Preinfarction Angina)	Prinzmetal Angina
Etiology	Occurs due to fixed coronary atherosclerosis with reduction in cross-sectional by 70% and luminal diameter <1 mm in epicardial arteries	Occurs due to rupture of an atheromatous plaque with superimposed thrombosis, incomplete occlusion of coronary arteries and microembolization	Occurs due to coronary artery vasospasm
Precipitating factors	Chest pain related to strenuous physical activity and emotional excitement of patient	Chest pain not related to strenuous physical activity, but prone to acute myocardial infarction	Chest pain not related to strenuous physical activity
Pathology	Represents reversible injury to myocytes without necrosis in subendocardial region	Represents reversible injury to myocytes without necrosis in subendocardial region	Represents reversible injury to myocytes without necrosis in transmural region
Electrocardiogram	ST segment depression due to subendocardial ischemia	ST segment depression due to subendocardial ischemia	ST-segment elevation due to transmural ischemia

Contd...

Table 16.5 Comparison of stable angina, unstable crescendo angina and Prinzmetal variant angina (*Contd...*)

Characteristics	Stable Angina	Unstable Crescendo Angina (also known as Preinfarction Angina)	Prinzmetal Angina
Clinical features	Chest pain in substernal region lasting <20 minutes, that radiates to the left arm and/or jaw, diaphoresis, and shortness of breath	Chest pain in the substernal region especially in the morning, that lasts for longer duration, high risk of progression to myocardial infarction	Intermittent chest pain in the substernal region even during rest
Management	Modification of risk factors, low-dose of aspirin, nitroglycerin, β-blockers and calcium channel blockers, percutaneous coronary intervention using balloon angioplasty, or coronary artery bypass grafting (CABG)	Potential thrombolysis or percutaneous coronary intervention using balloon angioplasty	Administration of sublingual nitroglycerin or calcium channel blockers
Outcome	Responds to medication vasodilator nitroglycerin	Requires hospitalization with interventional techniques to prevent myocardial infarction	Responds to medication vasodilator nitroglycerin

Table 16.6 Management of angina pectoris

Angina Pectoris Variants	Comments
Stable angina	▪ Stable angina can be managed by modification of risk factors, combination of drug therapy with low-dose of aspirin, nitroglycerin, β-blockers and calcium channel blockers ▪ Percutaneous coronary intervention using balloon angioplasty is performed to dilate coronary artery stenosis. ▪ Coronary artery bypass grafting (CABG) may be indicated in severe occlusive atheromatous plaque in the coronary artery
Unstable angina	▪ Patient with unstable angina should be hospitalized for ECG evaluation and potential thrombolysis or percutaneous coronary intervention using balloon angioplasty ▪ Such active measures reduce progression of myocardial infarction. Unstable angina is included in the non-ST-segment elevation myocardial infarction (NSTEMI) category of acute coronary syndrome
Prinzmetal crescendo angina	▪ Treatment during an episode of Prinzmetal crescendo angina is to relieve pain and shorten its duration by administration of sublingual nitroglycerin ▪ Patient is advised to take calcium channel blockers or long acting nitrates to reduce the frequency of episodes. β-Blockers are contraindicated, as these may worsen the attacks by blocking β_2 receptors

- Stable angina represents reversible injury to myocytes without necrosis. Patient presents with chest pain in substernal region lasting for <20 minutes, that radiates to the left arm and/or jaw, diaphoresis, and shortness of breath. Pain is relieved by taking rest and sublingual nitroglycerin. Electrocardiogram shows ST-segment depression due to subendocardial ischemia.
- About 20–30% of patients may develop unstable angina and myocardial infarction within one year of diagnosing stable angina.
- Stable angina can be managed by modification of major risk factors for atherosclerosis, combination of drug therapy with low-dose of aspirin, nitroglycerin, β-blockers and calcium channel blockers.
- Percutaneous coronary intervention using balloon angioplasty is performed to dilate coronary artery stenosis. Coronary artery bypass grafting (CABG) may be indicated in severe occlusive atheromatous plaque in the coronary arteries.

UNSTABLE ANGINA (CRESCENDO OR PREINFARCTION ANGINA)

Unstable angina is caused due to rupture of an atheromatous plaque with superimposed thrombosis, incomplete occlusion of coronary arteries and micro-embolization.

- Occluded coronary arteries are unable to supply oxygenated blood to support the increased myocardial demands during exertion. It usually begins as stable angina. It is an acute unpredictable event and unrelated to exercise, which represents reversible injury to myocytes without necrosis.
- Electrocardiogram shows ST segment depression due to subendocardial ischemia.
- Patient presents with recurrent chest pain in the substernal region especially in the morning, that lasts for longer duration. In patient with unstable angina there is high risk for progression to myocardial infarction.

- Patient with unstable angina should be hospitalized for ECG evaluation and potential thrombolysis or percutaneous coronary artery intervention using balloon angioplasty. Such active measures reduce progression of unstable angina to myocardial infarction. Unstable angina is included in the non-ST-segment elevation myocardial infarction (NSTEMI) category of acute coronary syndrome.

PRINZMETAL ANGINA

Prinzmetal angina is caused by vasospasm of coronary artery due to increased synthesis of thromboxane A_2 or decreased synthesis of endothelin vasodilator by vascular endothelium. It represents reversible injury to myocytes.

- Electrocardiogram shows ST-segment elevation due to transmural ischemia.
- Patient presents with intermittent chest pain in the substernal region even on rest. Pain is relieved by nitroglycerin. Disorder is self-limited. Sometimes chest pain may be severe. It may rarely result in myocardial infarction.
- Treatment during an episode of Prinzmetal angina is to relieve pain and shorten its duration by administration of sublingual nitroglycerin.
- Patient is advised to take calcium channel blockers or long-acting nitrates to reduce the frequency of episodes. β-Blockers are contraindicated, as these may worsen the attacks by blocking β_2 receptors.

MYOCARDIAL INFARCTION

Myocardial infarction is the most important cause of morbidity and mortality due to cardiac arrhythmias, cardiac failure, mitral valve regurgitation due to necrosis of the papillary muscle and hemopericardium. Mortality is about fourfold higher in elderly patients aged >75% as compared with young patients.

- Most myocardial infarcts occur in the left ventricle and interventricular septum, which receive blood supply from both the coronary arteries.
- Complete occlusion of the coronary artery produces transmural infarction from endocardium to epicardium.
- Subendocardial infarct involves inner third to inner half of myocardium as a result of prolonged ischemia induced by partially occluded coronary artery (Figs 16.2 to 16.4).
- Severe reduction in blood flow leads to circumferential myocardial infarct. It can be averted by immediate coronary artery angioplasty and administration of thrombolytic agent.
- Myocardial infarct undergoes a series of progressive gross and histologic changes. Altered permeability of necrosed myocytes releases cardiac troponins and enzymes into the circulation. Neutrophils, macrophages and fibroblasts participate in the evolution of myocardial infarct.
- Patients with acute coronary syndrome are classified into two groups to facilitate evaluation and management, namely patients with acute myocardial infarction with ST-segment elevation (**STEMI**) on electrocardiogram and those with non-ST-segment elevation (**NSTEMI**) with evidence with myocyte necrosis.
- Relative evidence of STEMI is declining due to greater use of aspirin, lipid lowering agents 'statins' and stoppage of tobacco smoking.
- When patients with prolonged myocardial ischemic discomfort at rest are examined, the working clinical diagnosis is that they are suffering from acute coronary syndrome. The 12-lead electrocardiogram is a pivotal diagnostic tool, that helps to decide pathway for management of the patients.
- Following disruption of a vulnerable atheromatous plaque, patients may experience ischemic discomfort

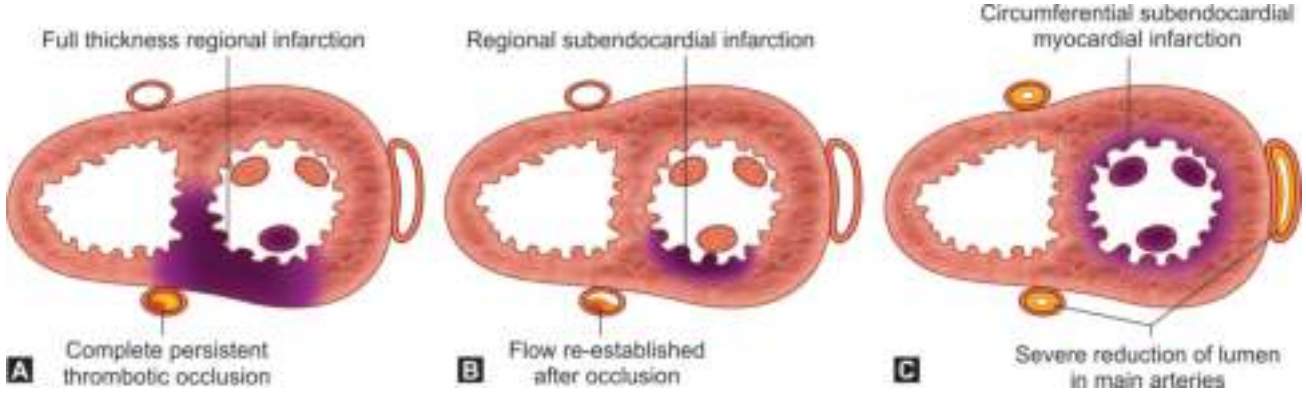

Fig. 16.2: Patterns of myocardial infarcts. (A) Transmural infarct due to persistent complete obstruction of coronary atherosclerosis with superimposed thrombus, (B) regional subendocardial infarct occurs as a result of re-establishment of blood flow after occlusion of coronary artery, (C) circumferential subendocardial infarct occurs due to svere reduction of lumen of coronary artery/arteries.

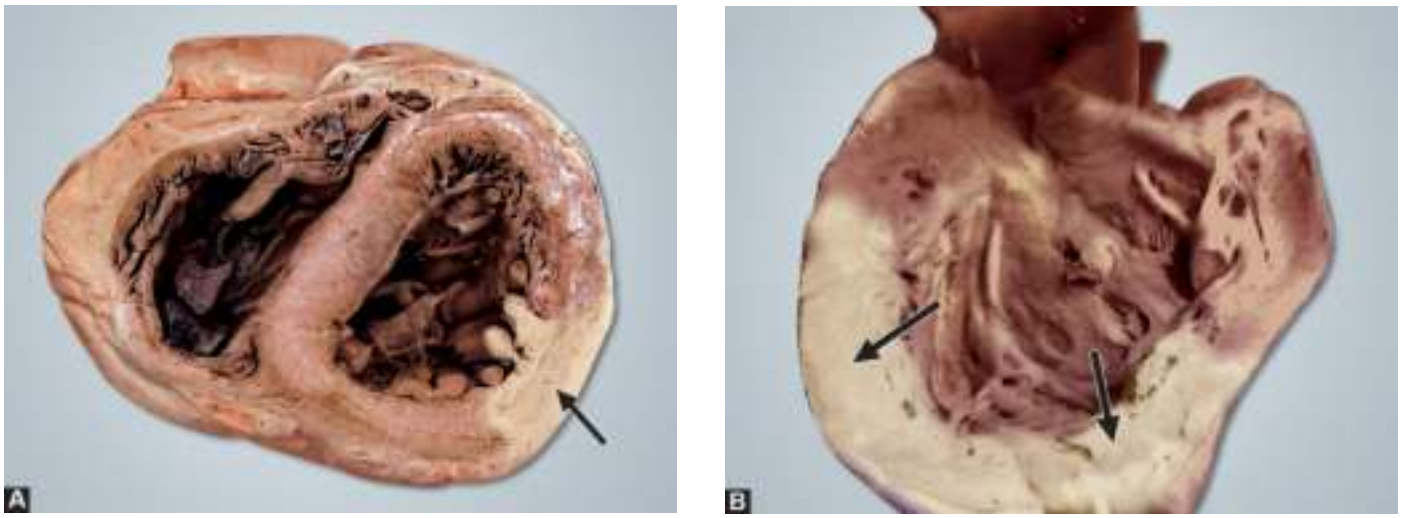

Fig. 16.3A and B: Transmural infarct due to persistent complete obstruction of coronary atherosclerosis with superimposed thrombus (arrows).

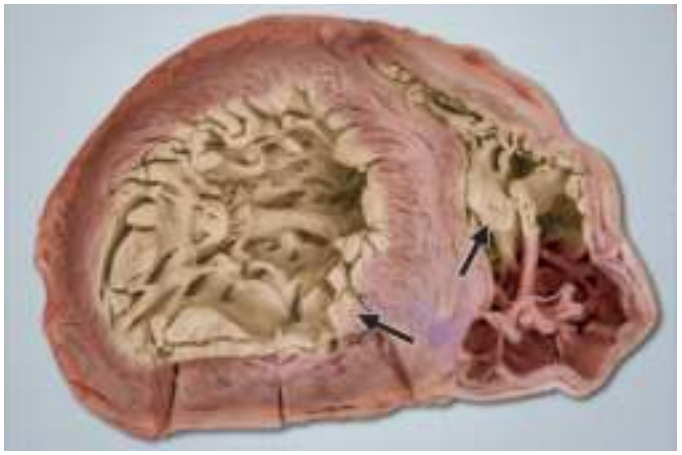

Fig. 16.4: Regional subendocardial infarct occurs as a result of re-establishment of blood flow after occlusion of coronary artery (arrows).

resulting from a reduction of oxygenated blood flow through the affected epicardial coronary artery/arteries. The reduction in blood flow may occur either due to complete occlusion or partial occlusion of the coronary artery.

- Patient may present with ischemic discomfort with or without ST-segment elevation.
- Patients with ST-segment elevation, the majority do not develop a new 'Q wave' on the electrocardiogram (Q wave MI), while a minority of cases do not develop a new 'Q wave' MI (NQMI). The patients who present without non-ST-segment elevation MI (NSTEMI), a distinction is based on the analysis of serum cardiac biomarkers such as CK-MB enzyme and cardiac troponins.

PATHOPHYSIOLOGY

Acute myocardial infarction with ST-segment elevation myocardial infarction (STEMI) usually occurs when the coronary blood flow decreases abruptly after a thrombotic occlusion of coronary artery previously affected by atheromatous plaque.

- Slowly developing severe coronary artery stenosis does not precipitate STEMI due to the presence of a rich collateral vascular network overtime. Instead, STEMI occurs when coronary artery thrombosis develops rapidly over disrupted atheromatous plaque.
- The amount of myocardial damage caused by coronary artery occlusion depends on the territory supplied by the affected coronary artery, partial or complete occlusion of the vessel, duration of coronary occlusion, quantity of blood supplied by the collateral blood vessels, demand of oxygen of the myocardium, endogenous factors and perfusion-induced injury.

Role of Acute Atheromatous Plaque Disruption

In most cases, STEMI occurs due to the disruption of an atheromatous plaque resulting in exposure of its contents to the blood favoring thrombogenesis. Formation of mural thrombus at the site of atheromatous plaque disruption leads to occlusion of the coronary artery/arteries. Histologic studies indicate that the coronary atheromatous plaques are prone to disruption. Causes of myocardial infarction are given in Table 16.7.

Role of Platelets

After an initial formation of platelet monolayer at the site of atheromatous plaque, various agonists (collagen, ADP, epinephrine, serotonin) promote platelet activation. After agonist activation of platelets, thromboxane A_2, a potent local vasoconstrictor is released by activatd platelets for further platelet activation. Formation of primary hemostatic plug by platelet adhesion activation, aggregation and degranulation is shown in Fig. 16.5.

Table 16.7 Causes of myocardial infarction

Lesions	Comments
Atheromatous lesions (most common)	
Complicated atheromatous plaque with rupture	Complicated atheromatous plaque fissuring leads to adhesion and aggregation of platelets and activation of coagulation cascade
Nonatheromatous lesions (less common)	
Vasculitis	Polyarteritis nodosa, systemic lupus erythematosus, Kawasaki disease
Embolization to coronary arteries	Emboli arising from left-sided heart due to infective endocarditis; or paradoxical emboli from right side of heart through patent foramen ovale resulting in blockage of coronary arteries.
Thrombotic disorders	Antithrombin III deficiency and polycythemia vera
Vasospasm of coronary arteries	Cocaine abuse causes sudden vasospasm of coronary arteries
Hemodynamic alterations	Hypotension due to spinal anesthesia and hypotensive shock
Congenital anomaly of origin of left anterior descending branch of left coronary artery	Congenital anomaly of origin of left anterior descending branch of left coronary artery results in blood flow obstruction to myocardium
Aortic dissection	Aortic dissection may obstruct coronary arteries
Trauma to coronary arteries	Direct trauma to the coronary arteries on road side accidents may obstruct blood flow in coronary arteries

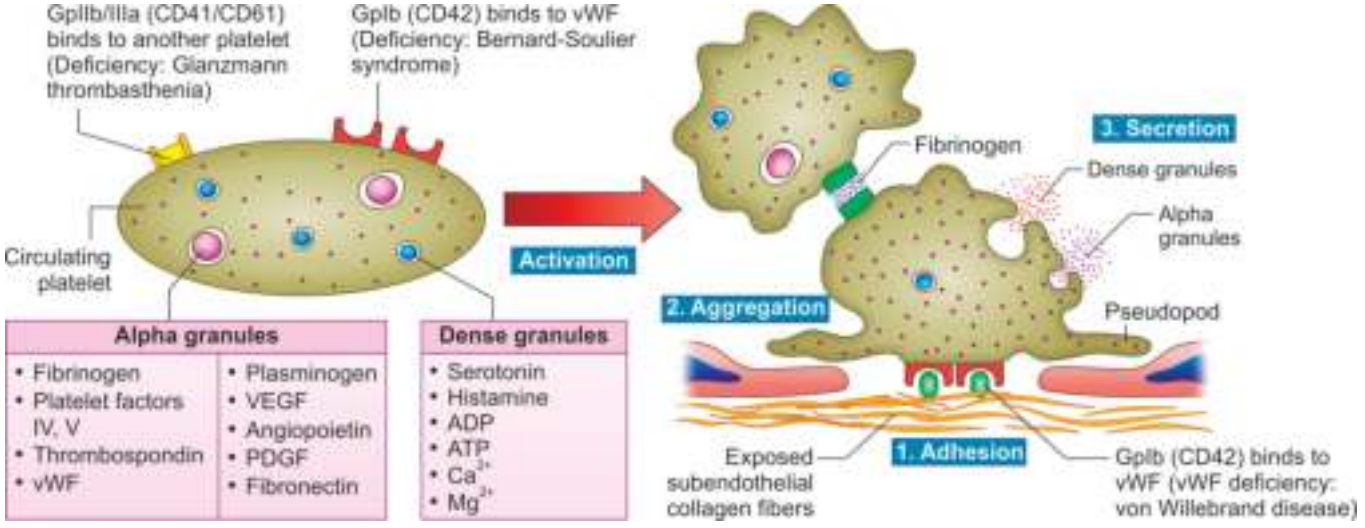

Fig. 16.5: Formation of hemostatic plug by platelet adhesion activation, aggregation and degranulation. Platelet activation involves three overlapping mechanisms. 1. Adhesion of platelets to the exposed subendothelium is mediated by the binding of von Willebrand factor (vWF) to glycoprotein (Gp) Ib/IX (CD42) resulting in initiation of signal for activation of platelets. 2. Exposure of GpIIb/IIIa (CD41/61) to the fibrinogen receptor on the platelet surface permits for platelet aggregation. 3. At the same time, platelets synthesize their granule contents, which facilitate further activation.

- **Platelet adhesion:** Tissue injury causes platelets to adhere to subendothelial collagen. Shape change, secretion of granule contents, and aggregation follow. Within seconds of tissue injury, vWF (von Willebrand factor), released from the Weibel-Palade of vascular endothelium and a granule of platelets, binds to the platelet using GP1a receptors resulting in adhesion of the platelets to the exposed collagen fibers of damaged blood vessels.
- **Platelet activation and degranulation:** The platelets become activated and release ADP and thromboxane A_2 (TXA_2). The ADP and TXA_2 attract additional platelets resulting in platelet aggregation and primary hemostatic plug formation. Platelet shape change after activation by an agonist by ADP and thromboxane A. Agonist is a substance, which initiates a physiologic response when combined with a receptor. Pseudopodia develop on the surface of platelet. The pseudopodia contain a network of actin and myosin. The microtubule circumferentially contracts resulting in activation of phospholipids and glycoprotein IIb/IIIa receptors. Internal biochemical changes occur in the platelets resulting in granule secretion.

- **Primary and secondary hemostasis:** Platelets aggregate at the site of injury via GpIIb/IIIa using fibrinogen from the plasma as a linking molecule; resulting in formation of platelet plug (primary hemostasis). Platelet plug is weak; coagulation system cascade (secondary hemostasis) stabilizes it.

Blood Coagulation System

- Activators and inhibitors of coagulation system and fibrinolysis keep the coagulation system in balance. Clotting occurs when blood vessels are injured and exposed to activators of coagulation factors. Clotting is controlled because fibrinolysis process is initiated in response to activation of coagulation factors. Inhibitors of both clotting and fibrinolysis serve to bring the coagulation system back to balance. An imbalance in the activation or inhibition of either blood clotting and/or fibrinolysis causes thrombosis.
- The terminal steps in both intrinsic and extrinsic coagulation pathways remain same. Both coagulation pathways lead to the activation of factor X. Intrinsic pathway is initiated by activation of circulating factor XII. Extrinsic pathway is activated by a cellular lipoprotein known as tissue factor that becomes exposed when tissues are injured. Calcium, factor X, factor V, and platelet phospholipids combine to form prothrombin activator, which then converts prothrombin to thrombin. The interaction causes conversion of fibrinogen into fibrin strands that create the insoluble and stable blood clot (Fig. 16.6).

MYOCARDIAL INFARCTS: TYPES

- Gross morphology of myocardial infarct depends on extent of involvement of myocardium. There are three types of myocardial infarcts (transmural, subendocardial and circumferential infarcts).
- ECG is diagnostic of AMI in 75–80% of cases (appearance of new Q wave). Appearance of new Q wave on ECG is dependent on the volume of myocardial infarct area (transmural infarction). That is the reason that ST segment study in the electrocardiogram is important, which differentiates transmural and subendocardial infarcts (Table 16.8).

Transmural Myocardial Infarct

Transmural myocardial infarct involves the entire left ventricular wall from endocardium to epicardium including involvement of interventricular septum.

- **Pathogenesis:** Transmural infarct is caused by disrupted atheromatous plaque with superimposed thrombus. Blood supply to the heart is not restored after ischemia. In small number of cases, transmural infarct is related to thromboemboli or vasospasm.
- **ECG study:** It reveals STEMI and appearance of new Q wave. ST-segment elevation indicates area of injury and loss of normal myocardial cell membrane ion pumps. Appearance of new Q wave indicates extent of myocardial infarct.
- **Therapeutic correlation:** Patients with transmural myocardial infarction require emergency treatment to reopen the obstructed coronary artery either by coronary angioplasty or thrombolytic drugs that

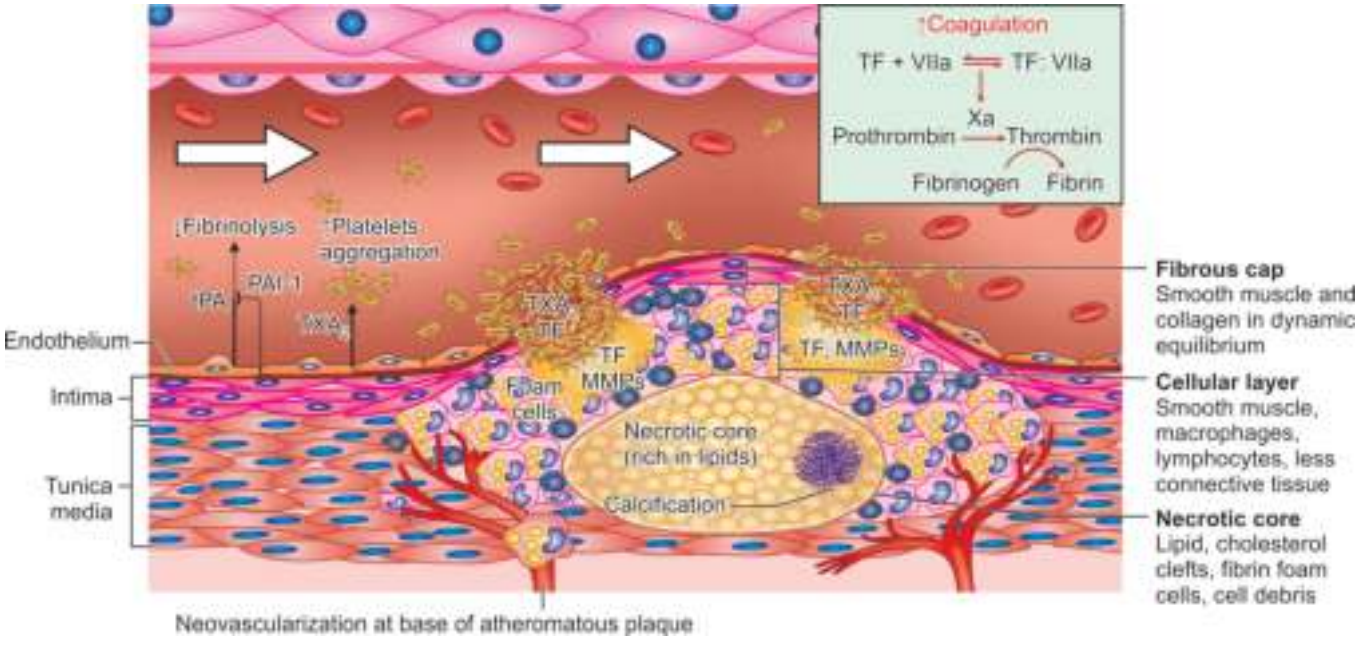

Fig. 16.6: When atheromatous plaque ruptures, the balance between fibrinolysis and coagulation is shifted to greater thrombosis, and occlusive thrombus formation (TF: Tissue factor, tPA: Tissue plasminogen activator, TXA_2: Thromboxane A_2, MMPs: Matrix metalloproteinases).

Table 16.8 Differences between transmural and subendocardial infarcts

Characteristics	Transmural Infarct	Subendocardial Infarct
Extent of myocardium involved due to infarction	Entire left ventricular wall from endocardium to epicardium including interventricular septum	One-third to inner-half of the ventricular thickness
Frequency	More common (85%)	Less common (5%)
Nature of lesion	Unifocal and solid area of coagulative necrosis	Multifocal and patchy areas of coagulative necrosis in circumferential distribution
Distribution	Area supplied by specific coronary artery	Circumferential pattern
Thrombosis superimposed on atheromatous plaque in the coronary artery	Common as a result of thrombosis superimposed on atheromatous plaque in the coronary artery resulting in persistent deprivation of blood supply to myocardium	▪ No evidence of thrombus superimposed ▪ Uncommon as a result of atheromatous plaque disruption followed by thrombus formation and lysis resulting in restoration of blood supply to myocardium
Cardiogenic shock	Often causes cardiogenic shock	Often results from hypotension or shock
Pericarditis	Common	Absent
Cardiac aneurysm	May be observed	Does not develop
ECG changes	▪ Elevation of ST segment and appearance of new Q wave ▪ ST elevation infarct (STEMI)	Non-ST elevation infarct (NSTEMI)

Coagulative necrosis occurs only 20–40 minutes after ischemia. Gross and microscopic changes develop only hours to days after the onset of ischemia.

activate the plasminogen system to lyse thrombosis in coronary arteries.

Subendocardial Myocardial Infarct

Under physiologic state, subendocardial region of heart receives oxygen and nutrients by diffusion directly from the circulating blood in the ventricular cavity. Subendocardial myocardial infarct involves inner one-third to inner-half of the left ventricular wall or sometimes right ventricle. It exhibits multifocal areas of coagulative necrosis. Isolated infarcts of right ventricle and right atrium are extremely rare.

- **Pathogenesis:** Typically, subendocardial myocardial infarct occurs as a result of decreased perfusion of myocardium in hypotensive shock, and restoration of blood supply.
- **ECG study:** It reveals absence of ST-segment elevation myocardial infarction (NSTEMI) as well as appearance of a new Q wave. In minority of cases, ECG study reveals absence of ST-segment elevation and appearance of a new Q wave.
- **Diagnostic approach:** These patients require estimation of cardiac troponins for establishing diagnosis.

REPERFUSION-INDUCED MYOCARDIAL INJURY

Reperfusion of the myocardial infarct by therapeutic administration of thrombolytic agents may cause further injury to myocardium by synthesis of oxygen-derived free radicals.

Oxygen-derived Free Radicals

Initially, myocardial ischemia produced cellular damage results in generation of oxygen-derived free radicals.

- Subsequently, myocardial reperfusion by thrombolytic agents provides abundant molecular oxygen (O_2) to generate more oxygen-derived free radicals through the xanthine oxidase pathway in activated neutrophils.
- These oxygen-derived free radicals injure viable myocytes.

Histologic Alterations

Reperfusion injury histologically alters irreversibly damaged myocardial cells. It produces contraction band necrosis of myofibrils in dying cells due to influx of calcium into the cytosol.

Removal of Necrosed Myocytes

Removal of irreversibly damaged myocytes improves short- and long-term function and survival. It prevents further damage to myocardial cells and limits the size of myocardial infarct.

Morphologic Changes: Myocardial Infarction

Gross Morphology

- No gross changes are evident within 24 hours of myocardial infarction.
- In autopsy specimen, myocardial infarct area can be appreciated by applying triphenyltetrazolium chloride (TTC) to slices of myocardial infarct (2–3 hours old). Due to depletion of lactate dehydrogenase (LDH) enzyme, infarct area of myocardium remains unstained.
- Normal myocardium is rich in LDH enzyme, hence gives uniform brownish discoloration to the dye TTC.

Light Microscopy

Irreversible injury to myocardium occurs in 20–40 minutes after cessation of blood supply. Myocardium shows wavy myocardial fibers within 1–3 hours of myocardial infarction. There may be eosinophilia of myocardial fibers.

- **Acute inflammatory changes:** Neutrophils accumulate at the peripheral zone and then infiltrate the necrotic tissue within 18–24 hours. Two days after myocardial infarction, the affected heart muscle demonstrates coagulative necrosis with loss of cross striations, contraction bands, edema, and hemorrhage. Neutrophils are replaced by macrophages.
- **Healing stage:** Proliferation of fibroblasts results in fibrosis of infarct area. Myocardial cells being terminally differentiated permanent cells are unable to regenerate and healing occurs by fibrosis. However, the patient may die due to electrical disturbances before the myocardial infarct heals. Examination of the heart in such cases at autopsy will reveal the typical macroscopic features of a myocardial infarct at various stages of evolution and/or healing (Figs 16.7, 16.8 and Table 16.9).

CLINICAL COMPLICATIONS

Clinical complications of acute myocardial infarction (AMI) depend upon the size and location of the myocardial infarct, as well as pre-existing myocardial damage. Ventricular arrhythmia is the most common cause of death in early 0–4 hours of AMI. Risk of myocardial rupture is fatal complication within first 3–7 days. Ventricular aneurysm is common in scarred area after 7 weeks of AMI.

Cardiogenic Shock

Cardiogenic shock is commonly associated with large transmural infarcts, which occurs in the first 24 hours in 10–15% of cases. Weakening of the myocardium leads to cardiac failure. Revascularization improves survival.

Cardiac Arrhythmias

- Cardiac arrhythmias account for 50% of all deaths within the first 24 hours after an AMI. The risk of cardiac arrhythmia is high within the first 6 hours after AMI.
- Acute myocardial infarction (AMI) is often associated with premature ventricular beats, ventricular tachycardia, complete heart block (anterior or posterior region), ventricular fibrillation and cardiogenic shock with fatal outcome within 2 days of AMI.

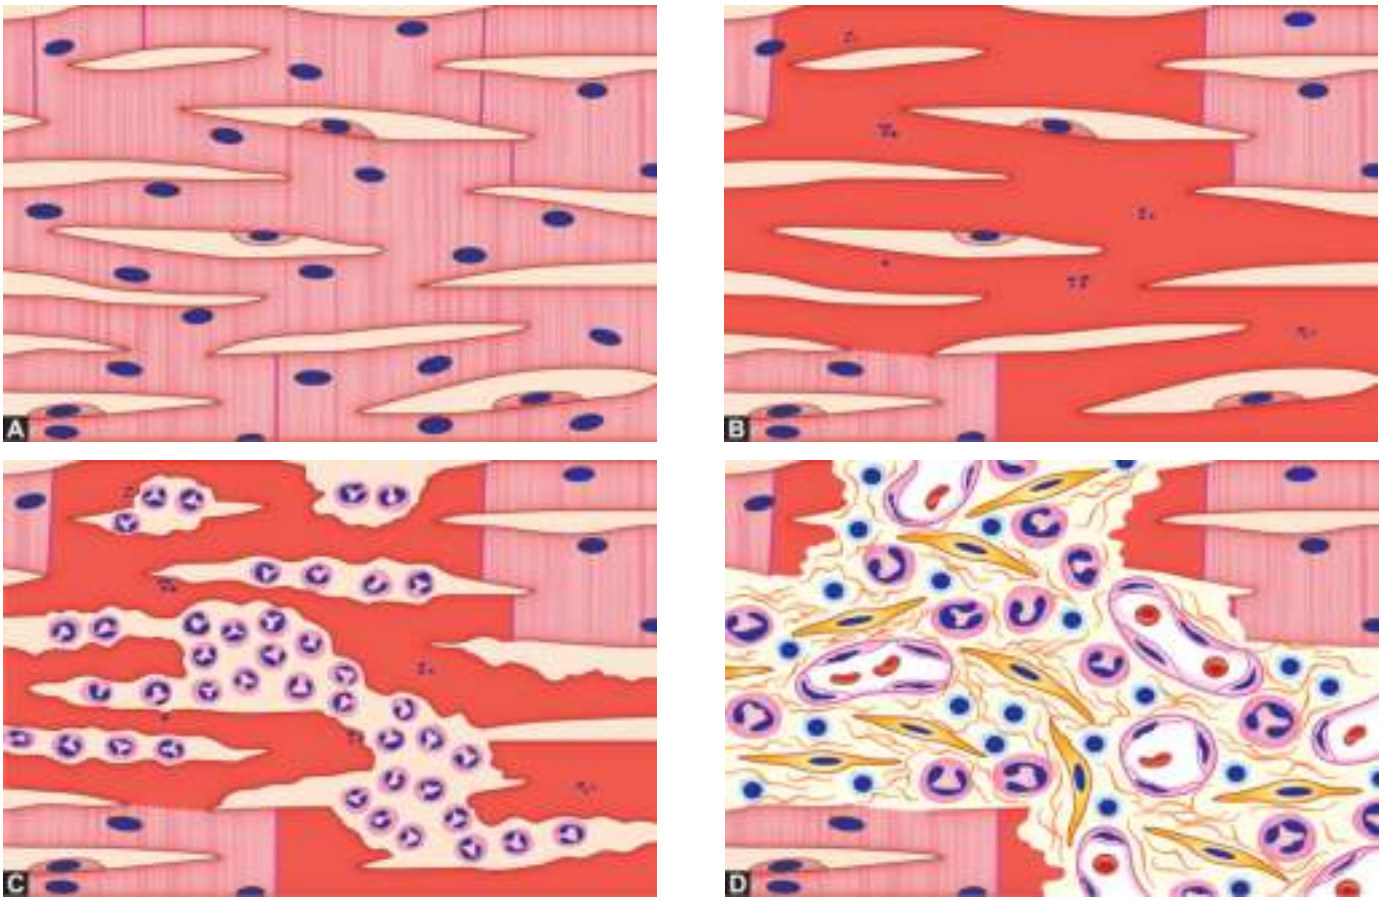

Fig. 16.7: Morphologic changes in acute myocardial infarction. (A) Normal heart muscles, (B) coagulative necrosis of acute myocardial infarction (AMI) after 12–18 hours, (C) PMN cells about 24 hours after acute myocardial infarction (AMI), (D) granulation tissue is formed after 3 weeks of acute myocardial infarction (AMI).

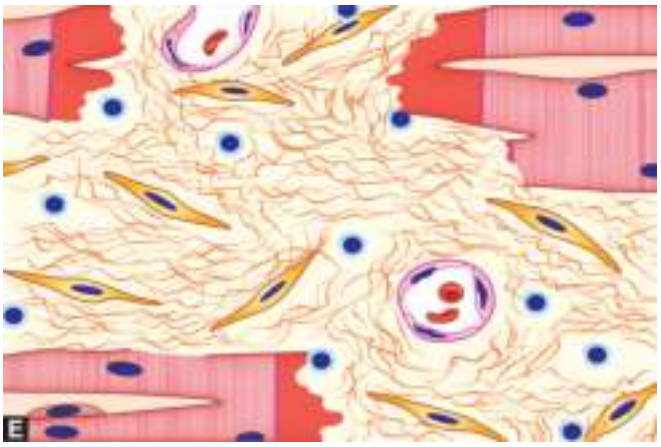

Fig. 16.7E: Morphologic changes in acute myocardial infarction—after 3 months or more, the infarct myocardium has been replaced by scar tissue.

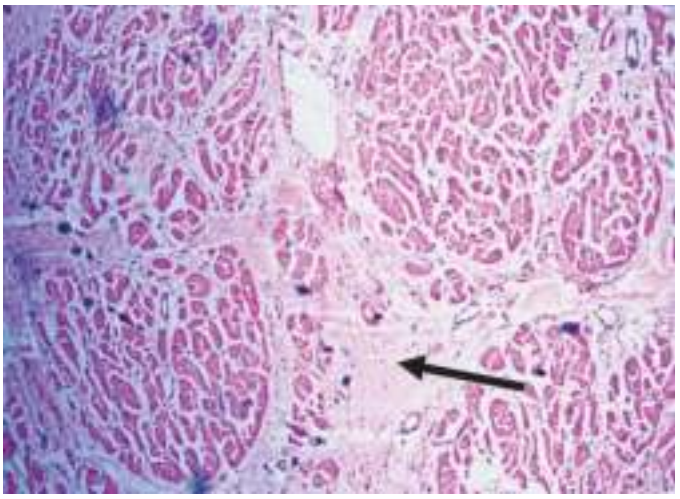

Fig. 16.8: Healed myocardium after myocardial infarction (arrow).

Table 16.9 Progressive morphologic changes in myocardial infarction

Time Post-AMI	Gross Morphology	Microscopic Examination	Laboratory Findings
0–4 hours	No change	▪ Wavy myocardial fibers ▪ Staining defect with triphenyl tetrazolium chloride in 2–3 hours	No change
4–12 hours	No change	Coagulative necrosis begins with loss of cross striations, contraction bands, edema, hemorrhage and early neutrophilic infiltrate	▪ CK-MB (4–8 hours) ▪ LDH (10 hours) ▪ Aspartate aminotransferase (AST) (6–12 hours)
12–24 hours	Early pallor of myocardium due to coagulative necrosis	▪ Continued coagulative necrosis with nuclear pyknosis, marginal contraction bands, loss of cardiac striations with eosinophilic cardiac fibers and neutrophilic infiltrate in interstitial tissue. ▪ Cytoplasm displays affinity for acidophilic dyes	▪ CK-MB (4–8 hours) and peaks in 24 hours ▪ LDH (10 hours) ▪ Aspartate aminotransferase (AST) (6–12 hours)
1–3 days (24–72 hours)	Definite pallor of the infarct area with zone of hyperemia	▪ On second day, total loss of striations and nuclei along with heavy neutrophilic infiltrate. ▪ Some macrophages start appearing in the infarct area	▪ CK-MB starts disappearing ▪ LDH flip peaks in 2–3 days ▪ Aspartate aminotransferase (AST) peaks 1–2 days
3–7 days	On 4th day, central yellow infarct area with well demarcated hyperemic border. There is maximum softness and danger of ventricular rupture	▪ On 4th day, there is influx of macrophages from hyperemic area, which slowly replace neutrophils and remove the dead myocardial cells ▪ At end of first week, it shows fibrovascular response with formation of granulation tissue surrounding area of infarct	LDH starts disappearing
7–10 days	Same findings as seen in 1–3 days. Central yellow area and well demarcated hyperemic border. There is maximum softness and danger of ventricular rupture	▪ By the end of first week, neovascularization marks the beginning of granulation tissue formation, i.e. repair with collagen synthesis. ▪ Macrophages infiltration is present	▪ CK-MB is absent, as it disappears in 3–4 days ▪ LDH disappears in 5–9 days ▪ Aspartate aminotransferase (AST) disappears
10–21 days	Maximum yellow and soft central area with vascular margins by third week (21 days)	▪ During second week, fibrovascular response begins to form granulation tissue to replace the yellow necrotic myocardium	No enzyme or cardiac troponins are detected in blood after 2 weeks

Contd...

Table 16.9 Progressive morphologic changes in myocardial infarction (*Contd...*)

Time Post-AMI	Gross Morphology	Microscopic Examination	Laboratory Findings
		▪ By third week, granulation tissue slowly transforms into a fibrous scar, i.e. repair. Phagocytosis of necrotic debris by macrophages is complete. Inflammatory infiltrate recedes	
7 weeks	White fibrosis	▪ Infarct tissue is replaced by white, patchy and non-contractile scar tissue by sixth week ▪ Ventricular aneurysm may occur in scarred area	No enzyme or cardiac troponins are detected in blood after 2 weeks

Sudden Cardiac Death

Most often, sudden cardiac death occurs due to ventricular arrhythmia and other electrical disturbances. It occurs within an hour of onset of symptoms in acute myocardial infarction. It occurs more frequently in the morning hours, when hypercoagulability is at its peak.

- **Pathogenesis:** Disrupted atheromatous plaque releases thromboplastin, which initiates thrombus formation in affected coronary artery. It results in complete occlusion of the coronary artery with superimposed thrombus (>80% lumen occlusion) resulting in myocardial ischemia. Ventricular arrhythmia is most common cause of death in these patients.
- **Autopsy findings:** Most patients have severe, fixed atherosclerotic coronary artery disease involving one or more coronary arteries. However, a grossly obvious coronary thrombosis or acute changes in the myocardium (coagulative necrosis) are not usually present on autopsy.

Congestive Heart Failure

Congestive heart failure usually occurs within the first 24 hours following acute myocardial infarction. Patient develops breathlessness due to pulmonary edema.

Fibrinous Pericarditis with or without Effusion

Acute fibrinous pericarditis occurs with transmural infarction usually within 2–10 days as a result of increased blood vessel permeability in the pericardium with pouring of fibrinous exudate in the pericardium (Fig. 16.9).

- Precordial friction rub is heard on auscultation.
- Fibrinous pericarditis may lead to obliteration of the pericardial cavity and formation of fibrous adhesions in the healing stage of the disease.
- Substernal chest pain is relieved by leaning forward and aggravated by leaning backward.

Myocardial Rupture

Rupture of the heart occurs within 3–7 days after myocardial infarction, when the necrotic area has the least tensile strength. It occurs in transmural infarction due to softening of the necrosed myocardium by increased neutrophil activity before organization is established (Figs 16.10 and 16.11).

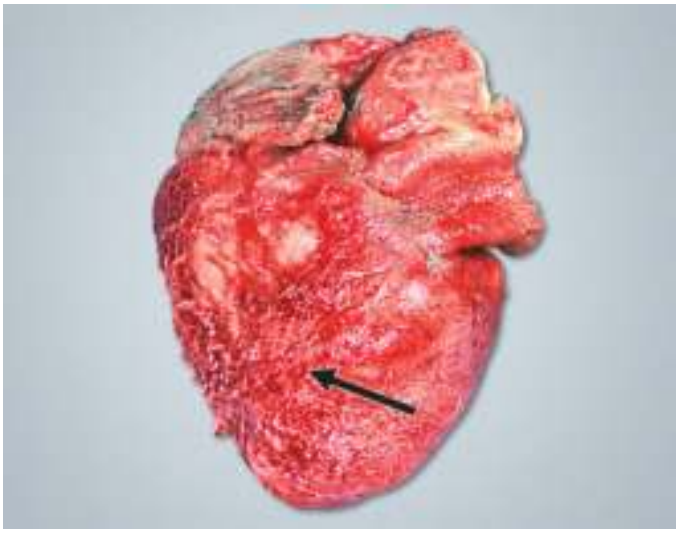

Fig. 16.9: Fibrinous pericarditis in rheumatic pancarditis (arrow).

- **Rupture of anterior wall of left ventricle:** The anterior wall of the heart is the most frequent site of rupture, usually resulting in fatal cardiac tamponade, which occurs in transmural infarct. High pressure in left ventricle blows out the necrotic myocardium resulting in rupture of anterior wall of heart and escape of massive blood into the pericardial cavity called hemopericardium. Patient dies of cardiac tamponade.
- **Posteromedial papillary muscle necrosis/dysfunction:** It is most often associated with right coronary artery thrombosis and inferior myocardial infarction. Since the damaged papillary muscle cannot contract, hence causes acute onset of mitral valve insufficiency/regurgitation resulting in left ventricular failure.
- **Interventricular septum rupture:** It is most often associated with thrombus formation in anterior descending branch of left coronary artery. Rupture of interventricular septum produces a left-to-right shunt resulting in right heart failure and pulmonary hypertension. Hence, there is increased O_2 saturation and pressure in right ventricle.

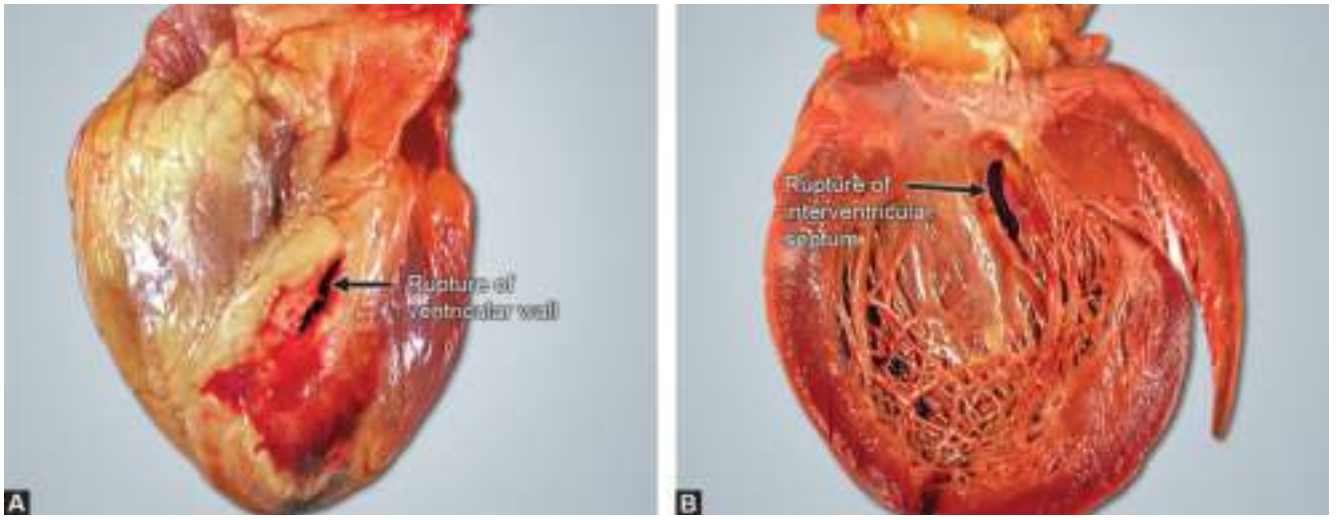

Fig. 16.10: Acute myocardial infarction. (A) Rupture of ventricular wall, (B) rupture of interventricular septum.

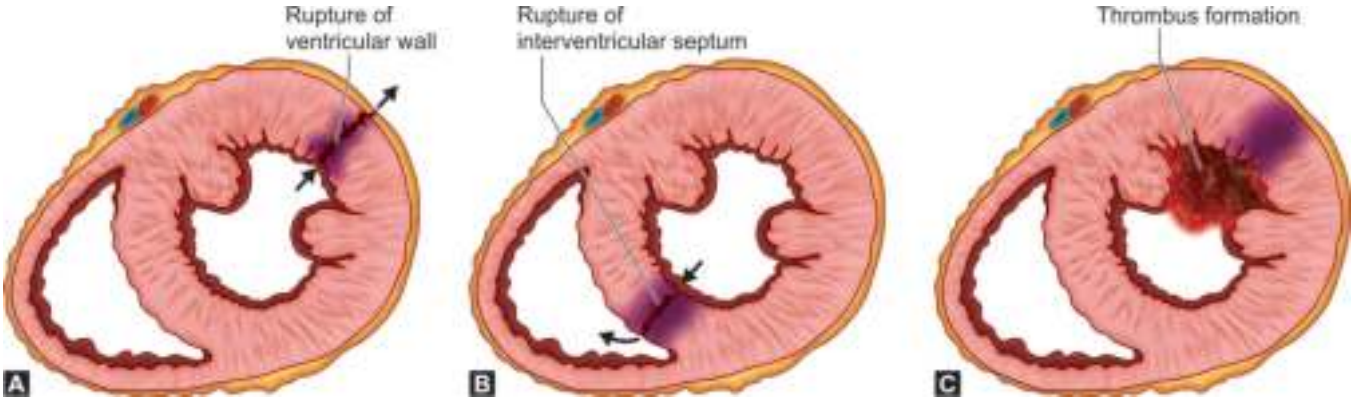

Fig. 16.11: Acute myocardial infarction. (A) Rupture of ventricular wall, (B) rupture of interventricular septum, (C) thrombus formation.

Mural Thrombi with Possible Embolization

Patient with acute myocardial infarction may develop thrombi in left ventricle, left atria and leg veins (Fig. 16.12).

- **Ventricular mural thrombi:** These are formed during first week of acute myocardial infarction as a result of left anterior descending (LAD) artery disease. Thrombi are attached to endocardium overlying myocardial infarct area of left ventricle. These thrombi have the potential for embolization to brain, intestine, kidney and lower limbs.
- **Atrial thrombi:** These develop in atrial appendages, especially if atrial rhythm is disturbed due to irregular blood flow inside the dilated and irregularly contracting left atrium, i.e. atrial fibrillation and atrial flutter.
- **Leg vein thrombosis:** It may develop due to prolonged bed rest and venous stasis. Patient presents with pain and swelling in the affected leg. Patient may have pulmonary embolism with fatal outcome.

Autoimmune Pericarditis

Dressler's syndrome is a complication of transmural myocardial infarct after 2–10 weeks, clinically presenting with pericardial pain associated with pleural effusion, joints and fever (i.e. symptoms suggestive of serum sickness).

- Autoantibodies are formed against pericardial proteins released from the necrotic cells resulting in pericarditis.
- Cortisone treatment is beneficial, also supporting an immunologic explanation.
- Other causes of immune-mediated pericarditis include systemic erythematosus, scleroderma and rheumatic heart disease.

Ventricular Aneurysm

- Ventricular aneurysm may develop in the large myocardial fibrotic scar within 3–6 months after myocardial infarction in 10–15% cases. During each systole, healed myocardial scar tissue does not

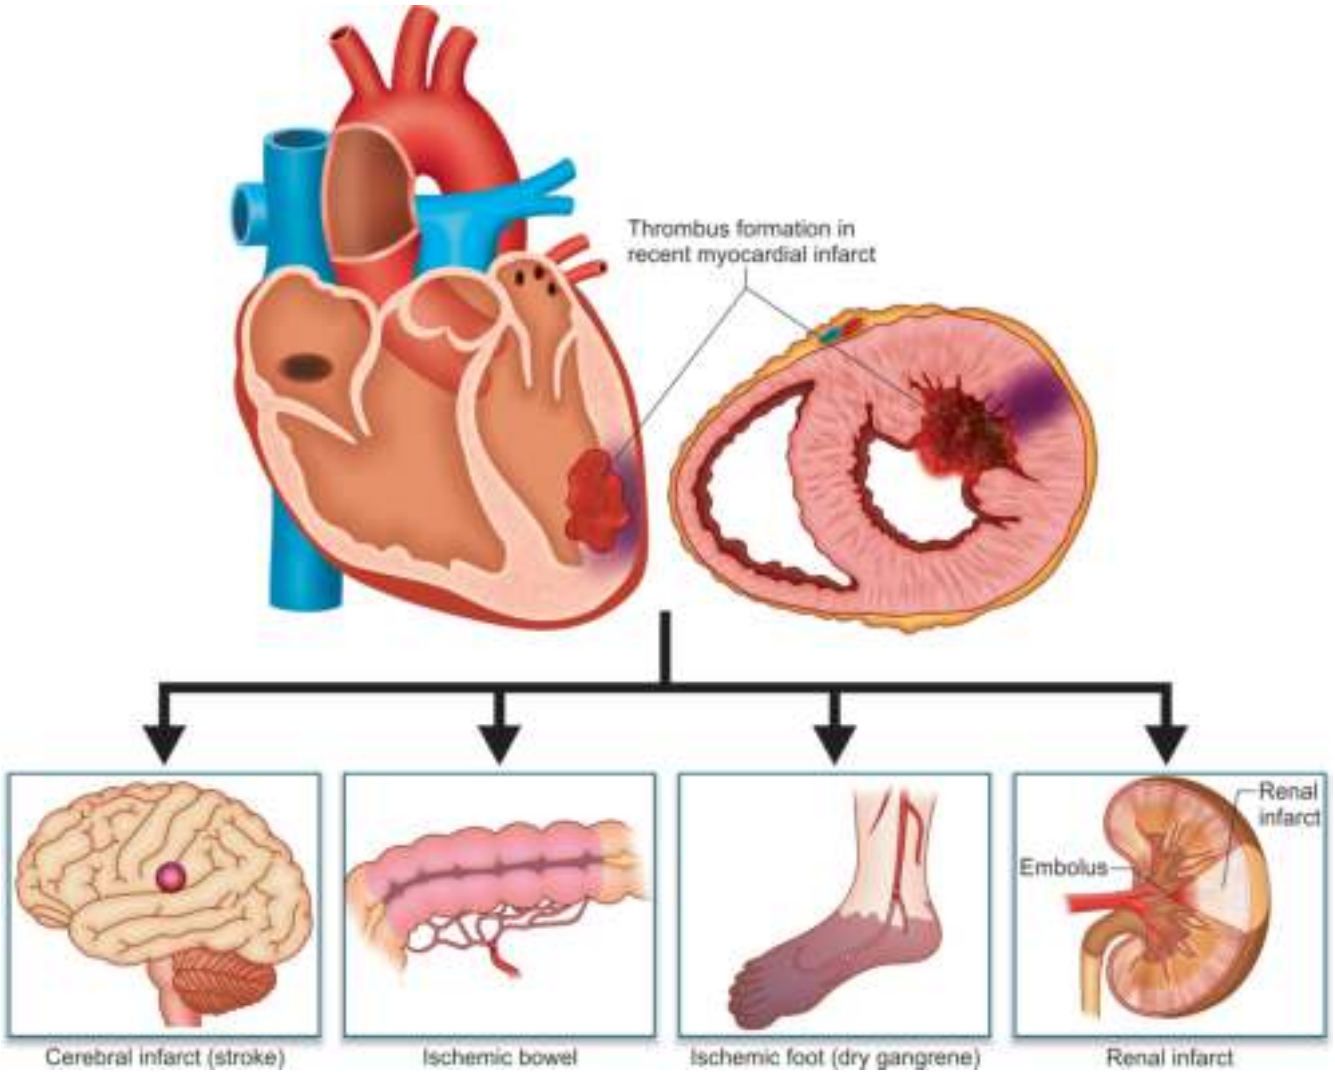

Fig. 16.12: Myocardial infarction. Thromboembolism phenomenon produces infarcts in vital organs.

contract, and actually bulges out resulting in ventricular aneurysm.

- Mural thrombi also form over ventricular aneurysms, which are found at the site of healed transmural myocardial infarct resulting in embolization. Aneurysm rupture is uncommon as scar tissue in healed myocardial infarct has good tensile strength.

Right Ventricular Infarct

Right ventricular infarct occurs in one-third of patients in the inferior region. It is associated with right coronary artery thrombosis. It is clinically significant in 30% of cases. Patient presents with hypotension, right heart failure and preserved left ventricular function.

Recurrent Myocardial Infarction

Recurrent myocardial infarction is characterized by the reappearance of CK-MB enzyme in blood after 3 days of acute myocardial infarction.

Expansion of Myocardial Infarct Area

Patient may develop expansion of myocardial infarct area with few hours of acute myocardial infarction.

Systemic Venous Thrombosis

Patient may develop systemic venous thrombus formation with fatal outcome.

Angina Pectoris (>12 Hours)

Patient may present with symptoms of angina pectoris after 12 hours of myocardial infarction.

CLINICAL FEATURES

Patient with acute myocardial infarction may be symptomatic (majority of cases) or asymptomatic (silent). Silent acute myocardial infarction occurs due to high pain threshold as a result of nervous system involvement in diabetes mellitus and elderly persons.

Table 16.10 Clinical complications of acute myocardial infarction

Complication	Interval	Diagnostic Tests	Treatment
Mechanical complication			
Cardiac failure due to ventricular dysfunction (cardiogenic shock)	Usually within hours	ECHO, Swan-Ganz catheter (right heart)	ACE inhibitors, urgent revascularization
Structural complications			
Mitral valve incompetence due to papillary muscle dysfunction, necrosis or rupture	First few days	ECHO	ACE inhibitors, intra-aortic balloon pump as a bridge that sits in aorta 2 cm away from the left subclavian
Myocardial wall rupture	3–5 days	ECHO	Pericardiocentesis, urgent cardiac repair
Interventricular septum and papillary muscles rupture	3–5 days	ECHO, Swan-Ganz catheter (right heart)	ACE inhibitors, nitroprusside, urgent surgery
Aneurysm at myocardial infarct	≥4 weeks	ECHO	Conservative treatment
Right ventricular infarction	Usually within hours	ECG	Fluid loading
Electrical complications			
Cardiac arrhythmias	First several hours	ECG (sinus bradycardia)	Atropine followed by pacemaker if symptoms persist
Conduction abnormalities (third degree block)	First several hours	ECG (cannon 'a' wave)	Atropine followed by pacemaker if symptoms resolve
Other complications			
Fibrinous pericarditis	2–4 days due to transmural infarct	ECHO	Conservative treatment
Dressler's syndrome (chest pain, pericardial effusion) due to autoimmune mechanism	Weeks to a few months	ECHO	Conservative treatment
Mural thrombi due to abnormal endocardial surface due to infarct	≥1 week	ECHO	Thrombolytic therapy
Progressive myocardial necrosis results in persistent pain	12 hours to a few days	ECHO	Conservative treatment
Myocardial infarct expansion	Usually within hours	ECHO	Conservative treatment

All the complications of myocardial infarction results in hypotension.
Septal rupture results in systolic murmur. Left ventricular pressure is greater than right ventricular pressure. This causes left-to-right shunt of oxygenated blood. Oxygen saturation in the right ventricle is markedly increased compared with right atrium.
Thrombolytic agents are only administered if there is ST-segment elevation or a new LBBB within 12 hours of the onset of chest pain.

Clinical complications of acute myocardial infarction are given in Table 16.10.

Chest Pain

Patient presents with sudden onset of severe crushing substernal chest pain for 30–45 minutes in central portion of chest, which is not relieved by nitroglycerin. Chest pain is often precipitated by exertion. It occurs most often in the morning hours due to catecholamine burst after awakening. Pain radiates down the left arm in 30% of cases to the shoulders or to the jaw or epigastrium or beneath xiphoid process or occipital region. Pain never radiates below umbilicus.

Constitutional Symptoms

Patient develops breathlessness, fever, discomfort, giddiness. Severe distress is marked by symptoms such as nausea, sweating and vomiting.

Clinical Examination

Clinical examination reveals pallor and cold extremities, tachycardia (sympathetic overactivity), bradycardia (parasympathetic overactivity), apical pulse difficult to palpate, apical systolic murmur due to mitral regurgitation as a result of papillary muscle necrosis pericardial friction rub—fibrinous pericarditis and raised jugular venous pressure due to right heart failure.

LABORATORY DIAGNOSIS

The prognosis of acute myocardial infarction (AMI) depends on the degree of left ventricular dysfunction. The electrocardiogram (ECG), cardiac enzyme (CK-MB), and cardiac-specific troponin I assays are the main diagnostic tools in confirming an AMI.

Electrocardiogram (12-Lead)

Electrocardiogram (ECG) (12-lead) gives a good guide as to which coronary artery is narrowed and the extent of myocardial damage. It is diagnostic of AMI in 75–80% of cases during the first 2 days of onset of myocardial infarction. Acute myocardial infarcts are now classified according to presence or absence of ST-segment elevation and appearance or absence of a new Q wave on ECG.

- **Transmural infarct:** ECG shows ST elevation (STEMI) along with appearance of new Q wave in 75–80% cases of AMI. It is more dependent on the volume of myocardial infarct area rather than transmural infarction (Fig. 16.13A and B).
- **Subendocardial infarct:** ECG shows absence of non-ST-segment elevation MI (NSTEMI), as well as appearance of a new Q wave. These patients require estimation of cardiac troponins for diagnosis.

Serum Cardiac Enzymes

Cardiac enzymes like creatine kinase-MB (CK-MB), lactate dehydrogenase (LDH) and aspartate aminotransferase (AST) are estimated to diagnose myocardial infarction (Table 16.11).

- **Creatine kinase-MB (CK-MB):** It exists in two isoforms, i.e. CK-MB1 and CK-MB2 with sensitivity in 95% of cases. If ratio of these two isoforms (CK-MB1 and CK-MB2) is 1.5 or more, it is an excellent indicator of early acute myocardial infarction. Its half-life is 16 hours. CK-MB enzyme appears within 4–8 hours, peaks at 24 hours and disappears within 1.5–4 days.

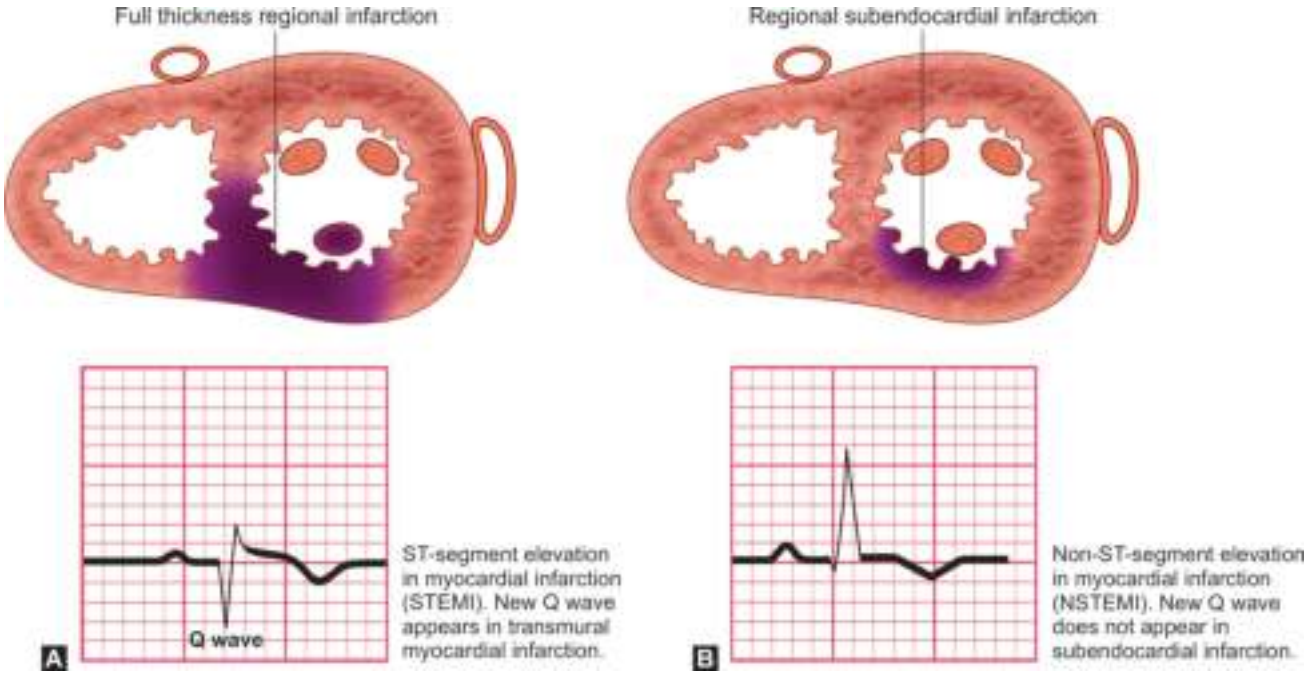

Fig. 16.13A and B: ECG changes in acute myocardial infarction.

Table 16.11 Serum estimation of cardiac enzymes in acute myocardial infarction

Cardiac Enzymes/Troponins	Half Life	Abnormal Activity Detectable	Peak Value Abnormality	Baseline
Troponin T or I	Not applicable	4–6 hours	12–24 hours	7–10 days
Creatine kinase-MB (CK-MB) isoenzyme	16 hours	3–10 hours	12–24 hours	Within 4 days
Cardiac-specific LDH	54 hors	8–16 hours	30–48 hours	7–10 days
SGOT (aspartate aminotransferase)	20 hours	12–24 hours	18–36 hours	3–4 days

Cardiac troponins and/or CK-MB are used to asses for myocardial infarction. Troponin C binds calcium. It is bound to both troponin T and troponin I. Troponin T is bound to tropomyosin. Troponin I is bound to actin. It holds the troponin–tropomyosin complex in one place.

Serial testing for a period of 9–12 hours after AMI will provide a pattern to determine whether CK-MB is rising, indicative of myocardial injury. Subsequent elevation of serum CK-MB after 4 days of acute myocardial infarction is indicative of recurrent myocardial infarction.

- **Lactate dehydrogenase (LDH):** It is an excellent indicator of acute myocardial infarction. Its half-life is 54 hours. It begins to rise within 12–24 hours, peaks at 2–3 days and disappears within 7–14 days due to its more half-life. It exists in two isoforms, i.e. LDH-1 and LDH-2. Ordinarily, ratio of LDH-1–LDH-2 is >1. But in AMI, this pattern is flipped and ratio of LDH-1–LDH-2 becomes higher.
- **Aspartate aminotransferase (AST):** Aspartate aminotransferase first appears in 6–12 hours, peaks in 1–2 days, and disappears within 3–4 days as half-life of AST is 20 hours. Remember AST analysis is not analyzed to diagnose acute myocardial infarction.

Cardiac Troponins (TnI and TnT)

Cardiac troponins (TnI and TnT) are structural components of cardiac muscle, which regulate calcium mediated contractions. Troponin T is bound to tropomyosin. Troponin I is bound to actin, that holds the troponin–tropomyosin complex in one place. Troponin C is bound to both troponin T and troponin I. Elevation of cardiac troponins level occurs due to myocardial infarction (Table 16.12).

- **Cardiac troponins analysis:** Following acute myocardial infarction, cardiac troponins are released into the bloodstream within 3–12 hours. Its level attains peak at 24 hours disappear within 7–10 days. Troponin I (TnI) is more specific indicator of myocardial injury. Troponin T lacks some specificity because its elevation can also appear in skeletal myopathies as well as in renal failure.

Table 16.12 Elevation of cardiac troponins due to myocardial injury but not due to myocardial infarction

Myocardial Injury not Related to Myocardial Ischemia
▪ Cardiac surgery, cardiac contusion, pacing, defibrillator shocks
▪ Rhabdomyolysis with cardiac involvement
▪ Myocarditis
▪ Cardiotoxic drugs
Multifactorial or Indeterminate Myocardial Injury
▪ Congestive heart failure
▪ Severe pulmonary embolism or pulmonary hypertension
▪ Renal failure
▪ Sepsis
▪ Subarachnoid hemorrhage
▪ Strenuous exercise

- **Serial cardiac troponins testing:** Serial testing of troponin I (TnI) in blood is a diagnostic tool in AMI patients. Its sensitivity is 84–96% and specificity is 80–95%. False positive results are usually related to myocardial ischemia in patients with unstable angina. CK-MB is used in conjunction in cardiac troponin I (TnI) to diagnose AMI. CK-MB detects re-infarction of myocardium, while troponins do not (Fig. 16.14).

Cardiac Imaging Techniques

- **Two-dimensional echocardiography:** This technique is useful for demonstration of abnormally contracting ventricular myocardium and visualizing thrombi or rupture in the wall of the myocardium. It is difficult to differentiate between acute myocardial infarct and old myocardial infarct. Doppler echocardiography is done to detect ventricular septal defect (VSD) and mitral valve regurgitation due to AMI.
- **High resolution MRI:** A standard imaging agent gadolinium is administered and analyzed on high resolution MRI. As normal cardiac myocytes are tightly packed, hence imaging agent does not penetrate. But the agent penetrates into the expanded intercellular junction of acute myocardial infarct zone.
- **Radionuclide scanning (99mTc) stannous pyrophosphate:** It is performed 2–5 days after AMI. It is a chemical agent which emits radioactive γ-rays after intravenous dose or oral dose. More active cells of myocardium take up more of the radionuclide hence, emit radioactive γ-rays as (hot spots) on the picture of the computer monitor. Poor blood flow to organs, emit low levels of γ-rays that may be shown as blue cold spots.
- **Perfusion scintigraphy:** Thallium 201 or Tc 99m sestamibi is administered. It is concentrated in viable myocardium. It is difficult to differentiate acute myocardial infarct from old myocardial infarct.

Other Important Parameters

- **Hyperhomocysteinemia:** Serum homocysteine level >100 μm/L is associated with increased risk of coronary arterial disease and peripheral vascular disease.
- **C-reactive protein:** C-reactive protein (CRP) synthesized by liver causes opsonization of bacteria and activation of complement. Its level is increased in patients with disrupted coronary atheromatous plaques resulting in acute myocardial infarction. It may be a strong predictor of cardiovascular events, e.g. acute myocardial infarction, cerebral stroke and peripheral vascular disease than serum LDL level.

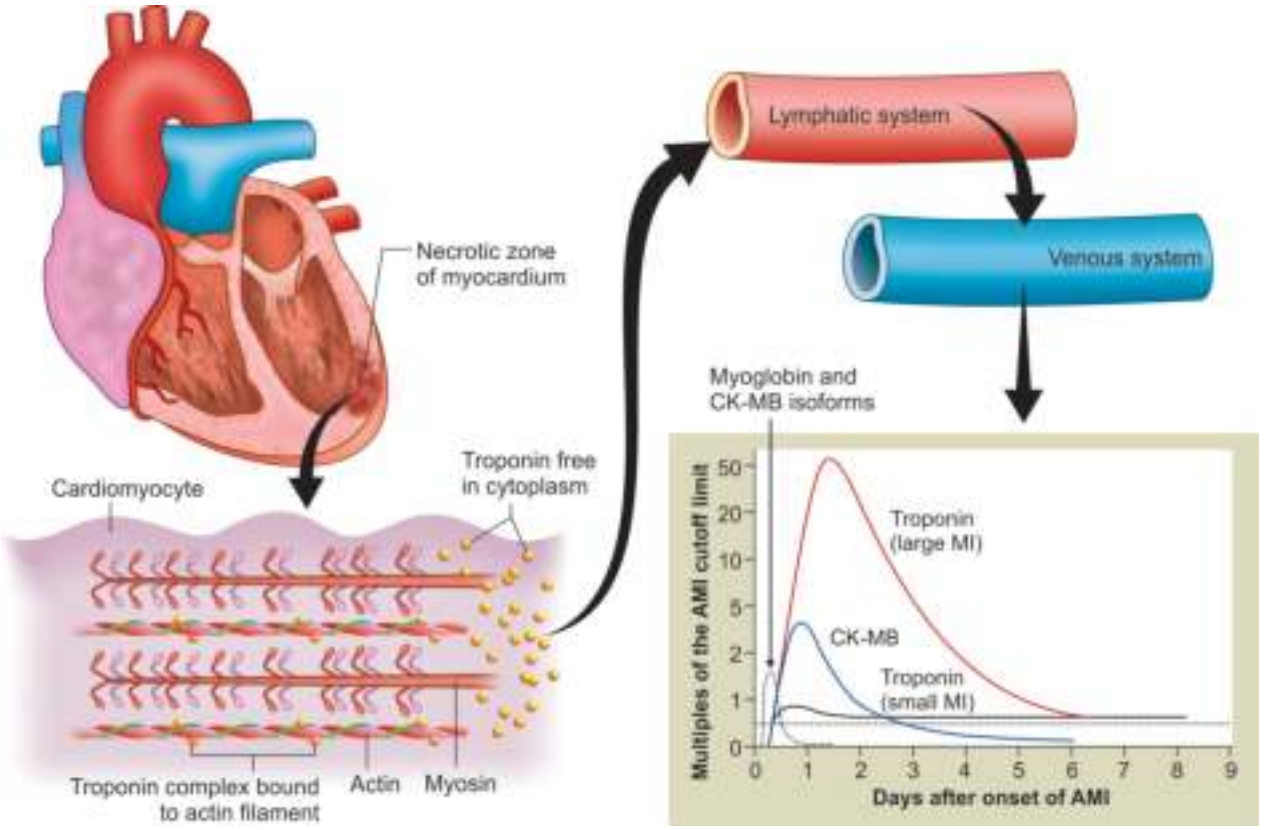

Fig. 16.14: Acute myocardial infarction (AMI)—CK-MB and cardiac troponins.

- **Nonspecific indexes of tissue necrosis:** Leukocytosis (neutrophilia) occurs within 6 hours of AMI and persists for 3–7 days. Patient has fever 39°C before a new Q wave appears and persists for a week. ESR rises more slowly and persists for 1–2 weeks in these patients.

Clinical Pearls: Management of ST-segment Elevation Myocardial Infarction (STEMI)

- A 50-year-old man with history of diabetes mellitus and hypertension comes to the emergency with crushing, substernal chest pain that radiates to his left arm for 30 minutes to several hours in duration. Past history revealed that he had chest pain on exertion before cardiac CK-MB and troponin levels are increased. 12-lead electrocardiogram shows STEMI. C-reactive proteins are raised.
- After diagnosing STEMI, oxygen, morphine and heparin should be administered. Heparin administration reduces mortality. It potentiates the effect of antithrombin. Antithrombin inhibits every step of coagulation system cascade. Therefore, heparin does not work with antithrombin deficiency. Heparin only prevents formation of new blood clots.
- Thrombolytic agent (e.g. streptokinase) is only administered if there is ST-segment elevation or new LBBB develops within 12 hours of the onset of chest pain. Failure to streptokinase therapy, patient should be immediately transferred for rescue percutaneous coronary intervention (PCI).
- Percutaneous coronary intervention is most effective, if performed within 12 hours of onset of chest pain following myocardial infarction. Earlier is the percutaneous coronary intervention, better the prognosis.
- Heparin anticoagulant should be started to prevent myocardial reinfarction and reduce thromboembolic phenomenon.
- Complete bed rest is advised for first 24–48 hours in the coronary care unit.
- Later, patient should be put on aspirin, β-blockers, angiotensin converting enzyme (ACE) inhibitors and statins (lipid lowering drugs).

Troponin C binds to calcium to activate actin–myosin interaction. Troponin T binds to tropomyosin. Troponin I blocks or inhibits actin–myosin interaction.

Clinical Pearls: Recombinant Tissue Plasminogen Activator use in Clinical Practice

- Tissue plasminogen activator (tPA) functions by catalyzing the conversion of plasminogen to plasmin, the primary enzyme involved in dissolving blood clots.
- Recombinant biotechnology has allowed to manufacture tissue plasminogen activator (tPA) such as alteplase, reteplase and teneplase in the laboratories.
- Recombinant tissue plasminogen activators are administered in AMI within 3 hours before percutaneous transluminal coronary angioplasty, severe pulmonary thromboembolism causing severe instability due to pressure in heart and deep vein thrombosis.

CHRONIC ISCHEMIC HEART DISEASE

Chronic ischemic damage to myocardial tissue results in progressive congestive heart failure.

- Focal replacement of injured myocardium results in non-contractile scar tissue.
- Myocardial fibrosis tends to be progressive, reflecting the progression of atheromatous plaque in coronary arteries.
- Loss of myocardium in scar tissue is accompanied by increased oxygen demand.

Clinical Features

Patient presents with symptoms related to congestive cardiomyopathy, congestive heart failure (CHF) and coronary artery insufficiency such as chest pain, after physical exertion, dyspnea, swelling over feet or ankles.

RHEUMATIC FEVER AND RHEUMATIC HEART DISEASE

RHEUMATIC FEVER AND RHEUMATIC HEART DISEASE: OVERVIEW

- **Rheumatic fever:** Rheumatic fever is a multisystem autoimmune disorder which affects periarteriolar connective tissue. It usually occurs 1–4 weeks after an episode of exudative pharyngitis caused by group A Streptococcus β-haemolyticus. Patient develops pancarditis, transient mild migratory polyarthritis, Sydenham chorea, erythema marginatum and subcutaneous nodules.
- **Rheumatic heart disease:** Rheumatic heart disease (RHD) comprises spectrum of cardiac lesions from pericarditis, myocarditis, and valvulitis during rheumatic fever to chronic valvular lesions that evolve over years following one or more episodes of acute rheumatic fever. Damage to cardiac valves may be chronic and progressive, resulting in cardiac decompensation.

AGE GROUP

Rheumatic fever most often affects children between 5 and 15 years of age (80%). It may affect 20% of adults. It rarely affects children <4 years and adults >40 years. Poverty and overcrowding contribute to increased incidence of under developed countries.

ETIOLOGY

- Rheumatic fever usually occurs 1–4 weeks after an episode of exudative pharyngitis caused by group A Streptococcus β-haemolyticus. An elevated titer of antistreptolysin *O* (ASO) is evidence of a recent streptococcal infection.
- Rheumatic fever is believed to be caused by antibody cross-reactivity, with antigens in multiple systems, which mimic streptococcal antigen that can affect heart, big joints, skin and brain.

MULTIPLE SYSTEMS INVOLVEMENT

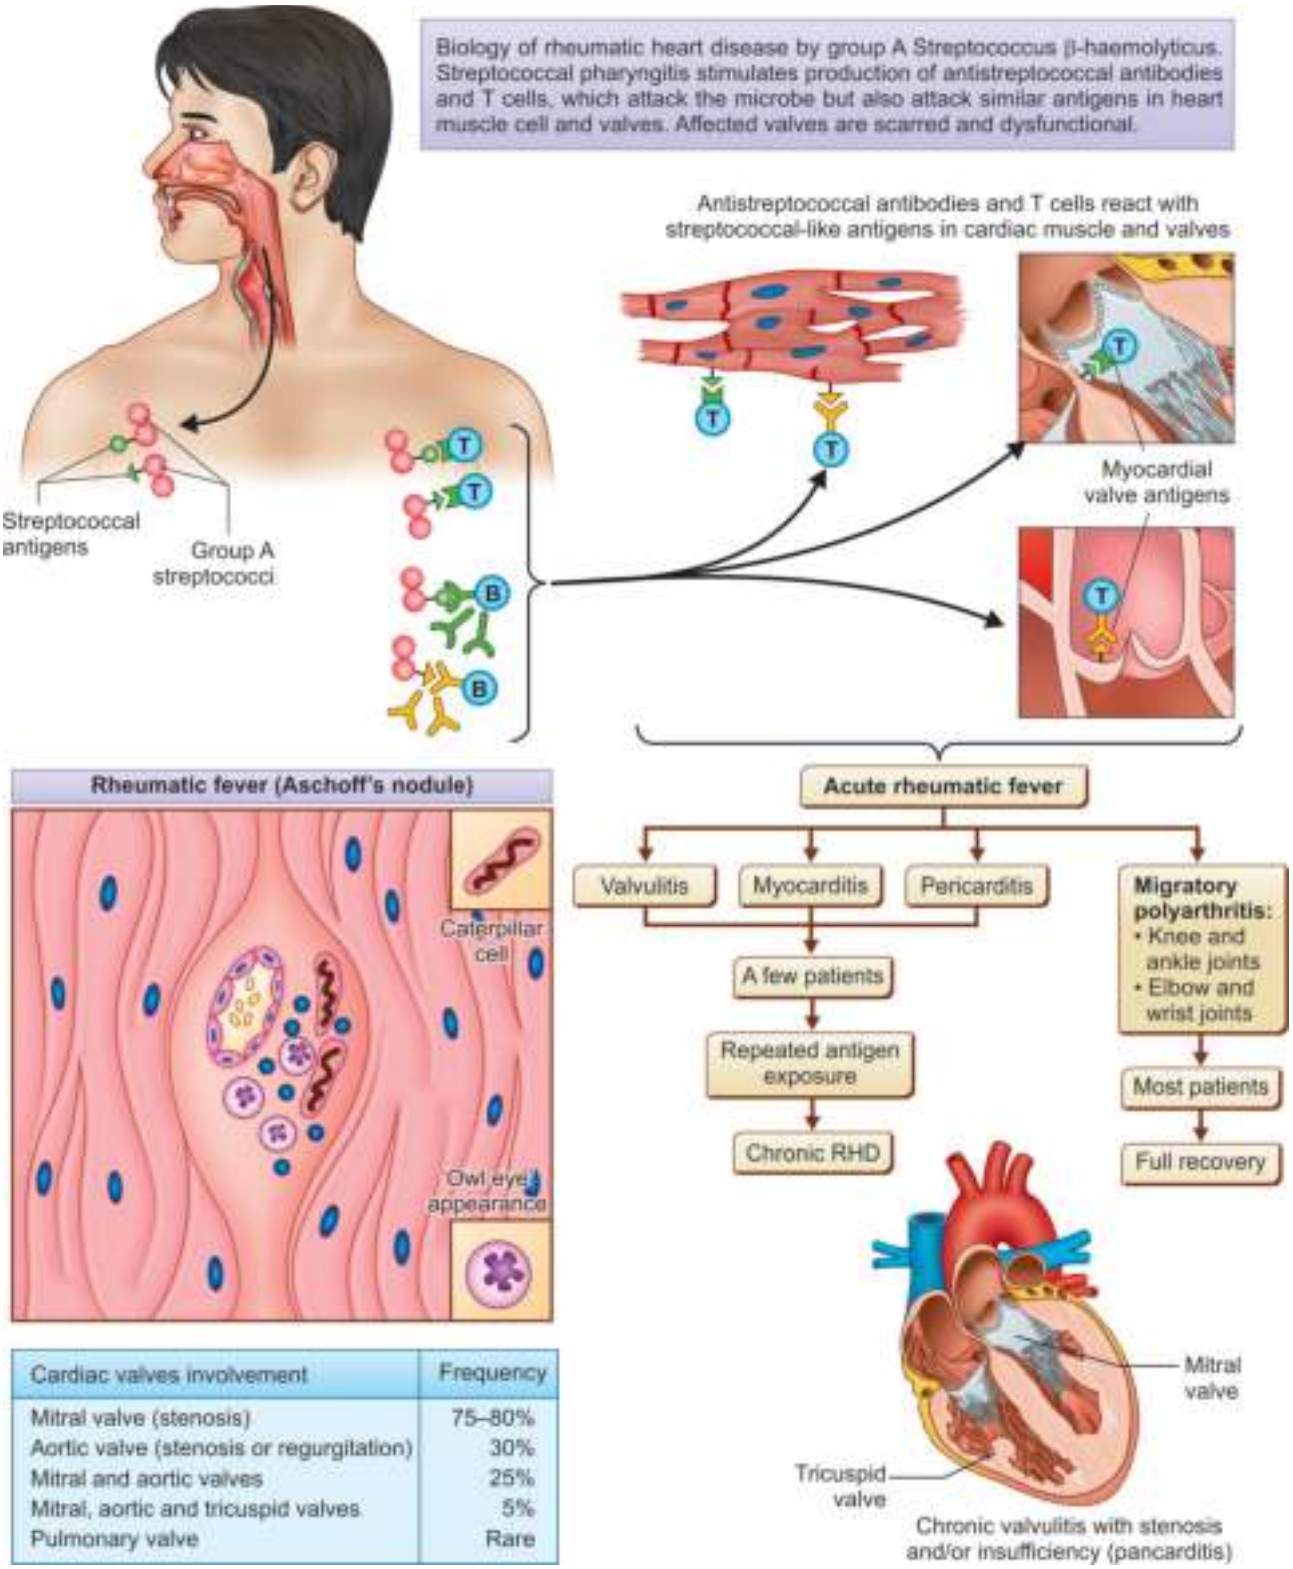
Shortly after group A Streptococcus β-haemolyticus infection, signs appear within 2–3 weeks (1–5 weeks) in the heart (pancarditis), joints (migratory polyarthritis), skin (erythema marginatum), basal ganglia (Sydenham's chorea) and subcutaneous nodules in soft tissues.

PATHOGENESIS

The pathogenesis of rheumatic fever, RHD and complications is known to involve molecular mimicry and genetic predisposition (Fig. 16.15).

Genetic Predisposition

HLA-DR7 located on chromosome 6 is most often associated with development of cardiac valvular lesions in rheumatic heart disease. Exact mechanism is unknown. It is suggested that HLA molecules may play role in presenting antigens to CD4+ helper T cells, thus triggering an immune response. There is increased expression of TNF-α cytokine in HLA-DR7 patients, which may exacerbate cardiac valvular tissue inflammation, contributing to pathogenesis of RHD.



Mannose-binding Lectin 2 (MBL-2)

Mannose-binding lectin is an inflammatory protein involved in pathogen recognition. Increased synthesis of mannose-binding lectin protein is associated with mitral stenosis in rheumatic heart disease.

Type 2 Hypersensitivity Reaction

Molecular mimicry involves epitope sharing between host antigens and highly antigenic streptococcal M proteins.

- Development of antibodies against streptococcal capsular M protein antigens (virulence factor), cross react with some proteins in human connective tissue (e.g. heart–myosin, joints, skin, brain, arteries), and induce cytokine release resulting in tissue destruction in rheumatic fever.
- Antistreptolysin *O* (ASO), anti-DNase and hyaluronidase are estimated to establish streptococcal etiology of rheumatic fever.
- An elevated antistreptolysin *O* (ASO) titer is a proof of previous streptococcal infection.

Cardiac valves involvement	Frequency
Mitral valve (stenosis)	75–80%
Aortic valve (stenosis or regurgitation)	30%
Mitral and aortic valves	25%
Mitral, aortic and tricuspid valves	5%
Pulmonary valve	Rare

Fig. 16.15: Pathogenesis of rheumatic fever and heart disease and clinical manifestations.

Type 4 Hypersensitivity Reaction

Type 4 hypersensitivity reaction has been implicated in pathogenesis of rheumatic fever, as cardiac valvular lesions predominantly contain CD4+ helper T cells and macrophages. Cardiac valves display increased expression of VCAM-1, a protein that mediates the adhesion of CD4+ helper T cells.

ASCHOFF'S NODULE

Aschoff's nodule is the classic lesion of rheumatic fever. It develops after several weeks after the onset of symptoms.

Composition

Aschoff's nodule is composed of swollen eosinophilic collagen fibers, central fibrinoid necrosis surrounded by macrophages (Anitschkow myocytes), lymphocytes, plasma cells and occasional multinucleated giant cells demonstrated on light microscopy. It is globular, elliptic, or fusiform microscopic structure (Figs 16.16 and 16.17).

Phases of Aschoff's Nodule

- **Early phase of Aschoff's nodule:** Early phase of Aschoff's nodule is also known as **exudative phase**, which persists up to the 4th week of rheumatic fever. It is characterized by swelling of collagen fibers around blood vessels.
- **Granulomatous phase of Aschoff's nodule:** Granulomatous phase of Aschoff's nodule is also known as **proliferative phase**, which is evident during the 4th–13th weeks of the disease. It assumes granulomatous appearance.
- **Late phase of Aschoff's nodule:** Late phase of Aschoff's nodule is also known as **fibrous or healing phase**. Eventually Aschoff's nodule is replaced by formation of scar tissue.

Anitschkow Cells

Normally, cardiac macrophages are small in number. But in rheumatic fever, macrophage number as well as size is increased. Macrophages participating in formation of Aschoff's nodule are known as Anitschkow cells. Nuclei of these **Anitschkow cells** contain a central band of clumped chromatin, that gives **caterpillar-like appearance** in longitudinal sections (also called caterpillar cells); and owl-eyed appearance in cross sections (Fig. 16.18).

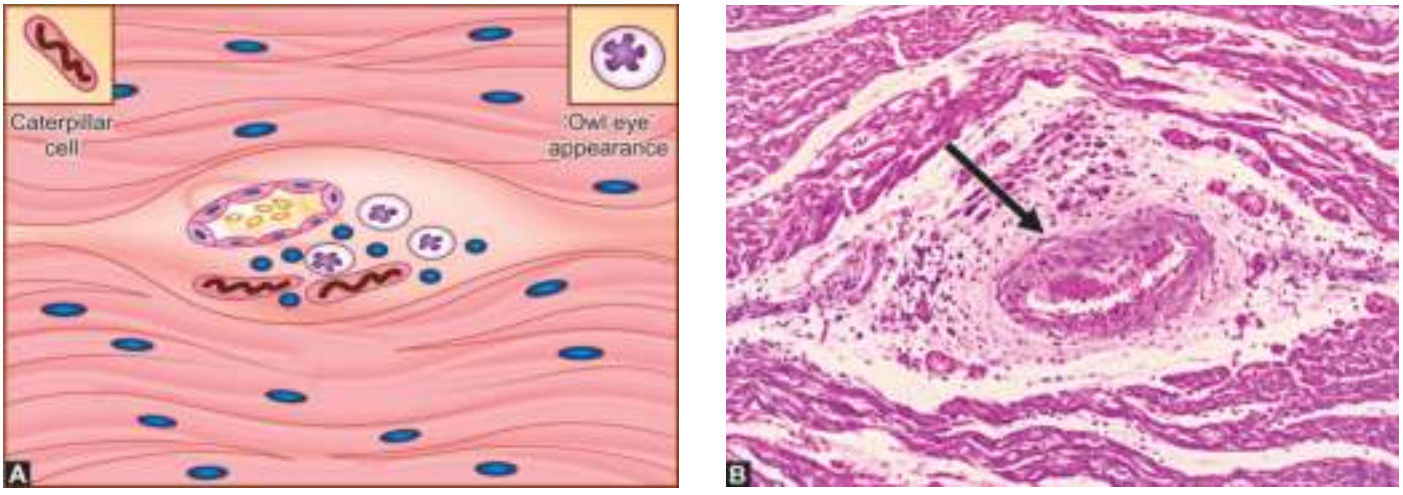


Fig. 16.16: (A) Aschoff's nodules schematic, (B) Aschoff's nodules in myocardium—these are centered in interstitium around vessels as shown here. The myocarditis may be severe enough to cause congestive heart failure (arrow) (100X).

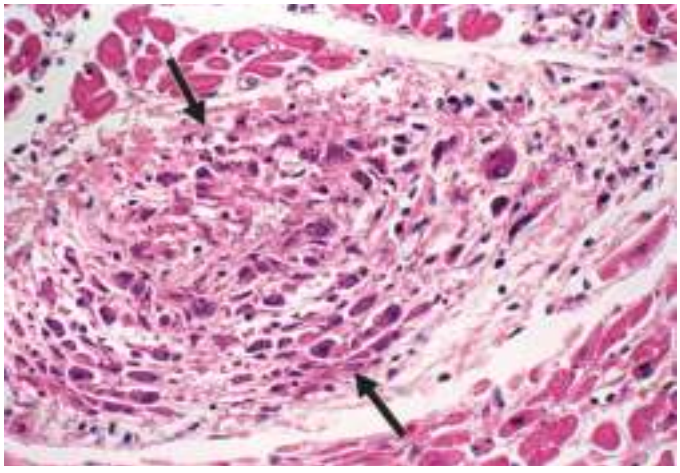

Fig. 16.17: Aschoff's nodules in myocardium (arrows) (400X).

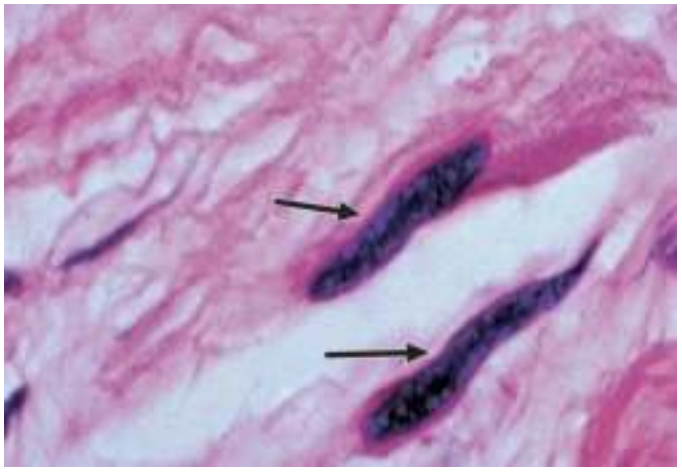

Fig. 16.18: Anitschkow/caterpillar cell in myocardium (arrows) (400X).

Giant Aschoff's Bodies

Fusion of multiple Aschoff's nodules produces giant Aschoff's bodies, located over bony prominences and tendons in subcutaneous regions.

Locations

In rheumatic fever, Aschoff's nodules can be seen in periarteriolar tissue of any layer of the heart (most common in myocardium) and hence called pancarditis. Occasionally, these are present in the pericardium. Aschoff's nodules have also been described in the adventitia of the aorta.

Nature and Lesions

As Aschoff's nodules in big joints are more exudative and less proliferative in nature, thus inflammatory changes in the joints completely resolve and hence no residual effect like joint deformity. On the other hand, Aschoff's nodules in heart are more proliferative and less exudative type, resulting into fibrosis of cardiac valves (stenosis/incompetence of cardiac valves).

JONES DIAGNOSTIC CRITERIA

Diagnostic criteria for rheumatic fever were first published in 1944 by T Duckett Jones. According to revised Jones criteria by American Heart Association, the diagnosis of rheumatic fever can be made when two of the major criteria, or one major criterion plus two minor criteria, are present along with evidence of streptococcal infection: elevated or rising antistreptolysin *O* titer or DNase. Exceptions are Sydenham chorea and indolent carditis, each of which by itself can indicate rheumatic fever. Jones criteria for diagnosis of rheumatic fever are given in Table 16.13.

Major Jones Diagnostic Criteria

- **Migratory polyarthritis (≤75%):** It is a temporary migrating inflammation of the large joints, usually starting in the legs and migrating upwards in the upper extremities.
- **Pancarditis (<35%):** Inflammation of the cardiac muscle (myocarditis) can manifest as congestive heart failure with shortness of breath, pericarditis with a friction rub, or a new cardiac murmur.
- **Subcutaneous nodules (<10%):** Patient develops painless, firm collections of collagen fibers over bony prominences or tendons in adults, i.e. wrists, elbows, scapula, ankles, knees, patella margins and spinous processes of vertebrae.
- **Skin rashes (erythema marginatum):** Skin rashes have bathing suit distribution in <10% of cases. A long-lasting reddish skin rash that begins on the trunk or arms as macules, which spread outward and clear in the middle to form rings, which continue to spread and coalesce with other rings, ultimately taking on a snake-like appearance. Skin rashes typically spare the face and become worse with heat.
- **Sydenham's chorea:** It is known as **St. Vitus dance** in <10% of cases. A characteristic series of random rapid involuntary and purposeless movements of face and arms. This can occur very late in the disease for at least three months from onset of infection.

Minor Jones Diagnostic Criteria

- **Fever:** Patient has 38.2–38.9°C (101–102°F)
- **Arthralgia:** Patient presents with joint pain without swelling. It cannot be included if polyarthritis is present as a major symptom.
- **Increased acute phase reactants:** ESR and C-reactive protein are raised.

Table 16.13 Jones criteria for diagnosis of rheumatic fever

Category of Jones Criteria	Diagnostic Criteria
Major diagnostic criteria	▪ Pancarditis (pericarditis, myocarditis, endocarditis) ▪ Migratory polyarthritis ▪ Subcutaneous nodules over bony prominences ▪ Sydenham chorea ▪ Erythema chronicum migrans
Minor diagnostic criteria	▪ Fever ▪ Arthralgia ▪ Previous history of rheumatic fever ▪ Chronic rheumatic heart disease ▪ Raised erythrocyte sedimentation rate ▪ C-reactive proteins (CRP) elevated ▪ Prolonged PR interval on ECG (first degree AV block)

Patients have two major criteria, or one major criterion and two minor criteria.

- **Total leukocyte count:** Peripheral smear examination shows leukocytosis (neutrophilia).
- **ECG study:** It shows features of first degree heart block such as a prolonged PR interval. The minor diagnostic criteria cannot be included if pancarditis is present as a major symptom.
- **Past history:** Previous episode of rheumatic fever or inactive RHD is minor diagnostic criteria.

Other Signs and Symptoms

There is preceding streptococcal infection of rheumatic fever: recent scarlet fever raised antistreptolysin *O* or other streptococcal antibody titer, or positive throat culture. Supportive evidence of streptococcal infection is absent in ≤10% of cases.

SYSTEMIC MANIFESTATIONS

Migratory Polyarthritis

Migratory polyarthritis is most common initial presentation of acute rheumatic fever up to 75% of cases.

- Patient develops temporary migrating inflammation of the large joints, usually starting in the lower extremities (knees and ankles) and migrating upwards in the upper extremities, i.e. elbows and wrists. It reaches maximum severity in 12–24 hours.
- Affected joints are painful, swollen, warm, erythematous, and limited in their range of motion.
- Articular cartilage and synovial membrane are never involved; hence there is no permanent joint deformity. As the Aschoff's nodules in big joints are more exudative and less productive in nature, thus inflammatory changes in the joints completely resolve and hence there is no residual effect such as joint deformity.
- Aspirin improves symptoms in affected joints and prevents further migration of the arthritis. Complete resolution of the symptoms typically occurs with improvement in 1–2 weeks and full recovery of joints in 2–3 months.

Pancarditis

Pancarditis is the most common and serious complication of rheumatic fever (50% of cases). It involves all three layers of heart.

- Degree of involvement of cardiac valves depends on severity of the initial attack and number of recurrent episodes by group A Streptococcus β-haemolyticus.
- If cardiac murmur is not cleared within three weeks time after an episode of rheumatic fever; prognosis is poor due to cardiac valve deformity. New or changing cardiac murmurs are considered necessary for diagnosis of rheumatic valvulitis.
- Doppler echocardiography evidence of mitral valve insufficiency in association with aortic valve involvement may be sufficient for diagnosis of pancarditis.

Myocarditis

- Myocardium is first to be involved in acute rheumatic fever. During early stage of rheumatic fever, myocarditis may lead to congestive heart failure associated with fatal outcome.
- Aschoff's nodules are present in periarteriolar interstitial tissue of myocardium, which usually heal and transform into fibrous scar. Spread of inflammation results into serofibrinous pericarditis and endocarditis.

Serofibrinous Pericarditis

- Inflammation may cause a serofibrinous pericardial exudate described as 'bread and butter pericarditis' due to deposition of fibrin giving shaggy appearance (Fig. 16.19).
- Patient presents with precordial pain. On auscultation, friction rub can be heard.
- Other causes of serofibrinous pericarditis must be excluded which include uremic pericarditis, systemic lupus erythematosus, acute myocardial infarction, uremia and chest radiation.
- Resolution of serofibrinous pericarditis is uncommon, which most often gets organized and resulting in constrictive pericarditis.

Endocarditis

- Endocarditis leads to cardiac valvular damage. Usually left-sided cardiac valves are inflamed, i.e.

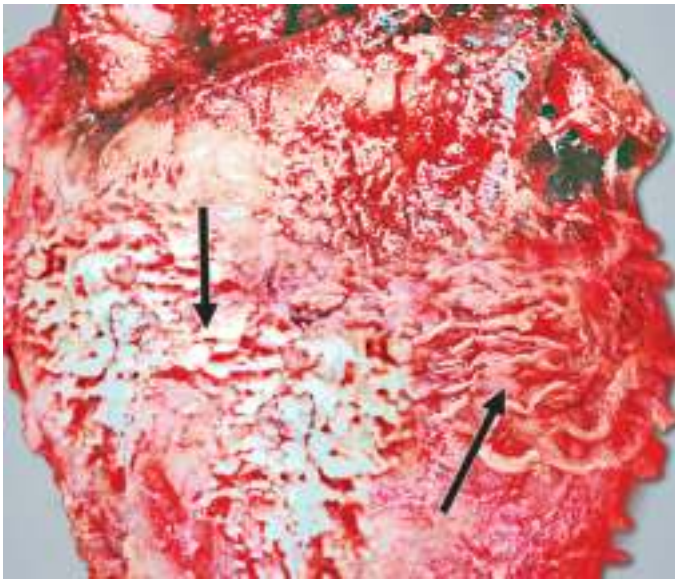

Fig. 16.19: Serofibrinous pericarditis (arrows).

mitral valve (75–80%), aortic valve (30%), mitral and aortic valve (25%), and tricuspid valve (<5%).

- Residual fibrosis effects occur in mitral and aortic valves. Mitral stenosis is marked by high diastolic pressure in the left atrium than in the left ventricle.
- The aortic valve is affected most often along with the mitral valve. Aortic valve may undergo stenosis or insufficiency.
- The tricuspid valve is affected along with the mitral valve and aortic valves (trivalvular involvement) in approximately 5% of cases of rheumatic heart disease. The pulmonary valve is rarely involved (Table 16.14).
- In acute phase of the disease, all the cardiac valves and chordae tendineae are swollen due to inflammation. Mitral valve regurgitation occurs in acute phase, while mitral valve stenosis in chronic phase of disease.

Table 16.14 Cardiac valves involvement in rheumatic fever and RHD

Cardiac Valves Involvement	Frequency
Mitral valve (stenosis)	75–80%
Aortic valve (stenosis or regurgitation)	30%
Mitral and aortic valves	25%
Mitral, aortic and tricuspid valves	5%
Tricuspid	<5%
Pulmonary valve	Rare

- Fibrin-rich exudate forming tiny, warty, bead-like, rubbery sterile cardiac vegetations measuring 1–2 mm in size are present along the line of opposition of cardiac valvular cusps and chordae tendineae; but never present behind cusps.
- Cardiac vegetations are nonfriable and hence not source of peripheral emboli. These cardiac valvular changes resolve with minimal fibrosis (Figs 16.20 to 16.22).

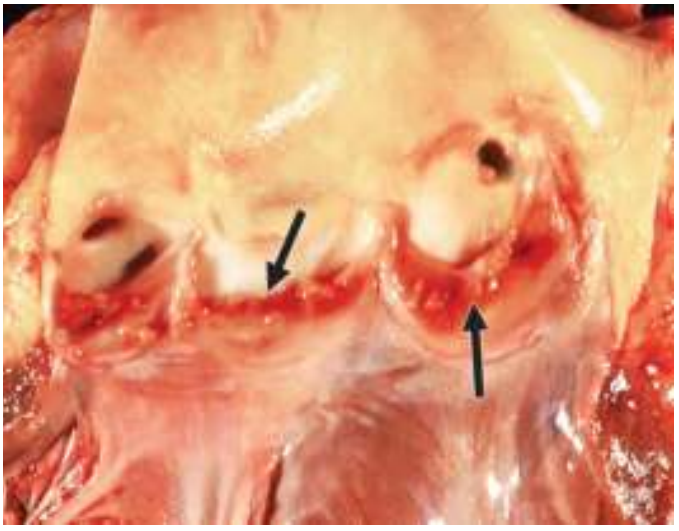

Fig. 16.20: Acute rheumatic endocarditis. Small verrucous vegetations measuring a few mm are seen along the closure line of this mitral valve (arrows).

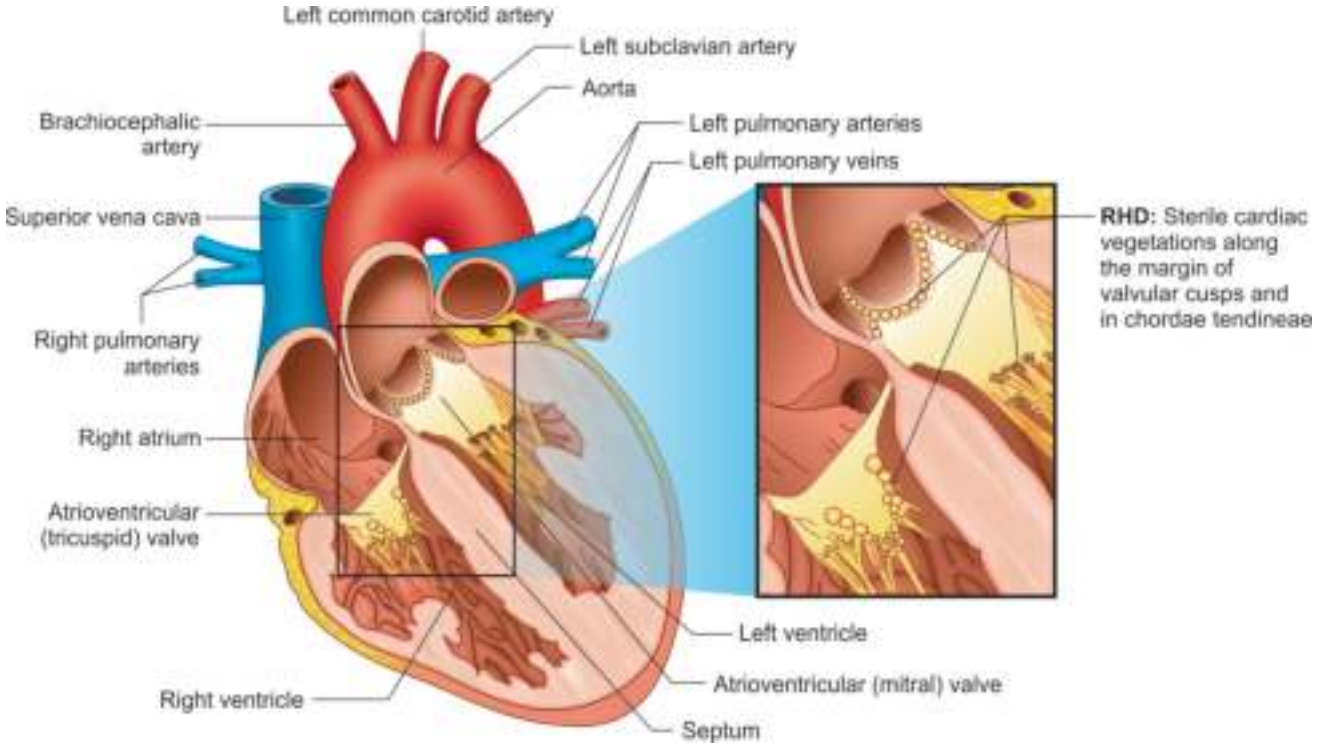

Fig. 16.21: Cardiac vegetations in rheumatic heart disease.

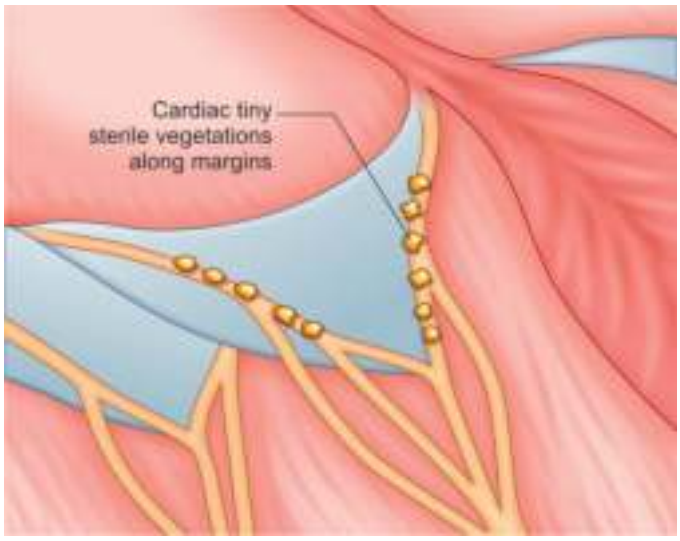

Fig. 16.22: Cardiac vegetations in rheumatic heart disease. Cardiac vegetations are tiny, few mm in diameter present along the margin of the cardiac valves and chordae tendineae.

- McCallum plaque is a healed lesion located in posterior wall of left atrium. Blood regurgitation jets result in subendocardial thickening known as McCallum plaque.
- Aschoff's nodules in heart are more proliferative and less exudative lesions, and hence resulting in valvular leaflet fibrosis, commissural fusion, thickening and shortening of the chordae tendineae. Aschoff's nodules are replaced by fibrosis hence not demonstrated on light microscopy.
- Buttonhole stenosis of mitral valve with dystrophic calcification results in fish-mouth appearance (Fig. 16.23). Mitral valve stenosis is accompanied by cardiac murmurs that can be heard on auscultation.
- In advanced cases, patients may manifest with congestive heart failure, dyspnea, mild to moderate chest discomfort, pleuritic chest pain, edema, cough, or orthopnea or a new cardiac murmur.
- Residual cardiac vegetations often become infected even with low virulent bacteria and known as subacute infective endocarditis.
- Superimposed infection may cause ulceration of the cusps, perforation of cardiac valves, and rupture of chordae tendineae. The infected cardiac vegetations are more likely to be detached and cause embolism resulting in infarction of organs (Figs 16.24 and 16.25). Sites of radiation of cardiac murmurs are given in Table 16.15.

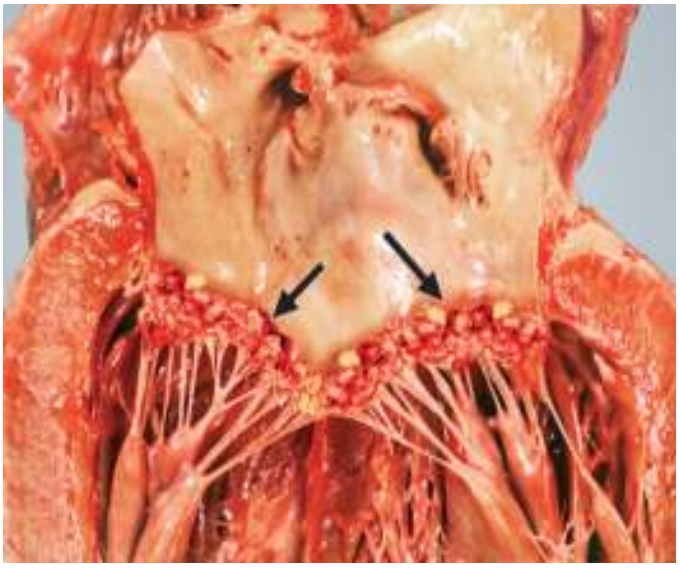

Fig. 16.24: Development of endocarditis in RHD (arrows). Cardiac vegetations are tiny, few mm in diameter present along the margin of the cardiac valves and chordae tendineae.

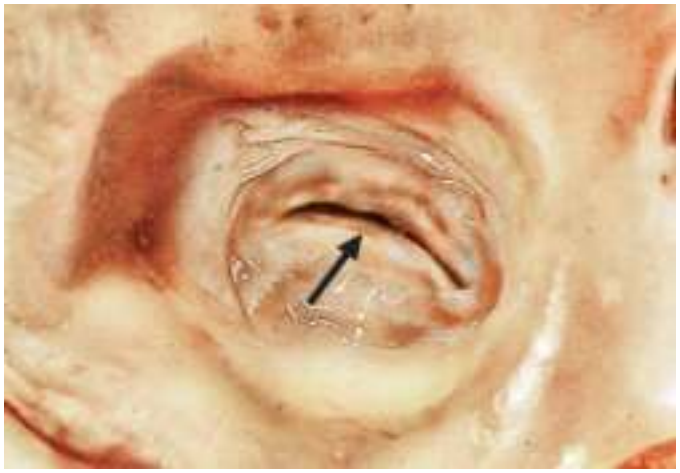

Fig. 16.23: Severe mitral stenosis in RHD shows fish-mouth appearance. Cusps are rigid, fibrotic and calcified with narrowing of orifice (arrow).

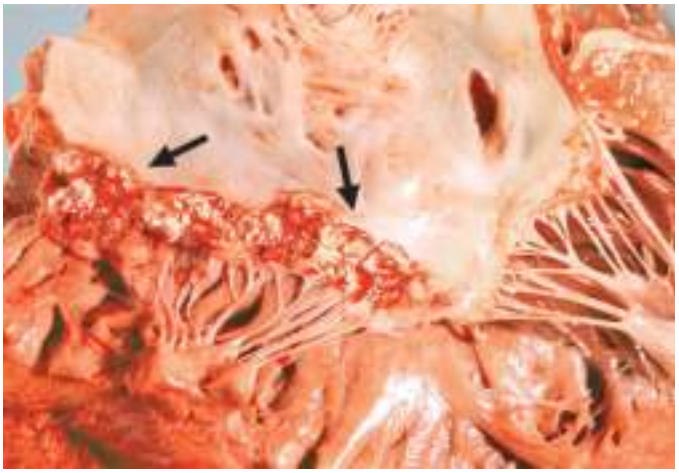

Fig. 16.25: Vegetations on the mitral valve in subacute bacterial endocarditis. These are also a source of peripheral emboli (arrows).

Table 16.15 Sites of radiation of cardiac murmurs

Cause	Primary Site of Cardiac Murmur	Radiation of Cardiac Murmur
Mitral stenosis	Apex	Cardiac murmur does not radiate
Mitral regurgitation	Apex	Cardiac murmur radiates to left axilla beneath left scapula
Aortic stenosis	Apex	Cardiac murmur radiates towards upper right sternal edge over carotids
Aortic regurgitation	Left sternal edge	Cardiac murmur radiates down left sternal edge towards apex
Ventricular septal defect	Left sternal edge	Cardiac murmur radiates all over precordium
Pulmonary stenosis	Left sternal edge in upper part	Cardiac murmur radiates towards left clavicle beneath left scapula

Clinical Pearls: Long-term Complications of Pancarditis

- **Infective endocarditis:** Valvular stenosis and/or incompetence and predisposes to infective endocarditis.
- **Congestive heart failure:** Patient develops congestive heart failure in long-standing cases secondary to severe valve insufficiency or myocarditis. Patient presents with dyspnea, orthopnea, and peripheral edema, pleuritic chest pain, cough and rheumatic pneumonitis. On clinical examination, patient presents with right heart failure and shows signs of raised jugular venous pressure, hepatomegaly and peripheral edema. Right ventricular hypertrophy is very common in mitral stenosis, and left ventricular hypertrophy seen in aortic regurgitation.
- **Cardiac arrhythmias (atrial fibrillation):** Patient may develop atrial fibrillation, tachycardia, and arrhythmias.
- **Thromboembolism:** Mural thrombi are very common in left atrium. Patient is prone to thromboembolism associated with infarction of affected organs.
- **Constrictive pericarditis:** There is deposition of fibrinous exudate between two layers of pericardium giving shaggy appearance. It is known as bread and butter pericarditis. Its resolution is uncommon. It most often gets organized resulting in constrictive pericarditis. Patient presents with precordial pain. On auscultation, friction rub can be heard.
- **Other organs involvement:** Blood vessels and lungs may be involved in rheumatic fever, i.e. coronary arteries, renal arteries, mesenteric arteries, cerebral arteries, aorta, pulmonary arteries and lungs (pneumonitis and pleuritis). A few patients may develop abdominal pain and nose bleeds.

Subcutaneous Nodules

Subcutaneous nodules are formed due to fusion of multiple Aschoff's nodules. Patient develops a few mm to 1–2 cm size firm, painless subcutaneous nodules, over bony prominences or tendons in adults, i.e. wrists, elbows, scapula, ankles, knees, patella margins, scalp and spinous processes of thoracic and lumbar vertebrae especially in adults in 10–60% of cases.

Skin Rashes (Erythema Marginatum)

Skin rashes exhibit bathing suit distribution in ≤10% of cases. Patient presents with 1–3 cm ring-shaped reddish rashes such as macules/papules on the trunk and extremities (bathing suit distribution), which coalesce to exhibit snake-like appearance. These rashes typically spare the face and becoming worse with heat.

Sydenham's Chorea (St. Vitus Dance)

Sydenham's chorea is delayed manifestation of rheumatic fever. This can occur at least 3 months from onset of infection up to 10% of cases.

- Patient presents with series of random rapid involuntary purposeless muscular movements of the face and arms. Patient has difficulty in writing, drawing, handwork, and talking.
- Patient develops hyperextension of joints, hypotonia of muscles, diminished deep tendon reflexes, and relapsing grip (e.g. alternate increase and decrease in tension).
- Patient starts improving in 1–2 weeks, and full recovery occurs in 2–3 months. CSF examination reveals no pathologic findings.

LABORATORY DIAGNOSIS

JONES DIAGNOSTIC CRITERIA

Rheumatic fever is diagnosed clinically using Jones criteria, which are divided into two groups: major and minor manifestations. The diagnosis is established by presence of two major and one minor; or one major and two minor criteria as discussed.

ANTISTREPTOLYSIN *O* TITER (ASO TITER)

- Antistreptolysin *O* titer (ASO titer) is estimated in patient with rheumatic fever. Peak level is achieved at 4–5 weeks after streptococcal infection. High ASO titers are supportive but not diagnostic.

- ASO titer is expressed in Todd units. ASO titers >400 Todd units in adults and >300 Todd units in children >5 years of age are significant.

ANTI-DNase B/ANTI-HYALURONIDASE TITER

Anti-DNase B titer is less reliable diagnostic parameter than ASO titer. It is raised in cases of Sydenham's chorea.

ANTISTREPTOZYME TEST

- Antistreptozyme test is very sensitive in recent case of rheumatic fever.
- Hemagglutination test value >200 units/ml is associated with polyarthritis suggestive of acute rheumatic fever.

ELECTROCARDIOGRAM

Electrocardiogram (ECG) study demonstrates first-degree block and prolonged PR interval.

IMAGING TECHNIQUES

Echocardiography is done to visualize cardiac motion. Chest radiograph is done to evaluate heart and lungs.

BLOOD CULTURE

- Blood culture is done to diagnose or rule out infective endocarditis in these patients. Blood culture is positive in 95% of cases due to presence of bacterial colonies not covered by fibrin (Fig. 16.26).
- Presence of deep seated bacterial colonies covered by fibrin leads to negative blood culture (Fig. 16.27).

ACUTE PHASE REACTANTS

Serum complement, mucoproteins, α_2-globulin and β-globulin levels are increased. Peripheral blood smear examination shows leukocytosis. Erythrocyte sedimentation rate and C-reactive protein (CRP) levels are raised in migratory polyarthritis.

DECREASED ERYTHROPOIESIS

Chronic inflammatory changes suppress erythropoiesis leading to anemia.

MANAGEMENT

- **Aspirin:** Aspirin is the drug of choice for treatment of migratory polyarthritis by reducing inflammation. Patients with positive throat cultures should be treated with antibiotics.
- **Corticosteroids:** These drugs are reserved for cases where there is evidence of pancarditis. Use of corticosteroids prevents further scarring of tissue and development of mitral stenosis. Unlike congestive heart failure, rheumatic heart disease responds well to corticosteroids.
- **Penicillin:** Basic aim of monthly injections of long-acting penicillin is to prevent development of infective endocarditis in rheumatic heart disease. It must be administered for a period of five years in patients having one attack of rheumatic fever. If there is evidence of carditis, the length of long acting penicillin therapy may be continued up to 40 years of age.
- **Other drugs:** Angiotensin converting enzyme (ACE) inhibitors, diuretics, β-blockers, and digoxin drugs are used for treatment of carditis, which manifests as congestive heart failure.

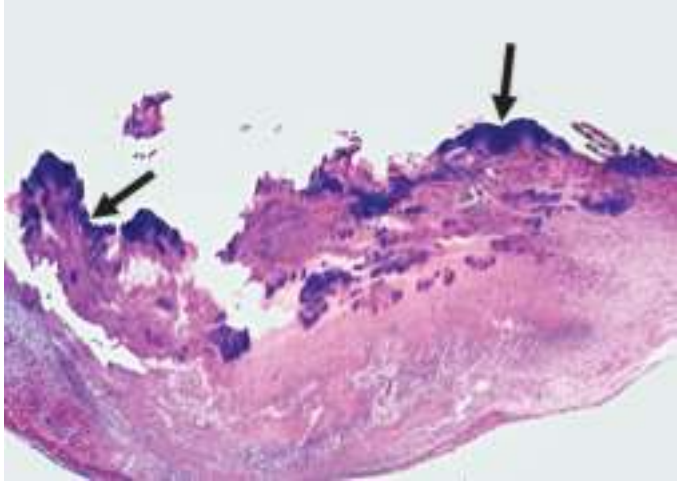

Fig. 16.26: Infective endocarditis. Valves are relatively avascular, so high dose antibiotic therapy is needed to eradicate the infection. Blue bacterial colonies are extending into the pink fibrin, platelets and connective tissue of the valve. Blood culture is positive (arrows) (400X).

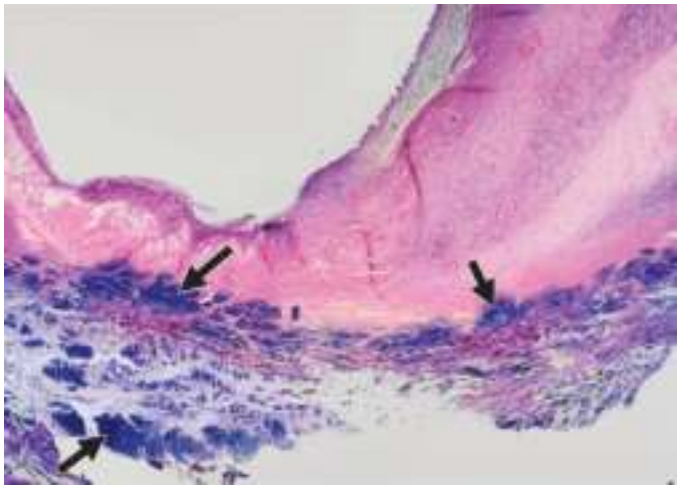

Fig. 16.27: Infective endocarditis. Valves are relatively avascular, so high dose antibiotic therapy is needed to eradicate the infection. Blue bacterial colonies are extending into the pink fibrin, platelets and connective tissue of the valve. Blood culture is negative (arrows) (400X).

DISORDERS OF MYOCARDIUM

MYOCARDITIS

Myocarditis is focal or diffuse inflammation of the myocardium affecting any age group. Myocarditis constitutes 10% of cases of new onset cardiac dysfunction. If myocarditis is not fatal, it often progresses to congestive cardiomyopathy. Causes of myocarditis include viral infections, autoimmune disorders, environmental toxins and adverse reactions to medications.

- Diagnosis of active myocarditis is based on inflammatory infiltrate usually lymphocytes and myocyte necrosis not of ischemic etiology.
- Patient presents with congestive heart failure, tachypnea, peripheral edema, and hepatomegaly. Atrial or ventricular arrhythmias are common resulting in fatal outcome.
- Electrocardiogram (ECG) may show low voltage QRS complex, ST elevation, or heart block. Serial 24-hour Holter recordings should be obtained in all patients.
- Chest radiograph shows pulmonary edema. Echocardiography is extremely useful in excluding congenital structural cardiac defects; pericardial effusion with cardiac tamponade.
- Cardiac catheterization with endomyocardial biopsy remains the gold standard for the diagnosis of myocarditis.

PRIMARY VIRAL MYOCARDITIS

Primary viral myocarditis is most often caused by Coxsackie B virus. It may be caused by HIV, EB virus, poliovirus, cytomegalovirus. Infectious virus triggers an autoimmune, cellular, and humoral reaction resulting in viral myocarditis. Primary viral myocarditis has four clinicopathologic manifestations described as under.

Fulminant Myocarditis

Patient with fulminant myocarditis develops ventricular dysfunction without dilatation within 2 weeks of viral infection. Complete histological and functional recovery occurs. Some patients die within 2 weeks.

Surgical Pathology: Fulminant Myocarditis
Light Microscopy
Histopathologic examination of myocardium in fulminant myocarditis shows multiple foci of active inflammation comprising lymphocytes and necrosis (Fig. 16.28).

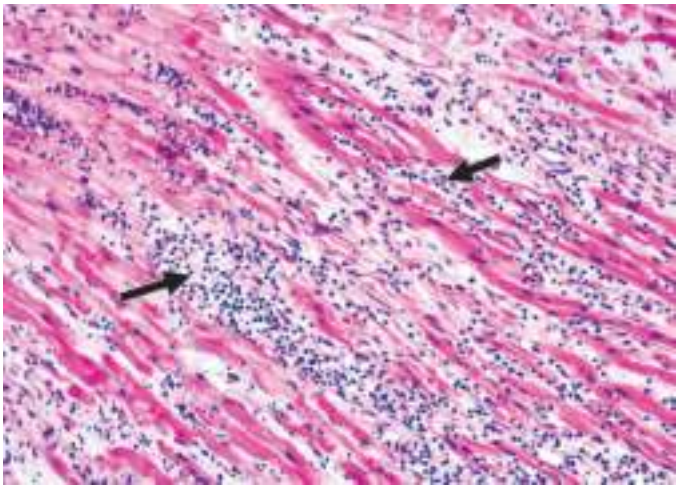

Fig. 16.28: Viral myocarditis. It is caused by Coxsackie B virus showing heavy but focal increase of lymphocytes in the interstitial tissue of the myocardium. Outcome is subclinical or fatal (arrows) (100X).

Chronic Active Myocarditis

Patient has an indistinct onset with moderate cardiac dysfunction. Patient may develop restrictive cardiomyopathy within 2–4 years of clinical manifestations.

Surgical Pathology: Chronic Active Myocarditis
Light Microscopy
Histologic examination shows active or borderline myocarditis.

Eosinophilic Myocarditis

Eosinophilic myocarditis is attributed to allergic reactions, which leads to left ventricular dysfunction. It is linked to treatment with methyldopa, penicillin, para-aminosalicylic acid, streptomycin, anticonvulsants and antidepressants.

Surgical Pathology: Eosinophilic Myocarditis
Light Microscopy
▪ Histologic examination of eosinophilic myocarditis shows infiltration by eosinophils and occasional giant cells. ▪ There is presence of a little myocardial necrosis and infiltration by lymphocytes and histiocytes around blood vessels. In a few cases, inflammation is present in subendocardium with poorly formed epithelioid cell granulomas.

Idiopathic Giant Cell Myocarditis

Idiopathic giant cell myocarditis is also known as **Friedler's myocarditis** and associated with autoimmune diseases such as inflammatory bowel disease. It affects young adults of myocardium in idiopathic giant cell myocarditis.

Table 16.16 Comparison of cardiomyopathies (CMPs)

Parameters	Congestive CMP	Hypertrophic CMP	Restrictive CMP
Etiology	Alcohol toxicity Peripartum postviral genetic mutation	▪ Autosomal dominance with gene mutation encoding beta heavy chain on chromosome 14 (50%) ++++ ▪ Troponin T gene mutation on chromosome 1 (15%) ▪ α-Tropomyosin gene mutation on chromosome 15 (3–5%)	▪ Unknown in majority of cases ▪ Amyloid deposition in subendocardial region ▪ Hemosiderin deposition in subendocardial region
Age	Any age	Young age	Infants, children
Valves motion	Normal motion	Anterior motion of mitral valve during systole	Normal motion
Heart wall and chambers	All chambers are dilated and congested	Left ventricle is hypertrophied	Endocardial thickening is marked
Heart contraction	Poor contraction	Marked contraction	Poor contraction due to heart rigid
Congestive heart failure	Slow onset	Rapid onset	Rapid onset
Cardiomegaly	++++ (marked)	++ (moderate)	+ (less)
Arrhythmias	++	Absent	++++ (marked)
Atrial fibrillation	Absent	++++ (marked)	Absent
Thrombus	Common	Common	Absent
Infective endocarditis	Absent	Present	Absent
Prognosis	Poor	Poor	Poor

Surgical Pathology: Idiopathic Giant Cell Myocarditis

Light Microscopy

- Histologic examination shows infiltration of myocardium by lymphocytes, macrophages, and multinucleated giant cells in the absence of granulomas.
- Giant cells have immunohistochemical profile of histiocytes.

CARDIOMYOPATHIES

Cardiomyopathy refers to noninflammatory disease of myocardium. It is diagnosed by exclusion of all cases of hypertension, ischemic heart disease, valvular diseases and congenital heart diseases. It is characterized by unexplained ventricular dysfunction unresponsive to digitalis.

- Primary cardiomyopathies include congestive (dilated), hypertrophic and restrictive types. Secondary cardiomyopathies occur due to specific causes (e.g. hemochromatosis, amyloidosis, and alcohol and thiamine deficiency).

Table 16.17 Etiology of secondary cardiomyopathies

Causes	Example
Infection and inflammation	Myocarditis
Toxic and metabolic disturbances	▪ Alcohol ▪ Adriamycin ▪ Catecholamines
Multisystem diseases	▪ Diabetes mellitus ▪ Amyloidosis ▪ Hemochromatosis ▪ Thyroid dysfunction
Primary skeletal muscle disorders	▪ Muscular dystrophy ▪ Mitochondrial cytopathy

- Diagnostic evaluation of cardiomyopathies is based on clinical history, clinical examination, imaging techniques, ECG, cardiac catheterization and myocardial biopsy examination (Table 16.16).
- Etiology of secondary cardiomyopathies is given in Table 16.17. Selected genetic defects associated with cardiomyopathy are given in Table 16.18.

Table 16.18 Selected genetic defects associated with cardiomyopathy

Gene Features	Gene Product	Inheritance	Cardiac Phenotype
Sarcomere	▪ MYH7 (myosin heavy chain 7) ▪ MYBPC3 (myosin binding protein C3) ▪ MYL2 (myosin regulatory light chain 2) ▪ MYL3 (myosin essential light chain 3) ▪ TNNT2 (troponin T2) ▪ TNNI3 (troponin I3) ▪ TPMα_1 (tropomyosin α_1) ▪ TNNC1 (troponin C1) ▪ TTN (titin)	▪ Autosomal dominant ▪ Autosomal dominant ▪ Autosomal dominant ▪ Autosomal dominant ▪ Autosomal dominant ▪ Autosomal dominant/autosomal recessive ▪ Autosomal dominant ▪ Autosomal dominant ▪ Autosomal dominant	▪ HCM, DCM, LVNC ▪ HCM ▪ HCM ▪ HCM ▪ HCM, DCM, LVNC ▪ HCM, DCM, LVNC ▪ HCM, DCM ▪ DCM ▪ DCM
Sarcolemmal membrane	▪ DMD (Duchenne muscular dystrophy) ▪ DMPK (dystrophica myotonica protein kinase) ▪ SGCD (δ-sarcoglycan)	▪ X-linked disorder ▪ Autosomal dominant ▪ Autosomal dominant	▪ DCM ▪ DCM ▪ DCM
Z-disc and cytoskeleton	▪ DES (desmin) ▪ ACTN2 (α-actin-2) ▪ CRYAB ($\alpha\beta$-crystallin) ▪ FLNC (filamin C) ▪ ANKRD1 (CARP) ▪ CSRP3 (MLP)	▪ Autosomal recessive ▪ Autosomal dominant ▪ Autosomal dominant ▪ Autosomal dominant ▪ Autosomal dominant ▪ Autosomal dominant	▪ DCM ▪ DCM ▪ DCM ▪ DCM ▪ DCM, RCM ▪ HCM (DCM)
Nuclear membrane	▪ LMNA ▪ EMD	▪ Autosomal dominant/autosomal recessive ▪ X-linked disorder	▪ CDDC ▪ CDDC
Mitochondria	Mitochondrial DNA	Maternal transmission	DCM, HCM
Desmosome	▪ DSP (desmoplakin), JUP (junctional plakoglobin) ▪ DSG2 (desmoglein 2), DSC2 (desmocollin 2), PKP2 (plakophilin 2)	▪ Autosomal dominant/autosomal recessive ▪ Autosomal dominant	▪ ARVC ▪ ARVC
Cellular metabolism	▪ PRKAG2 (γ-subunit of AMP kinase) ▪ TMEM43 (transmembrane protein 43) ▪ FXN (frataxin) ▪ LAMP2 (lysosomal-associated membrane protein 2) ▪ TAZ (taffazin)	▪ Autosomal dominant ▪ Autosomal dominant ▪ Autosomal recessive ▪ X-linked disorder ▪ X-linked disorder	▪ HCM ▪ ARVC ▪ HCM ▪ HCM ▪ DCM, LVNC
Other examples	▪ RBM20 (RNA-binding motif protein 20) ▪ ALK3 (α-kinase 3) ▪ BAG3 (BCL-2-associated athanogene 3) ▪ PSEN1 (presenilin 1)	▪ Autosomal dominant ▪ Autosomal dominant ▪ Autosomal dominant ▪ Autosomal dominant	▪ DCM ▪ HCM ▪ DCM ▪ DCM

DCM: Dilated cardiomyopathy; HCM: Hypertrophic cardiomyopathy; RCM: Restrictive cardiomyopathy; LVNC: Left ventricular noncompaction; CDDC: Conduction disease dilated cardiomyopathy, ARVC: Arrhythmogenic right ventricular cardiomyopathy.

CONGESTIVE CARDIOMYOPATHY

Congestive cardiomyopathy is most common form of cardiomyopathy (CMP). Damage to cardiac muscle fibers results in poor contraction. The resulting loss of myocardium tone dilates all four chambers of the heart, resulting in cardiomegaly (>500 g) and giving the heart, a globular shape (Figs 16.29 and 16.30).

- Patient is prone to thrombus formation and cardiac arrhythmias (atrial and ventricular). Mural thrombi may fragment and enter circulation in the form of emboli.
- Emboli from left side of heart are carried to brain, kidney, coronary arteries and peripheral tissues resulting in interruption of blood supply to organs.

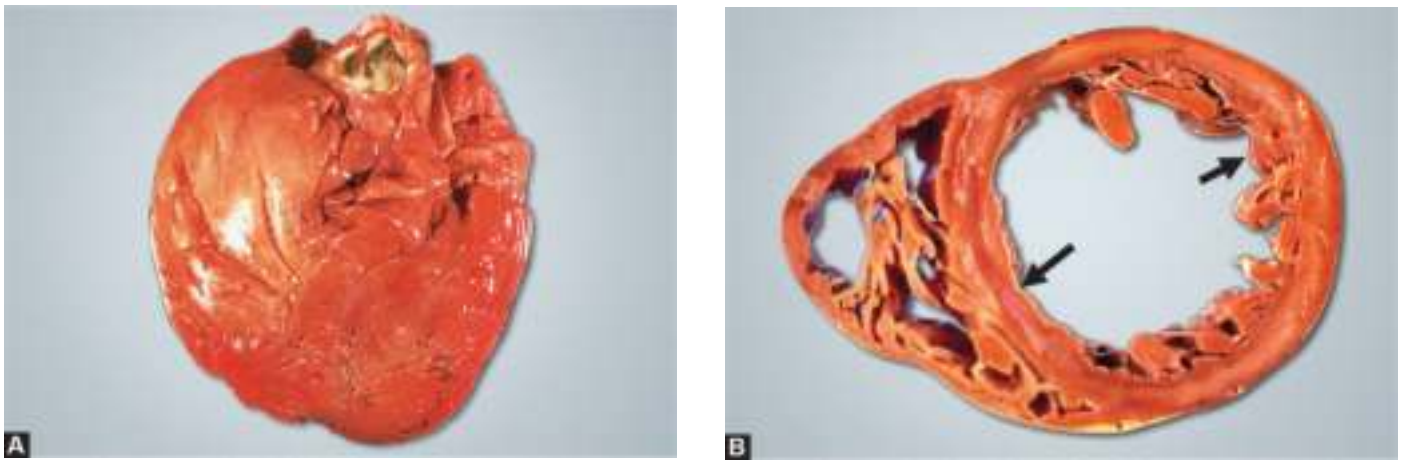

Fig. 16.29: Congestive cardiomyopathy. (A) Heart has a globoid shape because all of the chambers are dilated, (B) heart is very flabby, large and the myocardium is poorly contractile (arrows).

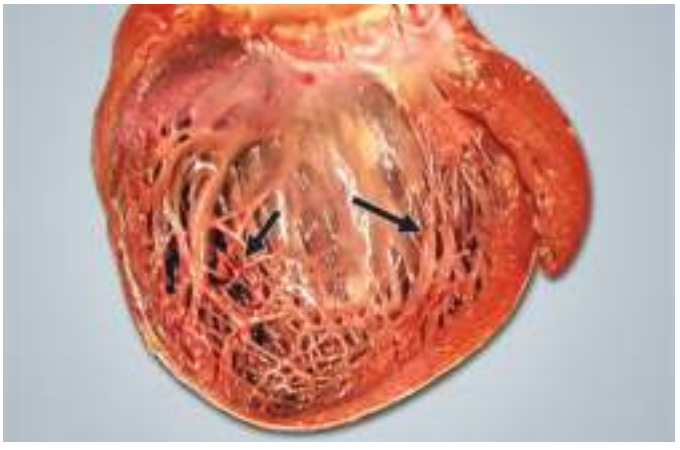

Fig. 16.30: Congestive cardiomyopathy. Cut opened chamber is showing marked dilatation. Heart is very flabby, large and the myocardium is poorly contractile (arrows).

- Emboli from right-sided heart reach pulmonary artery resulting in pulmonary infarction.

Etiology

Etiology of congestive cardiomyopathy (CMP) is most often unknown. In some cases, it is associated with chronic alcoholism, thiamine deficiency (beriberi heart), peripartum period (last trimester or within 6 months in postpartum period), end stage of viral myocarditis, myxedema, drug toxicity (e.g. doxorubicin, daunorubicin, cocaine) and Friedreich ataxia.

- Some cases of congestive CMP are associated with mutant cytoskeletal proteins (i.e. dystrophin or desmin), sarcomeric proteins (troponin), cardiac myosin heavy chain; and other muscle proteins, such as actin.
- Mutations in mitochondrial genes have also been implicated in congestive CMP. Causes of congestive cardiomyopathy are given in Table 16.19.

Table 16.19 Causes of congestive cardiomyopathy

Inflammatory Myocarditis
▪ Infective myocarditis
▪ Viral myocarditis (coxsackievirus, adenovirus, hepatitis C, HIV)
▪ Parasitic myocarditis (*Trypanosoma cruzi*—Chagas' disease, toxoplasmosis)
▪ Systemic fungal disease
▪ Noninfective myocarditis
▪ Sarcoidosis
▪ Giant cell myocarditis
▪ Eosinophilic myocarditis
▪ Collagen vascular diseases
▪ Polymyositis
▪ Dermatomyositis
▪ Checkpoint inhibitor chemotherapy
▪ Transplant rejection
Toxic Agents
▪ Alcohol
▪ Cocaine abuse
▪ Catecholamines: Amphetamines
▪ Interferon
▪ Therapeutic drugs (chloroquine, hydroxychloroquine)
▪ Drugs of misuse (anabolic steroids, emetine)
▪ Heavy metals (mercury, lead)
▪ Occupational exposure (hydrocarbons, arsenic)
Metabolic Disorders
▪ Nutritional deficiencies (thiamine, carnitine, selenium)
▪ Electrolyte deficiencies (calcium, phosphate, magnesium)
▪ Thyroid diseases
▪ Diabetes mellitus
▪ Pheochromocytoma
▪ Hemochromatosis
▪ Obesity
Miscellaneous Disorders
▪ Peripartum cardiomyopathy
▪ Tachycardia-related cardiomyopathy

Surgical Pathology: Congestive Cardiomyopathy
Gross Morphology
▪ The heart assumes a globular shape. ▪ There is pronounced ventricular dilatation, diffuse endocardial thickening and atrial enlargement often with thrombi in the appendages.
Light Microscopy
▪ Normal myocytes are filled with myofibrils, hence exhibit a uniform pink cytoplasm. ▪ Damaged myocytes undergo loss of myofibrils in myocytes, hence exhibit empty spaces within cytoplasm. There is presence of focal myocyte necrosis, interstitial fibrosis, and infiltration by T cells and macrophages (Fig. 16.31A and B).

Clinical Features

Patient presents with slow onset congestive heart failure, shortness of breath, orthopnea, dyspnea on exertion, fatigue and dry cough at night.

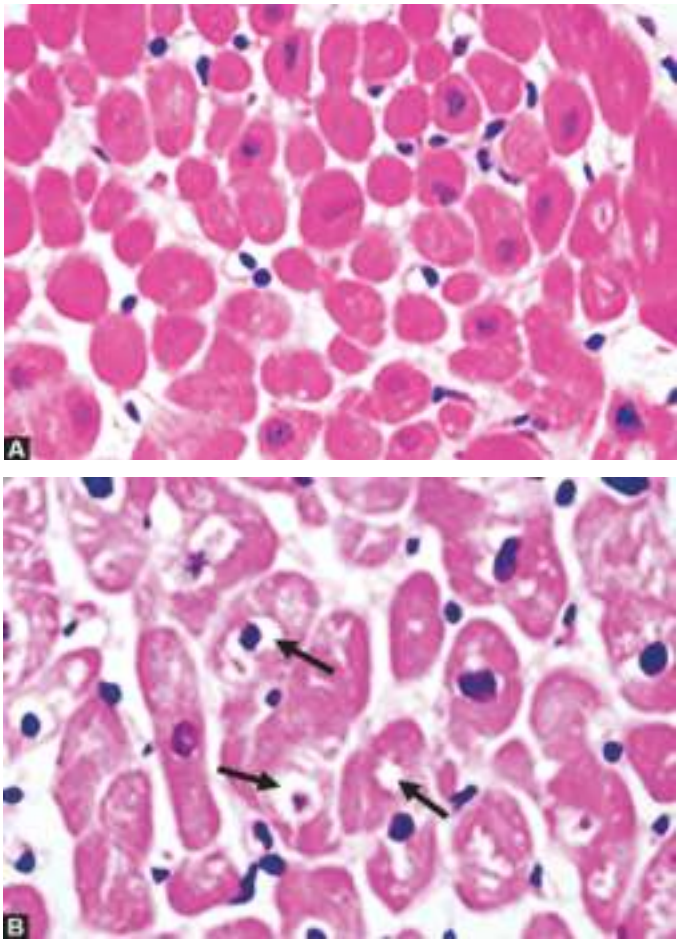

Fig. 16.31: (A) Each normal myocyte in cross section has a uniform pink cytoplasm owing to the majority of the cell being filled by myofibrils, (B) congestive cardiomyopathy. The myocytes have lost myofibrils and empty spaces have appeared within the cytoplasm (arrows).

Physical Examination

Physical examination reveals jugular vein distension, peripheral edema, hepatomegaly, peripheral cyanosis, irregular pulse and tachycardia.

Auscultation

Congestive CMP weakens papillary muscles resulting in mitral and tricuspid valve insufficiency. On auscultation, pansystolic murmur is heard.

Clinical Course

Prognosis is very poor and death occurs within 2 years from onset of symptoms. Cardiac transplantation is recommended for congestive CMP patients.

HYPERTROPHIC CARDIOMYOPATHY

Hypertrophic cardiomyopathy is also known as idiopathic hypertrophic subaortic stenosis (**IHSS**) and transmitted as an autosomal dominant trait in 50% of cases. It is most common form of cardiomyopathy with hypercontracting heart affecting younger adults.

Genetic Basis of HCMP

Hypertrophic cardiomyopathy is inherited as an autosomal dominant trait in >50% of cases. Gene mutations implicated in this disorder include gene coding for β-myosin heavy chain mapped on chromosome 14 (most common and severe form in 50% of cases), cardiac troponins T and I (less severe form in 15% of cases), α-tropomyosin gene on chromosome 15 (less severe in 3–5% of cases), myosin-binding protein C, and myosin light chain.

Surgical Pathology: Hypertrophic Cardiomyopathy
Gross Morphology
▪ Heart shows hypertrophy of all the chambers especially asymmetric interventricular septum hypertrophy. It becomes stiff and noncompliant. It is unable to relax during ventricular filling. ▪ Lumen of the left ventricle is markedly reduced assuming banana-shaped chamber (Fig. 16.32).
Light Microscopy
▪ The myocytes in normal myocardium are arranged in parallel, and within the myocyte myofibrils. ▪ But in hypertrophic cardiomyopathy, the myocytes are arranged in disoriented tangled criss-cross whorls losing their normal parallel arrangement (Figs 16.33 and 16.34).

Fig. 16.32: Hypertrophic cardiomyopathy. Left ventricular hypertrophy with asymmetrical septal hypertrophy, systolic anterior motion of mitral valve, banana-shaped left ventricular chamber and hypercontracting heart (arrow).

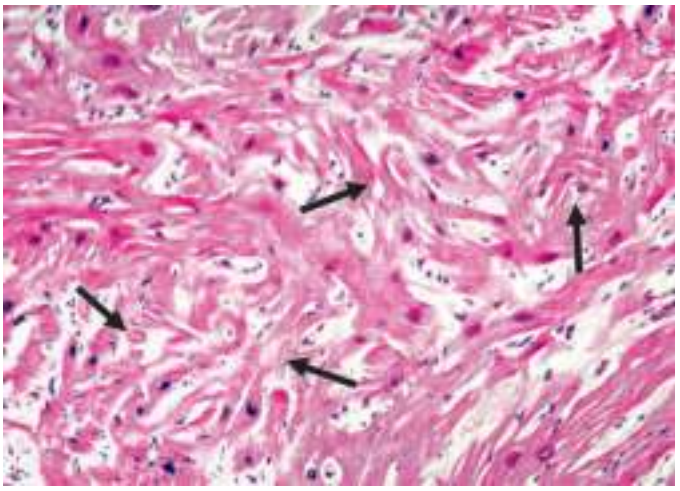

Fig. 16.34: Hypertrophic cardiomyopathy. The cells arranged in whorls around foci of connective tissue. Higher power magnification shows the myofibrils within the cell criss-cross whorls losing their normal parallel arrangement (arrows) (400X).

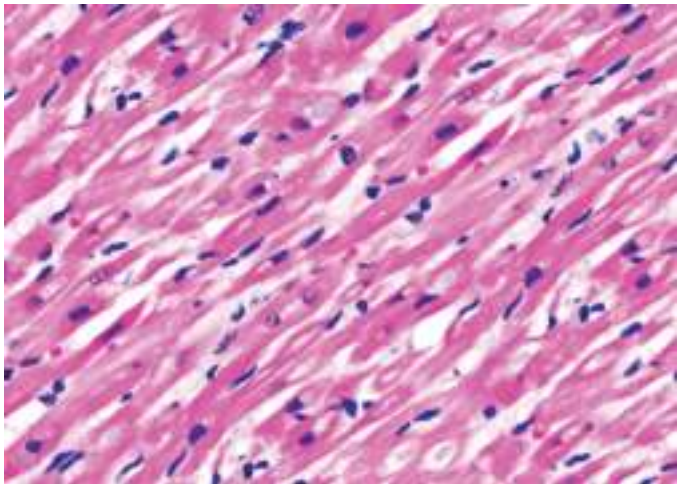

Fig. 16.33: Normal cardiac muscle biopsy. The myocytes in normal myocardium are arranged in parallel, and within the myocyte myofibrils (400X).

Pathophysiology

In patient, asymmetrical hypertrophy of the interventricular septum is responsible for subaortic stenosis resulting in obstruction to blood flow and systolic motion of anterior leaflet of mitral valve toward the interventricular septum. It impairs ventricular filling resulting in increased pressure in left atrium and pulmonary veins. It causes unexpected death in young athletes.

Clinical Features

Patient presents with breathlessness on exertion, dizziness, fainting, precordial pain, and cardiac arrhythmias. The obstruction to blood flow from the left ventricle increases the ventricle's work, and harsh systolic ejection cardiac murmur may be heard along the left sternal border and at the apex. Patient develops abrupt irregular arterial pulse due to atrial fibrillation.

Complications

Patient may develop cardiac arrhythmia (most common), atrial fibrillation, infective endocarditis, congestive heart failure and thrombus formation with fatal outcome.

RESTRICTIVE CARDIOMYOPATHY

Restrictive cardiomyopathy is least common but serious disorder, which affects infants and children. Infiltration of extraneous material in the ventricles causes left ventricular hypertrophy with decreased ventricular chamber lumen and endocardial fibrosis. The stiffness reduces the ventricle's ability to relax and filling during diastole. The rigid myocardium fails to contract completely during systole. As a result, cardiac output falls. ECG shows low-voltage QRS complex.

Etiopathogenesis

In adults, cardiac amyloidosis and hemochromatosis cause restrictive cardiomyopathy, which is characterized by reduced diastolic filling and right-sided heart failure. Infiltration of the conduction system by amyloid material can result in cardiac arrhythmias or sudden cardiac death. Causes of restrictive cardiomyopathy are given in Table 16.20.

Table 16.20 Causes of restrictive cardiomyopathy

Infiltrative Causes between Myocytes
▪ Amyloidosis • Primary amyloidosis (light chain) • Familial (abnormal transthyretin) • Senile amyloidosis (normal transthyretin or atrial peptides) ▪ Inherited metabolic defects
Storage Disorders within Myocytes
▪ Hemochromatosis (primary or secondary) ▪ Inherited metabolic disorders • Glycogen storage disease (II and III) • Fabry's disease
Fibrotic Causes
▪ Scleroderma ▪ Radiation
Endomyocardial Causes
▪ Possibly related to fibrotic disease • Hypereosinophilic syndrome (Loffler's endocarditis) • Tropical endomyocardial fibrosis ▪ Carcinoid syndrome ▪ Drugs (serotonin, ergotamine) ▪ Radiation
Overlap with other Cardiomyopathy
▪ Hypertrophic cardiomyopathy ▪ Sarcoidosis ▪ Minimally dilated cardiomyopathy • Early-stage dilated cardiomyopathy • Partially recovery from dilated cardiomyopathy

Surgical Pathology: Restrictive Cardiomyopathy

Gross Morphology

- Gross examination of the heart shows bilateral dilatation due to increased filling pressures.
- Ventricles are relatively of normal size.
- Ventricular cavity is within normal range.
- Ventricular wall thickness is abnormal with a rubbery texture.
- Thickening of the endocardium may be observed.

Light Microscopy

- Amyloid appears amorphous, glassy, and eosinophilic material in extracellular compartment.
- Amyloid is readily documented using Congo red stain, which demonstrates green birefringence when viewed under polarized light.
- Prussian blue staining is done to demonstrate iron in hemochromatosis involving heart (Fig. 16.35).

Clinical Features

In restrictive cardiomyopathy (RCM), myocardium of ventricles become stiff leading to enlarged atria and impairment of ventricular filling during diastole.

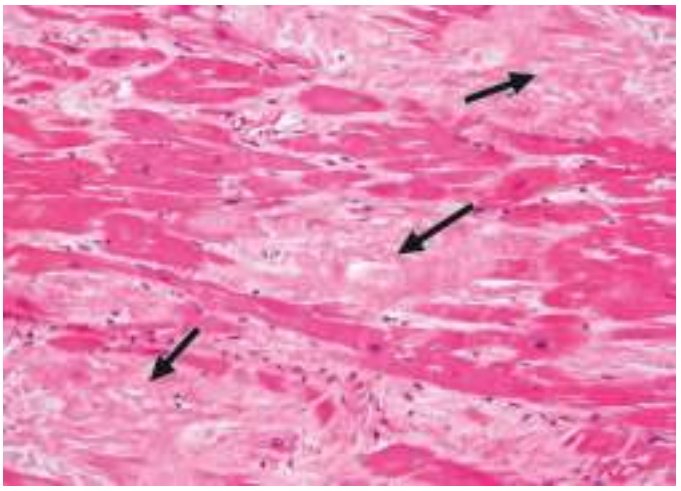

Fig. 16.35: Restrictive cardiomyopathy. Pale pinkish amorphous material is deposited between myocardial fibers due to amyloid deposition. Arrhythmias occur during surgery (arrows).

Symptoms of RCM vary depending on severity such as congestive heart failure and cardiac arrhythmias especially during surgery. Patient presents with dyspnea, orthopnea, cough, chest pain, fatigue, and swelling of feet and ankles. Physical examination reveals distended neck veins, peripheral edema, hepatomegaly, lung crackles, peripheral cyanosis, and pallor. Auscultation reveals S3 or S4 gallop rhythm. Restrictive cardiomyopathy may appear like constrictive pericarditis. Cardiac catheterization may help confirm the diagnosis.

ARRHYTHMOGENIC RIGHT VENTRICULAR CARDIOMYOPATHY

- Arrhythmogenic right ventricular cardiomyopathy is an autosomal dominant disorder of cardiac muscle. In arrhythmogenic right ventricular cardiomyopathy (ARVC), fibrofatty tissue gradually replaces normal myocardium of right ventricular apex, base region, and right ventricle outflow tract. Patient has left bundle branch block morphology. Pathology of ARVC may also extend to involve left ventricle associated with left ventricular dysfunction. ARVC interrupts normal electrical signals in the heart and may cause right-sided heart failure, irregular heartbeat, chest pain, and potentially life-threatening cardiac arrhythmias. Osteoglycin (OGN) gene has been observed in patients with ARVC. Mutations in desmosomal gene encoding defective desmosome-associated protein have been linked to ARVC and Nexos syndrome. Patient with Nexos syndrome presents with ARVC and hyperkeratosis of plantar and palmar skin surfaces.

DISORDERS OF ENDOCARDIUM

ENDOCARDIUM AND ENDOCARDITIS: OVERVIEW

The endocardium is the innermost layer of the heart and lines the cardiac chambers that extends over the cardiac valves, chordae tendineae, and papillary muscles. It serves as a barrier between cardiac muscles and the blood stream. Endocardium is thicker in the atria than in ventricles, and is more thick in left than right cardiac chambers, and in the outflow tracts than in the inflow tracts. Depending on etiology, endocarditis is categorized in two groups—infective and noninfective endocarditis.

- **Infective endocarditis:** Acute endocarditis affects normal heart due to highly virulent bacteria. Subacute endocarditis occurs in previously diseased heart due to even low virulent bacteria. Systemic symptoms of acute infective endocarditis are fever, weight loss and malaise due to synthesis of cytokines. Patient develops skin petechiae and microhemorrhages around the fingernails due to deposition of immune complex in small blood vessels in these regions. Splenomegaly and anemia are present due to persistent bacteremia. Finger clubbing, Janeway lesions and/or Osler lymph nodes are present.
- **Noninfective endocarditis:** Examples of noninfective endocarditis are Libman-Sacks endocarditis due to systemic lupus erythematosus (SLE), nonbacterial thrombotic endocarditis due to mucin secreting carcinoma of colon and pancreas, and small sterile verrucous vegetations in rheumatic heart disease.

INFECTIVE ENDOCARDITIS

Infective endocarditis is an infection of the endocardium, cardiac valvular surfaces, or cardiac prosthesis resulting from bacterial (most common) or fungal invasion. Infective endocarditis may be acute or subacute. There are, however, no strict criteria for separating clinically acute bacterial endocarditis from subacute bacterial endocarditis (Fig. 16.36 and Table 16.21). Predisposing conditions for infective endocarditis are rheumatic heart disease (RHD), valve and myxomatous aortic valve.

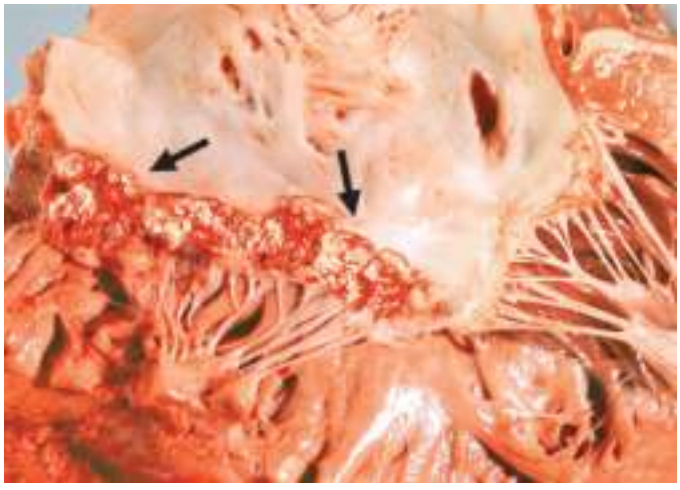

Fig. 16.36: Infective endocarditis. Large friable vegetations are seen along the margin of cusps and chordae tendineae of mitral valve. Patient presents with a 4-week history of fever, fatigue and weight loss. Physical examination revealed petechial hemorrhages and clubbing of fingers (arrows).

Table 16.21 Differences between acute and subacute bacterial endocarditis

Characteristics	Acute Bacterial Endocarditis	Subacute Bacterial Endocarditis
Heart status	Previously normal	Previously diseased
Onset	Rapid onset	Gradual onset
Pathogen's virulence	Highly virulent organisms, e.g. *Staphylococcus aureus*	Less virulent organisms β-hemolytic streptococci
Cardiac vegetations size and location	More bulky and friable, present along edges of cusps	Less bulky and present along edges of cusps myocardium
Nature of lesions	More erosive and destructive lesions result in perforation of cusps (quite common) and chordae tendineae	Less erosive and destructive lesions may cause perforation of cusps (less common)
Myocardial involvement	Myocardium microabscesses ++++	Myocardium microabscesses ++
Clinical features	Fever high-grade with chills and arthralgia ++	Fever slight (flu-like syndrome)
Physical examination	▪ Splenomegaly present ▪ Splinter hemorrhages due to microemboli beneath nails known as Janeway's lesions	▪ No splenomegaly ▪ No splinter hemorrhages beneath nails (Janeway's lesions absent)
Auscultation	Cardiac murmurs are quite common	Cardiac murmurs may be present

- **Cardiac valves affected:** Mitral valve is most frequently involved, followed by the aortic, tricuspid, and the pulmonary valves in infective endocarditis cases. The mitral valve along with the aortic valve is involved in about 40% of cases. The tricuspid valve is involved in >50% of cases of endocarditis due to intravenous drug abuse, in whom endocarditis is most often caused by *Staphylococcus aureus* infection.
- **Risk factors:** Infective endocarditis occurs most commonly secondary to bacterial pathogens. Predisposing factors include dental procedures, immunodeficiency, intravenous drug addicts, surgery, tooth extractions, venous access devices, such as central or peripheral catheters and artificial heart valves.
- **Source of infection:** Organisms reach the endocardium by hematogenous route from oropharynx flora (dental procedures), skin flora, gastrointestinal tract flora, and genitourinary procedure and lung infections.
  - **Highly virulent bacteria:** *Staphylococcus aureus* produces abscess at multiple sites in >30% of cases.
  - **Low virulent bacteria:** These include streptococci group A and B (55%), oropharyngeal flora HACEK (e.g. Haemophilus, Actinobacillus, Cardiobacterium, Eikenella, Kingella), enterococci-penicillin resistant (6%) by genitourinary manipulations. *Streptococcus viridans* and Staphylococcus may be indolent or associated with minimal symptoms.

ACUTE ENDOCARDITIS

Acute endocarditis is caused by highly virulent bacteria. *Staphylococcus aureus* produces an acute bacterial endocarditis in previously normal heart in 50% of cases. Acute endocarditis is often secondary to infection occurring elsewhere in the body.

Cardiac Vegetations

Cardiac vegetations are large, bulky, destructive, and extremely friable on the cardiac valve cusps that can extend onto the chordae tendineae, hence predisposing to systemic embolization producing infected infarcts in various organs in patients with acute endocarditis.

Clinical Features

The symptoms are more pronounced which develop acute endocarditis much rapidly. Fever is most consistent sign in 95% of cases.

Blood Cultures

Blood cultures are positive in 95% of cases. Negative blood culture is either due to deep seated organisms covered by fibrin, or prior antibiotic therapy and endocarditis caused by fungus, Coxiella or Chlamydia.

SUBACUTE ENDOCARDITIS

Subacute endocarditis is caused by low-virulent bacteria Streptococcus viridans in >50% of cases or fungi (e.g. Candida and Aspergillus).

Predisposing Factors

Subacute endocarditis tends to occur in patients with congenital heart disease or pre-existing valvular heart disease or acquired.

- Congenital heart diseases such as atrial septal defect (ASD), ventricular septal defect (VSD), patent ductus arteriosus, coarctation of aorta, tetralogy of Fallot, and mitral valve prolapse lead to subacute endocarditis.
- Acquired causes include chronic rheumatic endocarditis, prosthetic valve, syphilitic aortitis, calcific aortic stenosis, arteriovenous fistula and degenerative heart disease.

Cardiac Vegetations

Cardiac vegetations are smaller, less fragile, and associated with fewer destructive lesions in subacute endocarditis. Thrombus formation and septic embolization can subsequently occur.

Clinical Features

Patient presents with gradual onset of nonspecific symptoms such as slight fever (flu-like syndrome).

Pathology Pearls: Complications of Infective Endocarditis

Complications of infective endocarditis include destruction of cardiac valves, dissemination of bacteria, embolization and immune complex formation (Figs 16.37 and 16.38). Remote embolic complications of infective endocarditis are given in Table 16.22.

Destruction of Cardiac Valves

- Endocarditis may impede the blood flow and cause turbulence reflecting cardiac murmurs. As the disease advances, bacteria may destroy parts of the cardiac valve and cause cardiac valve perforation, rupture of chordae tendineae, or abscesses at the base of the cusps.
- All these pathologic changes adversely affect the function of cardiac valve and may cause valvular insufficiency. Stenosis of cardiac valve may also develop, even though more often it is found in the healing stages of the disease, characterized by fibrosis and dystrophic calcification of cusps. Cardiac vegetations are demonstrated by echocardiography.

Dissemination of Bacteria

- The entry of bacteria into the circulation results in bacteremia that causes bronchopneumonia. The patient typically has symptoms of sepsis.
- Positive blood culture will reveal bacteria as the cause of these relatively nonspecific symptoms.

Embolization

- Fragments of infected cardiac vegetations are carried by the blood, lodging in terminal arteries.
- Such microemboli interrupt the blood supply to the affected areas resulting in septic infarcts in various organs, i.e. brain (cerebral strokes), retina, spleen, kidney (glomerulonephritis and renal infarct) and digits.
- Thromboemboli from tricuspid valve endocarditis may result in bronchopneumonia and pulmonary infarcts.

Immune Complex Deposition

- Antibodies formed against bacterial antigens are released in the infected endocardial vegetations. These immune complexes circulate in the blood and are deposited in the wall of glomeruli and small blood vessels resulting in rupture.
- Patients develop Roth's retinal hemorrhages, Osler's nodes (painful nodules on pads of the fingers and toes), glomerulonephritis and Janeway's lesions.
- Janeway's lesions are splinter hemorrhages (linear red streaks) on palms, soles beneath nails; due to rupture of small vessels by microemboli.

Clinical Pearls: Laboratory Diagnosis of Infective Endocarditis

- **Blood culture:** Serial blood cultures two to six specimens over 48 hours have been shown to confirm the diagnosis of infective endocarditis in 95% of cases. Blood culture is negative either due to deep seated colonies of organisms, covered by fibrin or prior antibiotic therapy and infective endocarditis due to organisms like fungus, Coxiella or Chlamydia.
- **Electrocardiogram study (ECG):** ECG may show prolongation of the P-R interval or bundle branch block.
- **Echocardiography:** Echocardiography is done to localize the lesion in heart.
- **Blood Investigations:** Peripheral smear shows leukocytosis and anemia. Erythrocyte sedimentation rate (ESR) is raised.

Fig. 16.38: Complications of infective endocarditis. It shows splinter hemorrhage on index finger and thumb.

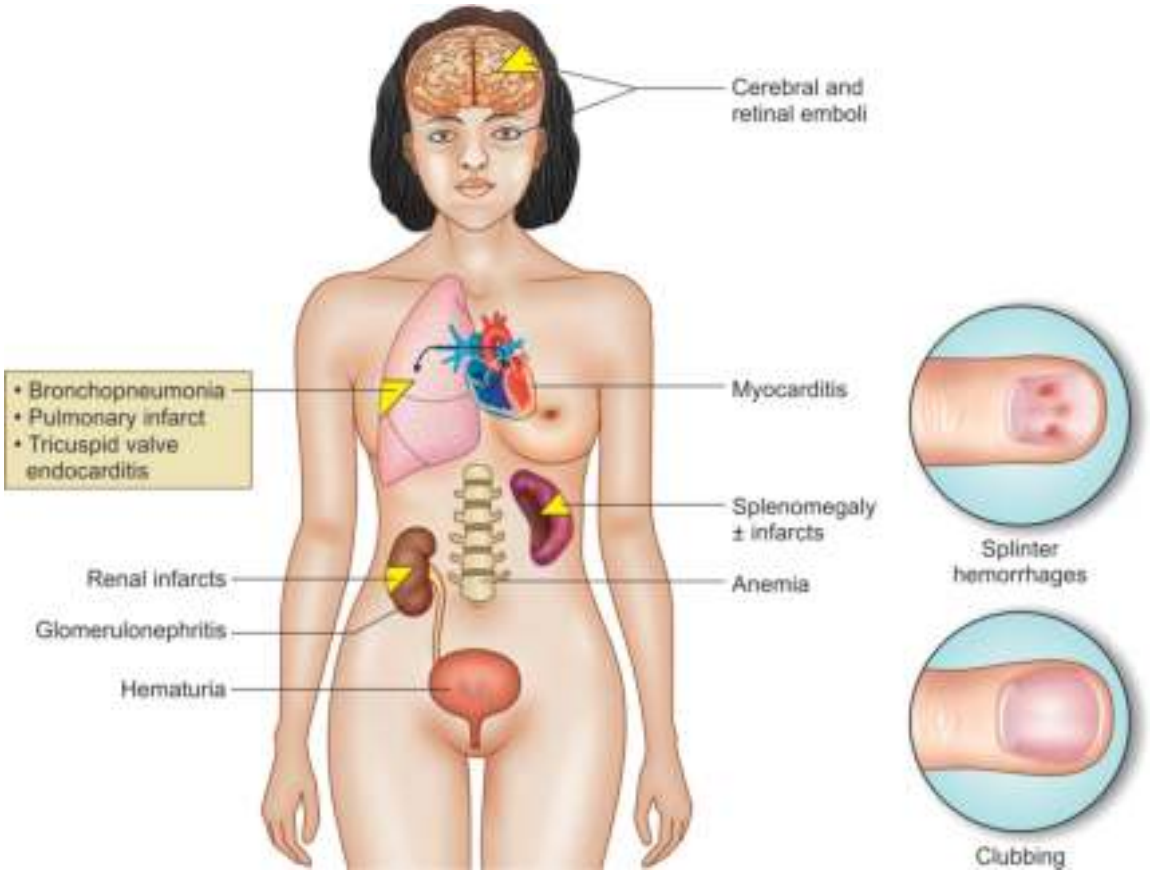

Fig. 16.37: Complications of infective endocarditis. Septic emboli may lodge in various organs causing infarcts, bronchopneumonia and splinter hemorrhages.

ENDOCARDITIS IN PROSTHETIC VALVES

Prosthetic valve endocarditis accounts for approximately 20% of all clinically diagnosed cases of endocarditis. Aortic valve is commonly affected along the suture of prosthetic valve, which occurs in two forms, i.e. early-onset and late-onset.

- Early-onset endocarditis occurs within 60 days of cardiac valve surgery (i.e. plastic, metal and bioprosthesis of animal origin) in 2 or 3% of patients. It occurs either due to contamination during surgery or with drug resistant pathogens in postoperative period. *Staphylococcus aureus* and *Staphylococcus epidermidis* account for >50% of infections, gram-negative bacteria and fungi (Candida, Aspergillus).
- Late-onset endocarditis occurs after 60 days of cardiac valve replacement in 0.5% of patients. It is usually related to transient bacteremias. It is most often caused by Staphylococcus (50%) and *Streptococcus viridans* (40%).
- The most important complications of prosthetic valve include thromboembolism, paravalvular leaks, mechanical malfunction, mechanical deterioration (rupture and calcification of valves), microangiopathic hemolytic anemia with hemoglobinuria and mechanical dysfunction with heart failure. The thrombi developing on the prosthetic valves may also become infected.

ENDOCARDITIS IN INTRAVENOUS DRUG ABUSE

Intravenous drug abuse persons develop endocarditis due to *Staphylococcus aureus* (50% of cases), streptococci (15% of cases), enterococci and opportunistic fungal infections, i.e. Candida and Aspergillus.

- Tricuspid valve (55% of cases) is most often affected in drug addicts followed by bicuspid valve (20% of cases) and aortic valve (25% of cases) (Fig. 16.39).

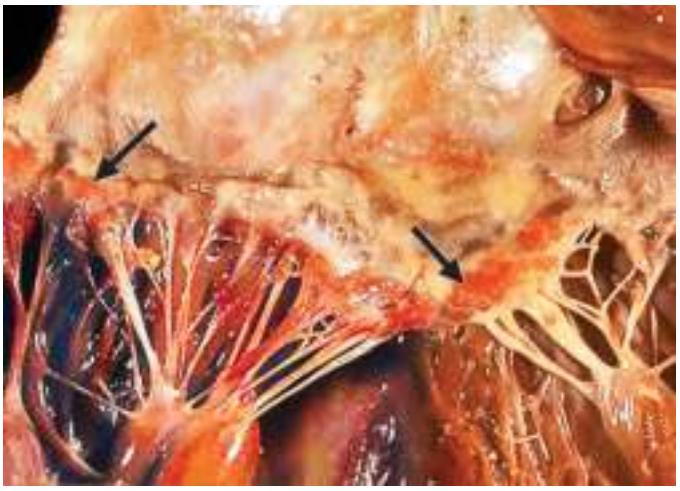

Fig. 16.39: Libman-Sacks endocarditis in SLE. The verrucous 1 to 2 mm, multiple, sterile widely spaced vegetations along margins of the mitral valve and less commonly tricuspid valve in 30–50% of cases of systemic lupus erythematosus. These vegetations usually heal without residual effect (arrows).

- Patient with prosthetic valve endocarditis may develop cellulitis, thrombophlebitis and embolic episodes in femoral arteries and lungs. It is worth mentioning that tricuspid valve may also be affected in patients with indwelling catheters, cardiac surgery, ventricular septal defects and carcinoid tumors.

LIBMAN-SACKS ENDOCARDITIS

In patient with systemic lupus erythematosus (SLE), endocarditis is the most striking cardiac lesion, termed Libman-Sacks endocarditis in 10–30% of patients. Immune complex-mediated injury of the valvular endocardium results in formation of sterile cardiac vegetations.

- Cardiac vegetations in Libman-Sacks endocarditis are 1–4 mm in size widely spaced, present on the undersurface of the mitral valve (most common) close to the origin of the leaflets from the valve ring.

Table 16.22 Remote embolic complications of infective endocarditis

Organs	Clinical Manifestations
Brain	Infarction of brain with secondary hemorrhage from embolus to anterior cerebral arteries, small infarcts of basal ganglion
Retina	Embolus in ocular fundus with retinal infarction and petechial hemorrhages
Hands skin and fingers	Multiple petechial hemorrhages of skin and clubbing of fingers
Mucous membrane	Petechial hemorrhages of mucous membrane
Kidneys	Petechial hemorrhages
Spleen	Mycotic aneurysms of splenic arteries and infarct of spleen. It shows splenomegaly

Embolization is a serious complications of infective endocarditis.

Cardiac vegetations are less often present in tricuspid valve and adjacent endocardium.

- Mitral valve deformity and regurgitation may occur in Libman-Sacks endocarditis. There is fibrinoid necrosis of small vessels with focal degeneration of interstitial tissue. These cardiac vegetations can be identified in living patients by echocardiography.
- Libman-Sacks endocarditis is not a serious complication during the course of the disease. Cardiac vegetations usually heal without residual effect, hence are clinically of limited significance.

NONBACTERIAL THROMBOTIC ENDOCARDITIS

Nonbacterial thrombotic endocarditis (**NBTE**), also known as marantic endocarditis, refers to the presence of sterile cardiac vegetations on apparently normal cardiac valves, almost always in association with metastatic cancer or debilitating disorders. The principal danger of sterile cardiac vegetations is embolization to distant organs.

PATHOGENESIS

The cause of nonbacterial thrombotic endocarditis is poorly understood, but it has been attributed to increased blood coagulability and immune complex deposition.

- **Mechanical injuries during intracardiac procedures:** Thrombi are formed on sites of minute mechanical injuries of the endothelium due to intracardiac procedures, turbulent blood flow, deformed valves, and old scars in chronic rheumatic heart disease.
- **Malignant tumors:** Sterile cardiac vegetations may develop as part of a paraneoplastic syndrome in malignancies associated with procoagulant effect of circulating mucin secreting tumors of colon, pancreas and lung.
- **Cachexia:** In debilitated people, cancer, chronic infection, and defective normal repair mechanisms increase risk for NBTE. Small thrombi formed are not removed by plasminogen activators and fibrinolytic substances. These thrombi grow and transform into large excrescences.

CARDIAC VEGETATIONS

Cardiac vegetations are composed of fibrin, platelets, and red blood cells which resemble thrombi. These cardiac vegetations are sterile, measuring 1–5 mm in size, and nondestructive (single or multiple) loosely attached randomly (Fig. 16.40).

- Cardiac vegetations are present on superior surface of aortic, mitral, tricuspid and pulmonary valves as a result of mild inflammation and associated with endothelial damage.

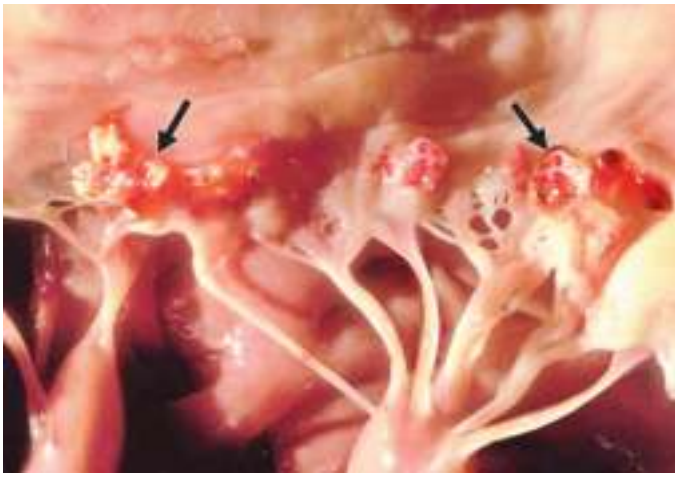

Fig. 16.40: Nonbacterial thrombotic endocarditis—sterile large vegetations are loosely attached along margins of normal cardiac valves on both sides (arrows). These are associated with cancer and wasting diseases. There is principal risk of bacterial endocarditis and embolization to brain, heart, lungs and kidneys.

- Cardiac vegetations may cause peripheral embolization to brain, heart, lungs and kidneys.

THERAPEUTIC SIGNIFICANCE

Sterile cardiac vegetations in NBTE require treatment with anticoagulants. Remember anticoagulant therapy is contraindicated in bacterial infective endocarditis. It is important to distinguish these two diseases. Administration of anticoagulants in infective endocarditis may result in fragmentation of cardiac vegetations and embolization to distant organs.

ENDOCARDITIS IN RHEUMATIC HEART DISEASE

Cardiac vegetations in rheumatic heart disease are sterile measuring 1–2 mm in diameter, present along the line of opposition of cusps and chordae tendineae. These cardiac vegetations are never present behind cusps (Fig. 16.41).

CARDIAC VALVES INVOLVED

Frequency of cardiac valves involved in rheumatic heart disease includes: (a) mitral valve (75–80%), (b) aortic valve (30%), (c) mitral and aortic valves (25%), (d) mitral and tricuspid valves (<5%) and (e) pulmonary valve (rare).

- These cardiac vegetations with super-added infection lead to subacute bacterial endocarditis.
- Subacute bacterial endocarditis in RHD patients is caused by *Streptococcus viridans* and treated with high doses of intravenous antibiotics.

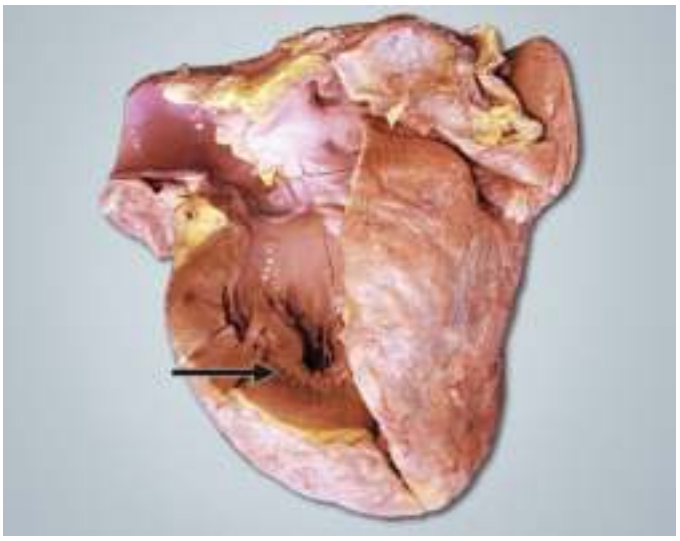

Fig. 16.41: Rheumatic heart disease. Sterile vegetations are seen along margin of mitral valve (arrow).

RIGHT-SIDED ENDOCARDITIS IN CARCINOID SYNDROME

Right-sided endocarditis in carcinoid syndrome is caused by secretory products of intestinal carcinoid tumors, i.e. vasoactive amines (serotonin) and vasoactive peptide hormones (somatostatin and glucagon).

PATHOGENESIS

- The secretory products of nonmetastasizing intestinal carcinoid tumor are inactivated and metabolized in liver and lungs.
- In case of metastases of carcinoid tumor to liver, the secretory products of carcinoid tumor enter circulation, reach to right-sided heart and cause tricuspid valve regurgitation and pulmonary trunk stenosis.
- Cardiac valves on the left side of the heart are rarely involved, because serotonin and other carcinoid secretory products are detoxified in the lung. These valvular lesions heal by fibrosis in cases of carcinoid syndrome.

CLINICAL FEATURES

Patient presents with cutaneous flushing, diarrhea, and valvular disease (tricuspid regurgitation and pulmonary trunk stenosis). Comparison of cardiac vegetations in various disorders involving endocardium is shown in Fig. 16.42A to D and Table 16.23.

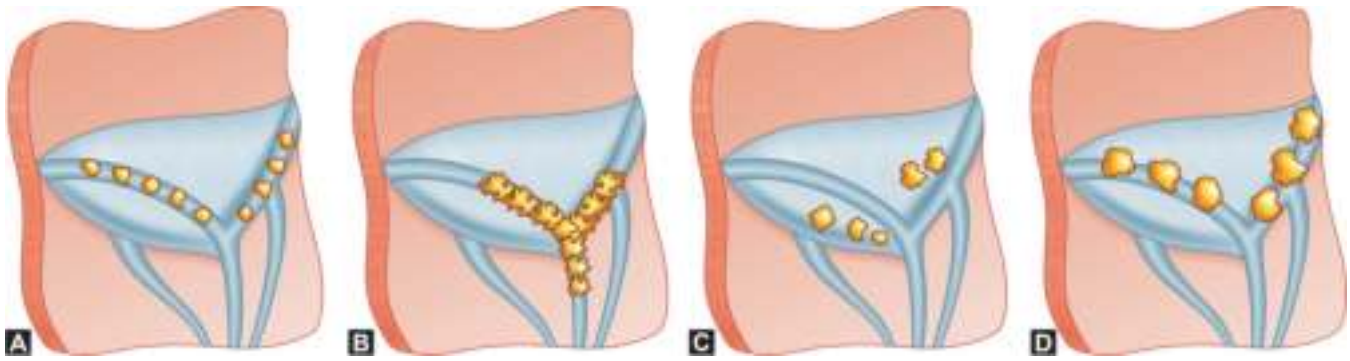

Fig. 16.42: Cardiac vegetations. (A) Cardiac vegetation in RHD, (B) infective endocarditis (IE), (C) Libman-Sacks endocarditis (LSE), (D) nonbacterial thrombotic endocarditis (NBTE).

Table 16.23 Comparison of cardiac vegetations in various disorders involving endocardium

Parameters	Rheumatic Fever	Nonbacterial Thrombotic Endocarditis	Libman-Sacks Endocarditis (SLE)	Infective Endocarditis
Etiology	Group A Streptococcus β-haemolyticus	Hypercoagulable state, mucin secreting carcinoma of colon and pancreas	Autoimmune disorder	Infective organisms
Mechanism	Type 2 and Type 4 hypersensitivity reaction (molecular mimicry)	Noninflammatory disorder	Immune complex mediated by DNA-anti-DNA autoantibody	Acute inflammation
Size of cardiac vegetations	1–2 mm size firm and warty	1–5 mm single/multiple friable results in embolism	1–4 mm single or multiple widely spaced	Large, friable bulky loosely attached to valves

Contd...

Table 16.23 Comparison of cardiac vegetations in various disorders involving endocardium (*Contd...*)

Parameters	Rheumatic Fever	Nonbacterial Thrombotic Endocarditis	Libman-Sacks Endocarditis (SLE)	Infective Endocarditis
Nature	Sterile, nondestructive	Sterile nondestructive	Sterile small and non-destructive	Infective, destructive
Composition	Aschoff's nodule	Fibrin, platelets, and RBCs	Fibrin, platelets, and RBCs	Acute inflammation in PMN with bacteria
Location	Along the lines of closure of valvular cusps	Along the lines of closure of cusps or both sides of valvular cusps	Present on both sides of mitral valvular cusps. Most common on inferior surface. Pocket of valves. Less common on mural endocardium	Upper surface of valvular cusps. It can extend to the chordae tendineae
Valves affected	Mitral valve (75–80%), aortic valve (30%), mitral valve and aortic valve (25%), tricuspid valve and pulmonary valve <5%	Any cardiac valve	Mitral valve (most common), tricuspid valve +ve	Aortic, tricuspid and pulmonary values
Chances of embolization	Low incidence	High incidence	Absent	High incidence
Blood test	Antistreptolysin *O* titer raised	Not diagnostic	LE cells preparation	Blood culture positive (95%)

DISORDERS OF CARDIAC VALVES

CARDIAC VALVULAR DISORDERS: OVERVIEW

Cardiac valvular diseases most often occur as a result of rheumatic heart disease or secondary to various inflammatory processes.

- Prosthetic valves are the site of thrombus formation or development of infective endocarditis.
- Prosthetic valves cause mechanical disruption of red blood cells which result in hemolytic anemia with formation of schistocytes. Major causes of cardiac valve disease are given in Tables 16.24 to 16.28.

Table 16.24 Pathological causes and clinical manifestations of mitral and aortic valvular diseases

Cardiac Valvular Disease	Cause	Effects on Organs	Physical Findings
Mitral valve stenosis	Rheumatic heart disease	▪ Left heart failure with predisposition to atrial thrombus ▪ Left atrial dilated ▪ Pulmonary edema ▪ Right heart failure	▪ Left atrium and right ventricle hypertrophy ▪ Rumbling late diastolic murmur following a loud S1 sound open snap ▪ Fine crepitations on auscultation
Mitral valve regurgitation	▪ Acute myocardial infarction involving papillary muscle ▪ Rheumatic heart disease ▪ Floppy mitral valve prolapse syndrome ▪ Hypertrophic obstructive CMP ▪ Blunt injury to mitral valve	▪ Left heart failure ▪ Pulmonary edema ▪ Left ventricular hypertrophy and dilation resulting in left heart failure ▪ Progressive left heart failure ▪ Impairs ventricular filling and resulting in increased pressure in left atrium and pulmonary veins	▪ Variable hemodynamic effects ▪ Pansystolic murmur

Contd...

Table 16.24 Pathological causes and clinical manifestations of mitral and aortic valvular diseases (*Contd...*)

Cardiac Valvular Disease	Cause	Effects on Organs	Physical Findings
Aortic valve stenosis	▪ Rheumatic heart disease ▪ Calcification in congenital bicuspid aortic valve ▪ Senile cardiac valve degeneration	▪ Progressive left ventricular hypertrophy ▪ Left heart failure ▪ Pulmonary congestion ▪ Coronary arteries insufficiency	▪ Early systolic ejection murmur reaching peak intensity in mid- and late-systole at apex of left sternal border ▪ Narrow pulse pressure ▪ Slow rising of carotid artery pressure ▪ Angina pectoris, syncope and sudden cardiac death
Aortic valve regurgitation	*Acute aortic valve regurgitation due to:* ▪ Endocarditis ▪ Chest trauma ▪ Prosthetic valve dysfunction ▪ Aortic dissection ▪ Cystic medial necrosis ▪ Marfan's syndrome *Chronic aortic regurgitation occurs due to:* ▪ Rheumatic heart disease ▪ Hypertension ▪ Marfan's syndrome ▪ Syphilitic aortitis ▪ Ankylosing spondylitis ▪ Ventricular septal defect	▪ Left ventricular hypertrophy and dilation ▪ Progressive development of left heart failure	▪ High pitched blowing diastolic murmur following an open snap ▪ Collapsing pulse ▪ Wide pulse pressure

Pulmonary artery stenosis occurs in the setting of tetralogy of Fallot, carcinoid heart disease and rarely in rheumatic heart disease.
Calcific aortic stenosis occurs due to rheumatic heart disease, senile calcific aortic stenosis and congenital aortic stenosis.

Table 16.25 Major causes of mitral valve disease

Mitral Stenosis		
▪ Rheumatic heart disease ▪ Infective endocarditis with large vegetations ▪ Congenital (parachute valve, cor triatriatum)	▪ Severe mitral annular calcification with leaflet involvement ▪ Systemic lupus erythematosus	▪ Rheumatoid arthritis ▪ Myxoma tumor
Mitral Regurgitation		
▪ Acute mitral regurgitation ▪ Infective endocarditis ▪ Papillary muscle rupture following myocardial infarction ▪ Chordae tendineae rupture/leaflet flail (mitral valve prolapse, infective endocarditis) ▪ Blunt injury to mitral valve ▪ Chronic causes primarily involving leaflets and chordae tendineae	▪ Rheumatic heart disease ▪ Healed infective endocarditis ▪ Myxomatous change (mitral valve prolapse, Barlow's forme fruste) ▪ Congenital mitral regurgitation ▪ Chronic causes involving leaflets, chordae tendineae as 'innocent bystanders' ▪ Ischemic cardiomyopathy	▪ Congestive cardiomyopathy ▪ Hypertrophic cardiomyopathy (HCM) ▪ Chronic atrial fibrillation with left atrial enlargement and annular dilatation ▪ Mitral annular calcification

MITRAL VALVE STENOSIS

Mitral valve is most commonly affected in chronic rheumatic heart disease, which undergoes fibrosis and dystrophic calcification, with fusion of the commissures resulting in stenosis giving fish-mouth appearance (Fig. 16.43).

CONSEQUENCES

Mitral valve stenosis hampers normal blood flow from left atrium to left ventricle during diastole. It leads to hypertrophy of the left atrium, pulmonary congestion and brown induration; and hypertrophy of right ventricle.

Table 16.26 Major causes of aortic valve disease

Aortic Stenosis
▪ Rheumatic heart disease ▪ Senile calcific aortic stenosis
Aortic Regurgitation
▪ Valvular causes • Endocarditis • Rheumatic fever • Aortic prolapse (myxomatous change) • Traumatic injury • Syphilitic aortitis • Ankylosing spondylitis ▪ Aortic root disease • Aortic dissection • Marfan syndrome • Bicuspid aortic valve • Systemic hypertension • Aortitis ▪ Nonsyndromic familial aneurysm

Table 16.27 Causes of tricuspid valve disease

Tricuspid Stenosis
▪ Rheumatic heart disease ▪ Congenital mitral valve stenosis
Tricuspid Regurgitation
▪ Primary (structural) causes • Rheumatic heart disease • Endocarditis (intravenous drug abuse) • Myxomatous changes causing tricuspid valve prolapse • Carcinoid heart disease • Radiation induced tricuspid regurgitation • Congenital tricuspid regurgitation (Ebstein's anomaly) • Traumatic injury • Papillary muscle injury following myocardial infarction
▪ Secondary (functional) causes producing right ventricular and tricuspid annular dilatation due to multiple causes of right ventricular enlargement due to the following: • Long-standing pulmonary hypertension • Remodeling of post-right ventricular hypertrophy following myocardial infarction • Left sides valve disease • Cardiomyopathy • Atrial fibrillation

CLINICAL FEATURES

The patient presents with chest pain, palpitations, fatigue, dizziness, breathlessness, orthopnea and hemoptysis secondary to pulmonary congestion, dysphagia for solids owing to left atrial enlargement, abdominal pain due to hepatomegaly and leg swelling.

- Mural thrombi in left atrium result in systemic embolization dislodged by atrial fibrillation.

Table 16.28 Causes of pulmonic valve disease

Pulmonic Stenosis
▪ Congenital pulmonic stenosis ▪ Carcinoid heart disease ▪ Endocarditis ▪ Tumor
Pulmonic Regurgitation
▪ Primary pulmonic valve disease • Congenital pulmonic valve regurgitation • Post-valvotomy • Endocarditis • Carcinoid heart disease ▪ Annular enlargement • Pulmonary hypertension • Idiopathic dilatation of pulmonic valve • Marfan's syndrome

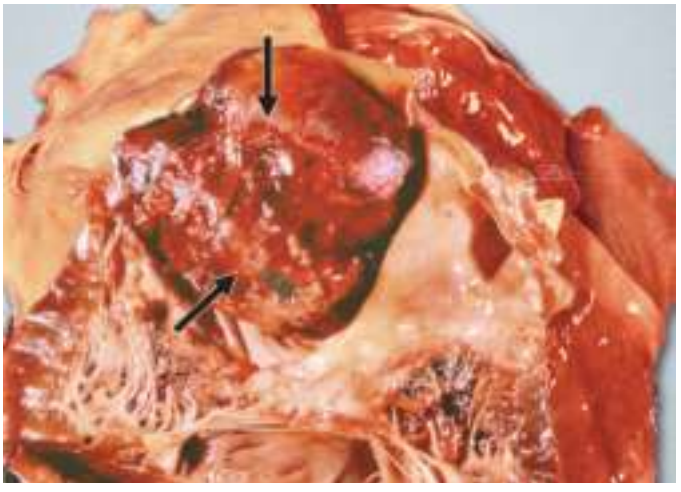

Fig. 16.43 Mitral valve stenosis. Ball thrombus (arrows) in the left atrium is complication in mitral stenosis and atrial fibrillation.

- Turbulent blood flow through the mitral stenosis leads to mid-diastolic murmur heard best at apex.

MITRAL VALVE INSUFFICIENCY/ REGURGITATION

Mitral valve insufficiency/regurgitation usually occurs due to rheumatic heart disease. It can also result from mitral valve prolapse, hypertrophic obstructive cardiomyopathy, damage to papillary muscle in myocardial infarction, ruptured chordae tendineae and transposition of great arteries. It can be secondary to left ventricular dilatation, with stretching of the mitral valve ring. Blood from the left ventricle flows back into the left atrium during systole, causing the atrium enlargement to accommodate the backflow. Patient eventually leads to left-sided and right-sided heart failure.

CLINICAL FEATURES

Patient presents with exertional dyspnea, paroxysmal nocturnal dyspnea, orthopnea, weakness, fatigue and palpitations. Physical examination reveals peripheral edema, jugular vein distension, ascites, and hepatomegaly due to right-sided heart failure. On auscultation, crackles and a loud S1 or opening snap and holosystolic murmur are heard at the apex.

MITRAL VALVE PROLAPSE

Mitral valve prolapse is the most frequent valvular lesion resulting in mitral valve insufficiency. Normally, mitral valve closes during systole. Mitral valve prolapse commonly affects young women. It most often occurs patients with Marfan's syndrome (90%) (Fig. 16.44).

PATHOGENESIS

Mitral valve prolapse shows myxoid degeneration of ground substance due to stromal accumulation of glycosaminoglycans. Architecture of the mitral valve is maintained and shows elongation and thinning of chordae tendineae of mitral valve. It leads to stretching of the posterior valve leaflet resulting in floppy cusp, i.e. parachute deformity with prolapse into the left atrium during systole.

CONSEQUENCES

Regurgitation of the blood across the incompetent mitral valve leads to reflux of blood from left ventricle into left atrium. Back pressure is transmitted to lungs resulting in pulmonary congestion and then right-sided heart failure.

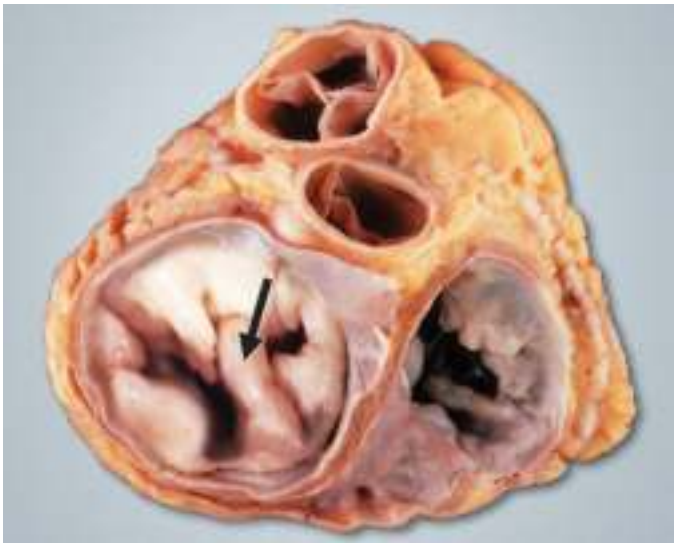

Fig. 16.44: Mitral valve prolapse. Many patients are asymptomatic. There is increased risk of cerebral embolism (arrow).

CLINICAL FEATURES

Patient presents with pulmonary symptoms, i.e. breathlessness and cough occurring late in the disease. Regurgitation of the blood across mitral valve prolapse presents with pansystolic murmur radiating into the axilla heard best at the apex on auscultation and increases in intensity on expiration. Mid-systolic click can be heard on auscultation in cases of mitral valve prolapse.

COMPLICATIONS

Mitral valve prolapse is often associated with cardiac arrhythmias. Infective endocarditis with arterial embolization is a possible consequence of mitral valve prolapse. Antibiotic prophylaxis for dental procedures is recommended.

AORTIC VALVE STENOSIS

Aortic valve is frequently involved in rheumatic heart disease. Normally, aortic valve is closed during diastole. Aortic valve stenosis prevents the outflow of blood from left ventricle into the aorta during systole. Aortic valve stenosis may result from rheumatic fever, idiopathic aortic valve fibrosis and calcification of aortic valve in old age >60 years and congenital aortic bicuspid valve.

CLINICAL FEATURES

Aortic valve stenosis increases blood pressure inside the left ventricle resulting in concentric ventricular hypertrophy associated with decreased chamber size.

- Patient develops left ventricular failure leading to pulmonary congestion and right heart failure.
- Patient presents with breathlessness, cough, syncope, chest pain or sudden death. High-pitched ejection systolic murmur is heard on auscultation.

AORTIC VALVE INSUFFICIENCY/ REGURGITATION

Aortic valve insufficiency/regurgitation is the incomplete closure of the aortic valve. During diastole, blood from aorta flows back into the left ventricle resulting in dilatation of chamber and eccentric ventricular hypertrophy.

- Stroke volume is increased often >100 ml. Widening of pulse pressure leads to hyperdynamic circulation, i.e. water-hammer pulse.
- Ultimately, it leads to left-sided heart failure and pulmonary edema. Aortic valve insufficiency can be acute or chronic and usually caused by scarring or retraction of valve leaflets.

ETIOLOGY

- **Acute aortic valve insufficiency:** It occurs due to endocarditis, chest trauma, prosthetic valve malfunction, acute ascending aortic dissection and non-dissecting aneurysm due to cystic medial necrosis.
- **Chronic aortic valve insufficiency:** It occurs due to hypertension, chronic rheumatic heart disease, Marfan's syndrome, ankylosing spondylitis, syphilitic aortitis and ventricular septal defect.

CLINICAL FEATURES

Patient develops left-sided heart failure and pulmonary congestion, and presents with dyspnea, orthopnea, paroxysmal nocturnal dyspnea, fatigue, palpitation and exercise intolerance. Auscultation reveals S3 heart sound and high-pitched blowing diastolic murmur at left sternal border.

CALCIFIC AORTIC STENOSIS

Calcific aortic stenosis refers to narrowing of the aortic valve orifice as a result of the deposition of calcium in the valve cusps and ring (Fig. 16.45).

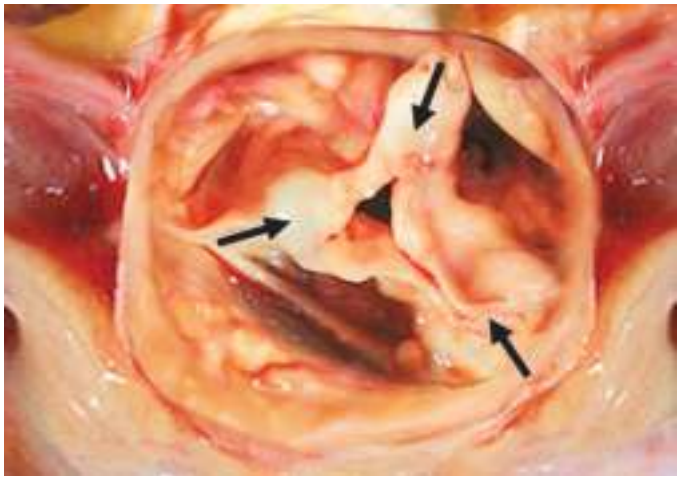

Fig. 16.45: Calcific aortic stenosis. A 75-year-old man presented with history of recurrent syncope underwent surgery for aortic valve disease. Valve was markedly deformed and calcified (arrows).

PATHOGENESIS

Calcific aortic stenosis occurs due to rheumatic disease, senile calcific stenosis, and congenital aortic stenosis. It is related to the cumulative effect of years of trauma due to turbulent blood flow around the aortic valve. It becomes progressively narrowed with some degrees of regurgitation.

TRICUSPID VALVE INSUFFICIENCY

Tricuspid valve insufficiency secondary to bacterial endocarditis is one of the most common complications of intravenous drug abuse. It may be involved together with the mitral and aortic valves in 5% cases of rheumatic heart disease. The cardiac lesions consist of plaque-like deposits of dense fibrous tissue on the tricuspid and pulmonary valves.

PULMONIC VALVE STENOSIS

Pulmonic valve stenosis usually occurs due to congenital malformations either alone or in tetralogy of Fallot. Pulmonic valve stenosis may be involved in the carcinoid syndrome.

CARCINOID HEART DISEASE

The cardiac lesions in carcinoid syndrome consist of plaque-like deposits of dense fibrous tissue on the tricuspid and pulmonary valves in the carcinoid syndrome.

CLINICAL FEATURES

Patient develops tricuspid valve insufficiency and pulmonary valve stenosis in carcinoid heart disease due to release of active tumor products, characterized by diarrhea, flushing, bronchospasm, and skin lesions. Increased excretion of 5-HIAA (5-hydroxyindoleacetic acid), a metabolite of serotonin in urine, is diagnostic of carcinoid syndrome.

DISORDERS OF PERICARDIUM

ANATOMY AND PHYSIOLOGY

Pericardium of heart consists of outer parietal and inner visceral layers, which are intimately related to the myocardium.

- Pericardial cavity contains 20–50 ml of fluid, which provides protection to the heart and prevents intracardial pressure changes associated with postural variation and respiration.
- Pericardium surrounds heart and helps it function properly. It also covers the roots of major blood vessels as they extend from heart.
- Pericardium minimizes friction of pericardial layers.

- Pericardium facilitates atrial filling during ventricular systole, prevents sudden dilatation of chambers during exercise and increased blood volume.
- Pericardium prevents displacement of heart and kinking of the blood vessels and prevents spread of infection from lung and pleura to heart.

PERICARDIAL EFFUSION

Pericardial effusion is sudden excessive collection of fluid in the pericardial sac without cardiac chamber enlargement beyond the 20–50 ml normally present. There is filling of the retrosternal space, and effacement of the normal cardiac borders giving a 'water bottle configuration'. Causes of transudative pericardial effusion include cardiac surgery, congestive heart failure, uremia, myxedema and collagen vascular diseases.

- Pericardial exudative effusions are caused by pericarditis (e.g. fibrinous, suppurative, hemorrhagic or tubercular), metastatic deposits from lung carcinoma, breast carcinoma or lymphomas. Tubercular pericardial effusion is straw/pale-colored fluid formed by Mycobacterium tubercle bacilli.
- Laboratory diagnosis of pericardial effusion includes imaging techniques (such as X-ray chest showing water bottle configuration) and echocardiography (to demonstrate amount of fluid), complete urine analysis for proteins and sugar, liver function tests, kidney function tests, blood sugar, and fluid cytology.

HYDROPERICARDIUM

Accumulation of serous transudate in the pericardial cavity is known as hydropericardium. It is caused by congestive heart failure and hypoproteinemia. Malnutrition, chronic liver disease and nephrotic syndrome are important causes of hypoproteinemia.

HEMOPERICARDIUM

Accumulation of blood in the pericardial cavity is known as hemopericardium. It may cause cardiac tamponade with fatal outcome.

- Hemopericardium occurs due to traumatic perforation of the heart or dissecting aortic hematoma, myocardial rupture associated with acute myocardial infarction or malignant neoplasm.
- As the first part of the aorta (root) lies within the pericardial sac, rupture of the aortic wall due to aortic dissection may cause intrapericardial bleeding.

CARDIAC TAMPONADE

Rapid accumulation of excessive fluid or blood in pericardial cavity leads to cardiac tamponade, resulting in interference in cardiac filling (Figs 16.46 and 16.47).

- Cardiac tamponade is characterized by cardiogenic shock (hypotension), reduced cardiac output and raised jugular venous pressure.
- Pulsus paradoxus, the hallmark of cardiac tamponade is >10 mm falls in systolic blood pressure during inspiration.

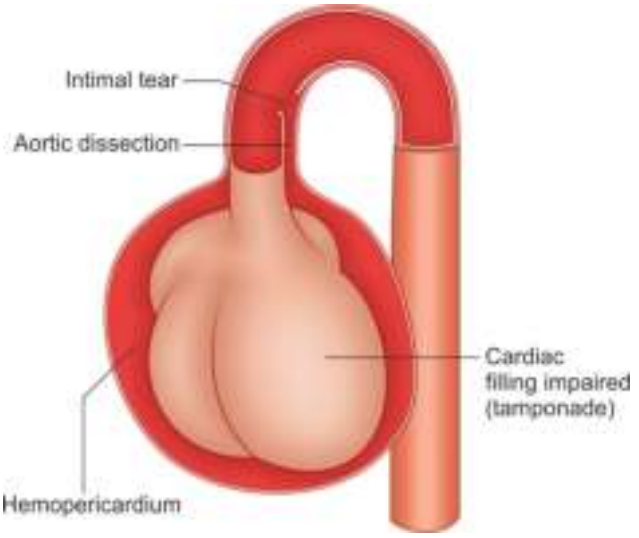

Fig. 16.46: Hemopericardium—pericardial cavity is filled with blood.

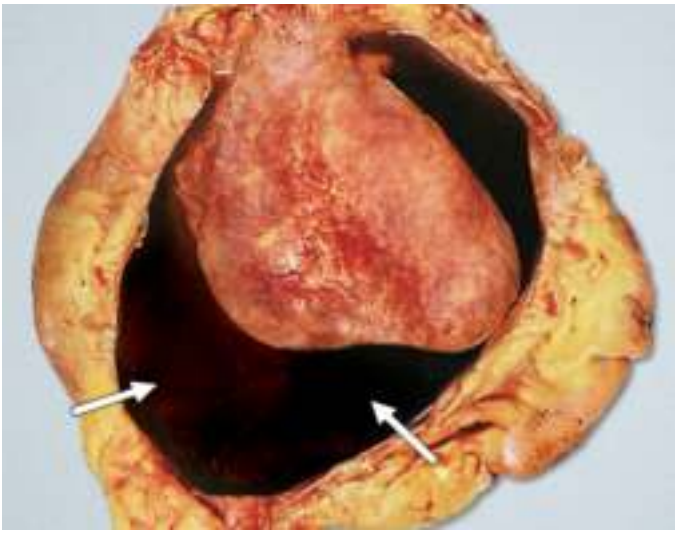

Fig. 16.47: Hemopericardium—aortic dissection may lead to hemopericardium when blood dissects through the media proximally. Such a massive amount of hemorrhage can lead to cardiac tamponade (arrows).

PERICARDITIS: OVERVIEW

Pericarditis is inflammation of the pericardium. In most instances, pericarditis is mild and unrecognized. Acute pericarditis may contain fibrinous exudate, purulent, serous, or hemorrhagic exudate. Chronic constrictive pericarditis is characterized by dense, fibrous pericardial thickening. Common symptoms of pericarditis are pain at the sternum and shallow and rapid respiration.

ETIOLOGIC CLASSIFICATION

Pericarditis is an inflammation of the pericardium that develops suddenly and may last up to several months.

- **Infective pericarditis:** Infective pericarditis can be caused by pyogenic bacteria, Mycobacterium tubercle bacilli, *Treponema pallidum*, viruses and fungi. Infection may occur after cardiac surgery.
- **Noninfective pericarditis:** Noninfective pericarditis known as 'bread and butter pericarditis' is associated with uremia, and acute myocardial infarction (Dressler syndrome), and rheumatic fever. Other causes include high dose radiation to mediastinum, or metastasis (lung, breast or lymphomas), sarcoidosis, myxedema and chylopericardium.
- **Pericarditis presumably related to hypersensitivity or autoimmunity:** Causes of pericarditis presumably related to hypersensitivity or autoimmunity include rheumatic pancarditis, rheumatoid arthritis, systemic lupus erythematosus (very common), scleroderma and drugs (e.g. procainamide and hydralazine).

Clinical classification and etiologic classification of pericarditis are given in Tables 16.29 and 16.30.

Table 16.29 Clinical classification of pericarditis

Acute Pericarditis (<6 Weeks)
▪ Fibrinous pericarditis ▪ Effusive pericarditis (serous or sanguineous type)
Subacute Pericarditis (6 Weeks to 6 Months)
▪ Effusive constrictive pericarditis ▪ Constrictive pericarditis
Chronic Pericarditis (>6 Weeks)
▪ Constrictive pericarditis ▪ Adhesive pericarditis (nonconstrictive type)

Table 16.30 Etiologic classification of pericarditis

Infective Pericarditis

- Viral pericarditis (Coxsackievirus A and B, herpesviruses, mumps, echovirus, adenovirus, HIV, hepatitis viruses)
- Pyogenic pericarditis (staphylococci, streptococci, pneumococci, *Haemophilus influenzae*, Chlamydia, Legionella, Neisseria)
- Tuberculous pericarditis (spread from mediastinal lymph node)
- Fungal pericarditis (*Histoplasma capsulatum*, Coccidioidomycosis, Candida, Blastomycosis)
- Pericarditis caused by other organisms (*Treponema pallidum*, Protozoa and parasites)

Noninfective Pericarditis

- Acute idiopathic pericarditis
- Uremic pericarditis in chronic renal failure
- Pericarditis induced by tumors
- Primary tumors of heart
- Metastatic tumors invading pericardium (lung carcinoma, breast carcinoma, lymphoma, leukemia)
- Traumatic penetrating chest injury or nonpenetrating injury to pericardium following open heart surgery
- Aortic dissection results in involvement of pericardium
- Myocardial infarction inducing fibrinous pericarditis
- Post-irradiation pericarditis
- Metabolic pericarditis (myxedema, cholesterol)
- Familial pericarditis seen in Mulibrey nanism
- Familial Mediterranean fever

Pericarditis Presumably Related to Hypersensitivity or Autoimmunity

- Fibrinous pericarditis in rheumatic fever
- Collagen vascular disorders induced pericarditis
- Systemic lupus erythematosus
- Rheumatic fever, scleroderma
- Rheumatoid arthritis
- Ankylosing spondylitis
- Wegener granulomatosis
- Drug-induced pericarditis
  - Phenytoin
  - Isoniazid
  - Procainamide
  - Hydrazine
  - Anticoagulants
  - Methysergide
  - Minoxidil
- Postcardiac injury induced pericarditis
- Post-traumatic
- Postmyocardial infarction (Dressler's syndrome)
- Postpericardiotomy

PATHOGENESIS

Pericardial tissue damaged by injurious agent releases chemical mediators of inflammation into the surrounding tissue. Chemical mediator such as histamine increases vascular permeability resulting in leakage of inflammatory exudate.

- Neutrophils, macrophages begin to phagocytose and degrade the injurious agent, remove necrotic tissues and dead inflammatory cells which are eventually reabsorbed into healthy tissue.
- Friction rub is heard on auscultation due to inflamed pericardial layers rubbing against each other.

CLINICAL FEATURES

Patient presents with sharp sudden pain at the sternum radiating to the neck, shoulders, and arms; shallow and rapid respiration, mild fever, dyspnea and orthopnea.

PHYSICAL EXAMINATION

Patient may develop congestive heart failure, i.e. elevated jugular pressure, hepatomegaly and peripheral edema. Patient develops Beck's triad (e.g. hypotension, elevated jugular venous pulse, and muffled distant heart sounds). Friction rub is appreciated on auscultation. Apex pulse may vanish. Dullness beneath angle of left scapula is known as Ewart's sign.

ACUTE PERICARDITIS

Acute pericarditis is characterized by rapid accumulation of fluid or exudate in the pericardial cavity known as pericardial effusion and usually diagnosed by echocardiography. Several pathologic forms of pericarditis are described below.

SEROUS PERICARDITIS

Serous pericarditis is associated with viral infections, rheumatic heart disease and systemic lupus erythematosus. Pericardial cavity contains clear, straw-colored, protein-rich exudate containing small numbers of inflammatory cells. These patients may develop chest pain due to pericardial effusion (Fig. 16.48).

FIBRINOUS OR SEROFIBRINOUS PERICARDITIS

Fibrinous or serofibrinous pericarditis is characterized by fibrin-rich exudate due to increased vascular permeability. It may be caused by chronic renal failure (uremia), acute myocardial infarction, or acute rheumatic fever or systemic lupus erythematosus.

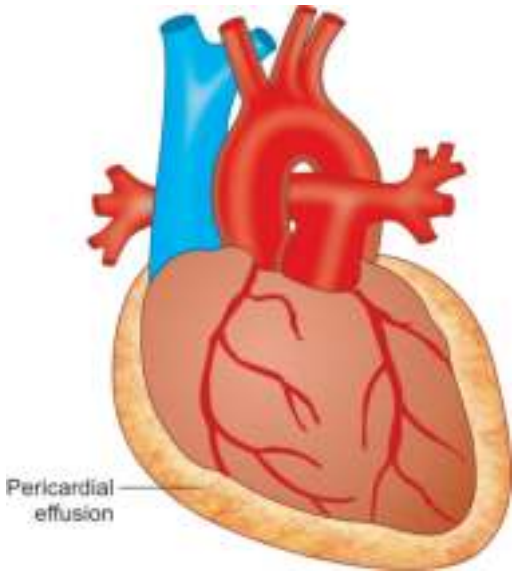

Fig. 16.48: Pericardial effusion shows accumulation of serous fluid in pericardial cavity.

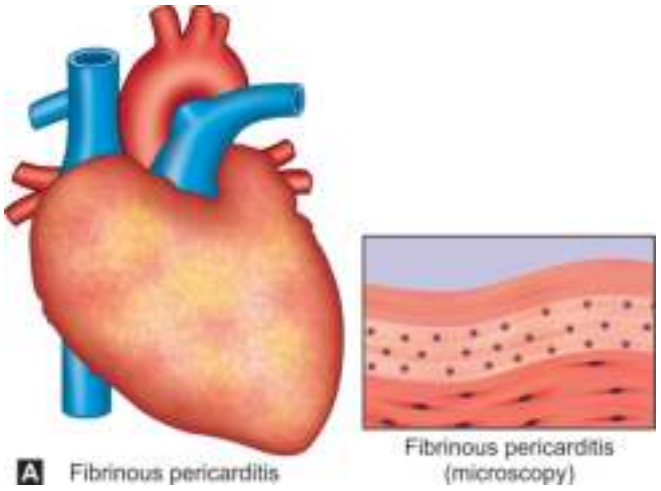

- Fibrin deposited in pericardium exhibits bread and butter appearance. Friction rub is heard on auscultation.
- Fibrinous debris may be removed by fibrinolysis and macrophages resulting in restoration of normal tissue structure.
- When fibrinogen is not removed, there is danger of obliteration of pericardial cavity due to fusion of parietal and visceral layers (Figs 16.49 and 16.50).

PURULENT OR SUPPURATIVE PERICARDITIS

Pus or purulent exudate accumulates in the pericardial cavity. It is almost always caused by pyogenic bacterial infection as a consequence of direct spread from lung infection due to *Staphylococcus aureus* or *Streptococcus pneumoniae*. Pericardium exhibits yellowish microabscesses. On histologic examination, microabscess consists of blue bacterial colonies and is surrounded by acute inflammatory cells (Fig. 16.51).

HEMORRHAGIC PERICARDITIS

Accumulation of bloody inflammatory exudate in the pericardial cavity is known as hemorrhagic pericarditis, which usually results from invasion of the pericardium by lung cancer, esophageal cancer, breast cancer or lymphomas in 5–10% of cases. Surface of the epicardium shows pale white-tan nodules of metastatic tumor. Cardiac surgery and tubercular etiology may also result in hemorrhagic pericarditis (Fig. 16.52).

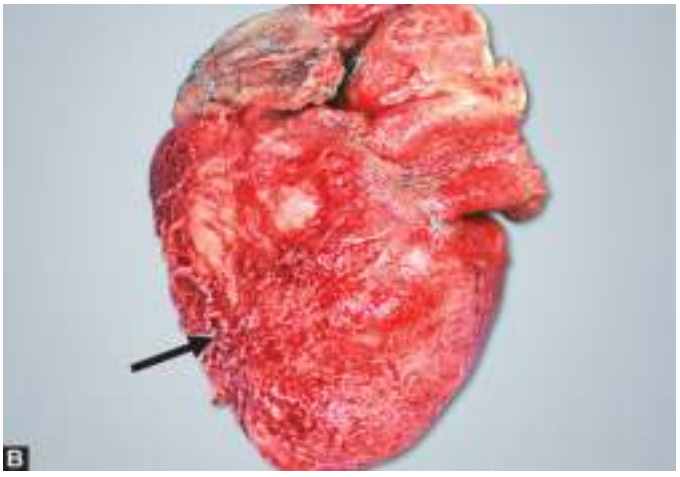

Fig. 16.49: Fibrinous pericarditis after acute myocardial infarction (arrow).

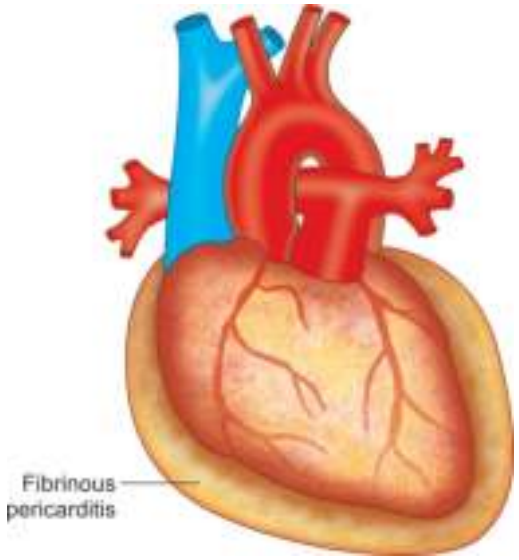

Fig. 16.50: Fibrinous pericarditis shows deposition of fibrin in pericardial sac.

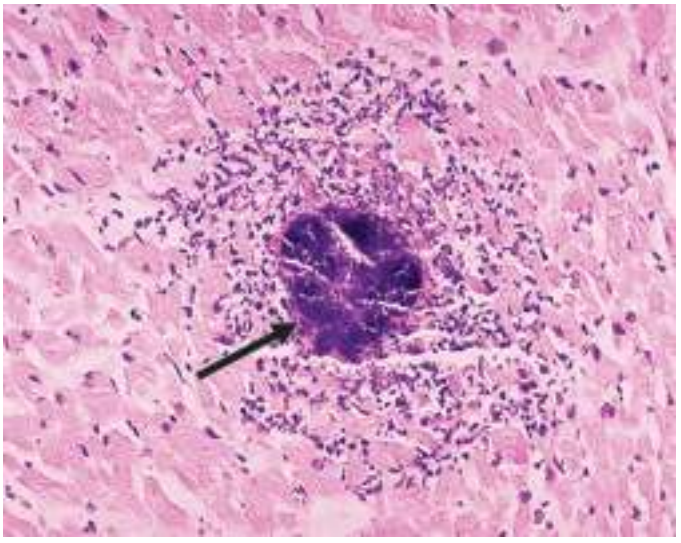

Fig. 16.51: Purulent or suppurative pericarditis. Yellowish purulent exudate is visible on the surface of pericardium. Bacterial colonies are shown (arrow).

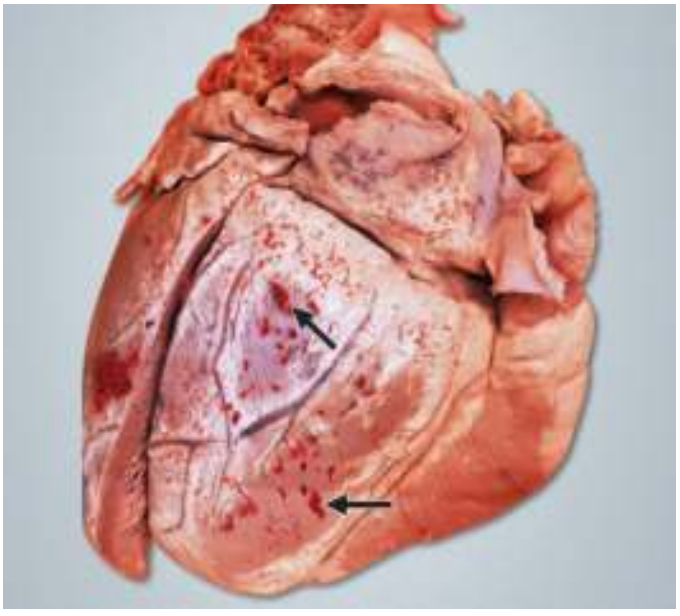

Fig. 16.52: Petechial hemorrhages on epicardium. It occurs due to low platelets count and sudden hypoxia (arrows).

CHRONIC PERICARDITIS

Patient develops chronic pericarditis, when fluid or fibrinous exudate is not removed from pericardial sac.

- Chronic pericarditis is characterized by thickening and scarring of the pericardium with resultant loss of elasticity. Proliferation of fibrous tissue with occasional small foci of calcification is marked. This prevents the pericardium from stretching and thus interferes

with cardiac function and venous return, often mimicking the signs and symptoms of right-sided heart failure.

- Patient develops obliteration of pericardial cavity due to fusion of parietal and visceral layers, known as constrictive pericarditis.
- Pericardial adhesions are formed in cases of constrictive pericarditis, which impairs cardiac filling by limiting the total cardiac volume compliance and diastolic filling function.

CONSTRICTIVE PERICARDITIS

Constrictive pericarditis represents a chronic phase of fibrous scarring, pericardial thickening and obliteration of the pericardial cavity. It can result in restriction of diastolic cardiac filling. Acute pericardial injury and exuberant healing response by forming granulation tissue leads to fusion of parietal and visceral layers of pericardium (Fig. 16.53).

Etiopathogenesis

Constrictive pericarditis may be caused by bacteria, viruses, or fungi. Previous radiation therapy to mediastinum and cardiac surgery account for one-third of cases.

- Tuberculosis is the most common cause of constrictive pericarditis. Stiffness of the pericardium is often enhanced by dystrophic calcification.
- Constrictive pericarditis restricts the heart's ability to pump effectively. The return of venous blood to the right heart is also compromised. Thickened pericardium compresses epicardial coronary artery resulting in under perfusion of the heart. Constrictive pericarditis should be differentiated from angina pectoris.

Clinical Features

Patient presents with chest pain, cough, exertional dyspnea and orthopnea. Elevated systemic venous pressure results in raised jugular venous pressure, hepatomegaly, marked ascites and peripheral edema.

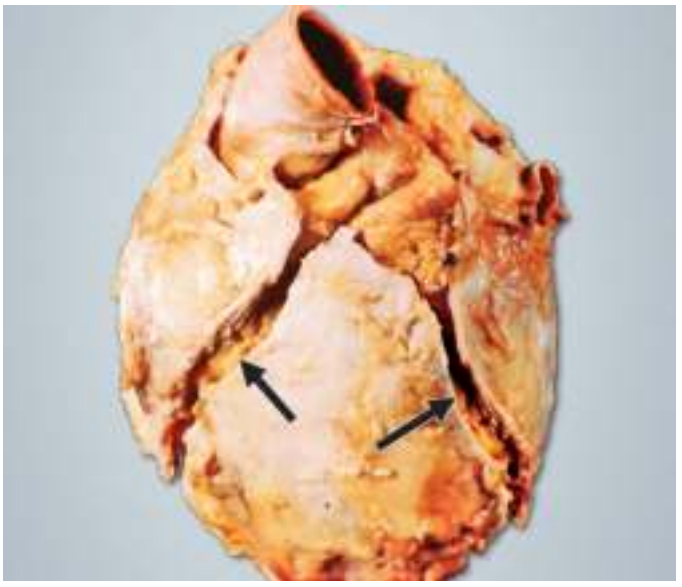

Fig. 16.53: Constrictive pericarditis in a case of tuberculosis. Patient presents with dyspnea, chest pain and abdominal discomfort. Physical examination revealed hepatomegaly, ascites and pitting edema. Cardiac auscultation revealed pericardial rub, respiratory crackles in both lungs and bases (arrows).

Reduced cardiac output causes fatigue and tachycardia (Table 16.31).

Cardiac MRI Techniques

Cardiac magnetic resonance imaging (MRI) in constrictive pericarditis demonstrates pericardial thickening, i.e. 4 mm, pericardial calcification, reduced right ventricular volume, a dilated right atrium, superior vena cava and inferior vena cava, hepatomegaly and ascites.

ADHESIVE PERICARDITIS

In some cases, adhesions formed between pericardium and thoracic cage leads to systolic retraction of thoracic cage and cardiac hypertrophy (cardiomegaly demonstrated by X-ray). Differences between constrictive and adhesive pericarditis are shown in Table 16.32.

Table 16.31 Clinical features of constrictive pericarditis

Systemic Changes	Clinical Features
Reduced cardiac output	Fatigue, hypotension, reflex tachycardia
Elevated systemic venous pressure	Jugular venous distension, hepatomegaly with marked ascites, peripheral edema
Pulmonary venous congestion	Exertional dyspnea, cough and orthopnea
Chest pain typical of angina may be related to under perfusion of the coronary arteries or compression of an epicardial coronary artery by the thickened pericardium	▪ Because the most impressive physical findings are often the insidious development of hepatomegaly and ascites, such patients are often mistakenly thought to suffer from hepatic cirrhosis or an intra-abdominal tumor ▪ It is only after a careful inspection of the jugular veins that a cardiac source is identified

Table 16.32 Differences between constrictive and adhesive pericarditis

Parameters	Constrictive Pericarditis	Adhesive Pericarditis
Etiology	▪ Bacteria, viruses, parasites and fungi ▪ Rheumatic fever, AMI, uremia and SLE causing fibrinous pericarditis leads to constrictive pericarditis	▪ Bacteria, viruses, parasites and fungi ▪ Rheumatic fever, AMI, uremia and SLE causing fibrinous pericarditis leads to adhesive pericarditis
Pathology	Parietal and visceral layers are fused	Adhesions between pericardium and thoracic cage
Clinical effects	It restricts the heart's ability to pump effectively	Cardiac hypertrophy results in cardiomegaly

CARDIAC HYPERTROPHY AND HEART FAILURE

CARDIAC HYPERTROPHY

Cardiomyocytes exit the cell cycle and become terminally differentiated soon after the birth. Cardiac hypertrophy initially develops as an adaptive response to physiologic and pathologic stimuli, that augments myocardial contractile strength by increase in the cardiomyocytes number in response to an increased workload during adult life.

- There is distinction between physiologic and pathologic cardiac hypertrophy. Physiologic cardiac hypertrophy develops in highly trained athletes. On the other hand, pathologic cardiac hypertrophy occurs due to injury or disease.
- Pathologic cardiac hypertrophy is a compensatory response to hemodynamic overload, which occurs in association with chronic systemic hypertension or cardiac valvular stenosis (pressure overload), myocardial injury, valvular insufficiency (volume workload), that increase the cardiac overload.
- Cardiac hypertrophy is initially a compensatory and possibly a reversible phenomenon, but with persistent stress, the myocardium becomes irreversibly increased in thickness and dilated resulting in heart failure.
- The overall weight of the heart increases exceeding 375 g in men and 350 g in women. The thickness of the left ventricle increases exceeding (normal 1.2–1.5 cm) and right ventricle (normal 3–5 mm).
- Hypertrophic cardiomyocytes exhibit increased in size containing hyperchromatic rectangular nuclei. Left ventricular hypertrophy in systemic hypertension is shown in Fig. 16.54. Histology of cardiac hypertrophy is shown in Fig. 16.55.

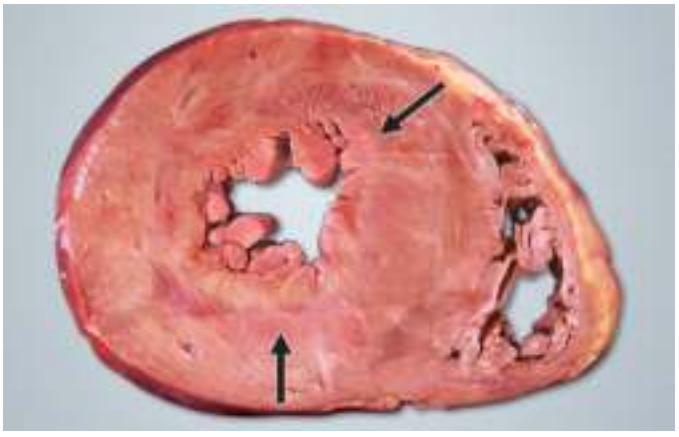

Fig. 16.54: Left ventricular hypertrophy in systemic hypertension. The wall of the left ventricle is markedly thickened (normal thickness 1.2–1.5 cm) as a result of increase in size of the cardiac myocytes (arrows).

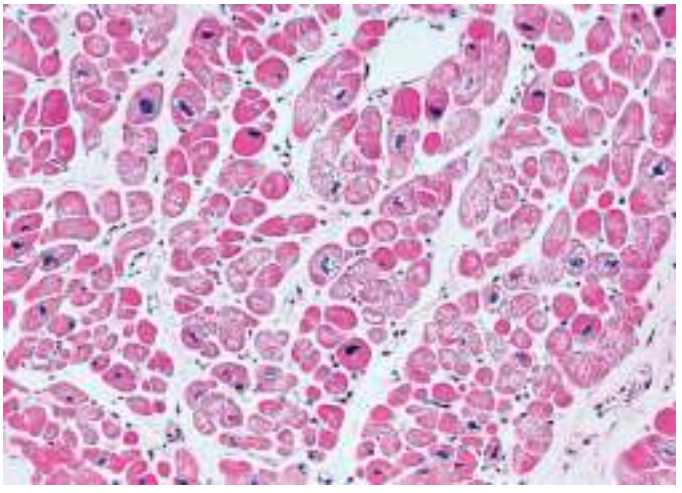

Fig. 16.55: Histology of cardiac hypertrophy. It shows marked hypertrophy of cardiac myocytes with interstitial fibrosis (400X).

MOLECULAR PATHOGENESIS

Numerous mechanisms are involved in the pathogenesis of cardiac hypertrophy affecting gene transcription, calcium handling, protein synthesis, cellular metabolism, autophagy, oxidative stress and inflammation. New mediators participating in the pathogenesis of cardiac hypertrophy include signaling proteins, microRNAs, long noncoding RNAs and calcineurin and calcium/calmodulin-dependent protein kinase.

Signaling Pathways

Each form of cardiac hypertrophy is regulated by distinct cellular signaling pathways. Receptor-mediated myocardial events in response to mechanical stimuli promote the hypertrophic response regulated by autocrine and paracrine mechanisms.

- Cardiomyocytes respond to mechanical stimuli release various ligands such as angiotensin II, endothelin 1 (ET-1), norepinephrine, insulin-like growth factor 1 (IGF-1), fibroblast growth factor (FGF), transforming growth factor 1 (TGF-1) and transforming growth factor β (TGF-β). These ligands activate signaling pathways to induce cardiac hypertrophy.
- Some of these ligands (mediators) may also act on interstitial fibroblasts in the myocardium to promote synthesis and deposition of extracellular matrix.
- These ligands bind to G-coupled receptors and receptor tyrosine kinases to initiate intracellular signaling cascades.
- G-coupled receptors activate various signaling pathways such as mitogen-activated protein kinases (MAPKs), phosphoinositide 3-kinases (PI3Ks) and protein kinase C (PKC).
- Calcium calmodulin-dependent protein kinase pathways are regulated by calcium.
- Events mediated by β-adrenergic receptors are implicated in the transition from compensatory cardiac hypertrophy to congestive heart failure.

Expression of Fetal Genes

Gene expression varies during prenatal and postnatal life. During prenatal life, fetal ventricles synthesize atrial natriuretic factor (ANF), however synthesis of ANF is shut off in normal adult tissue.

- Cardiac hypertrophy and congestive heart failure can result in reactivation of some embryonic genes encoding ANF and fetal isoforms of creatine kinase and myosin light chains.
- Changes in fetal gene expression are mediated by mechanical stress, which induces synthesis of cytokines and hormones, that redirect gene expression.
- Cardiomyocytes sense mechanical stress through integrin-mediated signaling through PI3K, RAS, AKT signaling pathways. Induction of some cardiac-specific transcription factors may be important in programmed change in gene expression.

PATHOLOGY

Structural damage or gene mutation may lead to heart failure. Ischemic heart disease is the most important cause of heart failure. Cardiomyopathies and congenital heart diseases lead to heart failure. Ventricular hypertrophy is demonstrated in virtually all conditions associated with chronic heart failure.

Table 16.33 Causes of left-sided and right-sided heart failure

Left-sided Heart Failure: Causes	Right-sided Heart Failure: Causes
Ischemic heart disease	Left heart failure (most common)
Systemic hypertension	Pulmonary hypertension
Aortic valve disease	Tricuspid valve disease
Mitral valve disease	Pulmonic valve disease
Myocarditis	Myocarditis
Cardiomyopathies	Cardiomyopathies
Chemotherapy treatment for cancer	Intrinsic pulmonary disease

- Initially left cardiac hypertrophy occurs as in compensated hypertensive heart disease. But when the left ventricle fails to perform normal functions, right ventricular hypertrophy follows as a result of increased workload on the right ventricle.
- The distribution of end-organ involvement is dependent on whether the heart failure is predominantly left-sided or right-sided. In heart failure, heart is unable to pump out blood to meet the body's metabolic needs resulting in poor perfusion of tissues.
- In adults, acute heart failure occurs after acute myocardial infarction, while chronic heart failure due to long-standing systemic hypertension.
- Children develop heart failure due to congenital heart diseases and blood vessel malformations. Causes of left-sided and right-sided heart failure are given in Table 16.33. Clinical manifestations in heart failure are shown in Fig. 16.56.

HEART FAILURE

LEFT-SIDED HEART FAILURE

Left-sided heart failure is most common and caused due to cardiac injury (ischemic heart disease, systemic hypertension) primarily affect the left ventricle.

- To compensate for left ventricular failure, venous pressures in left atrial and pulmonary vein increase, resulting in passive pulmonary congestion. Alveolar septal capillaries filled with blood rupture resulting in escape of red blood cells. As a result, alveoli contain numerous hemosiderin macrophages, so-called heart failure cells. If capillary hydrostatic exceeds plasma oncotic pressure, fluid leaks from alveolar capillaries into the alveoli. Resultant pulmonary edema may be massive with alveoli being filled with transudate.
- Clinical examination eveals dyspnea, orthopnea, decreased breath sounds, crackles and dull percussion note.
- Presence of congestion in pulmonary capillaries over an extended period results in interstitial pulmonary

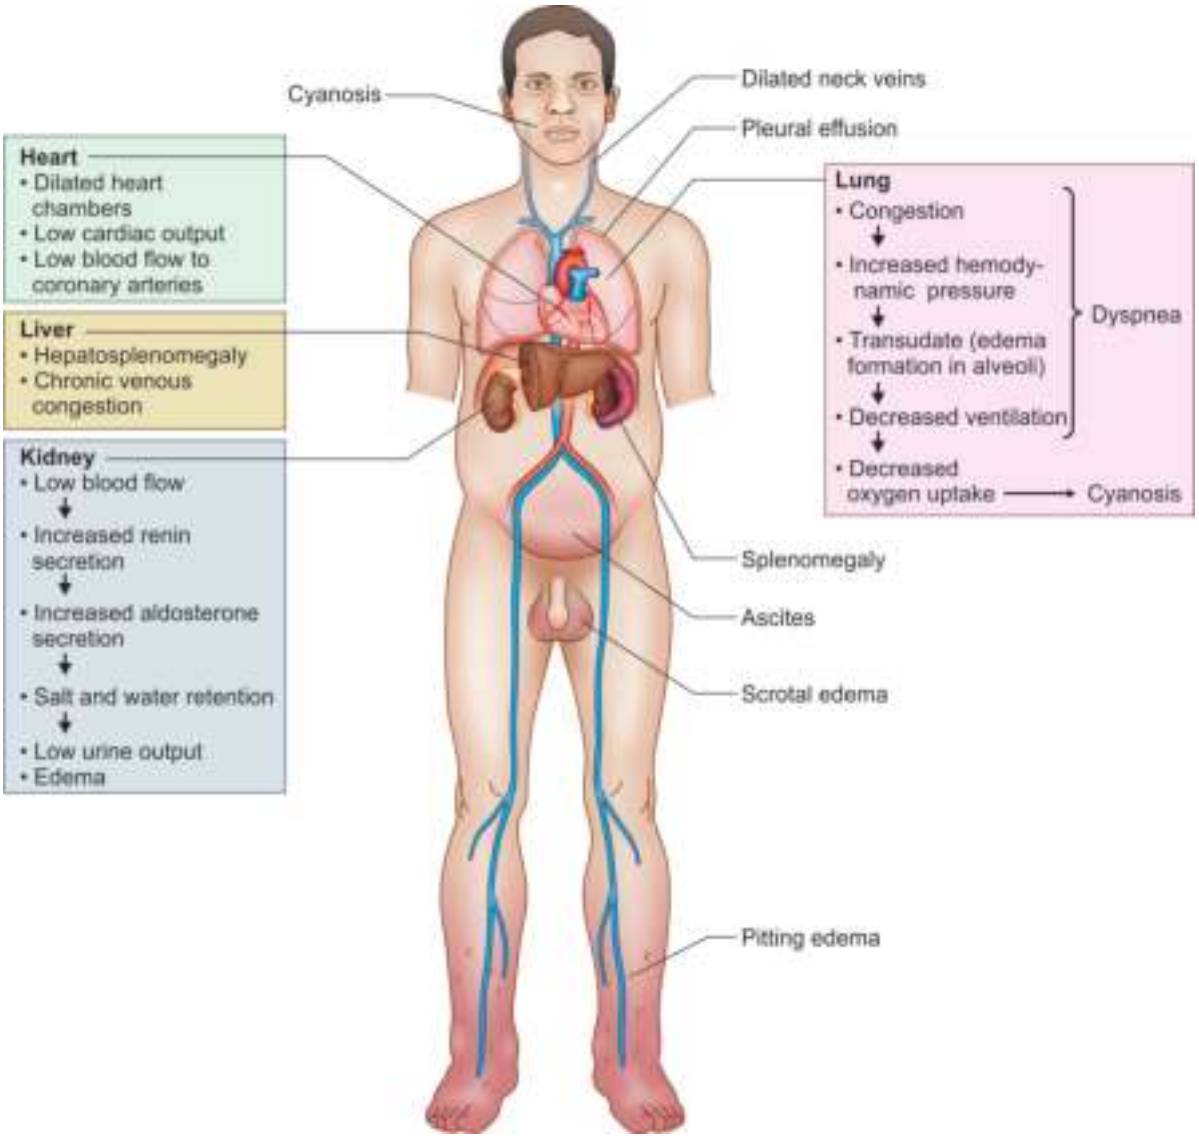

Fig. 16.56: Clinical manifestations in heart failure. Left-sided heart failure results in pulmonary congestion, dyspnea on exertion, dyspnea on lying down (orthopnea), awakening from sleep (paroxysmal nocturnal dyspnea) and cough with frothy sputum. Right-sided heart failure results in systemic venous congestion, peripheral edema over ankles, hepatosplenomegaly and raised jugular venous pressure.

fibrosis. Pulmonary edema with heart failure cells is shown in Fig. 16.57A and B.

Clinical Features

Patient developing left-sided heart failure presents with dyspnea on exertion, dyspnea on lying down (orthopnea), awakening from sleep (paroxysmal nocturnal dyspnea) and cough with frothy sputum.

- Dyspnea on exertion is related to increased pulmonary congestion as a result of higher end-diastolic pressure in the left atrium and left ventricle.
- Orthopnea and paroxysmal nocturnal dyspnea occur, when pulmonary blood volume increases owing to reduced blood volume in the legs during recumbent (lying down) position.
- Many of the clinical manifestations of heart failure can be explained on the basis of venous congestion (backward failure) and inadequate perfusion of vital organs (forward failure).
- Majority of patients with left-sided heart failure retain sodium and water (peripheral edema) owing to poor renal perfusion, decreased glomerular filtration rate and activation of renin-angiotensin-aldosterone system.
- Inadequate cerebral perfusion results in confusion, memory loss and disorientation.
- Inadequate perfusion of skeletal muscles leads to weakness and fatigue.
- On clinical examination, patient has weak pulse and cool moist skin as a result of vasoconstriction, and shunting of blood to vital organs.

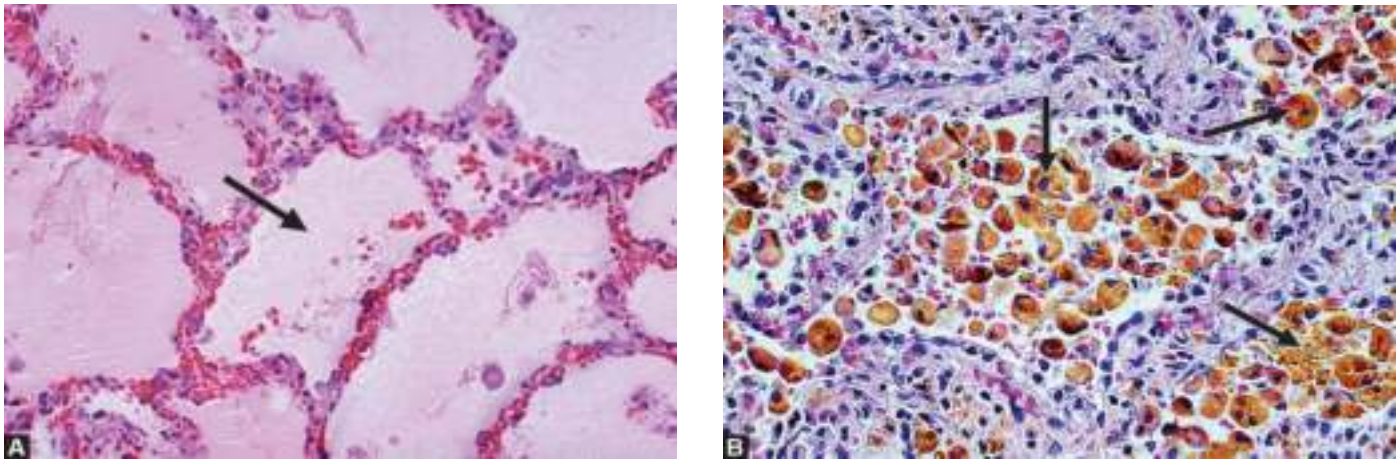

Fig. 16.57: (A) Pulmonary edema. Histologic examination of lung demonstrates congested alveoli filled with a smooth to slightly floccular pink material (arrow) (400X), (B) pulmonary edema with hemosiderin laden alveolar macrophages called heart failure cells (arrows) (400X).

RIGHT-SIDED HEART FAILURE

Right-sided heart failure most commonly complicates left-sided heart failure, which can also develop independently due to intrinsic pulmonary disease or pulmonary hypertension.

- Pulmonary hypertension creates resistance to blood flow through the lung resulting in increase in right atrial pressure and systemic venous pressure. Jugular veins are congested and distended. Increased pressure in vena cava results in congestion of liver and spleen; and pitting edema in legs.
- Hepatic congestion in heart is characterized by congestion and distension of central veins and sinusoids. Cut surface of the liver is dark red giving '**nutmeg appearance**' when compared to the cut surface of a nutmeg.
- Fibrocongestive splenomegaly occurs in right-sided heart failure. Increased pressure results in hemorrhage in the spleen, that becomes organized and calcified (dystrophic calcification) with formation of Gamna-Gandy bodies.
- Chronically injured cardiomyocytes lose myofibrils. Regardless of the nature of injury, dysfunctional cardiomyocytes lose sarcomeres and correspondingly increased glycogen in cytosol. Cardiomyocytes become vacuolated termed **cardiomyocytolysis**.

Liver Manifestations

In long-standing right-sided heart failure, increased pressure results in chronic passive congestion and dilatation of the central veins and sinusoids. Hepatocytes undergo ischemic changes in zone 3 of hepatic lobule.

- Long-standing chronic venous congestion in liver may result in cardiac cirrhosis. Cut surface of liver due to chronic venous congestion exhibits dark red areas against ischemic areas giving '**nutmeg appearance**'. Histologic examination demonstrates congestion and dilatation of central veins and sinusoids of liver.
- Chronic venous congestion in gross specimen in a case of right-sided heart failure is shown in Fig. 16.58. Histology of chronic venous congestion of spleen is shown in Fig. 16.59.

Fibrocongestive Splenomegaly

Fibrocongestive splenomegaly occurs in right-sided heart failure. Increased pressure results in hemorrhage in the spleen, that becomes organized and calcified (dystrophic calcification) to form Gamna-Gandy bodies.

- Gross examination of spleen shows irregular tan-white fibrous plaques over the purple capsular surface.
- Light microscopy shows firm and brown fibrotic nodules termed **Gamna-Gandy bodies** which are organized hemorrhage forming nodule with dystrophic calcification and hemosiderin pigment.
- Histology of chronic venous congestion of spleen in long-standing right-sided heart failure is shown in Fig. 16.60.

Fig. 16.58: Chronic venous congestion in gross specimen in a case of right-sided heart failure. Cut surface demonstrates nutmeg appearance (arrows).

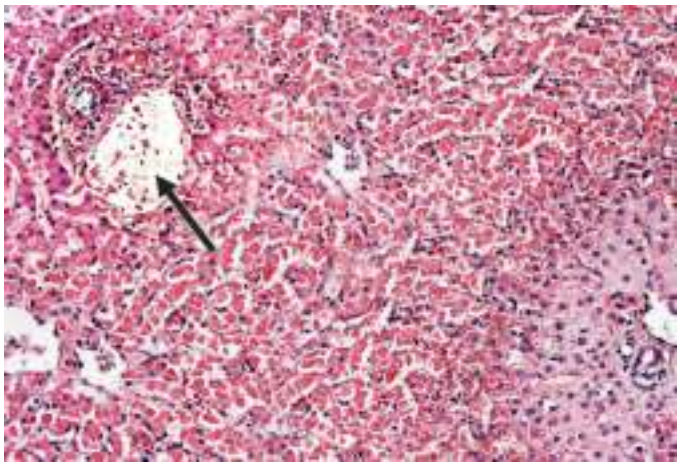

Fig. 16.59: Histology of chronic venous congestion of liver. It demonstrates central veins and sinusoids congested and dilated. At places, the hepatocytes have become atrophied (arrow) (400X).

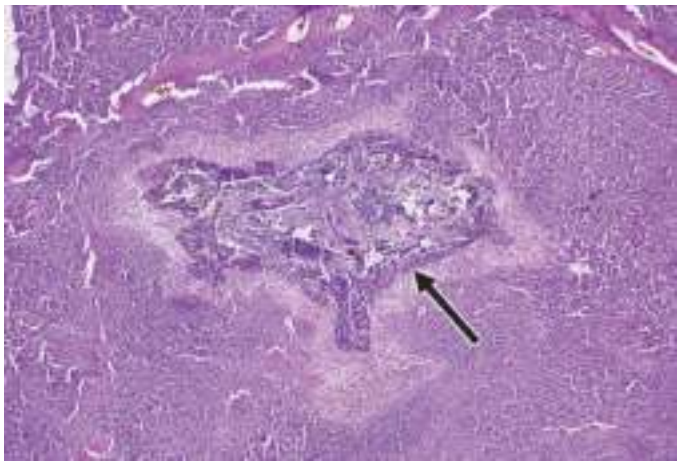

Fig. 16.60: Histology of chronic venous congestion of spleen in long-standing right-sided heart failure. It demonstrates Gamna-Gandy bodies (arrow) (400X).

DIASTOLIC HEART FAILURE

Diastolic heart failure most often occurs in elderly persons, which has become an important clinical problem. The ventricles become progressively stiffer with advancing age and require great diastolic pressure.

Some patients having normal systolic contractile function develop signs and symptoms of heart failure. These patients with normal heartbeats are unable to tolerate increased blood volume resulting in pulmonary edema in response to a fluid challenge. The patients demonstrate interstitial fibrosis in heart.

NEOPLASTIC DISORDERS OF HEART

NEOPLASMS: CLASSIFICATION

Cardiac neoplasms are classified into primary (benign or malignant) and secondary neoplasms. Myxoma is the most common primary cardiac neoplasm in adults. Secondary neoplasms are more common than primary.

PRIMARY NEOPLASMS

- **Benign neoplasms:** Benign cardiac neoplasms include atrial myxoma and rhabdomyoma. Myxoma of the left atrium is most common primary benign neoplasm of heart. Other tumors include papillary fibroelastoma and fibroma.
- **Malignant neoplasms:** Malignant cardiac neoplasms are extremely rare, which include angiosarcoma and mesothelioma. Cardiac angiosarcoma most commonly occurs in right atrium.

SECONDARY NEOPLASMS

Secondary neoplasms of heart are more common than primary. Tumors metastasizing to heart include lung carcinoma, breast carcinoma and malignant melanoma. Epicardial surface is covered by pale white-tan multiple nodules of metastases. Metastases may lead to a hemorrhagic pericarditis (Fig. 16.61).

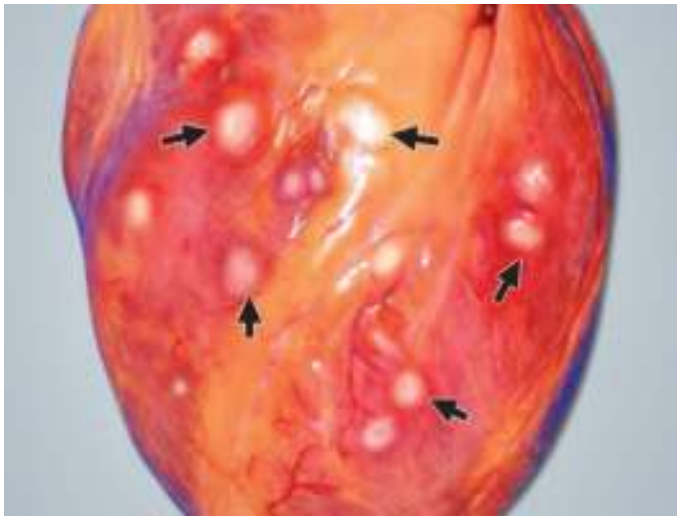

Fig. 16.61: Metastatic tumors to heart. It shows multiple metastatic pale, white-tan deposits on the pericardium (arrows).

ATRIAL MYXOMA

Atrial myxoma is most common benign primary cardiac neoplasm. It accounts for >50% of all primary tumors. Most cardiac myxomas are sporadic, but some occur as a part of Carney syndrome characterized by skin tumors and schwannomas (Fig. 16.62).

Fig. 16.62: Cardiac myxoma. 'Ball valve' effect of myxoma is partially obstructing mitral valve intermittently. It is diagnosed by echocardiography (arrow).

ORIGIN AND LOCATION

Cardiac myxoma arises from multipotent mesenchymal cells which exhibits endothelial and neural differentiation. Tumor is most often demonstrated in left atrium in 90% of cases, which arises from the left atrial septal wall around the fossa ovalis in 80% of cases, on valves and in ventricles.

PATHOLOGY

Most cardiac myxomas are pedunculated, however some myxomas are broad based and sessile. The size varies, between 5 mm to 5 cm. Ball valve effect of myxoma partially obstructs mitral valve intermittently, which prevents diastolic filling of the left ventricle simulating mitral valve stenosis.

Clinical Features

Patient presents with episodes of syncope and non-specific symptoms (e.g. fever, anemia and elevated ESR). Tumor may fragment and give rise to arterial emboli to the brain.

Surgical Pathology: Atrial Myxoma	
Gross Morphology	
On gross examination, cardiac myxomas appear gelatinous (myxoid).	
Light Microscopy	
Myxoma is composed of spindle-shaped cells with scant pink cytoplasm surrounded by loose myxoid matrix containing chondroid sulphate and hyaluronic acid.	
Immunohistochemistry Technique	
Tumor cells show positivity for vimentin, calretinin, CD31, CD34, and α-antitrypsin.	
Markers	**Expression**
▪ Vimentin	▪ Positive
▪ Calretinin	▪ Positive
▪ CD31	▪ Positive
▪ CD34	▪ Positive
▪ α-Antitrypsin	▪ Positive

DIAGNOSIS

Echocardiography is the most useful technique for visualizing myxoma. The left atrium is located in posterior region of heart.

CARDIAC RHABDOMYOMA

Cardiac rhabdomyoma is second most common primary neoplasm of the heart in infants and children. It is associated with tuberous sclerosis in adults. It arises from striated muscle of myocardium. At autopsy, a large firm, white tumor mass is found filling much of the left ventricle.

CONGENITAL HEART DISEASES AND BLOOD VESSEL MALFORMATIONS

DEVELOPMENTAL ANOMALIES: OVERVIEW

Developmental anomalies of the heart and the major blood vessels are seen in 6–8 per 1000 newborns. Some congenital defects become clinically apparent at birth or in infancy, others are recognized in early childhood. Patients with mitral valve prolapse are diagnosed in early adulthood.

- Most common congenital heart diseases (CHD) are ventricular septal defect (30% of cases), tetralogy of Fallot (10% of cases), atrial septal defect (8% of cases), patent ductus arteriosus (8% cases), coarctation of the aorta (6% of cases) and transposition of the great arteries (5% of cases).
- The most common acyanotic heart disease is ventricular septal defect, whereas the most common cyanotic heart disease is tetralogy of Fallot (Table 16.34). Clinical manifestations of congenital heart disease and blood vessel malformations are given in Table 16.35.

Table 16.34 Major groups of congenital heart diseases and blood vessel malformations

Left-to-right Shunt (Noncyanotic)	Right-to-left Shunt (Cyanotic)	Obstructive Congenital Defects
Ventricular septal defect (VSD)	Tetralogy of Fallot	Coarctation of aorta
Atrial septal defect (ASD)	Transposition of great arteries	Pulmonary artery stenosis
Patent ductus arteriosus (PDA)	Persistent truncus arteriosus	Aortic stenosis/atresia
Atrioventricular septal defect	Total anomalous venous connection	

Table 16.35 Clinical manifestations of congenital heart disease and blood vessel malformations

Cardiac Valvular Disease	Cause	Effects on Organs	Clinical Findings
Ventricular septal defect (VSD)	VSD nonclosure of interventricular septum within first two years of life	▪ Left to right shunt ▪ Pulmonary hypertension ▪ Right heart failure	▪ High-pitched holosystolic murmur over lower left sternal border and loud pulmonic S2 ▪ VSD spontaneous closure within the first six months
Atrial septal defect (ASD)	Congenital defect due to nonclosure of interatrial septum	▪ Most common type: patent foramen ovale ▪ Majority symptomatic	Loud S1, wide fixed splitting of S2, systolic ejection murmur along left upper sternal border
Patent ductus arteriosus (PDA)	Congenital defect due to nonclosure of ductus arteriosus at birth in premature and maternal rubella infection	Pulmonary hypertension	▪ Wide pulse pressure, bounding arterial pulses ▪ Continuous loud machine-like murmur
Coarctation of the aorta	Coarctation of the aorta at origin of left subclavian artery in 98% of cases	Blood pressure higher in arms than legs	▪ Bounding pulses in arms and decreased pulses in legs ▪ Stabilized by surgery
Tetralogy of Fallot	Most common congenital heart disease (ventricular septal defect, right ventricular hypertrophy, right outflow obstruction and overriding aorta)	Right to left shunt	▪ Substernal right ventricular impulse, systolic thrill along left sternal border ▪ Intermittent hyperpnea, cyanosis with decreased intensity of murmur, irritability ▪ Surgical repair at 4–12 months of age

Pulmonary artery stenosis occurs in the setting of tetralogy of Fallot, carcinoid heart disease and rarely in rheumatic heart disease.
Calcific aortic stenosis occurs due to rheumatic heart disease, senile calcific aortic stenosis and congenital aortic stenosis.

ETIOLOGY AND ASSOCIATIONS

- **Chromosomal disorders:** Patients with chromosomal disorders are associated with congenital heart disease. Child with Down syndrome is associated with atrial and ventricular septal defects. Turner syndrome has been associated with coarctation of the aorta.
- **Genetic predisposition:** Due to the multifactorial inheritance, tetralogy of Fallot can cluster in families.
- **High altitude:** There is increased incidence of patent ductus arteriosus (PDA) in persons living at high altitude, suggesting an association with decreased supply of oxygen to fetus.
- **Rubella infection (German measles):** Intrauterine exposure to rubella virus during the first trimester of pregnancy is important cause of congenital heart disease.
  - Newborn develops congenital rubella syndrome, characterized by cardiovascular defects, microcephaly with mental retardation, deafness, cataracts, and growth retardation. Cardiovascular defects include ventricular septal defect, aortic stenosis, patent ductus arteriosus, valvular stenosis and tetralogy of Fallot.
  - It is mandatory to determine mother's immune status to rubella. Presence of antirubella IgM antibodies indicates recent primary infection, and IgG antibodies indicate past infection. Gene defects associated with congenital heart diseases are given in Table 16.36.

FUNCTIONAL ABNORMALITIES OF CHD

- **Noncyanotic diseases (left-to-right shunt):** These include atrial septal defect (ASD), ventricular septal

Table 16.36 Gene defects associated with congenital heart diseases*

Disorder	Gene	Gene Product Function
Nonsyndromic disorders		
ASD or conduction defects	NKX2.5	Transcription factor
ASD or VSD	GATA4	Transcription factor
Tetralogy of Fallot	ZFPM2 or NKZ2.5	Transcription factor
Syndromic disorders**		
Alagille syndrome: Pulmonary artery stenosis or tetralogy of Fallot	JAG1 OR N0TCH2	Signaling proteins or receptors
Char syndrome: PDA	TFAP2B	Transcription factor
CHARGE syndrome: ASD, VSD, PDA, or hypoplastic right side of the heart	CHD7	Helicase-binding protein
DiGeorge syndrome: ASD, VSD, or outflow tract obstruction	TBX1	Transcription factor
Holt-Oram syndrome: ASD, VSD, or conduction defect	TBX5	Transcription factor
Noonan syndrome: Pulmonary valve stenosis, VSD, or hypertrophic cardiomyopathy	PTPN11, KRAS, S0S1	Signaling proteins

ASD—atrial septal defect, VSD—ventricular septal defect, PDA—patent ductus arteriosus, CHARGE—coloboma, heart defects, choanal atresia, growth retardation, genital and ear abnormalities.
**Different mutations can cause the same phenotype, and mutations in some genes can cause multiple phenotypes (e.g. NKX2.5). Many of these congenital lesions also can occur sporadically, without specific genetic mutation.*
***Only the cardiac manifestations of the syndrome are listed; the other skeletal, facial, neurologic and visceral changes are not.*

defect (VSD) and patent ductus arteriosus (PDA). In atrial septal defects, both pressure and oxygen saturation may be equalized between the two atria.

- **Cyanotic diseases (right-to-left shunt):** These include tetralogy of Fallot and transposition of the great vessels.
- **Malformations without left-to-right shunt:** These include hypoplastic left heart syndrome, coarctation of the aorta and total anomalous pulmonary venous return.

ATRIAL SEPTAL DEFECTS

Atrial septal defects (ASDs) account for 10% of all congenital heart diseases. Normally, the left atrial pressure keeps the foramen ovale closed. Fossa ovalis represents the remnant of foramen ovale on right interatrial septum. Patent foramen ovale is usually clinically insignificant. Depending on the location, there are three types of atrial septal defects. Complications of atrial septal defects include cyanosis, right-sided heart failure, bacterial endocarditis and paradoxical thrombi.

SEPTUM SECUNDUM

Septum secundum accounts for 90% of all atrial septal defects. It is a true defect and should not be confused with patent foramen ovale.

- Atrial septal defect occurs in the middle portion of septum varying in size to involve entire fossa ovalis. It is most common disease usually diagnosed in adult life.
- Large atrial septal defects cause dilatation and hypertrophy of the right atrium and ventricle resulting in pulmonary hypertension. The defect may allow a thrombus formation from right atrium to left atrium known as **paradoxical embolus**, so-called because a thromboembolus arising from the venous circulation can enter in the systemic circulation.
- Lutembacher syndrome is characterized by atrial septal defect with mitral stenosis.

SEPTUM PRIMUM

Large defect in the lower part of septum is known as septum primum. It may be associated with deformities of atrioventricular valves.

SINUS VENOSUS

Defect in the upper part of the septum near the entrance of the superior vena cava is known as **sinus venosus**.

VENTRICULAR SEPTAL DEFECTS

The interventricular septum usually closes down spontaneously in the first 2 years of life. Ventricular septal defects (VSDs) occur within the membranous (80%) or muscular (20%) portions of interventricular septum that produce a left-to-right shunt. Ventricular septal defects may vary in size.

- Small ventricular septal defects constitute 50% of cases, which may close spontaneously. VSDs are recognized by high-pitched holosystolic cardiac murmur.
- Large ventricular septal defects produce more severe disease. Left-to-right shunt may lead to pulmonary hypertension and eventual right-sided heart failure. Reversal of the shunt occurs when the pulmonary hypertension exceeds the pressure in the aorta in Eisenmenger syndrome resulting in cyanosis. Patient develops left ventricular hypertrophy and dilatation.

PATENT DUCTUS ARTERIOSUS

During intrauterine life, ductus arteriosus permits the blood from the venous system to bypass the lungs. During fetal life, its patency is maintained by combined effects of low oxygen tension and prostaglandin synthesis. Patent ductus arteriosus (PDA) normally closes soon after birth. If the ductus arteriosus remains open, left-to-right shunt develops (Fig. 16.63).

- Failure of closure of the fetal ductus arteriosus leads to pulmonary hypertension and right ventricular hypertrophy. The left-to-right shunt is associated with a loud machinery-like cardiac murmur during systole and diastole.
- Patent ductus arteriosus (PDA) can be closed surgically or pharmacologically treated with injection indomethacin (prostaglandins inhibitor).

COARCTATION OF THE AORTA

Coarctation of the aorta accounts for 6% of all cases of congenital heart disease. It is localized narrowing of the aortic lumen leading to outflow obstruction.

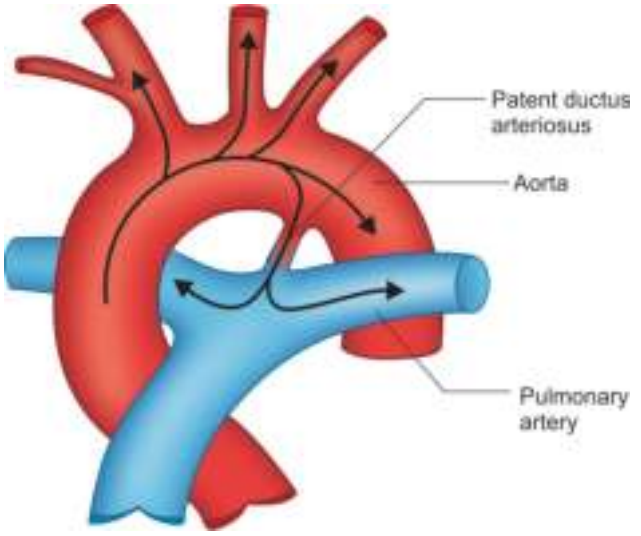

Fig. 16.63: Patent ductus arteriosus. There is persistence of patency of duct communicating aorta and pulmonary trunk.

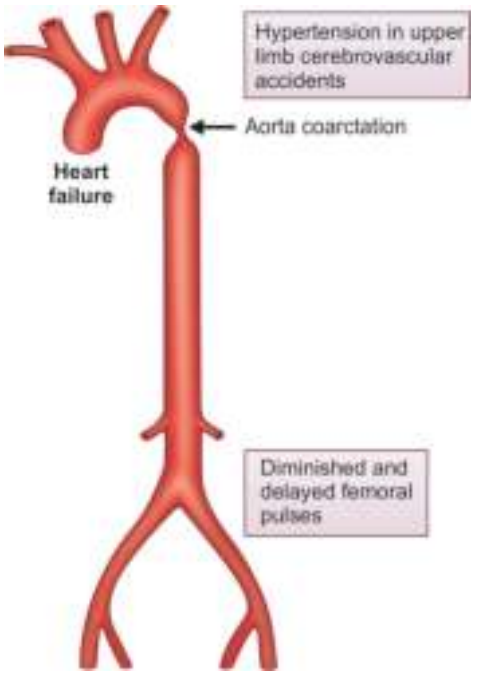

Fig. 16.64: Coarctation of the aorta leads to diminished blood flow to lower extremities.

- Disorder usually occurs in the thoracic portion of the descending aorta, distal to the take off of the left subclavian artery at the site of the ductus arteriosus.
- The cardinal physical finding is diminution or absence of femoral pulses and hypertension in the upper extremities. It occurs in two types—infantile and adult (Fig. 16.64).

INFANTILE TYPE OF COARCTATION OF THE AORTA

Infantile type of coarctation of the aorta constitutes 70% of cases. Ascending aorta and aortic arch is markedly narrowed with persistence of ductus arteriosus.

- Coarctation of the aorta is generally present at birth. Symptoms can range from mild to severe.
- Most infants do not survive without surgical correction of the defect.

ADULT TYPE OF COARCTATION OF THE AORTA

Adult type of coarctation of the aorta is distal to the origin of the subclavian arteries leading to hypertension.

Hypertension is limited to the upper extremities and cerebral vessels.

- The parts of the body below the obstruction become hypoxic, and the blood pressure measured on the legs is lower than the pressure measured on the arms.
- Hypertension increases risk for developing dissecting hematoma in aorta and berry aneurysms in the cerebral vessels. Hypertension causes proximal aortic dilatation resulting in aortic regurgitation. Collaterals that involve the intercostal arteries cause notching of the ribs seen on radiograph.

- Diastolic hypertension occurs due to activation of the renin-angiotensin-aldosterone system from reduced blood flow.

TETRALOGY OF FALLOT

Tetralogy of Fallot is the most common cyanotic disease in newborn. Tetralogy of Fallot comprises four pathologic findings, i.e. (a) ventricular septal defect (membranous type), (b) overriding aorta sitting over the ventricular septal defect, (c) pulmonary artery stenosis (below pulmonary valve), and (d) right ventricular hypertrophy (Fig. 16.65).

PATHOPHYSIOLOGY

The obstruction to right ventricular outflow creates a right-to-left shunt that leads to cyanosis since birth in tetralogy of Fallot.

- Pulmonary artery stenosis does not permit entry of venous blood into the lungs for oxygenation.
- Overriding aorta sitting over the ventricular septal defect receives blood from both ventricles results in cyanosis.

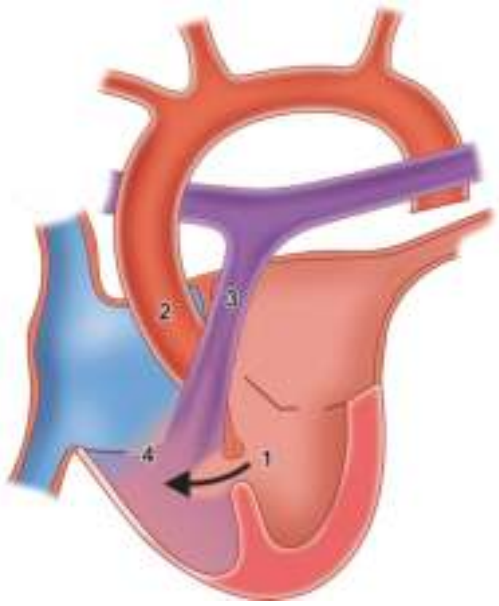

Fig. 16.65: Tetralogy of Fallot comprises four pathologic findings, i.e. (1) ventricular septal defect, (2) overriding aorta sitting over the ventricular septal defect, (3) pulmonary artery stenosis results in, and (4) right ventricular hypertrophy.

CLINICAL FEATURES

Newborn develops bluish discoloration of the skin and mucosa, i.e. cyanosis at birth. In most children, cyanosis is evident by the age of 4 months. Child presents with hypoxemic spells, i.e. faint or loss of consciousness, retarded growth, squatting position and clubbing of fingers.

PROGNOSIS

Some children may die in the first year of life. Death occurs due to hypoxia, infections and cerebrovascular accidents related to thromboembolism. Surgery is recommended as the treatment of choice for most cases. But it is associated with 3–15% mortality rate.

TRUNCUS ARTERIOSUS COMMUNIS

Truncus arteriosus communis refers to common trunk for the origin of the aorta, pulmonary arteries, and coronary arteries. Truncus arteriosus communis occurs due to incomplete separation of the aortic and pulmonary outflows and forming single vessel overriding both ventricles during development. It allows mixing of oxygenated and deoxygenated blood with right-to-left shunting.

MALFORMATIONS OF CVS

TRANSPOSITION OF THE GREAT VESSELS

The aorta arises from the right ventricle, and the pulmonary artery arises from the left ventricle. There is right-to-left shunting. It accounts for ≤5% of congenital heart disease. Its incidence is increased in maternal diabetes mellitus. Compensatory anomaly such as patent ductus arteriosus is necessary for survival.

HYPOPLASTIC LEFT HEART SYNDROME

There is varying degree of hypoplasia or atresia of the aortic and mitral valves, along with a small to absent left ventricular chamber.

TOTAL ANOMALOUS PULMONARY VENOUS RETURN

The pulmonary veins do not directly connect to the left atrium, but drain into left innominate vein, coronary sinus, or some other sites, leading to possible mixing of blood and right-sided overload.

CHAPTER

17

Nasal Cavity, Nasopharynx, Paranasal Sinuses, Ear, Larynx and Neck

Vinay Kamal, Anubhav and Vigyat

LEARNING OBJECTIVES

DISORDERS OF NASAL CAVITY, NASOPHARYNX AND PARANASAL SINUSES

- Inflammation and infections
  - Acute rhinosinusitis
  - Chronic rhinosinusitis
  - Wegener's granulomatosis
  - Allergic polyps
  - Fungal sinusitis
- Sinonasal neoplastic disorders
  - Schneiderian sinonasal papillomas
  - Sinonasal undifferentiated carcinoma
  - Nasopharyngeal carcinoma
  - Sinonasal squamous cell carcinoma
  - Sinonasal melanoma
  - Olfactory neuroblastoma
  - Nasopharyngeal angiofibroma
  - Alveolar rhabdomyosarcoma
  - Sinonasal plasmacytoma
  - Sinonasal adenocarcinoma
  - Sinonasal hemangioblastoma
- Miscellaneous sinonasal disorders
  - Rhinosporidiosis
  - Rhinoscleroma

DISORDERS OF EAR

- Anatomy of ear
- Ear: disorder
  - External ear disorders
    - Cauliflower ear
    - Chondrodermatitis nodularis chronica
    - Malignant neoplasm
  - Middle ear disorders
  - Inner ear disorders
    - Presbycusis
    - Toxic damage of inner ear
    - Acoustic neuroma

DISORDERS OF LARYNX

- Anatomy and histology
- Inflammatory disorders
- Tumors and tumor-like disorders

DISORDERS OF NECK

- Neck swellings: overview
- Cervical lymphadenopathy
- Branchial cyst
- Thyroglossal cyst
- Paraganglioma (carotid body tumor)

DISORDERS OF NASAL CAVITY, NASOPHARYNX AND PARANASAL SINUSES

INFLAMMATION AND INFECTIONS

ACUTE RHINOSINUSITIS

Upper respiratory tract infections are most common cause of rhinosinusitis, which occur as a result of extension of infection from nasal cavity or dental region. Blockage of paranasal sinuses results in accumulation of inflammatory exudates in ethmoid sinus in children and maxillary sinus in adults.

- Acute rhinosinusitis is caused by bacteria (*Streptococcus pneumoniae*, *Staphylococcus aureus*, or *Haemophilus influenzae*), viruses (adenovirus) and allergy (allergens).
- Acute rhinosinusitis caused by bacteria may be superimposed on acute viral or allergic rhinitis resulting in injury to mucosal cilia of airways.
- Adenovirus causes coryza (runny nose), sneezing, nasal congestion, and mild sore throat. Allergic rhinosinusitis is characterized by nasal discharge and peripheral eosinophilia. Respiratory epithelium is infiltrated by necrotic material, apoptotic neutrophils and nuclear debris.
- Diagnostic modalities include bacterial culture of sinus aspirate, sinus radiographs and CT scan (most sensitive).

CHRONIC RHINOSINUSITIS

Predisposing factors for chronic rhinosinusitis include allergy, upper respiratory tract infections, cystic fibrosis, and immotile cilia syndrome (Kartagener's syndrome) especially secondary to obstruction of paranasal sinuses outflow. It commonly affects children. Submucosa is

infiltrated by lymphocytes, plasma cells and eosinophils. Complications of chronic rhinosinusitis include superadded bacterial infection and inflammatory polyp.

WEGENER'S GRANULOMATOSIS

Wegener's granulomatosis is an autoimmune disorder, which shares some features with lethal midline granuloma. Both diseases are characterized by necrotizing, ulcerated, mucosal lesions of upper respiratory tract.

- Lethal midline granuloma is a sign of underlying lymphomas. Wegener's granulomatosis is characterized by necrotizing vasculitis (fibrinoid necrosis) involving arterioles, small arteries and veins. Wegener's granulomatosis also involves respiratory system and kidney.
- Patient suffering from Wegener's granulomatosis presents with rhinorrhea, sinusitis, headache, nasal obstruction and symptoms due to eustachian tube obstruction. More than 90% of patients with Wegener's granulomatosis exhibit antineutrophil cytoplasmic antibody (ANCA).

Surgical Pathology: Wegener's Granulomatosis

Light Microscopy

Histologic examination of lesion shows chronic inflammatory infiltrate, granulomas and necrotising vasculitis.

ALLERGIC POLYPS

Allergic polyps are most common non-neoplastic lesions in nasal cavity. Long-standing chronic allergic rhinitis causes non-neoplastic mucosal and submucosal projections forming nasal polyps.

- Allergic polyps most often affect adults. In case of nasal polyps in children, sweat test must be done to rule out cystic fibrosis.
- Patient presents with nasal obstruction and rhinorrhea. Unilateral or bilateral multiple polyps arise from lateral nasal wall or ethmoid recess. Allergic polyps may cause deviated nasal septum, destruction of bone and rarely extend to nasopharynx (Fig. 17.1).

Fig. 17.1: Nasal polyp.

Surgical Pathology: Allergic Polyps

Gross Morphology

- Allergic polyps may measure up to several centimeters.
- These polyps are boggy, gelatinous, and translucent with broad base (Fig. 17.2A and B).

Light Microscopy

- Histologic examination of allergic polyps reveals intact respiratory epithelium, edematous, myxomatous stroma, infiltrated by lymphocytes, plasma cells and eosinophils.
- There is absence of seromucinous glands (Fig. 17.3).

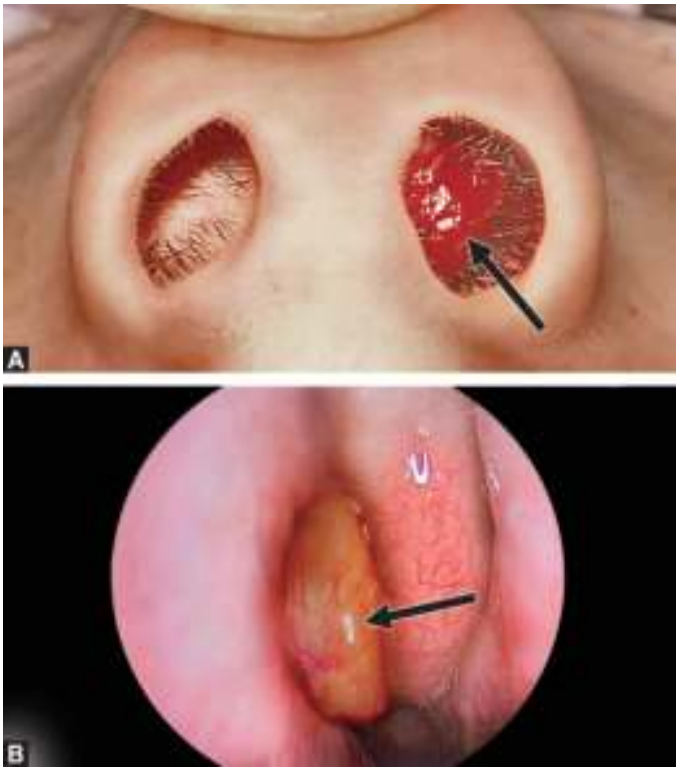

Fig. 17.2A and B: Nasal polyp (arrows).

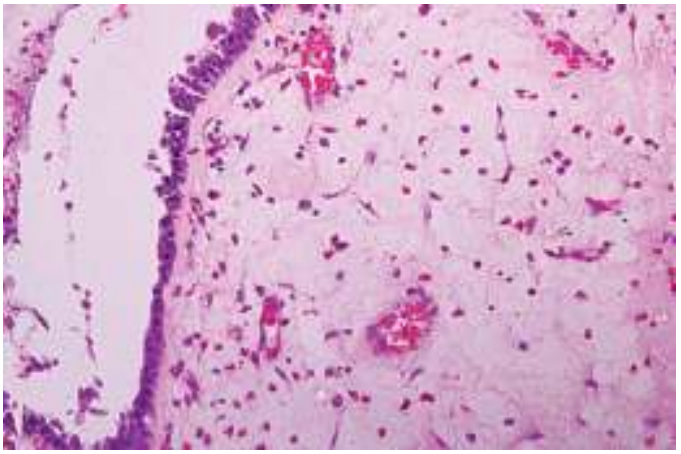

Fig. 17.3: Allergic nasal polyp. It shows dense eosinophilic infiltrate (400X).

FUNGAL SINUSITIS

Fungi may cause noninvasive or invasive sinusitis.

- Patient with noninvasive fungal sinusitis presents with polyps formation involving single or multiple paranasal sinuses.
- Patient with invasive fungal acute sinusitis presents with severe acute sinusitis, fever, and nasal discharge, ocular or neurologic deficits. Chronic invasive sinusitis is characterized by slowly progressive sinusitis with neurologic or orbital defects and mass.
- Fungi are demonstrated by Grocott's methenamine silver stain. Features of fungal sinusitis are given in Table 17.1.

SINONASAL NEOPLASTIC DISORDERS

A wide variety of neoplasms occurs in the sinonasal region (Fig. 17.4A and B). WHO classification of tumors of the nasal cavity, paranasal sinuses and skull base is given in Table 17.2.

SCHNEIDERIAN SINONASAL PAPILLOMAS

Schneiderian papillomas are the most common benign tumors of the nasal cavity, which are derived from Schneiderian membrane. Histologic variants of Schneiderian sinonasal papillomas are exophytic, endophytic and oncocytic. Histologic examination is essential due to their different clinical behavior and risk for development of invasive carcinomas.

Table 17.1 Features of fungal sinusitis

Entity	Clinical Manifestations	Light Microscopy	Causative Organism
Noninvasive fungal sinusitis			
Fungal sinusitis	Allergic polyps involving multiple sinuses	Eosinophils, Charcot-Leyden crystals and hyphae	Bipolaris, Curvularia, Alternaria, *Aspergillus dematiaceous*, Cladosporium
Mycetoma (fungal ball)	Nonallergic polyps involving single sinus	Fungal hyphae	Mycetoma
Invasive fungal sinusitis			
Acute invasive fungal sinusitis	Severe acute sinusitis, fever, nasal discharge, ocular or neurologic deficits	Fungal hyphae in blood vessels, granulomas, necrosis	Mucor, Rhizopus, Absidia, Cunninghammella *Aspergillus dematiaceous* (uncommon)
Chronic invasive sinusitis	Slowly progressive sinusitis onset, neurologic or orbital defects, mass	Fungal hyphae in blood vessels, granulomas, necrosis	*Aspergillus dematiaceous*

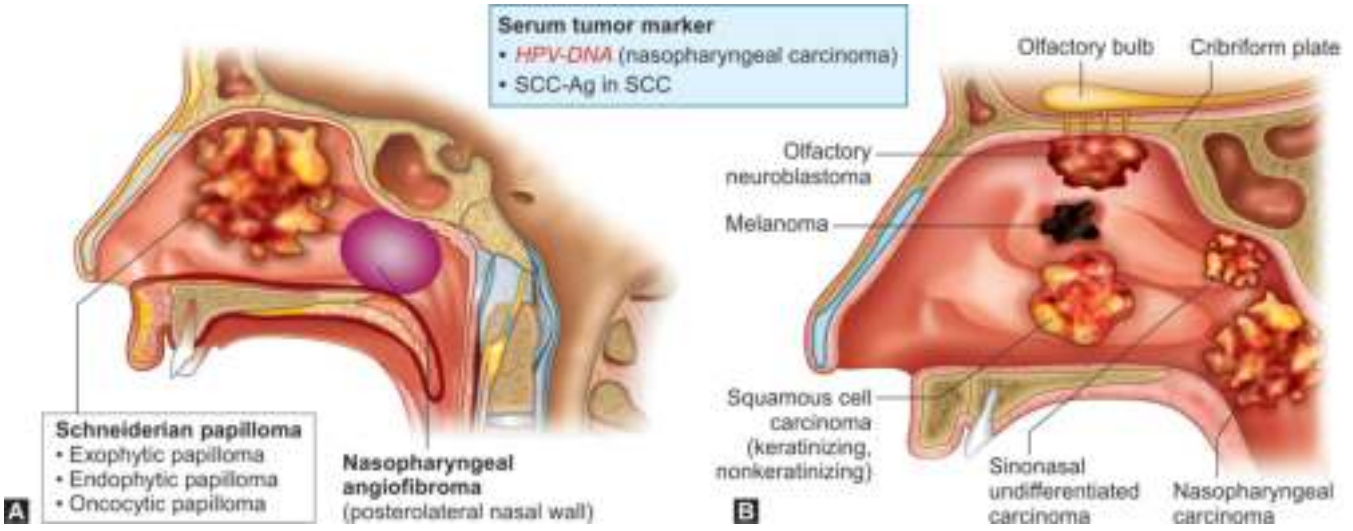

Fig. 17.4: Tumors of nasal cavity and paranasal sinuses. (A) Benign tumors, (B) malignant tumors.

Table 17.2 WHO classification of tumors of the nasal cavity, paranasal sinuses and skull base

Carcinomas
- Keratinizing squamous cell carcinoma
- Nonkeratinizing squamous cell carcinoma
- Spindle cell variant of squamous cell carcinoma
- Lymphoepithelial carcinoma
- Sinonasal undifferentiated carcinoma
- NUT carcinoma
- Neuroendocrine carcinomas
  - Small cell neuroendocrine carcinoma
  - Large cell neuroendocrine carcinoma
- Adenocarcinomas
  - Intestinal-type adenocarcinoma
  - Nonintestinal-type adenocarcinoma
- Teratocarcinoma

Benign Tumors
- Sinonasal papilloma
  - Sinonasal papilloma, inverted type
  - Sinonasal papilloma, oncocytic type
  - Sinonasal papilloma, exophytic type
- Respiratory epithelial lesions
  - Respiratory epithelial adenomatoid hamartoma
  - Seromucinous hamartoma
- Salivary gland tumor
  - Pleomorphic adenoma

Malignant Soft Tissue Tumors
- Fibrosarcoma
- Undifferentiated pleomorphic sarcoma
- Leiomyosarcoma
- Rhabdomyosarcoma, not otherwise specified
- Alveolar rhabdomyosarcoma
- Pleomorphic rhabdomyosarcoma, adult type
- Spindle cell rhabdomyosarcoma
- Angiosarcoma
- Malignant peripheral nerve sheath tumor
- Biphenotypic sinonasal sarcoma
- Synovial sarcoma

Borderline/Low Grade Malignant Soft Tissue Tumors
- Desmoid-type fibromatosis
- Sinonasal glomangiopericytoma
- Solitary fibrous tumor
- Epithelioid hemangioendothelioma

Benign Soft Tissue Tumors
- Leiomyoma
- Hemangioma
- Schwannoma
- Neurofibroma

Other Tumors
- Meningioma
- Sinonasal ameloblastoma
- Chondromesenchymal hamartoma

Hematolymphoid Tumors
- Extranodal NK/T cell lymphoma
- Extraosseous plasmacytoma

Neuroectodermal/Melanocytic Tumors
- Ewing's sarcoma/primitive neuroectodermal tumor
- Olfactory neuroblastoma
- Mucosal neuroma

Contd...

Sinonasal Exophytic Papilloma

Exophytic papilloma most often arises from nasal septum in 20–50 years males. Tumor is solitary and discrete. Human papillomavirus (6 and 11) has been demonstrated in large number of cases. Patient presents with epistaxis, unilateral nasal obstruction or symptomatic nasal mass. Recurrence of exophytic papilloma is common after surgery. There is no risk for development of carcinoma in these patients.

Surgical Pathology: Sinonasal Exophytic Papilloma

Gross Morphology

Tumor is gray pink, translucent mass with broad base (Fig. 17.5).

Light Microscopy
- Tumor is composed of exophytic papillary fronds lined by thickened epithelium (squamous to respiratory or transitional or features of both).
- Scattered mucin secreting cells are also present.
- Neutrophil collections are present in epithelial fronds. Surface keratinization is absent except in rare case.
- Tumor cells do not show atypia (Fig. 17.6).

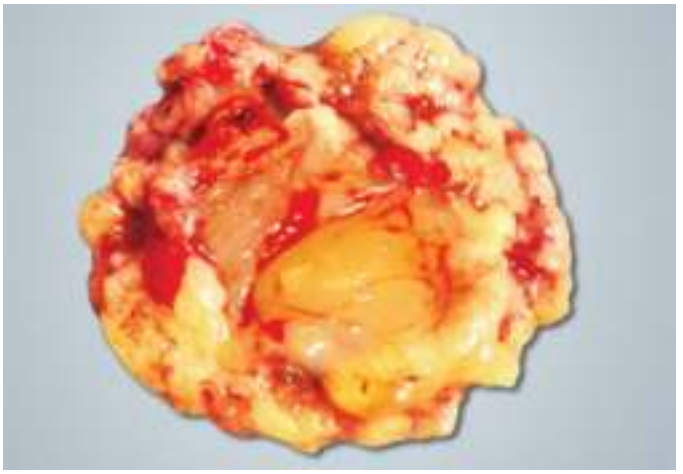

Fig. 17.5: Exophytic papilloma. Tumor is gray pink, translucent mass with broad base.

Sinonasal Endophytic Papilloma

Endophytic papilloma most often occurs in 40–70 years adults. Tumor arises from lateral nasal wall in the region of middle turbinate and ethmoid recesses. It may also arise from nasal septum in 8% of cases. Human papillomavirus (6 and 11) has been demonstrated in 50% of

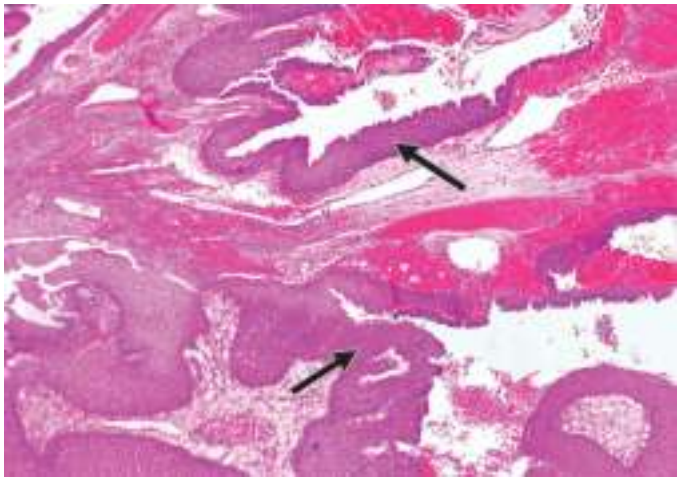

Fig. 17.6: Sinonasal exophytic papilloma: It shows exophytic papillary fronds lined by thickened epithelium (squamous to respiratory or transitional or features of both). Tumor cells do not show atypia (arrows) (100X).

cases. Patient presents with unilateral nasal obstruction or symptomatic nasal mass. Recurrence is common in 5–20% of cases after surgery. There is increased risk for development of carcinoma in 10–15% of cases.

Surgical Pathology: Sinonasal Endophytic Papilloma
Gross Morphology
Tumor is fleshy pink tan with papillary or polypoid (Fig. 17.7).
Light Microscopy
▪ Tumor is composed of numerous basement membrane enclosed, rounded ribbons of thickened epithelium ranging from squamous to transitional with minimal mitoses without atypia. ▪ Neutrophils are present in the epithelium (Figs 17.8 and 17.9).

Fig. 17.7: Sinonasal endophytic papilloma. It is fleshy pink-tan with papillary fronds.

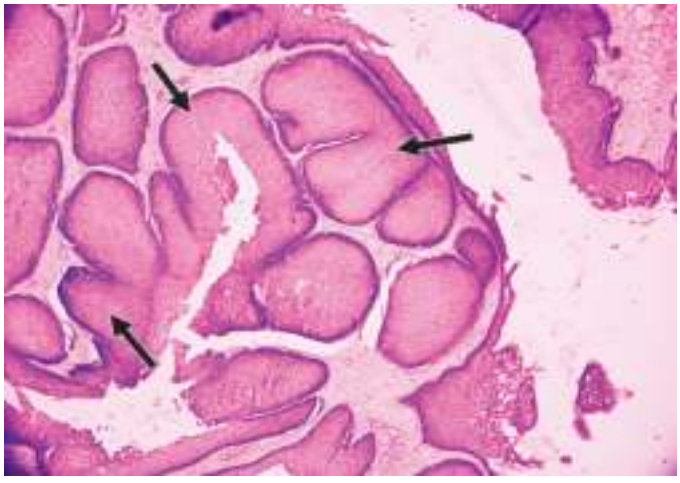

Fig. 17.8: Sinonasal endophytic (inverted) papilloma. Tumor is composed of numerous basement-enclosed, rounded ribbons of thickened epithelium ranging from squamous to transitional with minimal mitoses without atypia (arrows) (100X).

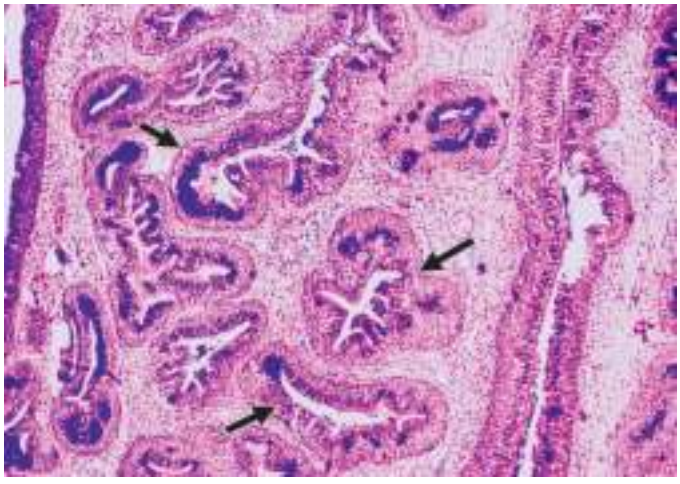

Fig. 17.9: Sinonasal endophytic (inverted) papilloma. It shows numerous rounded ribbons of thickened epithelium ranging from squamous to transitional with minimal mitoses without atypia (arrows) (200X).

Sinonasal Oncocytic Papilloma

Oncocytic papilloma is least common equally affecting men and women. HPV has not been demonstrated in oncocytic papilloma. Patient presents with unilateral nasal obstruction or symptomatic nasal mass. Recurrence is common after surgery. There is increased risk for development of carcinoma in 5–15% of cases.

Surgical Pathology: Sinonasal Oncocytic Papilloma
Light Microscopy
Tumor is composed of exophytic and endophytic nests of columnar, oncocytic cells with abundant, granular eosinophilic cytoplasm; intraepithelial neutrophils and microcysts (Fig. 17.10). Features of Schneiderian sinonasal papilloma are given in Table 17.3.

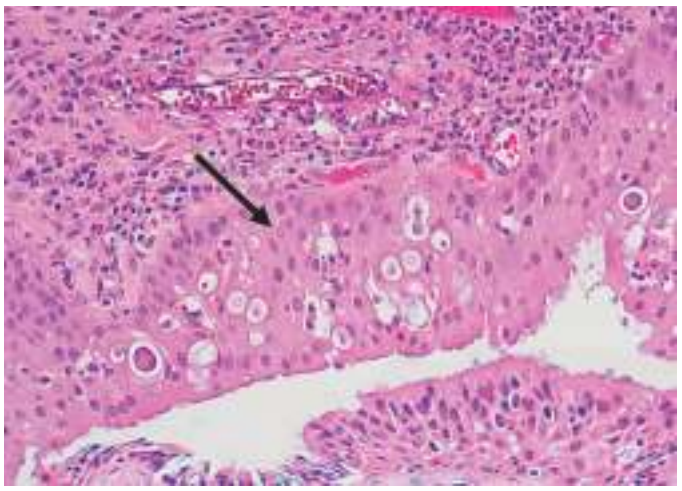

Fig. 17.10: Sinonasal oncocytic papilloma. Tumor is composed of nests of oncocytic cells with abundant, granular eosinophilic cytoplasm, and intraepithelial neutrophils (arrow) (400X).

SINONASAL UNDIFFERENTIATED CARCINOMA

Sinonasal undifferentiated carcinoma is an aggressive tumor. It most often occurs in elderly persons in their 6th decade. It arises from superior region of nasal cavity or maxillary or ethmoid sinuses. Patient presents with nasal obstruction, epistaxis, orbital or cranial nerve deficits.

Surgical Pathology: Sinonasal Undifferentiated Carcinoma
Gross Morphology
This bulky tumor has no unique gross features.
Light Microscopy
▪ Tumor is composed of small- to moderate-sized uniform cells with hyperchromatic to vesicular nuclei and prominent nucleoli. ▪ Tumor cells are arranged in nests, lobular or trabeculae pattern. ▪ There is abundant apoptosis, mitoses and necrosis in the tumor (Fig. 17.11).
Immunohistochemistry Technique
Panel of markers is employed on histologic sections obtained from tumor.

Markers	Expression
▪ Pancytokeratins (7, 8, 19) ▪ Epithelial membrane antigen (EMA) ▪ Neuron-specific enolase (NSE)	▪ Positive ▪ Positive ▪ Positive (30%)
Neuroendocrine markers: Tumor expresses NSE, but negative for chromogranin A and synaptophysin.	

NASOPHARYNGEAL CARCINOMA

Nasopharyngeal carcinoma is most common tumor of nasopharynx. It is associated with Epstein-Barr virus (EB virus). It is more prevalent in males especially in Chinese and African population. It metastasizes to cervical lymph nodes. Most patients have anti-EBV IgA in their serum.

Clinical Features

Patient presents with sinonasal mass, nasal obstruction, epistaxis and serous otitis media due to blockage of eustachian tube. Infrequently, patient may be asymptomatic even with neck metastases.

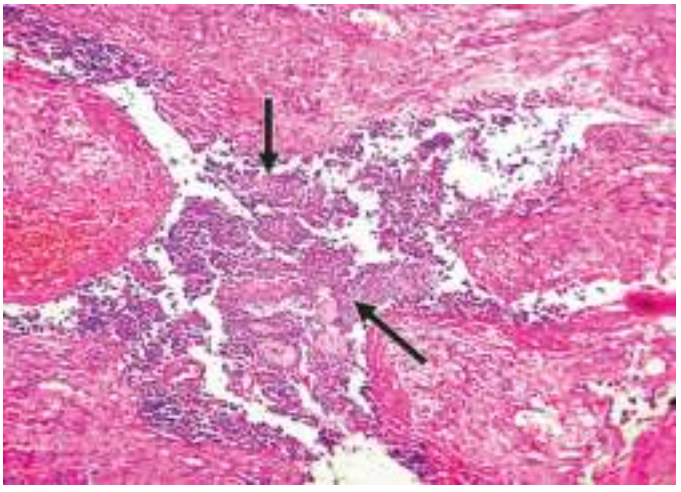

Fig. 17.11: Sinonasal undifferentiated carcinoma. Tumor is composed of atypical cells with hyperchromatic nuclei and prominent nucleoli arranged in nests (arrows) (100X).

Table 17.3 Features of Schneiderian sinonasal papillomas

Histologic Variants	Common Location	Pathology	Behavior after Surgical Excision	Malignant Transformation to Invasive Carcinoma
Exophytic papilloma	Nasal septum	Exophytic fronds of squamous or transitional, epithelium containing neutrophils	Local recurrence	No risk of malignancy
Inverted papilloma	Lateral nasal wall; paranasal sinuses	Endophytic fronds of squamous or transitional, epithelium containing neutrophils	Local recurrence	10–15%
Oncocytic papilloma	Lateral nasal wall; paranasal sinuses	Exophytic and endophytic nests of columnar, oncocytic cells with abundant, granular eosinophilic cytoplasm; intraepithelial neutrophils and microcysts	Local recurrence	5–15%

Surgical Pathology: Nasopharyngeal Carcinoma

Gross Morphology

Tumor is gray white to tan. Cut surface is gray white with areas of hemorrhage (Fig. 17.12).

Light Microscopy

WHO classification of nasopharyngeal carcinoma is given in Table 17.4. EB virus is strongly linked in the oncogenesis of nonkeratinizing nasopharyngeal carcinoma (types: WHO-2a and 2b).

- **Keratinizing squamous cell carcinoma (WHO-1):** Tumor has morphology similar to keratinizing squamous cell carcinoma elsewhere in head and neck and graded as well to poorly differentiated carcinoma (Fig. 17.13).
- **Nonkeratinizing differentiated carcinoma (WHO-2a):** Tumor has surface disease with stratified cells that have similar morphology to that of urothelial carcinoma of urinary bladder.
- **Nonkeratinizing undifferentiated carcinoma (WHO-2b):** Tumor is the most common variant of nasopharyngeal carcinoma. It is composed of tumor cells arranged in sheets/syncytial aggregates. Tumor cells contain eosinophilic cytoplasm, large vesicular nuclei and prominent nuclei. These tumor cells are admixed with chronic inflammatory cells (Fig. 17.14).
- **Basaloid squamous cell carcinoma (WHO-3):** Tumor is least common variant of nasopharyngeal carcinoma. It has similar morphology that occurs in head and neck.

Immunohistochemistry Technique

These are immunoreactive with antibodies to cytokeratins.

Clinical Course

- **Nonkeratinizing undifferentiated carcinoma:** It most often metastasizes to cervical lymph nodes in posterior triangle (level 5). The tumor responds well to systemic therapy. Radiotherapy is the first line of treatment. Surgery is reserved for salvage therapy.

Fig. 17.12: Squamous cell carcinoma. Tumor is arising from maxillary sinus.

Table 17.4 WHO classification of nasopharyngeal carcinoma

Histologic Variants	Types
Keratinizing squamous cell carcinoma	1
Nonkeratinizing differentiated carcinoma	2a
Nonkeratinizing undifferentiated carcinoma	2b
Basaloid squamous cell carcinoma	3

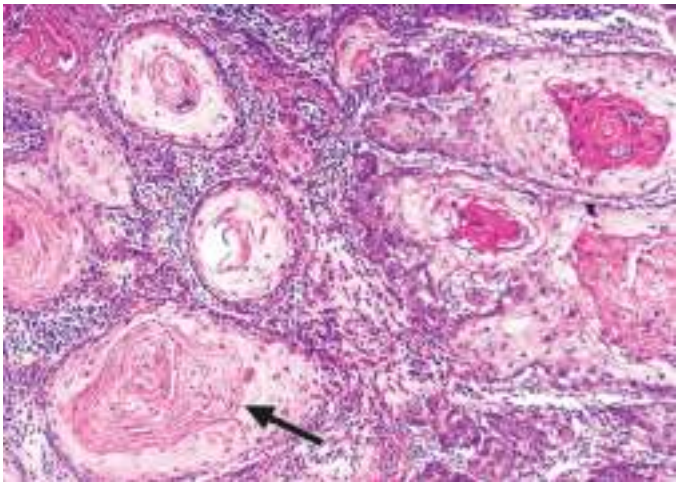

Fig. 17.13: Keratinizing squamous cell carcinoma (WHO-1). Tumor shows areas of keratinization (arrow) (400X).

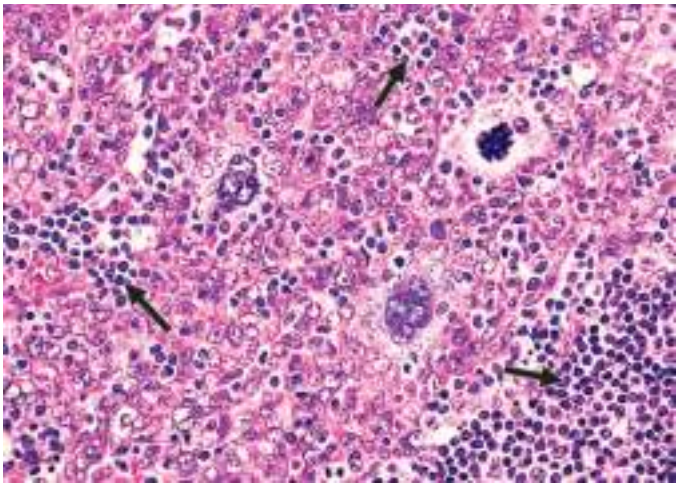

Fig. 17.14: Nonkeratinizing undifferentiated carcinoma most common variant (WHO-2b)—tumor cells contain eosinophilic cytoplasm, large vesicular nuclei and prominent nuclei, arranged in sheets syncytial aggregates and admixed with chronic inflammatory cells (arrows) (100X).

- **Keratinizing squamous cell carcinoma:** Patient most often presents with localized disease. It does not respond to systemic therapy.

SINONASAL SQUAMOUS CELL CARCINOMA

Squamous cell carcinoma is the most common tumor in head and neck. It constitutes 65% of carcinomas in the

nasal cavity and paranasal sinuses. Histologic variants of squamous cell carcinoma include keratinizing and nonkeratinizing squamous cell carcinoma.

- **Keratinizing squamous cell carcinoma:** It is associated with tobacco smoking, exposure to nickel, textile dusts and chlorophenols.
- **Nonkeratinizing squamous cell carcinoma:** It has papillary configuration. Tumor is composed of ribbons of pleomorphic cells lacking keratinization. It has been associated with HPV. This variant has better prognosis.

SINONASAL MELANOMA

Melanoma of sinonasal region constitutes 1% of all melanomas. It occurs in the nasal cavity and paranasal sinuses especially in middle or inferior turbinate in patients over 50 years. The tumor may be sessile/polypoidal growth with mucosal ulceration and heavily pigmented (brown or black). It metastasizes to sinonasal region. Prognosis of melanoma is poor.

Surgical Pathology: Sinonasal Melanoma

Light Microscopy

- Melanoma has a wide range of morphologic features. Tumor is composed of pleomorphic melanocytes. Some tumors are composed of mixture of epithelioid cells and spindle cells.
- There is also presence of junctional component with pagetoid spread of melanocytes in the intact mucosa.

Immunohistochemistry Technique

Panel of markers is employed on histologic sections obtained from tumor.

Markers	Expression
S-100	Positive
HMB-45	Positive
Melan-A	Positive
CAM 5.2	Positive
Ki-67	Positive

OLFACTORY NEUROBLASTOMA

Olfactory neuroblastoma most often occurs in the upper nasal cavity wall and superior turbinate of men between 30 and 40 years unlike pediatric neuroblastoma, which most often occurs in the adrenals/abdomen of infants and young children. Tumor arises from olfactory mucosa of the cribriform plate in the upper nasal cavity wall and superior turbinate. Patient presents with unilateral polypoid mass in nasal cavity causing nasal obstruction and epistaxis.

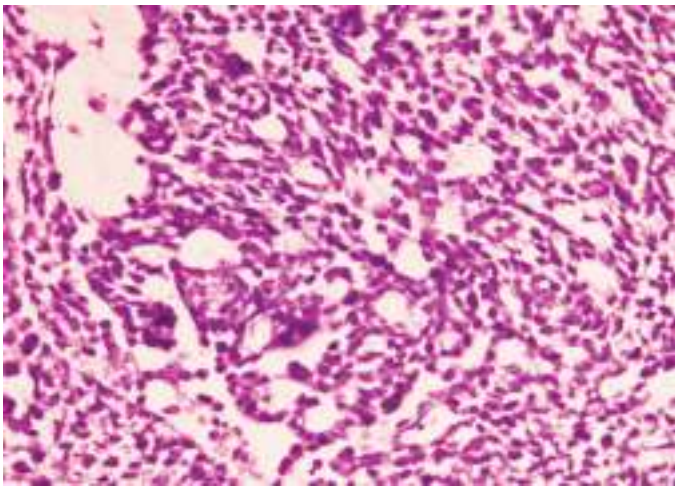

Fig. 17.15: Olfactory neuroblastoma (diffuse pattern) with neurofibrillary background (100X).

Surgical Pathology: Olfactory Neuroblastoma

Light Microscopy

- Tumor is composed of small round blue cells set in a neurofibrillary matrix.
- Tumor cells contain round uniform nuclei with uniform delicate stippled chromatin (Fig. 17.15).

Immunohistochemistry Technique

Panel of markers is used on histologic section to demonstrate expression by tumor cells.

- CD45 rules out lymphoma
- CD99 rules out Ewing/PNET
- Myogenin/MyoD1 rules out rhabdomyosarcoma
- Pituitary hormone markers rule out pituitary adenoma.

Markers	Expression
Synaptophysin	Positive
Chromogranin A	Positive
Neuron-specific enolase (NSE)	Positive
Calretinin	Positive
CAM 5.2	Positive

NASOPHARYNGEAL ANGIOFIBROMA

Nasopharyngeal angiofibroma is a rare vascular tumor, which arises from fibrovascular nidus in the posterolateral nasal wall adjacent to the sphenopalatine foramen. It may occur in maxilla and ethmoid bones in elderly females. It most often affects adolescent males between 10 and 20 years. It is histologically benign but locally aggressive tumor. It may destroy nearby bone and extend in cranial cavity. Patient presents with nasopharyngeal mass bulging in nasopharynx and nasal obstruction and epistaxis.

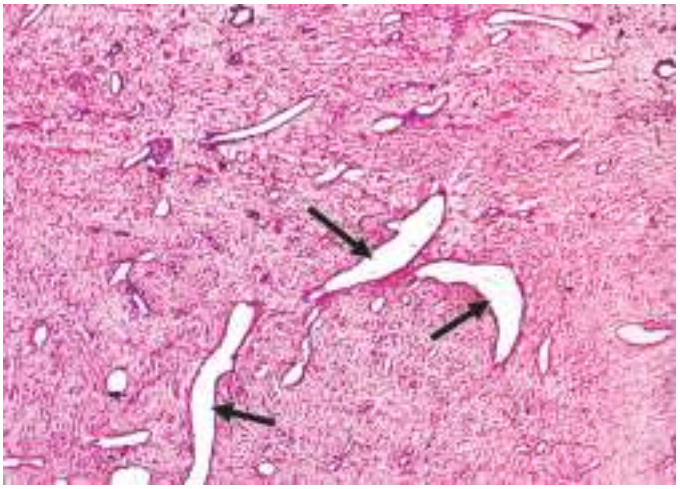

Fig. 17.16: Nasopharyngeal angiofibroma. It shows vascular channels lined by flat to plump endothelial cells of variable size dispersed in collagenized stroma (arrows) (100X).

Surgical Pathology: Nasopharyngeal Angiofibroma
Gross Morphology
Tumor is gray white to tan, smooth with lobulated appearance. Cut surface is homogenous.
Light Microscopy
▪ Tumor is composed of vascular channels of variable size dispersed in collagenized stroma containing scattered spindle and stellate cells. ▪ Vascular channels are lined by flat to plump endothelial cells without cytologic atypia. Stromal cells contain vesicular nuclei with vesicular chromatin without cytologic atypia (Fig. 17.16).
Immunohistochemistry Technique
▪ Vascular endothelium is positive with CD31 and CD34. ▪ Fibroblastic component expresses cytoplasmic vimentin.

ALVEOLAR RHABDOMYOSARCOMA

Alveolar rhabdomyosarcoma is an aggressive mesenchymal malignancy most common in young children. Tumor is always characterized by two characteristics translocations. Translocation (1;13) leading to PAX7-FKHR fusion transcription factor in 20% of cases is associated with better prognosis only in setting of metastatic disease. Translocation (2;13) causes PAX3-FKHR fusion transcription factor in 80% of cases.

Surgical Pathology: Alveolar Rhabdomyosarcoma
Gross Morphology
Tumor has fleshy to firm tan-gray appearance.
Light Microscopy
▪ Tumor is composed of small- to medium-sized cells with hyperchromatic nuclei and scant eosinophilic cytoplasm. ▪ Tumor cells are arranged in loosely cohesive sheets separated by fibrous septa.
Immunohistochemistry Technique
Panel of markers is used on histologic section to demonstrate expression by tumor cells.

Markers	Expression
▪ Desmin	▪ Positive
▪ Muscle-specific actin	▪ Positive
▪ Myoglobin	▪ Positive
▪ MyoD1	▪ Positive

SINONASAL PLASMACYTOMA

Plasmacytoma is a plasma cell tumor in its extraosseous form, present in the upper respiratory tract, which lacks radiographic or morphologic evidence of bone marrow involvement. Tumor is composed of plasma cells and their precursors at various stages of development. Accordingly, immunohistochemical reactivity for CD138 can be useful to confirm the diagnosis.

SINONASAL ADENOCARCINOMA

Nasal adenocarcinoma accounts for 5% of malignant tumor of the nose and throat. Histologic examination shows intestinal-type and nonintestinal-type of adenocarcinoma of nasal cavity.

SINONASAL HEMANGIOBLASTOMA

Hemangioblastoma is a benign tumor of nose. Tumor is treated by surgical excision. Tumor is composed of fascicles of spindle cells with indistinct borders arranged around blood vessels. Tumor may exhibit storiform pattern or whorled appearance.

MISCELLANEOUS SINONASAL DISORDERS

RHINOSPORIDIOSIS

Rhinosporidiosis is caused by *Rhinosporidium seeberi*. Patient presents with polypoidal masses containing sporangia in the nose (most common site), larynx, trachea, skin and ear.

Surgical Pathology: Rhinosporidiosis
Light Microscopy
▪ Nasal mucosa may undergo squamous metaplasia. Thick-walled sporangia containing numerous endospores are present beneath epithelium.

- Sporangia are surrounded by mixed inflammatory cells with numerous eosinophils.
- These sporangia may rupture resulting in formation of thick hyalinized wall (Fig. 17.17).

Histochemistry

Sporangia are demonstrated by PAS and silver methenamine stains.

RHINOSCLEROMA

Rhinoscleroma is caused by gram-negative Klebsiella rhinoscleromatis by droplet infection. It most often occurs in nose, which may extend to pharynx and upper respiratory tract. Patient presents with tumor mass in the nasal cavity protruding from the nostril and extending in the nasopharynx.

Surgical Pathology: Rhinoscleroma

Light Microscopy

- Rhinoscleroma is composed of large foamy histiocytes laden with organisms known as Mikulicz cells.
- Mikulicz cells are admixed with numerous plasma cells (Fig. 17.18).

Histochemistry

The organisms are demonstrated by Giemsa, PAS and silver impregnation stains.

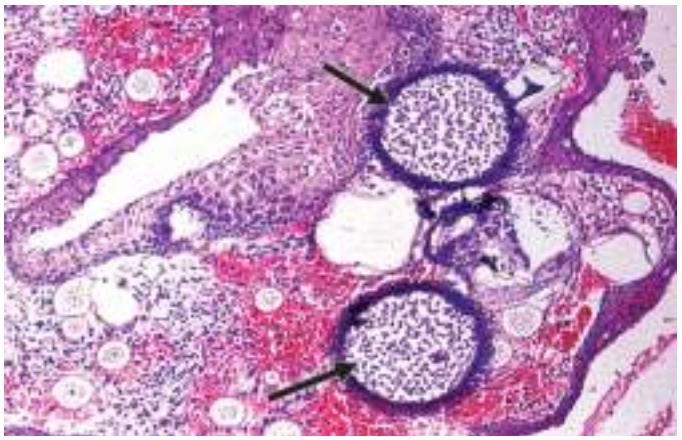

Fig. 17.17: Rhinosporidiosis. It shows many sporangia containing spores (arrows) (100X).

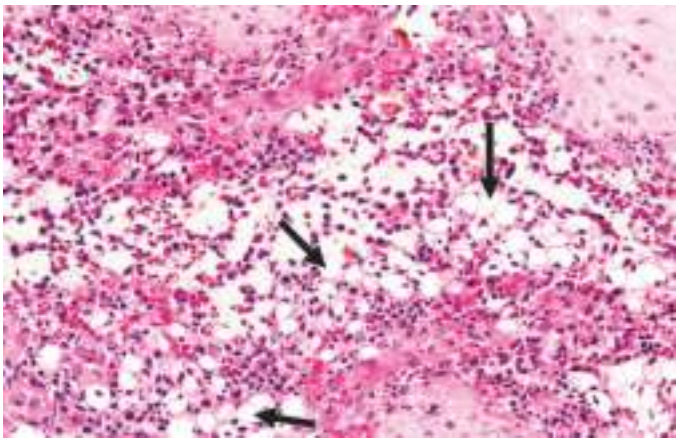

Fig. 17.18: Rhinoscleroma is composed of large foamy histiocytes laden with organisms known as **Mikulicz cells** (arrows) (400X).

DISORDERS OF EAR

ANATOMY OF EAR

Ear is composed of external, middle and internal portions. External ear consists of auricle, external auditory canal, and eardrum (tympanic membrane).

- The external auditory meatus extends up to the tympanic membrane. It is lined by wax secreting sebaceous glands.
- Middle ear consists of the auditory (eustachian tube), ossicles (malleus, incus and stapes), oval window and round window. Sound waves travel down the external auditory canal and strike tympanic membrane. Vibrations from eardrum pass to three tiny bones of the middle ear called ossicles.
- Eustachian tube or the auditory connects the middle ear cavity with the nasopharynx. It helps in equalizing the pressures on either sides of the eardrum.
- Inner ear consists of bony labyrinth, membranous labyrinth and vestibular apparatus. Common diseases affecting ear are shown in Fig. 17.19.

EAR: DISORDERS

EXTERNAL EAR DISORDERS

Preauricular Sinus

Preauricular sinus is commonest disorder arising as a result of abnormal fusion of facial folds, which leads to formation of blind-ending track opening on the skin just anterior to the external auditory meatus. Obstruction of sinus opening results in information of keratin-filled epidermal cyst. Sinus tract may undergo superadded infection resulting in abscess formation.

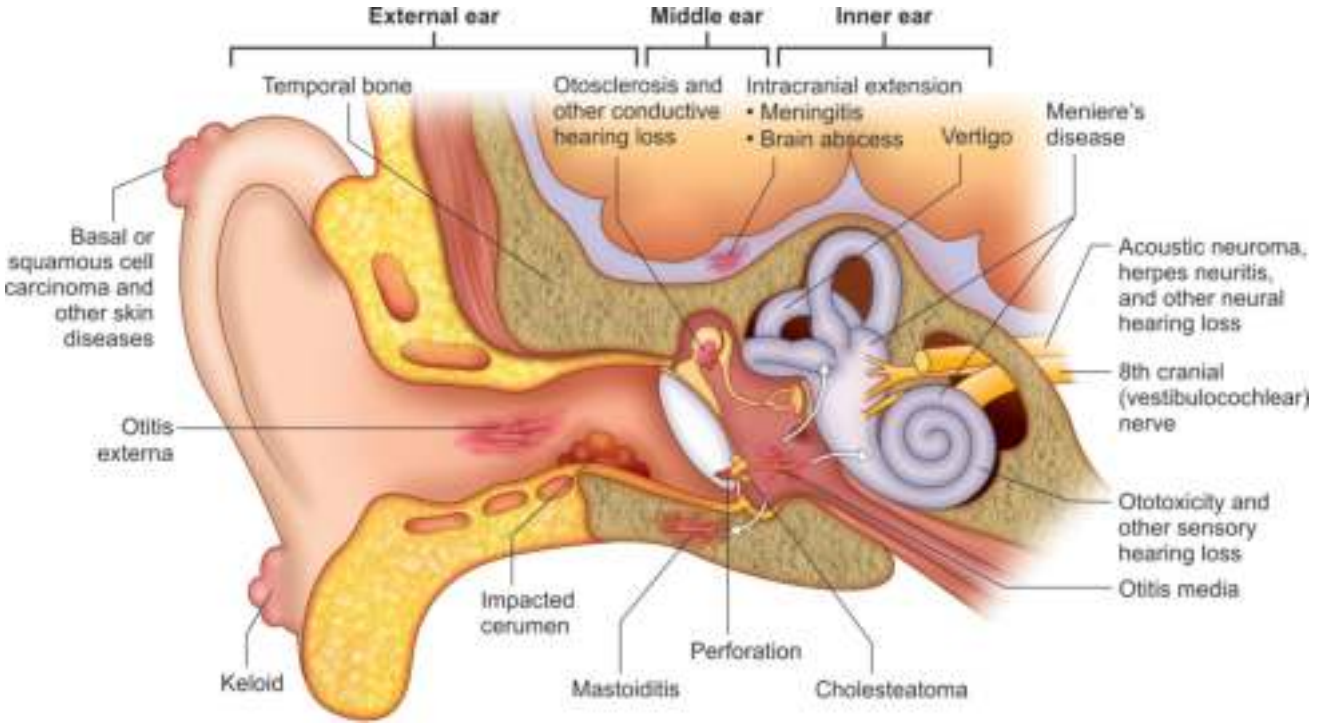

Fig. 17.19: Common diseases of the external, middle and internal ear.

Diagonal Ear Lobe Crease

Some persons show a crease of the ear lobe running downwards from the external auditory meatus. There is increased risk for development of cerebrovascular disease, most notably ischemic heart disease.

Cauliflower Ear

Cauliflower ear is characterized by thickening of the pinna due to partial organization of repeated hematoma resulting from trauma. It is commonly seen in boxers.

Chondrodermatitis Nodularis Chronica

Chondrodermatitis nodularis chronica is characterized by painful nodule on the superior portion of the helix. Skin ulceration extends to cause degenerated eosinophilic cartilage associated with inflammation of the perichondrium. Trauma is considered to be underlying etiology.

Relapsing Polychondritis

Relapsing polychondritis is characterized by involvement of cartilage, eye and heart. Patient presents with reddening, swelling and painful pinna followed by atrophy and destruction of cartilage. It is considered to be an autoimmune disorder related to autoimmune vasculitis.

Inflammation of Pinna and External Auditory Meatus

Inflammation may affect pinna and external auditory meatus caused by bacteria, viruses or fungi.

- *Pseudomonas aeruginosa* produces very severe otitis externa. Herpes simplex 1 and 2 produce painful blisters in the auditory canal and meatus.
- Varicella zoster lying dormant in ganglion involves pinna and meatus.
- Occasionally, varicella zoster may involve 8th cranial nerve ganglion leading to disturbances in hearing and balance known as **Ramsay Hunt syndrome**. Foreign bodies within tissues of the external ear produce non-infective inflammatory disease.

Ceruminous Gland Adenoma

Cerumic gland adenoma most often presents with blockage of the external auditory canal and unilateral deafness.

Malignant Neoplasms

Malignant neoplasms are rare in external ear.

MIDDLE EAR DISORDERS

Acute Serous Otitis Media

Acute serous otitis media is common in children most often associated with bacterial infection, i.e. *Streptococcus pneumoniae* and *Haemophilus influenzae* at the orifice of the eustachian tube, which may be precipitated by viruses, allergens or sudden changes in atmospheric pressure during flying in an aircraft or deep-sea diving resulting in obstruction of the eustachian tube.

- Repeated bouts of otitis media in early childhood often contribute to unsuspected hearing loss due to residual sterile fluid in the middle ear. Acute suppurative otitis media is unlikely without fever.
- In untreated cases, infection may spread to mastoid air spaces within bone, which further induce meningitis, encephalitis or brain abscess.

Chronic Otitis Media

Chronic otitis media most often develops without a preceding acute phase. It is usually caused by Proteus, *Pseudomonas aeruginosa*.

- Mastoid cells and tubotympanic region of the middle ear are most commonly involved. Chronic inflammation leads to formation of abundant granulation tissue that protrudes through tympanic membrane perforation as a polypoid mass, i.e. aural polyp. This process triggers scarring and new bone formation. Cholesteatoma and cholesterol granulomas are not associated with chronic otitis media.
- Patient presents with persistent earache, conduction deafness and chronic discharge from the external auditory meatus.

Cholesterol Granuloma

Cholesterol granuloma most often occurs as a consequence of previous hemorrhage. The lipid is being derived from cell membrane. Patient develops yellow nodules within tympanic membrane and mastoid. Histologic examination shows chronic inflammatory cells and foreign body giant cells.

Tympanosclerosis

Tympanosclerosis is special form of scarring associated with chronic otitis media. It is characterized by laying down of large amounts of dense hyalinized collagen fibers within the middle ear lining adversely affecting tympanic membrane and crura of stapes. There is presence of spotty calcification and new bone formation within plaques of fibrous tissue.

Otitis Media with Effusion (Glue Ear)

Otitis media with effusion is common cause of hearing loss in children. Patient develops thick effusion in the middle ear behind nonperforated tympanic membrane. As the drainage via eustachian tube is impaired, otitis media with effusion is treated by insertion of groomets through the tympanic membrane.

Cholesteatoma

Cholesteatoma refers to formation of actively growing, keratinizing, stratified squamous epithelium in the external ear canal resulting in extension into the middle ear through perforated eardrum and mastoid air cells.

- The keratin mass frequently becomes infected and shields the bacteria from antibiotics. Cholesteatoma is a complication of chronic suppurative otitis and rupture of the eardrum.
- Cholesteatoma may exist either as a closed cystic mass or open cystic mass, in which patient presents with keratin squames discharge into the middle ear cavity, which may show clinical evidence of bone destruction.

Classification

- **Congenital cholesteatoma:** It arises from an epithelial rest in the developing middle ear. Most common site of congenital cholesteatoma is, where middle ear epithelium joins eustachian tube.
- **Acquired cholesteatoma:** It most often occurs in the upper and posterior portion of middle ear filling most of middle ear cavity. Clinical significance of cholesteatoma is erosion of bony structures such as ossicles or the labyrinth and surrounding soft tissue especially facial nerve.

Surgical Pathology: Cholesteatoma

Light Microscopy

- Cholesteatoma is identical to epidermal inclusion cysts surrounded by granulation tissue and fibrosis.
- It erodes ossicles, labyrinth and soft tissues, especially facial nerve (Fig. 17.20).

Otosclerosis

Otosclerosis is commonest disorder of the cochlea and the footplates of stapes. It is an autosomal dominant disorder, which affects young and middle-aged adults in the United States. Approximately, 90% of cases are asymptomatic. Otosclerosis is characterized by formation

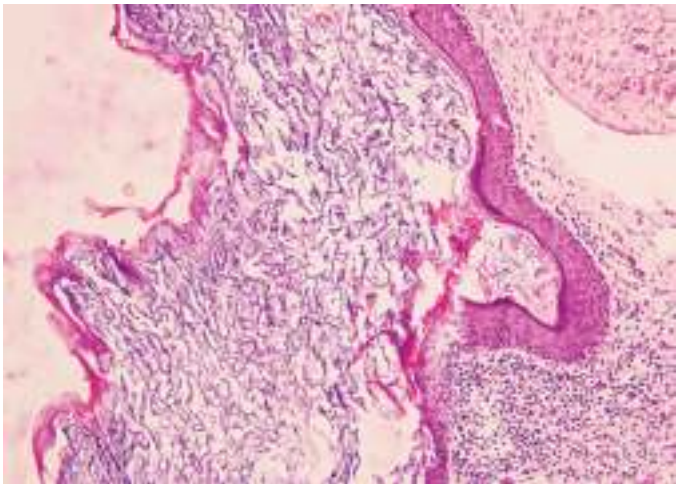

Fig. 17.20: Cholesteatoma is surrounded by granulation tissue and fibrosis. It is worth mentioning that it is identical to epidermal inclusion cysts. Squamous cell carcinoma rarely occurs in the ear (400X).

of new spongy bone over the stapes and the oval window, resulting in progressive conductive deafness. Fixation of stapes leads to failure of transmission of sound vibrations.

Surgical Pathology: Otosclerosis

Light Microscopy

- Stapedectomy specimen shows similar morphology resembling Paget's disease.
- Biopsy shows foci of woven bone rather than normal lamellar bone and numerous cement lines.

Electron Microscopy

Stapedectomy specimen shows structure resembling measles virus, and nucleocapsid antigen.

Paraganglioma (Glomus Jugulare Tumor)

Paraganglioma is the commonest slow-growing vascular tumor of the middle ear that bleeds freely on surgical excision. Tumor may invade the petrous temporal bone reaching the intracranial region in some cases.

- Paraganglioma arises from paraganglionic tissue in the wall of the jugular bulb in majority of cases, which tends to invade the petrous bone. Paraganglioma arising from paraganglion located near the middle ear surface of the promontory and remains localized to the middle ear.
- Patient presents with red mass either behind tympanic membrane or protruding out in the auditory canal. Metastases are very rare. Recurrence is common after surgical resection.

Surgical Pathology: Paraganglioma

Light Microscopy

- Paraganglioma has similar morphology in all sites.
- Tumor is composed of well-defined nests of catecholamine-containing cells.
- The tumor cells are separated by highly vascular fibrous tissue septa.
- Tumor cells are surrounded by sustentacular cells.
- Predicting malignant behavior from histologic appearance is impossible.

Immunohistochemistry Technique

Tumor cells do not contain catecholamine but react with monoclonal antibodies against the nuclear marker S-100.

INNER EAR DISORDERS

Patient presents with hearing loss, tinnitus and/or vertigo.

Viral Labyrinthitis

Mumps is the most common cause of deafness in 80% of cases among the postnatal viral infections. On the contrary, prenatal infection of the labyrinth with rubella is usually bilateral, with permanent loss of cochlear and vestibular function.

- Numerus viruses are suspected to cause viral labyrinthitis, i.e. influenza and parainfluenza viruses, Epstein-Barr virus, herpesviruses, and adenoviruses.
- Temporal bone specimens of such cases reveal severe damage to the organ of Corti, with almost total loss of both inner and outer hair cells.

Presbycusis

Presbycusis is the commonest cause of sensorineural hearing loss with aging. There is loss of outer hair cells at the base of lower end of the cochlea.

Meniere's Disease

Meniere's disease is characterized by both hearing loss and balance disturbance. Patient presents with episodic deafness, tinnitus and vertigo.

Toxic Damage of Inner Ear

Inner ear damage may be caused by genticin, loop of diuretics, salicylates, quinine and cisplatin. Patient presents with sensorineural deafness.

Acoustic Neuroma

Acoustic neuroma arises from the Schwann cells of 8th cranial nerve. Most patients develop unilateral acoustic neuroma. Patient presents with sensorineural deafness. Bilateral acoustic neuromas are characteristic of neurofibromatosis type 2 and characterized by deletion of chromosome 22.

DISORDERS OF LARYNX

ANATOMY AND HISTOLOGY

Larynx is composed of several cartilaginous structures such as thyroid, cricoid and arytenoid. Epiglottis guards the opening of the larynx, which prevents food from entering the larynx. Glottis refers to the vocal cords from the edge of the ventricle to the free edge of the vocal cords. Larynx is lined by mixture of squamous and pseudostratified ciliated columnar epithelium. True cords are covered by squamous epithelium.

INFLAMMATORY DISORDERS

Laryngitis is caused by viruses or bacteria, irritants, or overuse of the voice resulting in inflammation and edema of the vocal cords, with resultant hoarseness. Acute epiglottitis is usually caused by *Haemophilus influenzae* that may be life-threatening in young children. Acute laryngotracheobronchitis is acute inflammation of the larynx, trachea, and epiglottis most often caused by viral infection. It is potentially life-threatening in infants. Infant presents with harsh cough and inspiratory stridor.

TUMORS AND TUMOR-LIKE DISORDERS

VOCAL CORD NODULE

Vocal cord nodule is also known as **singer's nodule**. It is small reactive benign laryngeal polypoidal lesion usually induced by chronic irritation and localized to the true vocal cords.

Pathogenesis

Vocal cord nodule has been associated with excessive use of the voice and heavy cigarette smoking. Chronic cigarette smoking and excessive voice abuse injures, disrupts basement membrane and superficial layer of lamina propria resulting in hemorrhage in the stroma. Healing occurs by fibrosis and fibrin deposition.

Surgical Pathology: Vocal Cord Nodule
Gross Morphology
Macroscopically, vocal cord nodule appears as gray or white broad-based nodule or polyp.
Light Microscopy
▪ Vocal cord nodule is lined by hyperplastic squamous epithelium surrounding fibrovascular core composed of pinkish fibrin deposits, plump proliferating fibroblasts and blood vessels. ▪ Stroma is infiltrated by chronic inflammatory cells. ▪ Telangiectatic variant of vocal cord nodule is chiefly composed of dilated blood vessels. ▪ Gelatinous variant of vocal cord nodule shows fibrin deposits and thin blood vessels (Fig. 17.21).

SQUAMOUS CELL PAPILLOMA

Squamous cell papilloma arises around the true vocal cords. It is most often associated with low-risk HPV (6 and 11) infections. Children and adolescents may develop multiple lesions, i.e. juvenile laryngeal papillomatosis, that may extend into the trachea and bronchi leading to life-threatening state. Recurrence after tumor resection is common. It may rarely undergo malignant change.

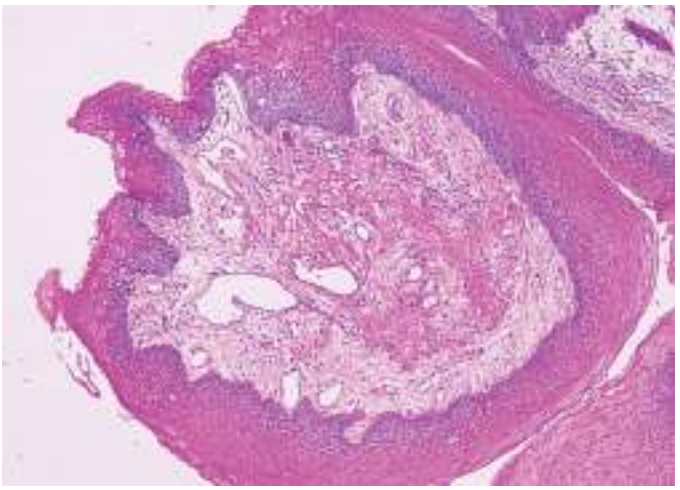

Fig. 17.21: Vocal cord nodule. Histologic examination shows hyperplastic squamous epithelium surrounding fibrovascular core composed of pinkish fibrin deposits, plump proliferating fibroblasts and blood vessels. Stroma is infiltrated by chronic inflammatory cells (100X).

Surgical Pathology: Squamous Papilloma
Gross Morphology
Tumor is exophytic, granular, friable, pink-red lesion.
Light Microscopy
▪ Tumor is composed of arborizing papillary fronds of squamous epithelium with some hyperplasia of the basal cells. ▪ Cells in the midlayer most often have clear cytoplasmic. ▪ Occasional suprabasal mitoses ciliated or columnar cells and koilocytes are common histologic findings in benign papilloma.

INTRAEPITHELIAL NEOPLASIA (CARCINOMA *IN SITU*)

Intraepithelial neoplasia is usually seen at the margins of invasive laryngeal carcinoma. It is characterized by variations in size and shape of dividing cells with mitotic activity arranged in disordered fashion with loss of cell maturation as cells progress to the surface, as a result of chronic irritation or inflammation.

Etiology

Tobacco smoking produces severe dysplasia (carcinoma *in situ*) in respiratory epithelium. It is potentially reversible if the patient stops tobacco smoking.

Diagnostic Criteria

Criterion for diagnosing intraepithelial neoplasia (carcinoma *in situ*) is the presence of atypia involving the epithelial covering of the vocal cord.

Clinical Features

Patient may present with hoarseness of voice as a result of slight reddening of vocal cords.

SQUAMOUS CELL CARCINOMA

Approximately 90% of malignant tumors of larynx are squamous cell carcinoma. Tumor most often arises from true vocal cords and affects 50–70 years of age. Men are more affected than women. Most cases develop squamous cell carcinoma of the glottic or supraglottic region. Patients are detected early. Squamous cell carcinoma of larynx arising from the vocal cord is shown in Fig. 17.22.

Risk Factors

Tobacco smoking appears to be main risk factor for development of laryngeal carcinoma. Excessive alcohol consumption is another risk factor.

Clinical Features

Patient presents with persistent hoarseness of voice, often associated with cervical lymphadenopathy.

Surgical Pathology: Squamous Cell Carcinoma of Larynx

Gross Morphology

Gross morphology of laryngeal squamous cell carcinoma is variable ranging from fungating, exophytic to endophytic, ulcerated tumors with raised edges (Fig. 17.23).

Light Microscopy

- **Keratinizing squamous cell carcinoma:** Tumor is composed of round to oval cells with abundant eosinophilic cytoplasm and prominent nucleoli arranged in nests and sheets and keratin pearls (Fig. 17.24).
- **Moderately differentiated carcinoma:** Tumor comprises pleomorphic cells with high nucleocytoplasmic ratio and moderate eosinophilic cytoplasm.
- **Poorly differentiated carcinoma:** Tumor is composed of small cells with less cytoplasm arranged singly or forming nests with marked mitotic activity.
- **Verrucous carcinoma:** Tumor is well differentiated nonmetastasizing variant of squamous cell carcinoma. Tumor appears as well circumscribed, warty exophytic growth with broad base white granular and friable mass. Tumor is composed of thick club-shaped papillae with broad pushing bases. There is absence of cytologic atypia and mitotic activity. Prognosis of this variant is excellent.
- **Spindle cell carcinoma:** Tumor is poorly differentiated carcinoma adopting spindle or sarcomatoid pattern. Patient develops polypoid mass with smooth ulcerated surface. Tumor is composed of sheets of spindle cells mimicking fibrosarcoma or malignant fibrous histiocytoma. There is presence of mitotic activity and necrosis.
- **Basaloid squamous cell carcinoma:** Tumor is a variant of squamous cell carcinoma. On gross examination, tumor shows central ulceration with thickening at edges. On histologic examination, tumor is composed of small basaloid cells.

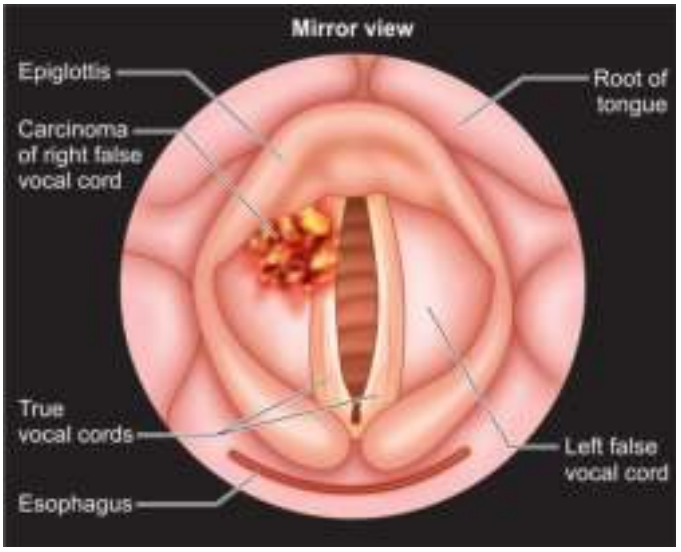

Fig. 17.22: Carcinoma of larynx. Tumor is arising from the vocal cord.

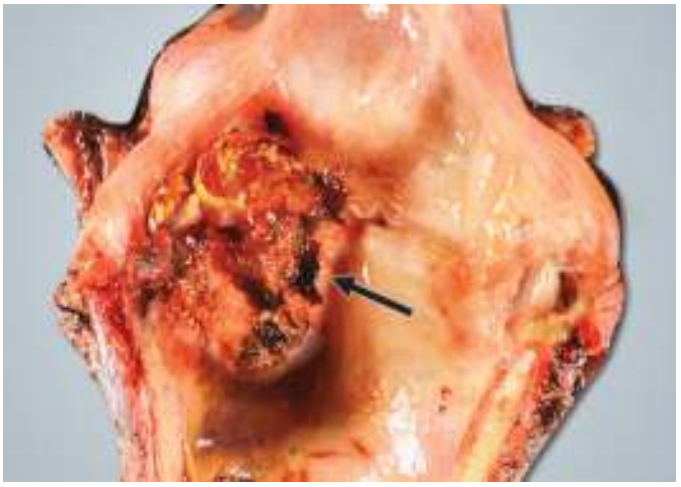

Fig. 17.23: Laryngeal carcinoma. Tumor shows fungating growth with ulceration (arrow).

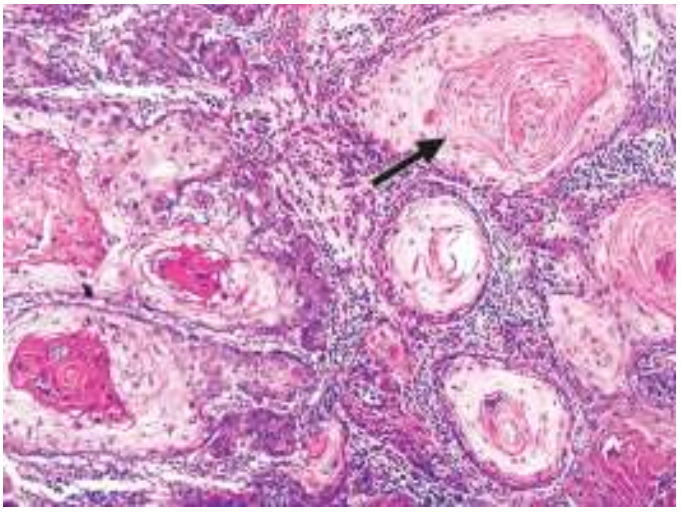

Fig. 17.24: Laryngeal keratinizing well differentiated squamous cell carcinoma. Tumor shows keratin pearls formation (arrow) (400X).

Table 17.5 Classification of laryngeal carcinoma based on location

Location	Frequency	Clinical Behavior	5-Year Survival Rate
Glottic region	60–65%	▪ Originating from true vocal cords (anterior portion) localized for long duration ▪ Cervical lymph node metastases late ▪ Tumor is treated by irradiation or surgical removal of vocal cords curative	80%
Supraglottic region	30–35%	▪ Tumor involving false vocal cord, laryngeal ventricle and epiglottis (33%) ▪ Surgical removal of tumor possible without permanent loss of voice ▪ Cervical lymph node metastases in 40% of cases	65%
Transglottic region	<5%	▪ Tumor crossing laryngeal ventricle ▪ Cervical lymph nodes frequently involved ▪ Total laryngectomy together with prophylactic cervical lymph node dissection curative	50%
Subglottic region	<5%	▪ Tumor arising from true vocal cord extending 1 cm or more into the subglottis region ▪ Thyroid gland and cricoid cartilage involved ▪ Cervical and paratracheal lymph nodes involved in 50% of cases	40%

Classification

Classification of laryngeal carcinoma is based on the location in decreased frequency: glottic, supraglottic, transglottic and subglottic regions (Table 17.5).

Prognosis

Prognosis is excellent in carcinoma arising from true vocal cord. Patient with carcinoma involving supraglottis and subglottis is less common but has poor prognosis.

DISORDERS OF NECK

NECK SWELLINGS: OVERVIEW

There are many causes of swellings in the neck region, which include lymphadenopathy, cysts, vascular masses, thyroid gland masses and salivary gland masses. The most common swellings are enlarged lymph nodes. Neck swelling may be congenital or acquired, solid or cystic, single or multiple, benign or malignant.

Primary and secondary tumors in the neck are shown in Fig. 17.25. Lateral neck swellings are given in Table 17.6. Midline neck swellings are given in Table 17.7.

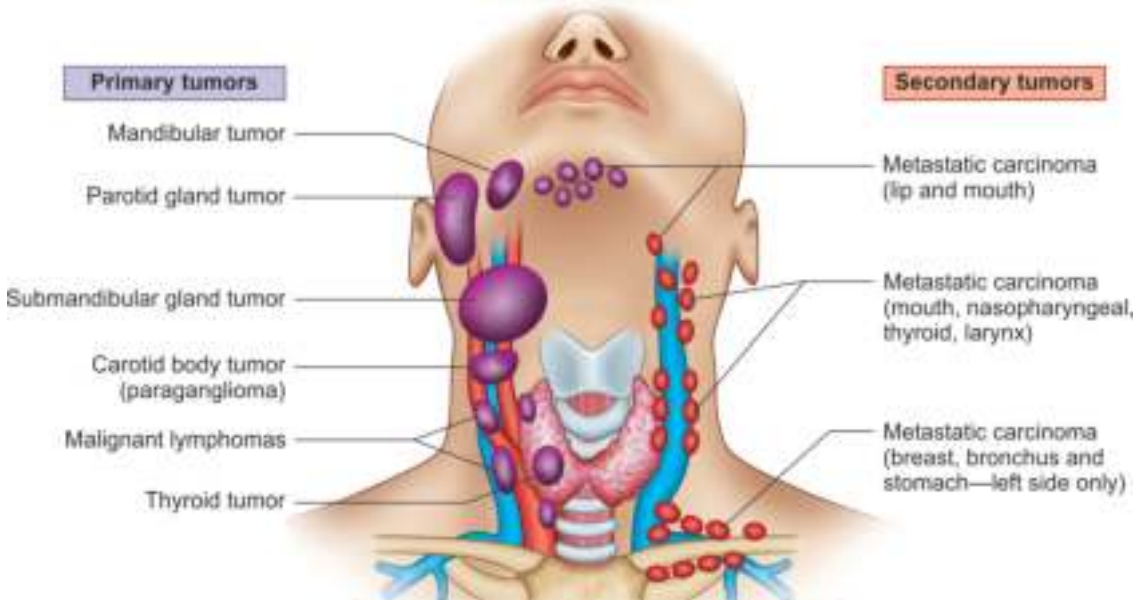

Fig. 17.25: Primary and secondary tumors in the neck.

Table 17.6 Lateral neck swellings

Nature of Swelling derived from Tissue and its Contents	Differential Diagnosis	
Solid swelling		
Glandular tissue	▪ Lymphadenitis ▪ Hodgkin disease ▪ Non-Hodgkin lymphoma ▪ Metastases in lymph nodes	▪ Thyroid neoplasms ▪ Multinodular goiter ▪ Thyroiditis ▪ Parathyroid adenoma
Blood vessels	▪ Carotid body tumor (paraganglioma) ▪ Glomus jugulare (tumor of the temporal bone involving middle and inner ear structures)	
Subcutaneous adipose tissue	Lipoma	
Nerves	▪ Schwannoma	▪ Neurofibroma
Sternocleidomastoid muscle	Organized hematoma of infants	
Bone	Cervical rib	
Cystic swelling		
Fluid in swellings	▪ Thyroglossal cyst ▪ Branchial cyst	▪ Epidermoid cyst ▪ Sebaceous cyst
Air in swellings	▪ Pharyngeal diverticulum ▪ Laryngocele	▪ Pneumatocele
Abscess (pus) in swellings	▪ Cold abscess (tubercular lymphadenitis) ▪ Parapharyngeal abscess	▪ Parotid abscess
Blood vessel swellings	▪ Hemangioma/malformation ▪ Carotid artery aneurysm ▪ Subclavian artery aneurysm	▪ Cystic hygroma (cystic lymphangioma in infants and children)

Table 17.7 Midline neck swellings

Nature of Swelling derived from Tissue and its Contents	Differential Diagnosis	
Solid swelling		
Glandular tissue	▪ Lymphadenitis (submental, prelaryngeal or pretracheal regions)	▪ Nodule in isthmus of thyroid gland ▪ Median ectopic thyroid tissue
Subcutaneous tissue	Lipoma in burns' space (suprasternal notch)	
Cystic swelling		
Glandular tissue	Lymphadenitis in submental region	
Fluid in swellings	▪ Thyroid gland cyst in the isthmus ▪ Thyroglossal cyst ▪ Dermoid cyst (sublingual or suprasternal regions)	▪ Sebaceous cyst ▪ Subhyoid bursa
Abscess (pus) in swellings	▪ Cold abscess (tubercular lymphadenitis)	▪ Pyogenic abscess in parapharyngeal and salivary glands
Blood vessel swellings	▪ Hemangioma/malformation ▪ Carotid artery aneurysm	▪ Subclavian artery aneurysm

AGE GROUP

Neck swellings are encountered in children ranging from infancy to adolescence, and adults with an extensive differential diagnosis ranging from congenital (cysts), and acquired (inflammatory/infective to neoplastic) diseases. Lymphadenopathy most often occurs in the neck region. The primary concern in adults with a persistent neck mass is malignancy.

HISTORY OF A NECK LUMP

History of duration of lump in neck region is most important. Seven days duration indicates infection, which results in reactive lymphadenitis. There is long history of seven weeks to months in patient with tumor. Congenital or developmental swellings occur within seven years of age. Past history of thyroid carcinoma, irradiation and previous scar must be enquired.

IMAGING TECHNIQUES

Neck swellings are assessed by imaging techniques, which include plain radiograph of neck (AP and lateral view), barium studies, sialography, laryngogram, carotid angiography and MRI studies. Endoscopic biopsy is oral cavity, nose and nasopharynx.

CERVICAL LYMPHADENOPATHY

The most common swellings in cervical region are enlarged lymph nodes. These are caused by bacterial or viral infections, lymphomas and secondary metastatic deposits. Inflammatory lymphadenopathy is most often painful, firm and mobile.

- Malignant lymph nodes are painless and hard, which may be located in the midline or lateral side of neck. Delphin lymph nodes located along thyrohyoid membrane are enlarged in thyroid carcinoma.
- Cervical lymph nodes showing draining areas and enlargement due to various disorders are shown in Fig. 17.26. Cervical lymph node swellings are given in Table 17.8.

BRANCHIAL CYST

Branchial cyst is also known as **lymphoepithelial cyst** present as solitary nodule anterior to sterno-cleidomastoid muscle. It is considered to arise from remnants of second branchial arch. It most often occurs in young adults. On clinical examination, branchial cyst measures 2–5 cm in diameter. Similar lesions may be encountered in parotid gland or oral cavity beneath tongue. It may rarely undergo malignant transformation.

Surgical Pathology: Branchial Cyst
Gross Morphology
▪ Cyst is well circumscribed measuring 2–5 cm in diameter. ▪ Cut section of cyst may contain clear, watery, mucoid or granular debris.
Light Microscopy
▪ Fibrous cyst wall is lined by stratified epithelium or pseudo-stratified columnar epithelium. ▪ Cyst wall contains lymphoid tissue forming germinal centers.

THYROGLOSSAL CYST

A thyroglossal cyst occurs due to persistence of thyroglossal duct. During normal development, thyroid gland descends from the base of the tongue to its final position in the neck. Thyroglossal cyst, a remnant of the thyroglossal duct is the most common thyroid anomaly. It may occur anywhere along the path of thyroid gland descent. It is midline cystic swelling that is close to or within the hyoid bone.

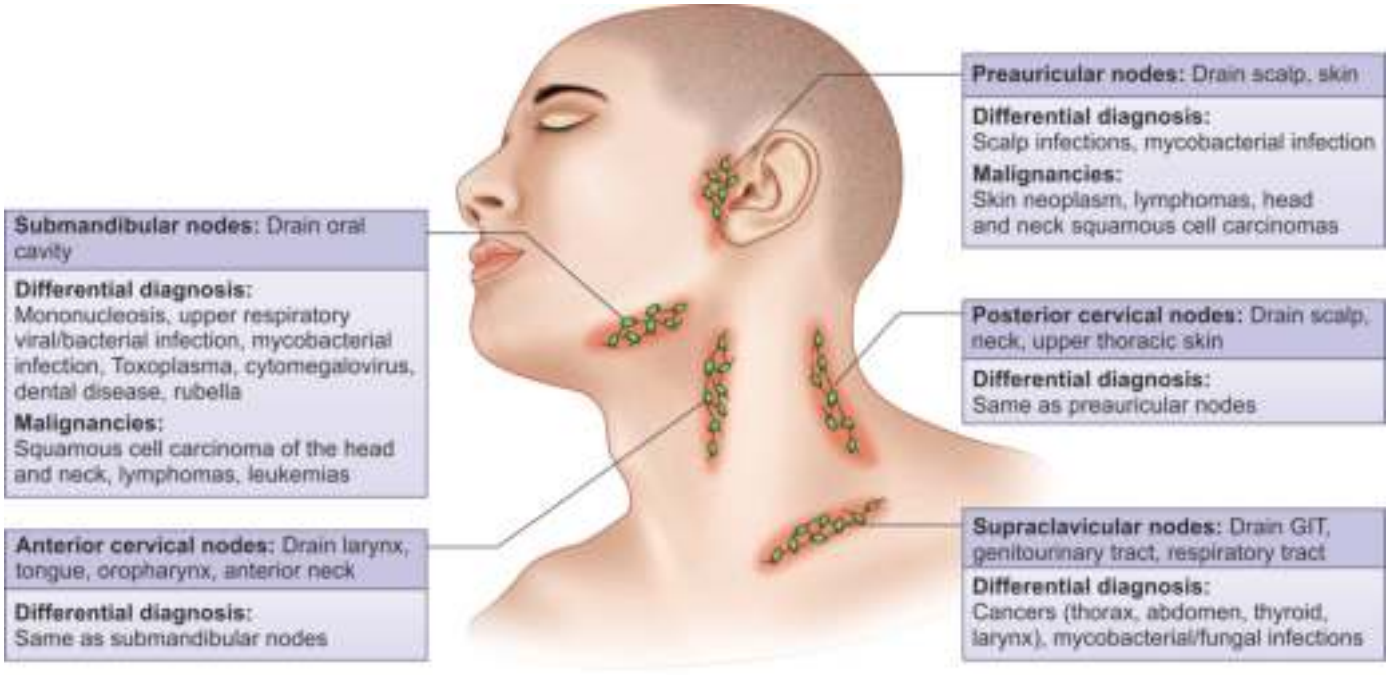

Fig. 17.26: Cervical lymph nodes showing draining areas and enlargement due to various disorders.

Table 17.8 Cervical lymph node swellings

Lymph Node Groups	Areas Drained by Lymph Node Group	Differential Diagnosis
Preauricular nodes	Scalp and skin	▪ Scalp infections, mycobacterial infections ▪ Skin neoplasms, Hodgkin's disease, NHL, SCC of head and neck
Posterior cervical nodes	Scalp, neck skin, thoracic skin	▪ Scalp infections, mycobacterial infections ▪ Skin neoplasms, Hodgkin's disease, NHL, SCC of head and neck
Supraclavicular nodes	Gastrointestinal tract, pulmonary and genitourinary systems	▪ Cancers of thorax, abdomen, thyroid and larynx ▪ Tubercular lymphadenitis ▪ Fungal infections
Submandibular nodes	Oral cavity	▪ Infectious mononucleosis, upper respiratory tract infections, tubercular lymphadenitis, Toxoplasma, cytomegalovirus, rubella, dental disease ▪ Squamous cell carcinoma of head and neck, leukemia, lymphomas
Anterior cervical nodes	Larynx, tongue, oropharynx, anterior neck	▪ Infectious mononucleosis, upper respiratory tract infections, tubercular lymphadenitis, Toxoplasma, cytomegalovirus, rubella, dental disease ▪ Squamous cell carcinoma of head and neck, leukemia, lymphomas

- Failure to surgical resection of hyoid bone often results in persistence of thyroglossal cyst.
- Patient presents with dysphonia, sore throat and midline swelling evident during adolescence and pregnancy. Patient does not develop endocrine complications. Surgery with removal of the proximal duct along with hyoid bone cures it.

Surgical Pathology: Thyroglossal Cyst

Light Microscopy

- Because thyroglossal cysts develop from a hollow tube, most of them do not show thyroid tissue on histopathologic examination.
- Thyroid tissue in surgical specimen is demonstrated in 5% of cases and 40% in serial sectioning. Otherwise, the lesion is lined by squamous or respiratory type of epithelium without a muscular wall.

PARAGANGLIOMA (CAROTID BODY TUMOR)

Paraganglia are clusters of neuroendocrine cells associated with sympathetic or parasympathetic nervous system.

- Cervical paraganglioma is a painless slow-growing tumor arising from the carotid body in the adventitia of the posteromedial aspect of the carotid artery bifurcation. There is higher incidence of paraganglioma in persons residing at higher altitude. It most often occurs in 50 years persons.
- Patient presents with firm, rubbery, mobile side to side and pulsatile tumor. It may decrease in size on carotid artery compression. Tumor recurs after incomplete surgical resection. Despite its benign nature, it may metastasize to regional lymph nodes and distant organs.
- Carotid angiography shows widening of carotid artery bifurcation. CT scan and MRI determine the extent of tumor.

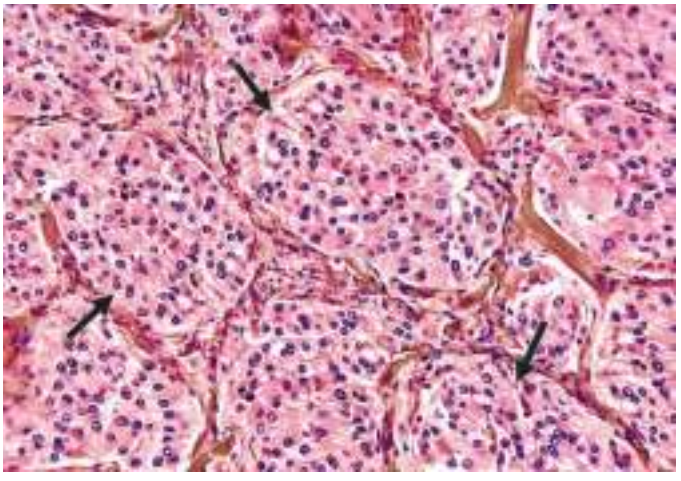

Fig. 17.27: Paraganglioma (carotid body tumor) shows clusters of large eosinophilic tumor cells separated by stroma containing elongated sustentacular cells (400X).

Surgical Pathology: Cervical Paraganglioma

Gross Morphology

- Tumor is well circumscribed mass with a fibrous pseudocapsule measuring 1–6 cm in diameter.
- Cut surface reveals gray-tan to pale brown color.

Light Microscopy

- Tumor is composed of uniform pale staining cytoplasm with finely granular nuclear chromatin surrounded by fibrovascular network.
- Compressed spindle-shaped cells are present at the periphery of nests of tumor cells (Fig. 17.27).

Immunohistochemistry Technique

Panel of markers is used to analyze expression in paraganglioma (chief cells) on histopathologic sections.

Markers	Expression
▪ Chromogranin	▪ Positive
▪ Synaptophysin	▪ Positive
▪ Neuron-specific enolase	▪ Positive
▪ CD56	▪ Positive
▪ CD57	▪ Positive

Compressed spindle-shaped cells at the periphery of nests of tumor cells show S-100 protein positivity.

Respiratory System

Vinay Kamal, Anubhav and Vigyat

LEARNING OBJECTIVES

- Respiratory system: overview
  - Anatomy
  - Physiology

PNEUMONIAS AND LUNG ABSCESS

- Pneumonias: overview
  - Anatomical classification
  - Etiologic classification
- Pneumonias
  - Lobar pneumonia
  - Bronchopneumonia
  - Interstitial pneumonia
  - Opportunistic pulmonary infections
- Lung abscess

TUBERCULOSIS

- Pulmonary and extrapulmonary tuberculosis
  - Mycobacterium tubercle bacillus
  - Risk factors
    - Tubercular infection and disease
  - Pathogenesis
- Tuberculosis: categories
  - Primary tuberculosis (primary complex)
  - Secondary tuberculosis
  - Tuberculosis in HIV cases

CHRONIC OBSTRUCTIVE PULMONARY DISEASES (COPDs)

- COPDs: overview and examples
  - Chronic bronchitis
  - Emphysema
    - Classification of emphysema
      - * Centriacinar emphysema
      - * Panacinar emphysema
      - * Distal acinar (paraseptal) emphysema
      - * Irregular emphysema
      - * Interstitial emphysema
  - Bronchiectasis
  - Bronchial asthma

RESTRICTIVE PULMONARY DISEASES

- Acute restrictive pulmonary diseases
  - Adult respiratory distress syndrome
  - Neonatal respiratory distress syndrome
  - Severe respiratory distress syndrome
  - Diffuse alveolar damage
- Chronic restrictive pulmonary diseases
  - Pneumoconiosis
    - Coal worker's pneumoconiosis
    - Asbestosis
    - Berylliosis
  - Drug-induced interstitial pulmonary fibrosis
  - Radiation-induced interstitial pulmonary fibrosis
  - Idiopathic pulmonary fibrosis
  - Sarcoidosis
  - Collagen vascular disease
  - Rheumatoid arthritis
  - Eosinophilic granuloma
  - Eosinophilic pneumonia
  - Hypersensitivity pneumonitis
  - Goodpasture syndrome
  - Byssinosis
  - Silo-filler's disease
  - Lymphangioleiomyomatosis
  - Pulmonary alveolar proteinosis

PNEUMOTHORAX AND ATELECTASIS LUNG

- Pneumothorax
  - Open pneumothorax
  - Closed pneumothorax
  - Tension pneumothorax
- Atelectasis of lung (pulmonary collapse)
  - Etiopathogenesis
    - Acquired atelectasis of lung
    - Atelectasis neonatorum of lung
  - Atelectasis: types
    - Obstructive atelectasis of lung
    - Compressive atelectasis of lung
    - Patchy atelectasis of lung
    - Contraction atelectasis of lung

PULMONARY VASCULAR DISORDERS

- Pulmonary thromboembolism
- Fat embolism syndrome
- Pulmonary hypertension
- Pulmonary edema
- Pulmonary vasculitis

NEOPLASTIC DISORDERS OF LUNG

- Benign tumors of lung
  - Pulmonary hamartoma
  - Bronchopulmonary carcinoids
- Primary malignant tumors of lung: overview
  - WHO classification of lung tumors
- Primary lung carcinomas
  - Small cell lung carcinoma
  - Squamous cell lung carcinoma
  - Lung adenocarcinoma
  - Large cell lung carcinoma
  - Adenosquamous lung carcinoma
  - Pleomorphic lung carcinoma
  - Carcinosarcoma of lung
- Tumors metastasizing to lungs
- Diagnostic approach of lung tumors
  - Imaging techniques
  - Other diagnostic modalitis
    - Fiberoptic bronchoscopy
    - Sputum examination
    - Bronchoalveolar lavage
    - Bronchopulmonary biopsy
    - Surgical pathology (gross morphology, light microscopy, histochemistry, immunohistochemistry technique)
    - Serum tumor markers in primary lung cancer
    - Serum tumor markers in metastatic lung cancer

PLEURAL DISEASES

- Non-neoplastic pleural disorders
  - Pleural effusion
  - Pleuritis
  - Pleural fibrosis
    - Pleural plaques
    - Diffuse fibrosis of pleural visceral layer
- Malignant pleural tumors
  - Malignant mesothelioma
  - Primary pleural effusion lymphoma
  - Pyothorax effusion lymphoma

RESPIRATORY SYSTEM: OVERVIEW

ANATOMY

Respiratory system comprises nose, pharynx, larynx, trachea, bronchi, bronchioles, terminal bronchioles and lungs. Major functions of the lungs are to supply oxygen (O_2) to the tissues and remove carbon dioxide (CO_2) from blood.

The respiratory epithelium is derived from endoderm. With the exception of the pharynx, epiglottis and vocal cords, the respiratory tract is lined by specialized ciliated mucus secreting epithelium. Structure of respiratory tract is shown in Fig. 18.1A and B.

Nose

Nose warms, moistens, and filters air and functions in olfaction and speech. Newborn with choanal atresia cannot breathe through the nose. Allergic polyps are most common polyps in the nasal cavity. In children with nasal polyps, sweat test must be done to rule out cystic fibrosis.

Pharynx

Pharynx comprises nasopharynx, oropharynx, and laryngopharynx lined by mucous membrane. The nasopharynx participates in respiration. The oropharynx and laryngopharynx function both in digestion and respiration.

Larynx

Larynx contains the thyroid cartilage (Adam's apple). The epiglottis guards the opening of the larynx, which prevents food from entering the larynx; the cricoid cartilage, which connects the larynx and trachea; and the paired arytenoids, corniculate, and cuneiform cartilages.

Trachea

Trachea measures 12 cm in length and 2.5 cm in diameter.

- Presence of incomplete (C-shaped) ring of hyaline cartilage prevents collapsing of trachea. It is lined with pseudostratified ciliated columnar epithelium. The carina is in located at approximately the T4 level.
- Two methods of bypassing obstructions in the airways are tracheostomy by making opening into trachea and intubation by putting tube into trachea.

Bronchi

The bronchial tree consists of the primary bronchi, secondary bronchi, tertiary bronchi, bronchioles, and terminal bronchioles.

- The walls of bronchi contain discontinuous foci of cartilage and seromucinous glands. Walls of bronchi contain plates of decreasing cartilage and increasing smooth muscles.
- Right bronchus is more vertical than left bronchus; hence foreign body enters more frequently in the right bronchus.

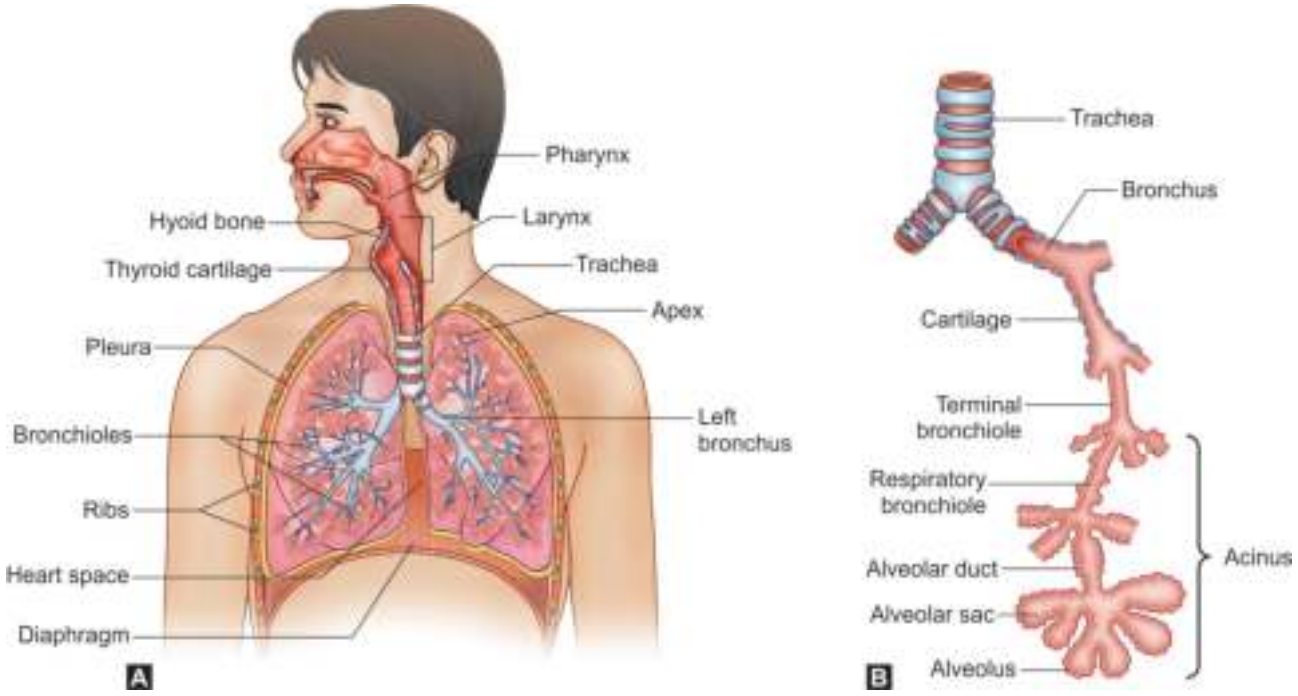

Fig. 18.1A and B: Structure of upper and lower respiratory tract.

- **Bronchogram** is a radiograph of the bronchial tree after introduction of an opaque contrast medium usually containing iodine.

Bronchioles

Bronchioles lack cartilage and submucous glands. The bronchioles are lined by ciliated columnar epithelium which contain Clara cells participating in synthesis of proteinaceous fluid. Terminal bronchiole divides to form respiratory bronchiole alveolar ducts and delicate alveoli.

Lungs

The lungs are a pair of organs surrounding mediastinum and in close proximity to the heart and major blood vessels. The lungs extend from above the clavicles to T1, T2 vertebral level with full inspiration. The right lung has 3 lobes, whereas the left lung has 2 lobes.

- **Pleura:** Pleural membrane covering lungs consists of outer parietal pleura and the deep visceral pleura derived from mesoderm. Pleural cavity contains 10–12 ml of pleural fluid low in protein content.
- **Root (hilum):** Root of lung consists of primary bronchus, pulmonary artery, two pulmonary veins and corresponding lymphatic channels. Each lung has a dual blood supply *via* the pulmonary and bronchial arteries. Bronchial arteries protect lungs from infarction. Dyspnea and tachypnea are common symptoms in a case of pulmonary infarction.
- **Bronchopulmonary segment:** It is the smallest functional unit of the lungs. Left lung consists of 8 bronchopulmonary segments and 10 bronchopulmonary segments in the right lung. A single bronchopulmonary segment can be resected when disease is confined to one segment. Each bronchopulmonary segment consists of lobules, which contain lymphatic channels, veins, arterioles, terminal bronchioles, respiratory bronchioles, alveolar ducts, and alveoli.
- **Alveoli:** Each lung consists of approximately 150 million alveoli. Alveolar walls consist of thin, delicate type 1 alveolar cells, i.e. pneumocytes lined by squamous cells, type 2 pneumocytes, and alveolar macrophages. Type 2 pneumocytes secrete surfactant dipalmitoylphosphatidylcholine, which decreases the surface tension exerted by alveolar fluid. Alveolar macrophages present in the lungs participate in phagocytosis. There are no lymphatic channels in the alveoli.
- **Pulmonary lymphatic drainage:** Each lung consists of superficial lymphatic plexus beneath visceral pleura and deep lymphatic plexuses located within the submucosa of the bronchi. The two plexuses communicate at the hilum, ending in bronchopulmonary lymph nodes which drain to tracheobronchial lymph nodes, which in turn drain to the left subclavian vein. Lung carcinoma generally spreads by the lymphatics to the hilar and mediastinal lymph nodes and then out of the thorax *via* the supraclavicular cervical lymph nodes. Axillary lymph nodes are generally not involved in lung cancer due to their lymphatic range.
- **Nerve supply:** The lungs are innervated by the sympathetic and parasympathetic supply.

Clinical Pearls: Applied Anatomy of Lungs

- **Compression of structures:** Direct extension of lung tumor itself or enlargement of adjacent lymph nodes may compress structures in close proximity to the lungs.
- **Hoarseness of voice:** Squamous cell lung carcinoma usually involves recurrent laryngeal nerve supplying left vocal cord leading to hoarseness of voice.
- **Horner's syndrome**: Pancoast tumor (usually squamous cell lung carcinoma) involves sympathetic chain/ganglion leading to Horner's syndrome. Horner's syndrome is characterized by drooping of upper eyelid, sunken eyes, constriction of pupil and loss of sweating on the affected side.
- **Diaphragm paresis:** Lung carcinoma involving phrenic nerve may lead to hemidiaphragm paresis.

PHYSIOLOGY

Exchange of Gases

Exchange of gases occurs across the alveolar–capillary (respiratory) membrane, which consists of 0.2 mm thick alveolar epithelium, epithelial basement membrane, thin interstitial space, capillary basement membrane and capillary endothelial cells.

- Alveoli are the primary sites of exchange of O_2 and CO_2 gases. Exchange of gases also occurs between blood and tissues by simple diffusion based on pressure/concentration gradient.
- Solubility of the gases and thickness of the respiratory membranes involved in diffusion are also important factors that can affect the rate of diffusion of gases. The solubility of CO_2 is 20–25 times higher than that of O_2 (Figs 18.2 to 18.4).

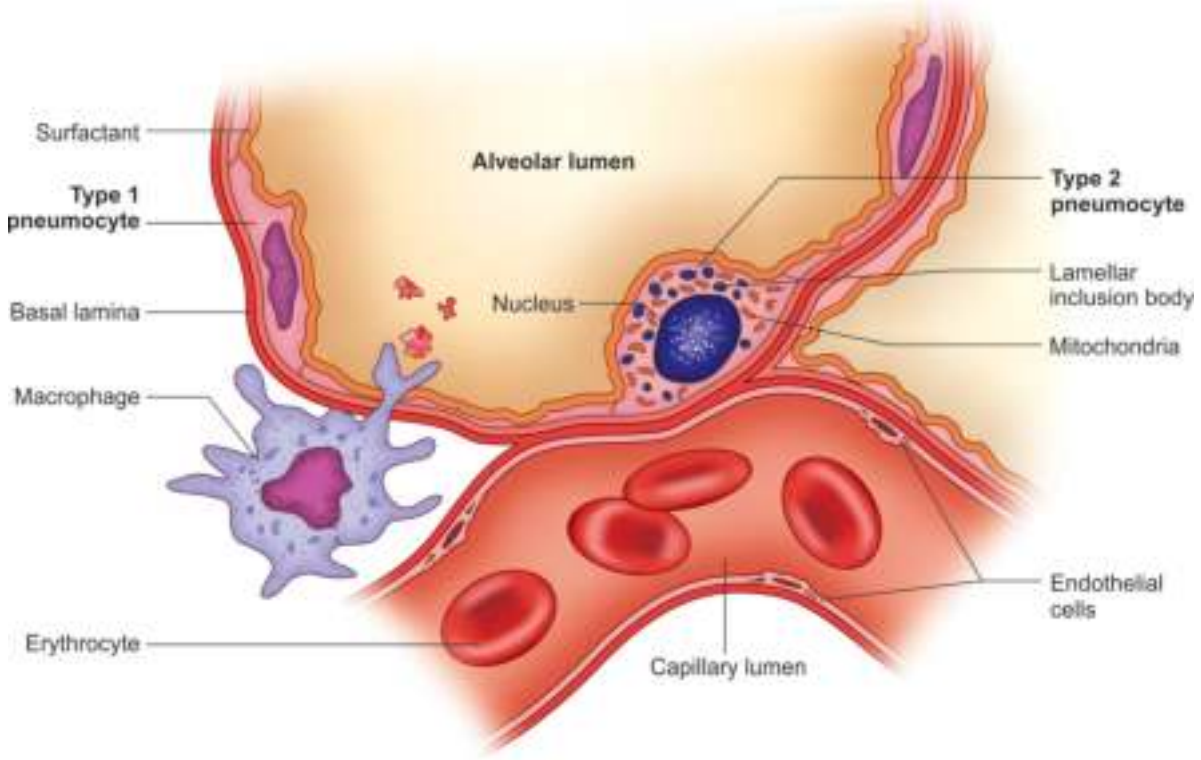

Fig. 18.2: Structure of alveolar–capillary (respiratory) membrane. Alveolus is lined by epithelial cells type 1 and type 2 pneumocytes. Alveolar basement membrane is thin on one side and widened where it is continuous with the interstitial space. Gas exchange occurs across the alveolar–capillary (respiratory) membranes. Type 2 pneumocytes secrete surfactant dipalmitoyl phosphatidylcholine, which decreases surface tension exerted by alveolar fluid.

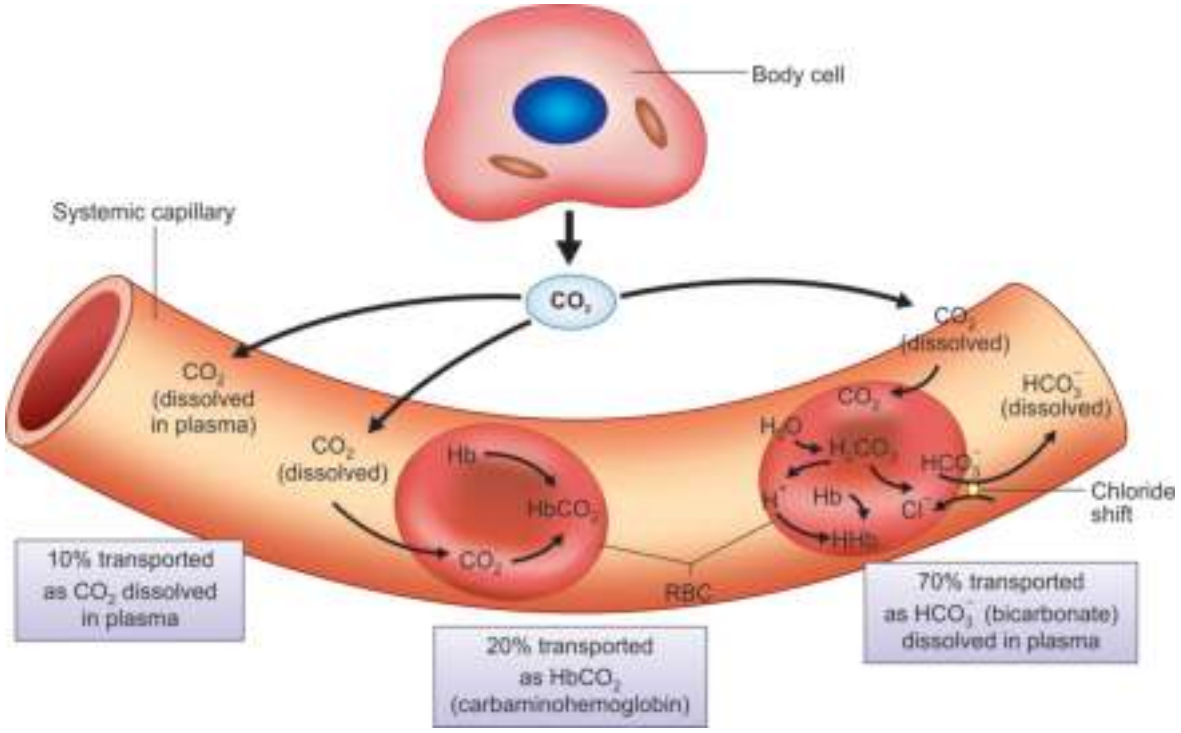

Fig. 18.3: Transport of CO_2 in blood. CO_2 circulates in blood vessel in three forms. Approximately 10% of CO_2 dissolved in plasma, 20% transported by red blood cells in the form of carbaminohemoglobin and 70% of bicarbonate dissolved in plasma.

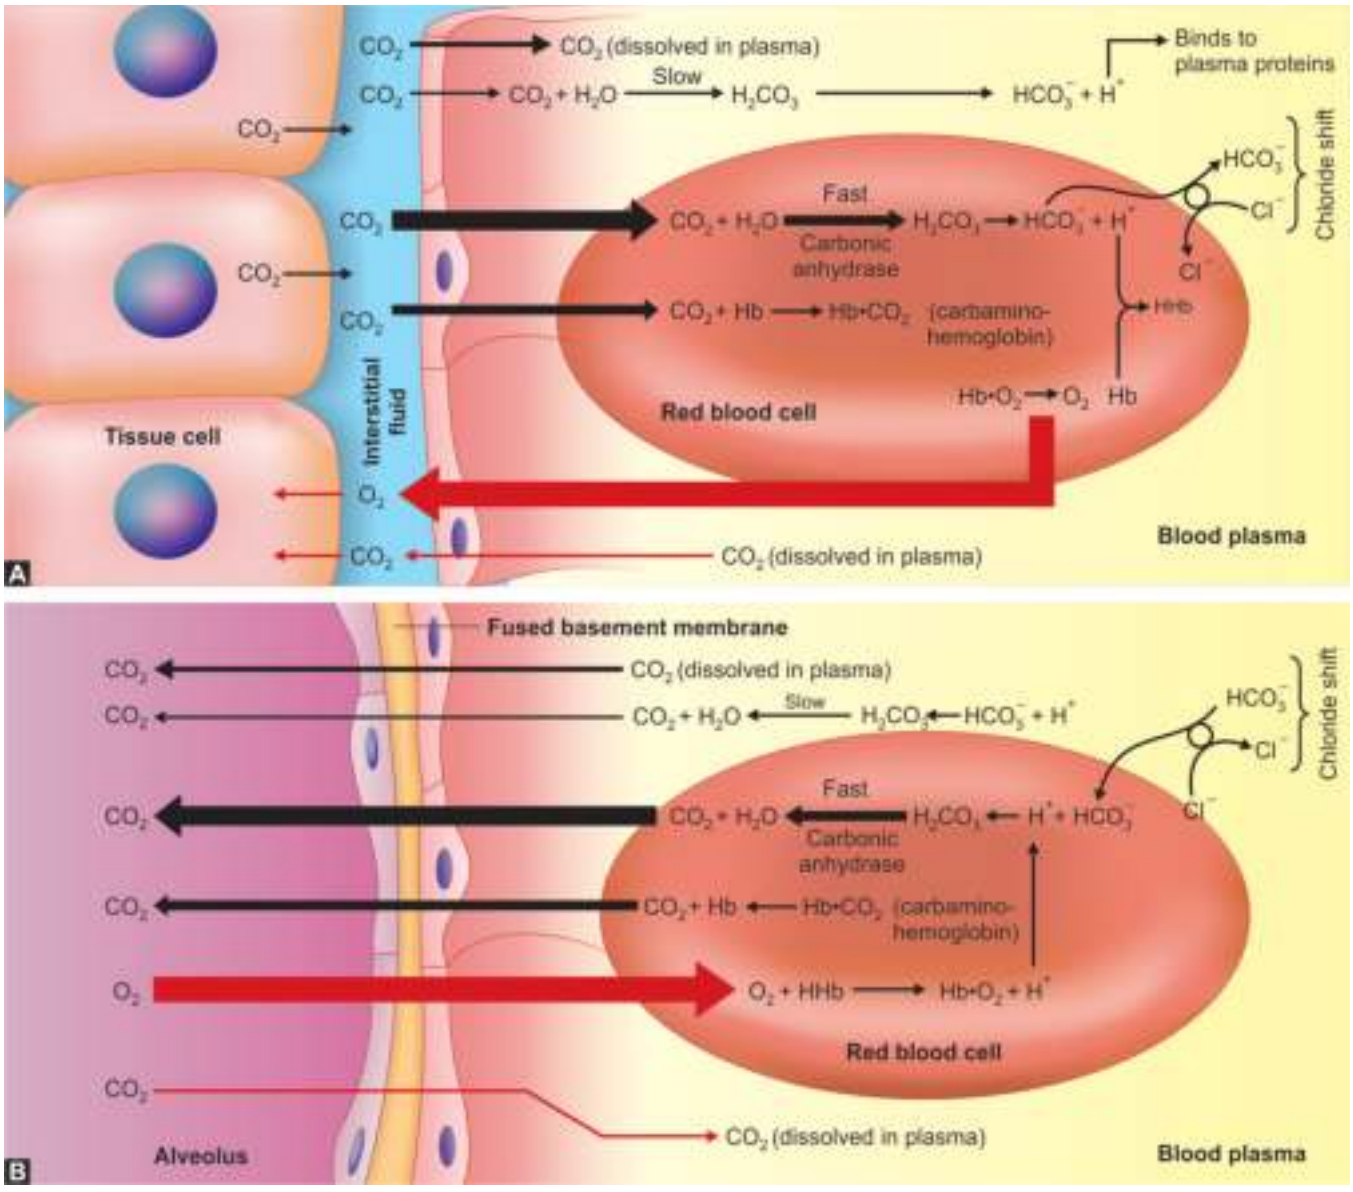

Fig. 18.4A and B: Exchange of gases in lung and tissue. It includes pulmonary ventilation, gas exchange in the lungs, transport of O_2 gas by the blood to tissues, gas exchange in the tissues. Transport of CO_2 gas by the blood to the heart and then to the lungs for oxygenation.

Partial Pressure of Gas

The partial pressure of gas is the pressure exerted by that gas in mixture of gases. It is represented as pO_2, pCO_2 and pN_2 for oxygen, carbon dioxide and nitrogen, respectively. Arterial blood gas, pO_2 and pCO_2, is equal to the alveolar pO_2 and pCO_2.

Pulmonary Volumes

Spirometer is an instrument used to measure volume of air in lungs. Alveolar ventilation is the volume of inspired air that reaches the alveoli.

Lung Capacities

Lung capacities are the sum of two or more volumes that include inspiratory, functional, residual, vital and total lung capacity. Lung volumes and capacities are given in Table 18.1.

Respiratory Disorders

Respiratory disorders affecting exchange of gases are caused by cystic fibrosis, α_1-antitrypsin deficiency, tobacco smoking, air pollution, pneumoconiosis and infectious agents. These disorders affect the respiratory airways, interstitial tissue and vasculature of lungs. Patient develops chronic obstructive diseases, acute lung injury, pulmonary infections, diffuse interstitial tissue infiltrative disorders, and lung tumors. General categories of pulmonary disease are given in Table 18.2.

Table 18.1 Lung volumes and capacities

Volume	Definition	Average Volumes (ml)
Tidal volume	Tidal volume is the amount of air moved in and out of the lungs in quite, relaxed breathing	500
Residual volume	The amount of air that remains in the lungs after maximum exhalation	1200
Inspiratory reserve volume	The additional amount of air that can be inhaled by force after a normal inhalation	2500–3000
Expiratory reserve volume	The additional amount of air that can be exhaled by force after a normal exhalation	1100–1200
Vital capacity	The volume of air that can be breathed out from the lungs by maximum exhalation after maximum inhalation	4000
Functional residual capacity	The amount of air remained in the lungs after normal exhalation	2500
Total lung capacity	The total volume of air that can be contained in the lungs after maximum inhalation	5200

Anatomical dead space refers to amount of air present in respiratory tract not participating in exchange of gases.

Table 18.2 General categories of pulmonary disease

Category	Subcategory
Infectious lung diseases	▪ Community acquired typical pneumonia ▪ Community acquired atypical pneumonia ▪ Nosocomial pneumonia ▪ Aspiration pneumonia ▪ Necrotizing pneumonia ▪ Pneumonia in immunocompromised persons
Obstructive lung diseases	▪ Bronchial asthma ▪ Chronic bronchitis ▪ Bronchiectasis ▪ Emphysema
Restrictive lung diseases	▪ Autoimmune (e.g. systemic lupus erythematosus, Wegener granulomatosis, rheumatoid arthritis) ▪ Idiopathic pneumonias, e.g. usual interstitial pneumonia (UIP), desquamative interstitial pneumonia (DIP) ▪ Occupational related, e.g. asbestosis, silica-induced lung disease, coal-induced lung disease ▪ Drug-related, e.g. bleomycin, busulfan, amiodarone, methotrexate
Neoplastic lung diseases	▪ Small cell lung carcinoma ▪ Squamous cell lung carcinoma ▪ Lung adenocarcinoma ▪ Large cell lung carcinoma ▪ Bronchopulmonary carcinoid tumors

PNEUMONIAS AND LUNG ABSCESS

PNEUMONIAS: OVERVIEW

Pneumonia is an inflammatory process of the lungs commonly caused by infectious agents (i.e. bacteria, viruses, fungi or *Pneumocystis jiroveci*), chemicals, and inhalation of secretions and aspiration of material.

Predisposing factors for pneumonias include loss of suppression of the cough reflex (i.e. cerebral stroke, dementia, Parkinson's disease), injury to mucociliary apparatus due to tobacco smoking, interference in the phagocytosis and bactericidal activity of alveolar macrophages, pulmonary congestion in heart diseases, chronic pulmonary obstructive disease), accumulation of secretions, frequent suction, immunosuppression, liver cirrhosis, diabetes mellitus and recent respiratory tract infections (Table 18.3).

Table 18.3 Type of immune deficiency determining the organisms responsible for pneumonia

Defects	Organisms
Neutrophil defects	▪ Klebsiella ▪ Aspergillus
Antibody defects	▪ *Haemophilus influenzae* ▪ Pneumococci
Cell-mediated immune defects	▪ Fungi ▪ *Pneumocystis carinii* ▪ Mycobacterium tubercle bacilli ▪ Measles virus ▪ Herpesvirus ▪ Cytomegalovirus

Pathology Pearls: Classification of Pneumonias

Pneumonias are classified as community acquired or nosocomial (hospital acquired pneumonias) or aspiration pneumonia.

- **Community acquired pneumonia:** It is the most common form of pneumonia caused by bacterial infection or a complication of flu.
- **Nosocomial or hospital acquired pneumonias:** Hospital acquired pneumonias are often fatal, in hospitalized patients suffering from serious, debilitating diseases. Patient develops infection within 48 hours being hospitalized or other health care settings. Respirator is most common source of *Pseudomonas aeruginosa* causing nosocomial pneumonia. *Escherichia coli* and *Staphylococcus aureus* may also be underlying cause. Endotoxins produced by these organisms play an important role in pulmonary infection.
- **Aspiration pneumonia:** This infection occurs, when a person accidentally inhales food, liquid or vomitus into the lungs. There is increased risk of aspiration pneumonia in persons with dysphagia or with a weakened cough reflex. Chest radiograph is gold standard for diagnosing pneumonia.

ANATOMICAL CLASSIFICATION

Pneumonias are classified according to etiology (i.e. bacteria, viruses, fungi) and involvement of the pulmonary lobes (i.e. lobar, bronchopneumonia and interstitial pneumonias). More than one type of pathogen may be present that makes diagnosis and treatment, a challenge. There are three morphologic and clinical patterns of pneumonias: lobar pneumonia, bronchopneumonia, and interstitial pneumonia (Fig. 18.5A to C). Clinical patterns of pneumonia and common causative organisms are given in Table 18.4.

- **Lobar pneumonia:** It is restricted to one lobe of the lungs. Eventually, the whole lobe may be affected.
- **Bronchopneumonia:** It starts as bronchial inflammation and extends to surrounding alveoli involving one or more lobules. It shows patchy and focal reddish-gray consolidation in relation to bronchi or bronchioles filled with pus (microabscesses) at the base of both lungs. Consolidation at the base of

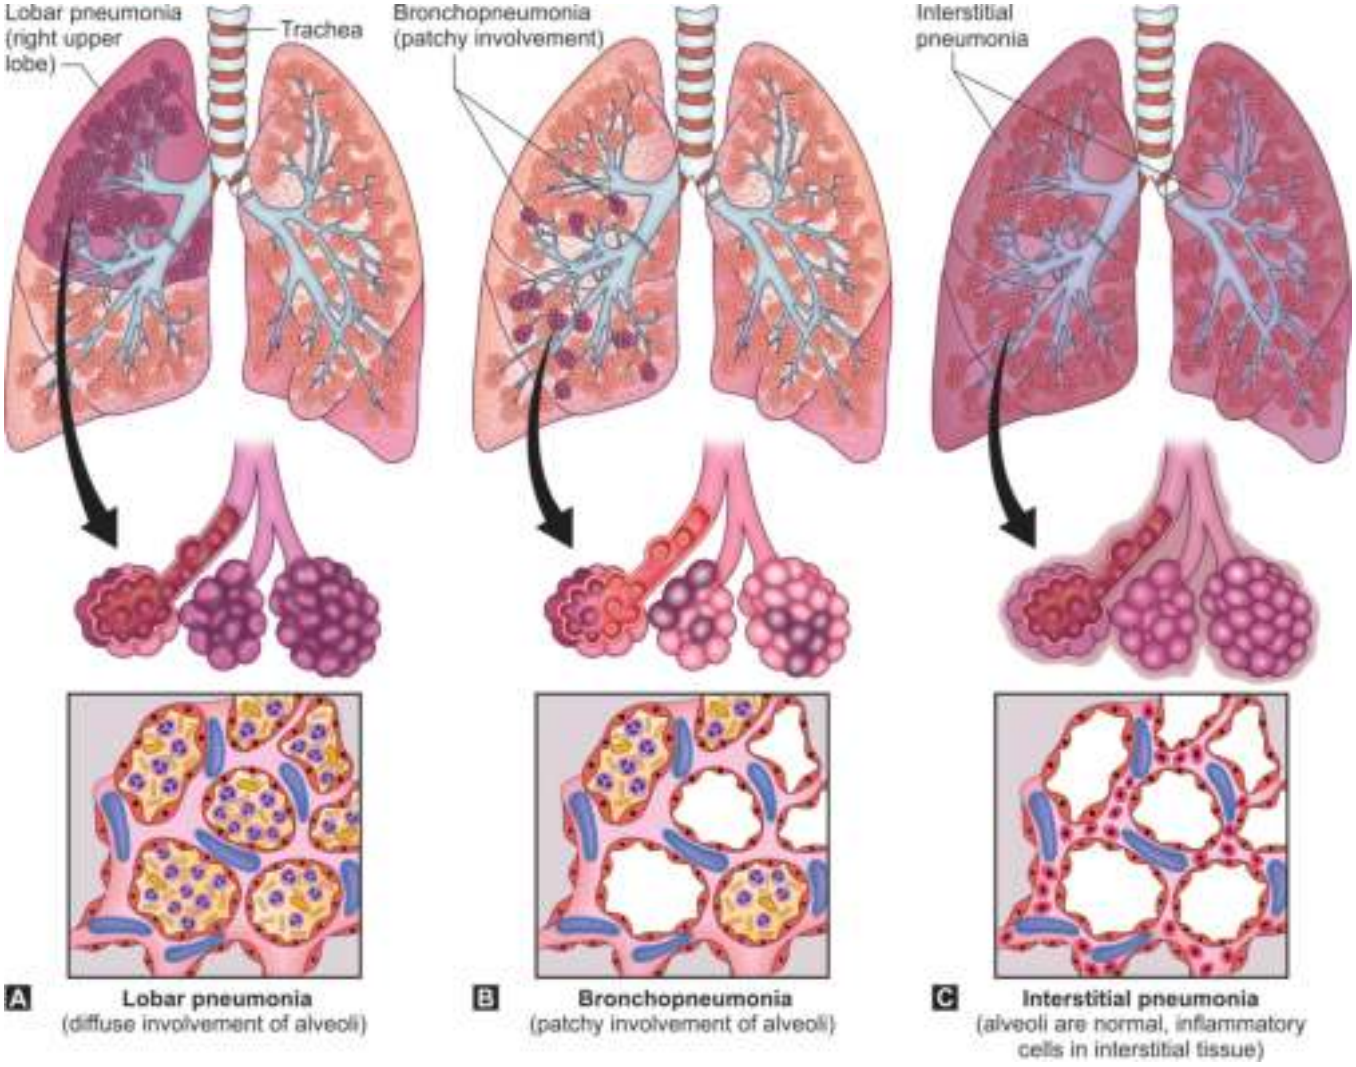

Fig. 18.5A to C: There are three morphologic and clinical patterns: Bronchopneumonia, lobar pneumonia, and interstitial pneumonia.

Table 18.4 Clinical patterns of pneumonia and common causative organisms

Pneumonia Variant	Clinical Pattern	Common Causative Pathogens
Bronchopneumonia	Patchy, multifocal consolidation	▪ *Streptococcus pneumoniae* ▪ *Staphylococcus aureus* ▪ *Haemophilus influenzae* ▪ *Escherichia coli* ▪ *Klebsiella pneumoniae* ▪ Enterococci ▪ *Pseudomonas aeruginosa* ▪ Anaerobes
Lobar pneumonia	Lobar consolidation	▪ *Streptococcus pneumoniae* (most common) ▪ *Klebsiella pneumoniae* (elderly, diabetics, alcoholic)
Interstitial pneumonia	Inflammation within alveolar interstitium	▪ Mycoplasma ▪ Chlamydia ▪ Legionella ▪ Viral (adenovirus, influenza, respiratory syncytial virus) ▪ Fungi (histoplasmosis, coccidioidomycosis, blastomycosis, cryptococci) ▪ *Pneumocystis jiroveci* in AIDS

lungs occurs because of the tendency of secretions to gravitate into the lower lobes or right middle lobe. It usually occurs in infancy and old age.

- **Interstitial pneumonia:** It is also called primary atypical pneumonia. Lung shows diffuse, patchy inflammation localized to interstitial areas of the alveolar walls. It involves one or more lobes.

Clinical Features

Patient presents with fever, chills, productive cough, blood-tinged or rusty sputum, pleuritic pain, hypoxia with shortness of breath, and sometimes cyanosis. If there is bacterial etiology, it is most characteristically associated with neutrophilic leukocytosis with an increase in band neutrophils with shift-to-the-left.

ETIOLOGIC CLASSIFICATION

Bacterial Pneumonia

- ***Streptococcus pneumoniae:*** *Streptococcus pneumoniae* is the most common cause of lobar pneumonia especially in immunocompromised persons. Capsule of *Streptococcus pneumoniae* prevents phagocytosis by inflammatory cells. This pathogen synthesizes copious mucoid secretion resulting in lobar pneumonia.
- ***Staphylococcus pneumoniae:*** *Staphylococcus pneumoniae* accounts for only 1% of bacterial pneumonias especially in intravenous drug abusers associated with bacterial endocarditis. These persons develop lung abscess and empyema. Hematogenous dissemination leads to abscess formation in distant organs such as brain and kidney.
- ***Klebsiella pneumoniae:*** *Klebsiella pneumoniae* is most common cause of bacterial pneumonia in debilitated hospitalized patients, diabetics or chronic alcoholic and elderly persons. The organism produces viscid capsular polysaccharide responsible for thick gelatinous sputum. Such individual may have difficulty in coughing up. The organism causes alveolar damage, necrosis and abscess formation.
- ***Pseudomonas aeruginosa:*** *Pseudomonas aeruginosa* causes pneumonia in patients with extensive burns, immunosuppression, and mechanical ventilation. The bacteria invade blood vessels with consequent extrapulmonary spread with fatal outcome within days. Histologic examination shows coagulative necrosis of lung parenchyma and vasculitis.
- ***Haemophilus influenzae:*** Capsule of *Haemophilus influenzae* prevents opsonization and phagocytosis by host cells. It can cause life-threatening pneumonias in infants and children. It may also affect debilitated adults with chronic obstructive pulmonary disease. Patient develops lobular or patchy pneumonia, but may involve entire lung.
- ***Legionella pneumophila:*** *Legionella pneumophila* is a gram-negative bacillus transmitted by inhalation of aerosol from contaminated water storage systems. It produces bilateral bronchopneumonia. Patient presents with cough, dyspnea, and chest pain with myalgia, headache, confusion, nausea, vomiting and diarrhea. On histopathologic examination, the alveoli are packed with fibrinous exudate, neutrophils and red blood cells. Alveolar capillaries are dilated and congested. The exudates may organize resulting in interstitial fibrosis with permanent loss of lung function.
- ***Moraxella catarrhalis:*** *Moraxella catarrhalis* constitutes one of the three most common causes of otitis media. The pathogen causes pneumonia in elderly persons.

Viral Pneumonia

Viral infections account for 50% of pneumonia cases. Influenza and respiratory syncytial viruses are the most common culprits. Other viruses include adenovirus, cytomegalovirus and herpes simplex. The incubation period is 1–3 days. Viral pneumonias most often affect children. Clinical course of viral pneumonia is short-lived and not serious in nature.

Fungal Pneumonia

Some endemic fungi are associated with pneumonia. These include Coccidioides, *Histoplasma capsulatum*, *Blastomyces dermatitidis*, *Aspergillus fumigatus* and Phycomycetes.

Pneumonias in Immunocompromised Persons

Pneumocystis jiroveci is an infection almost exclusively associated with immunocompromised persons such as HIV/AIDS, patients receiving radiotherapy or chemotherapy for cancer, immunosuppressive drugs given in organ transplant persons or nonfunctional spleen.

Mycoplasma Atypical Pneumonia

Mycoplasma pneumoniae is smallest free-living bacteria responsible for Mycoplasma atypical pneumonia after incubation period of 1 to 4 weeks. It is less serious pneumonia than caused by bacteria or viruses. This type of pneumonia is also known as walking pneumonia or atypical pneumonia. Mycoplasma atypical pneumonia responds well to antibiotics.

PNEUMONIAS

LOBAR PNEUMONIA

Lobar pneumonia refers to diffuse consolidation of entire lung due to acute inflammatory exudate within the alveoli without bronchial involvement. There is abrupt demarcation at the interlobar fissure. Lobar pneumonia involves portion of a lung resulting in consolidation. Purulent exudate is observed in bacterial pneumonia.

Etiology

Streptococcus pneumoniae is the most common cause of lobar pneumonia in young healthy adults between 20 and 50 years of age especially in immunocompromised persons. Capsule of *Streptococcus pneumoniae* prevents phagocytosis by inflammatory cells. This pathogen synthesizes copious mucoid secretion resulting in lobar pneumonia. However, *Klebsiella pneumoniae* typically affects elderly, diabetics and alcoholics persons.

Risk Factors

Lobar pneumonia occurs due to impairment of normal defense mechanisms. Spleen plays important role in degradation of *Streptococcus pneumoniae*. Risk factors for lobar pneumonia are described as under:

- **Respiratory diseases:** These include atelectasis, bronchiectasis, or cystic fibrosis, lung carcinoma and tracheostomy patients.
- **Immunosuppression disorders:** These include malnutrition, immunosuppressive therapy, chronic illness, diabetes mellitus, chronic alcoholism and premature birth.
- **Inhalation of toxic gases and cigarette smoke:** These play important role in pathogenesis of lobar pneumonia.
- **Hematologic disorder:** Sickle cell disease is a predisposing risk factor for lobar pneumonia.

Pathogenesis

The *Streptococcus pneumoniae* reach the alveoli and cause inflammation by pouring of inflammatory exudate into the lung alveolar spaces. White blood cells migrate to alveoli. The alveoli are filled with exudates resulting in consolidation of lungs. It leads to occlusion of alveoli causing decrease in alveolar oxygen content. Venous blood reaching the affected pulmonary areas is not oxygenated and returned to systemic circulation. It leads to arterial hypoxemia and even death due to interference with ventilation. Risk factors for early deterioration in community-acquired pneumonia are given in Table 18.5.

Stages of Pneumonia

In this antibiotics era, full blown lobar consolidation is infrequent. Untreated patients may morphologically evolve through four stages: (a) congestion, (b) red hepatization, (c) gray hepatization, and (d) resolution (Fig. 18.6).

- **Stage of congestion (12–24 hours):** The first stage of congestion in lobar pneumonia lasts for about 24 hours. Alveolar congestion correlates with the onset of the illness described as typical pneumonias.

Table 18.5 Risk factors for early deterioration in community-acquired pneumonia

Multilobar lung involvement
Severe hypoxemia (arterial saturation >90%)
Severe acidosis (pH <7.30)
Severe tachypnea (>30 breaths/minute)
Neutropenia
Thrombocytopenia
Hypoglycemia
Hypoalbuminemia
Hyponatremia

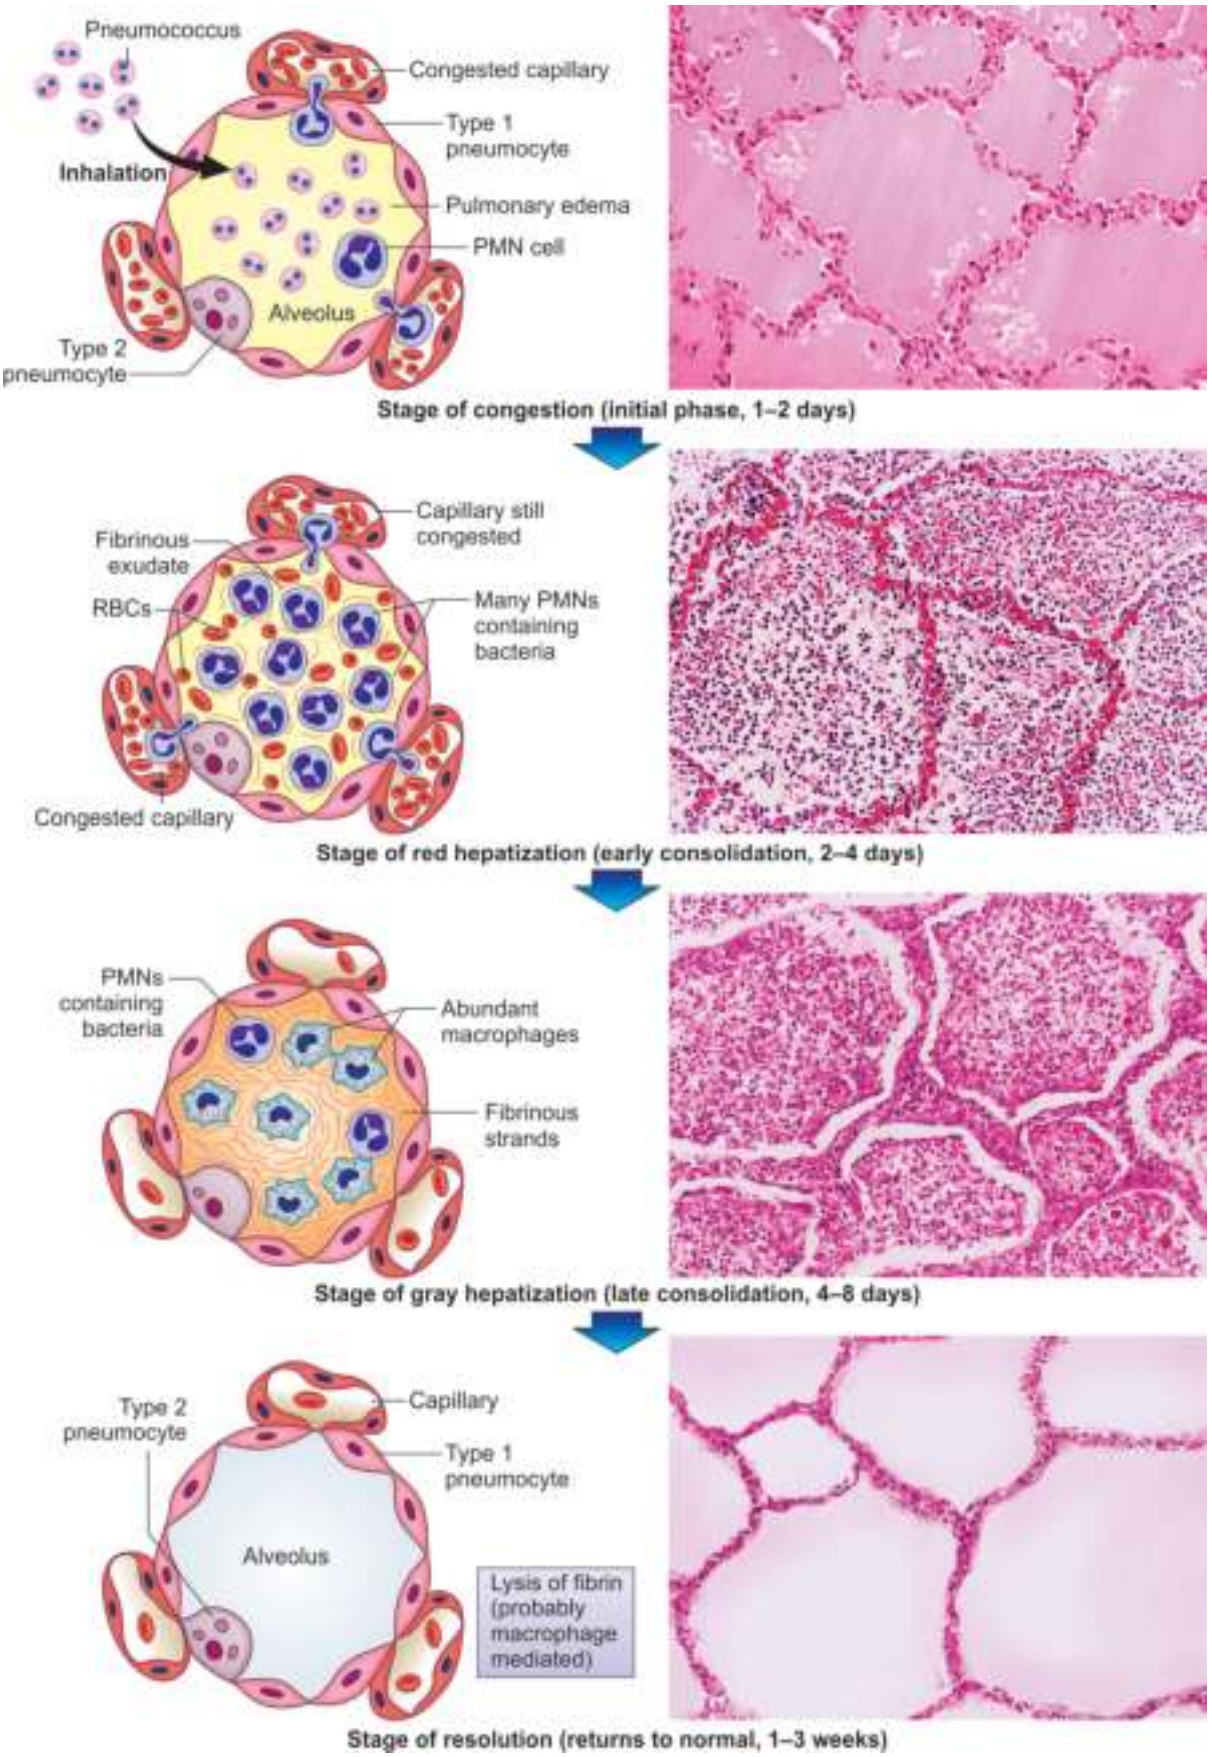

Fig. 18.6: Stages of lobar pneumonia: congestion, red hepatization, gray hepatization and resolution.

Surgical Pathology: Stage of Congestion in Lobar Pneumonia

Gross Morphology

Affected lung in early congestion stage of lobar pneumonia is heavy, edematous and red.

Light Microscopy

- Alveolar capillaries are congested.
- Increased alveolar capillaries permeability results to outpouring of protein-rich fluid with a few neutrophils (inflammatory exudate) and numerous bacteria into alveolar spaces.

Surgical Pathology: Stage of Red Hepatization in Lobar Pneumonia

Gross Morphology

The lung in stage of red hepatization of lobar pneumonia is brick red, solid and airless, with a consistency resembling fresh liver (Fig. 18.7).

Light Microscopy

- Alveolar capillaries are congested.
- The alveolar spaces are completely filled with fluid and polymorphonuclear cells, i.e. inflammatory exudates.
- Alveoli often show presence of many bacteria and RBCs.
- Overlying pleura bears fibrinous exudates (Fig. 18.8).

- **Stage of red hepatization (2–4 days):** Second stage of red hepatization in lobar pneumonia lasts for 2–4 days. There is progressive disintegration of red blood cells with persistent fibrinosuppurative exudate.
  - Clinical features in red hepatization stage in lobar pneumonia occur due to presence of inflammatory exudate. Onset of lobar pneumonia is usually abrupt. Patient presents with high grade fever 40°C with chills, productive 'rusty' sputum containing flecks of blood and occasionally patients may have hemoptysis.
  - Acute pleuritic chest pain on deep respiration reflects involvement of pleura. The clinical findings are dramatically modified by administration of antibiotics.
  - There is increased respiratory rate, guarding and lag on affected side. Children show sternal retraction and nasal flaring.
  - On palpation, chest expansion is decreased on affected side. Tactile fremitus is increased, if bronchus is patent, and decreased if bronchus is obstructed.
  - Percussion note is dull over lobar pneumonia, which recedes with resolution.

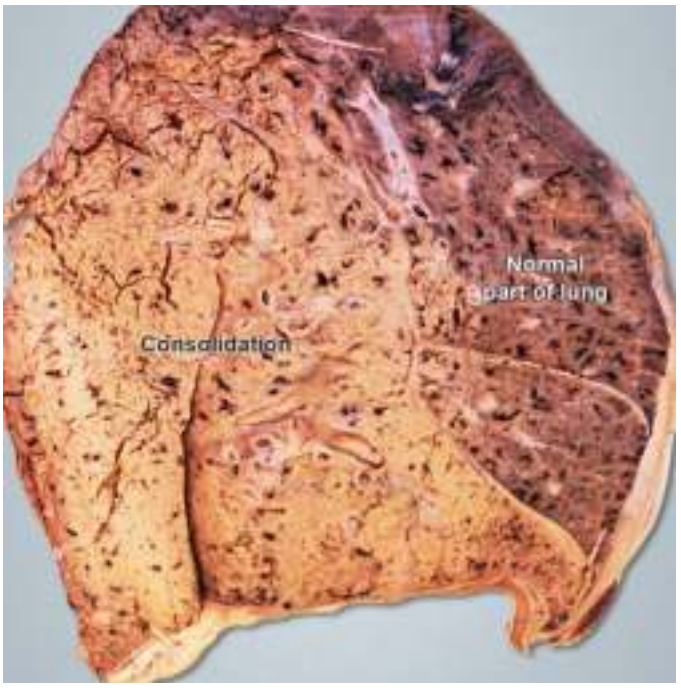

Fig. 18.7: Lobar pneumonia shows consolidation in major portion with small portion of normal lung.

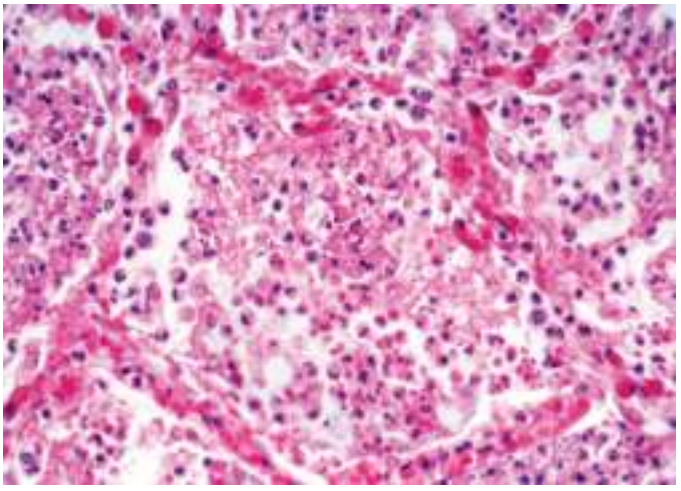

Fig. 18.8: Bacterial lobar pneumonia shows alveoli filled with exudate containing neutrophils. The surrounding alveolar walls having dilated capillaries filled with red blood cells. The exudate in alveoli gives rise to the productive cough of purulent yellow sputum (400X).

  - Breath sounds are louder with patent bronchus as if coming from larynx. Bronchophony, egophony and whispered pectoriloquy are present. Late inspiratory crackles of fine to medium size are heard.
- **Stage of gray hepatization (4–8 days):** Progression from red to gray hepatization in lobar pneumonia, there is progressive disintegration of red blood cells. There is persistent fibrinosuppurative exudate in alveoli resulting in consolidation of lung. Gray hepatization stage lasts for 4–8 days.

Surgical Pathology: Stage of Gray Hepatization in Lobar Pneumonia
Gross Morphology
▪ On cut section, lung in gray hepatization stage of lobar pneumonia appears gray brown and consolidated. ▪ Compression of alveolar capillaries by inflammatory exudates in alveoli reduces the pulmonary blood flow, thus giving this appearance.
Light Microscopy
▪ The alveoli are filled with fibrinopurulent exudates. ▪ The capillaries in the alveolar walls appear compressed and contain less blood than seen in red hepatization.

- **Stage of resolution (8–10 days):** It is characterized by granular, semi-fluid debris lobar pneumonia, which represents enzymatic digestion of inflammatory debris, ingested by macrophages with preservation of the underlying alveolar wall architecture.
- **Stage of organization:** Carnification of lung is also called organization of lobar pneumonia. When lobar pneumonia fails to resolve, it gets organized by formation of granulation tissue and finally fibrosis. Lung parenchyma becomes hard in consistency.

Complications of Lobar Pneumonia

- **Pleuritis:** Patient develops pleuritis as a result of extension of inflammation to the pleural surface.
- **Lung abscess:** Pulmonary abscess is a focal suppurative destructive necrosis within the lung parenchyma. It is most often caused by *Streptococcus pneumoniae*, *Pseudomonas aeruginosa*, Klebsiella, or Proteus, often in combination with anaerobic organisms.
- **Empyema:** It refers to collection of pus in pleural cavity. It follows spread of bacterial infection to the pleural space.
- **Bacterial dissemination (sepsis):** It results in endocarditis, pericarditis, meningitis, suppurative arthritis, abscesses in kidneys and spleen.

Laboratory Diagnosis

- **Imaging techniques:** Chest radiograph is gold standard diagnostic tool with 50–80% sensitivity to diagnose pneumonias. Bronchopneumonia shows patchy/focal opacities, whereas lobar pneumonia shows radiopaque infiltrate involving the entire lobe.
- **Sputum examination:** Gram stained sputum examination shows presence of neutrophils containing numerous lancet-shaped diplococci with tapered ends pointing to each other establishes evidence of pneumonia due to streptococcal pneumoniae. But it must be remembered that *Streptococcus pneumoniae* is a part of normal flora and may give false positive results.
- **Blood culture:** The identification of the causative microorganism and the subsequent determination of its antibiotic sensitivity are the key notes to appropriate therapy. During early phase of illness, blood culture is positive in 20–30% of persons with lobar pneumonia. Whenever possible, antibiotic sensitivity must be done.

BRONCHOPNEUMONIA

Bronchopneumonia is characterized by patchy distribution of inflammation that generally involves more than one pulmonary lobe.

- Bronchopneumonia results from extension of initial infection of bronchi or bronchioles extending into surrounding alveoli involving one or more lobules.
- Inflammatory pulmonary focus shows patchy reddish-gray consolidation and microabscesses in bronchi or bronchioles.
- The infection is often bilateral and basal because of the tendency of secretions to gravitate into the lower lobes or right middle lobe. It usually occurs during infancy and old age especially in immunosuppression state.

Etiopathogenesis

Bronchopneumonia is acute suppurative inflammation caused by *Staphylococcus aureus*, *Haemophilus influenzae*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa* and *Streptococcus pyogenes*. Other predisposing factors include whooping cough, measles, chronic bronchitis, malnutrition and cancer.

Clinical Features

Patient often becomes septicemic and toxic and presents with fever, productive cough with mucus, shortness of breath, chest pain, rapid breathing, chills and headache.

Surgical Pathology: Bronchopneumonia
Gross Morphology
▪ Consolidated region of lungs shows acute suppurative inflammation. ▪ Cut surface shows dry, granular, and grey-red to yellow patchy consolidation with poorly defined margins. ▪ Pleural involvement is less common than lobar pneumonia (Fig. 18.9 and Table 18.6).
Light Microscopy
Histologic examination shows focal suppurative exudate filling the bronchioles and surrounding alveolar spaces (Fig. 18.10).

Fig. 18.9: Bronchopneumonia. It shows tan yellow patchy consolidation. Areas of consolidation are more firm than the surrounding lung (arrows).

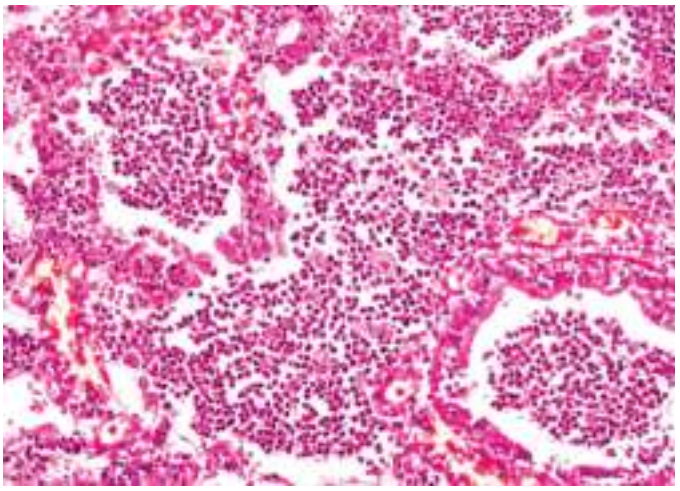

Fig. 18.10: Bronchopneumonia. It shows alveoli filled with neutrophilic exudate corresponding to the areas of consolidation seen on grow examination. Focal suppurative exudate filling the bronchioles involving surrounding alveolar spaces (100X).

INTERSTITIAL PNEUMONIA

Interstitial pneumonia is also called **primary atypical pneumonia**. Unlike typical acute pneumonias, sputum production is modest. There is absence of physical

Table 18.6 Differences between lobar pneumonia and bronchopneumonia

Parameters	Lobar Pneumonia	Bronchopneumonia
Definition	Acute respiratory tract infection involving alveoli	Acute respiratory tract infection involving bronchioles and extending to alveoli
Age group	Adults	Infants, old persons
Immunity status	Previously healthy persons	Immunocompromised persons
Organisms	Pneumococci, streptococccal pneumococci, *Haemophilus influenzae, Klebsiella pneumoniae*	Staphylococcus, streptococci, pneumococci, *Haemophilus influenzae, Pseudomonas aeruginosa* coliforms
Opportunistic infection	Absent	May be present
Pathology	Lung alveoli filled with exudate	Bronchitis/bronchiolitis involving lung alveoli
Consolidation lung	Diffuse consolidation	Patchy consolidation
Lobes involved	Part of lobe or entire lobe	Multiple lobes, often bilateral
Lung lobe involved	Upper or lower lobe or whole lung	Basal portion of lower lobe due to secretions
Stages of inflammation	Early congestion (1–2 days), red hepatization (2–4 days), gray hepatization (4–8 days) and resolution (7–21 days)/organization	Not clearly defined
Exudation seen on light microscopy	More exudate	Less exudate
Severity	More severe disease	Less severe disease
Sputum	Initially scanty, watery. Later on thick, purulent, hemorrhagic	Purulent
Complications	Uncommon, organization, pleural effusion, empyema, lung abscess	Uncommon, organization, pleural effusion, empyema, lung abscess and bronchiectasis

findings of consolidation. Bacteria and viruses are not isolated.

Surgical Pathology: Interstitial Pneumonia

Gross Morphology

- Lung in interstitial pneumonia shows diffuse, patchy inflammation localized to interstitial areas of the alveolar walls.
- Interstitial pneumonia involves one or more lobes. It occurs as a result of droplet infection.

Light Microscopy

- Inflammatory reaction in interstitial pneumonia is confined to the interstitium of lung.
- Alveolar spaces are usually free of exudates.
- The alveolar septa are widened and edematous, infiltrated by lymphocytes, macrophages and occasionally plasma cells.

Clinical Features

Patient has insidious onset of low-grade fever, non-productive cough, and chest pain, flu-like symptoms, i.e. pharyngitis, laryngitis, myalgia, and headache. Patient's lungs show no signs of consolidation.

Etiopathogenesis

- **Bacterial interstital pneumonia:** *Mycoplasma pneumoniae* is most common cause of primary atypical pneumonia, i.e. interstitial pneumonia with insidious onset. It usually occurs in children and young adults. It usually follows a mild self-limited course.
- **Viral interstitial pneumonia:** Viruses most often cause interstitial pneumonia in children. These include influenza virus, adenovirus, rhinovirus, and respiratory syncytial virus, rubeola (measles) or varicella (chickenpox). Cytomegalovirus produces a characteristic interstitial pneumonia with marked enlargement of infected cells containing intranuclear inclusions. Measles virus produces interstitial pneumonia and marked by numerous giant cells.
- **Lymphocytic interstitial pneumonia:** It is often associated with Sjögren's syndrome and HIV infection. Clinical course of the disease varies from an indolent condition to one of those progresses to end-stage lung disease and respiratory failure.
- **Hypersensitivity pneumonitis:** It occurs in response to repeated exposure to a variety of organic materials e.g. pigeon bird droppings, feathers, mushrooms, and tree bark. Inhalation to pigeon bird droppings is known as pigeon breeder lung. Hypersensitivity pneumonitis may be caused by *Thermoactinomyces sacchari* in sugarcane workers, *Cryptostroma corticale* fungus in maphe bark workers, fungus growing in airconditioners and swimming pools; and *Saccharopolyspora rectivirgula* in moldy hay seen in farmer's lung. Histologic examination of lung lesion shows poorly formed granulomas. Antigens associated with hypersensitivity pneumonias are given in Table 18.7.

Table 18.7 Antigens associated with hypersensitivity pneumonias

Disease	Antigen	Environmental Antigens Source
Farming/food processing		
Farmer's lung	Thermophilic actinomycetes (*Saccharopolyspora rectivirgula*)	Grain, moldy hay, silage
Bagassosis	Thermophilic actinomycetes	Sugarcane
Cheese washer's lung	*Penicillium casei*; *Aspergillus clavatus*	Cheese castings
Coffee worker's lung	Coffee bean dust	Coffee bean dust
Malt worker's lung	*Aspergillus* species	Barley
Miller's lung	*Sitophilus granaries* (wheat weevil)	Wheat flour
Mushroom worker's lung	Thermophilic actinomycetes; mushroom spores	Mushrooms
Potato riddler's lung	Thermophilic actinomycetes; *Aspergillus* species	Moldy hay around potatoes
Tobacco grower's lung	*Aspergillus* species	Tobacco
Wine maker's lung	*Botrytis cinerea*	Grapes
Birds and other animals		
Bird fancier's lung (also named by specific bird exposures)	Proteins derived by parakeets, pigeons, budgerigars	Bird features, droppings, serum proteins
Duck fever	Duck features, serum proteins	Ducks
Fish meal worker's lung	Fish meal dust	Fish meal

Contd...

Table 18.7 Antigens associated with hypersensitivity pneumonias (*Contd...*)

Disease	Antigen	Environmental Antigens Source
Furrier's lung	Dust from animal furs	Animal furs
Laboratory worker's lung	Rat urine, serum, fur	Laboratory rats
Pituitary snuff taker's lung	Animal proteins	Pituitary snuff from bovine and porcine sources
Poultry worker's lung	Chicken serum proteins	Chickens
Turkey handing disease	Turkey serum proteins	Turkeys
Other occupational and environmental exposures		
Chemical worker's lung	Isocyanates	Polyurethane foam, varnish
Detergent worker's lung	*Bacillus subtilis* enzymes	Detergent
Hot tub lung	*Cladosporium* species; *Mycobacterium avium* complex	Contaminated water, mold or ceiling
Humidifier fever and air conditioner lung	Several microorganisms including *Aureobasidium pollulans*; *Candida albicans*; thermophilic actinomycetes; *Mycobacterium* species; *Klebsiella oxytoca*; *Naegleria gruberi*	Humidifier (in water heaters) and air conditioners (contaminated water)
Machine operator's lung	*Pseudomonas* species' *Naegleria gruberi*	Metal working fluid
Sauna taker's lung	*Aureobasidium* species; other antigens	Sauna bath
Suberosis	*Penicillium glabrum*; *Chrysonilia sitophila*	Cork dust
Summer type pneumonitis	*Trichosporon cutaneum*	House dust mites, bird droppings
Wood worker's lung	*Alternaria* species; *Bacillus subtilis*	Oak, cedar, pine, mahogany dusts

- **Interstitial pneumonia of unknown etiology:** It is of unknown etiology in majority of cases. It occurs in various clinical settings, i.e. collagen vascular disease, chronic hypersensitivity pneumonitis, and drug toxicity.
- **Nonspecific interstitial pneumonia (NIP):** It is associated with collagen vascular disease, hypersensitivity pneumonitis, and drug reaction. Patient develops diffuse, temporarily uniform proliferative and fibrosing changes in the lungs. Prognosis is better than usual interstitial pneumonias with five-year survival in >80% of cases.
- **Desquamative interstitial pneumonia (DIP):** It is chronic fibrosing interstitial pneumonitis of unknown etiology. Lungs show minimal fibrosis with preservation of lung architecture. It primarily occurs in tobacco smokers. Prognosis is better than usual interstitial pneumonias with 10-year survival in 70–100% of cases. The pathologic changes can regress following tobacco smoking cessation.

OPPORTUNISTIC PULMONARY INFECTIONS

Immunocompromised patients may develop pneumonias due to opportunistic infections.

Pneumocystis Jiroveci

Pneumocystis jiroveci is most common pathogen causing pneumonia in acquired immune deficiency syndrome. This organism has been reclassified as a fungus.

- **Light microscopy:** Lung lesion shows interstitial infiltrate of plasma cells and lymphocytes, diffuse alveolar damage, and hyperplasia of type 2 pneumocytes. The alveoli contain foamy exudate. The organisms appear as small bubbles in a background of proteinaceous exudates.
- **Bronchoalveolar lavage:** Specimen obtained by bronchoalveolar lavage impregnated with silver shows a cluster of cysts. The cysts appear as round or indented (crescent moon) bodies measuring 2–3 μm in diameter.

Candida Albicans

In immunocompromised patients, invasing form of *Candida albicans* produces blood-borne dissemination, resulting in pulmonary, renal, and hepatic abscesses and vegetative endocarditis.

Cytomegalovirus

Cytomegalovirus (CMV) infection is now well recognized in immunocompromised persons. CMV causes

marked enlargement of infected cells, which contain typical intranuclear and often cytoplasmic inclusions. Diagnosis is confirmed by morphologic demonstration of cytomegalovirus in biopsy or bronchial washing specimens.

Nocardiosis

Nocardia are gram-positive aerobic, filamentous, weakly acid-fast bacteria closely related to *Actinomyces israelii*. Typically opportunistic infection may disseminate to lung, skin, brain and meninges.

Aspergillus Fumigatus

Invasion of blood vessels and tissue infarcts are common in *Aspergillus fumigatus* infection. *Aspergillus* species may also grow in pre-existing cavities caused by tuberculosis or bronchiectasis. The fungus proliferates to form fungus balls, which are also referred to as aspergillomas or mycetomas. Lung shows focal yellow areas of consolidation.

Invasive form of *Aspergillus fumigatus* has predilection for growth into vessels, with consequent widespread hematogenous dissemination.

Cryptococcus Neoformans

Pneumonia results from the inhalation of spores of *Cryptococcus neoformans*, a fungus frequently encountered in pigeon droppings. Most serious cases occur in immunocompromised persons. *Cryptococcus neoformans* stains positively with a mucicarmine stain or India ink for capsular polysaccharides.

Histoplasma Capsulatum

Histoplasma capsulatum results in multiple pulmonary lesions with late calcification. Disseminated form of disease is marked by multisystem involvement with infiltrates of macrophages filled with fungal yeast forms.

Coccidioidomycosis

Coccidioidomycosis occurs in primary and disseminated forms. Fungal spherules contain endospores found within granulomas of involved lung.

Actinomyces Israelii

Actinomyces israelii is gram-positive anaerobic filamentous bacteria no longer classified as a fungus. It is normal colonizer of the vagina, colon, and mouth. It is an opportunistic pathogen. Infection is established first by a breach of the mucosal barrier during various procedures (dental, gastrointestinal), aspiration, or diverticulitis. Patient develops lung abscess and sinus tract formation. Histologic examination shows exudates containing sulfur granules, yellow clumps of the organism in lungs.

LIPID PNEUMONIA

Lipid pneumonia is an uncommon noninfectious inflammatory pulmonary disease caused by the presence of lipids in the alveoli. It is classified into two groups, depending on whether the lipid/oil in the respiratory tract is from an exogenous or endogenous/idiopathic source. Pathologically, lipid pneumonia is a foreign body reaction characterized by lipid-laden macrophages.

- Exogenous lipid pneumonia is caused by various types of lipids such as mineral oils, animal oils, vegetable oils or use of nasal petroleum jelly, lip gloss.
- Endogenous lipid pneumonia results from breakdown of lung distal to obstructed airway either by tumor or bronchiolitis obliterans or following chemotherapy given for lung carcinoma and lymphoma or radiotherapy leading to release of cholesterol and other lipids in alveoli.
- Bronchoalveolar lavage fluid is initially turbid white. Lipid phagocytosis by alveolar macrophages is observed under a microscope with Sudan III staining. Physical examination reveals no abnormal findings, with the exception of inspiratory fine crackles in the lower fields on auscultation.
- Chest radiograph and CT scan reveal ground glass opacity and interseptal thickening in the bilateral lungs. Comparison of exogenous and endogenous lipid pneumonias is given in Table 18.8.

Table 18.8 Comparison of exogenous and endogenous lipid pneumonias

Features	Exogenous Lipid Pneumonia	Endogenous Lipid Pneumonia
Lipid	Usually mineral (saturated and therefore nonosmophilic)	Endogenous derived lipid (unsaturated and therefore osmophilic)
Obstructing lesion	Absent	Present
Foamy macrophages	Intra-alveolar space and interstitial tissue	Intra-alveolar space
Giant cells	Present around droplets	Absent (except around crystals)
Extracellular fat droplets	Fat droplets of varying size present	Fat droplets absent

Endogenous lipid pneumonia is caused by airway obstruction by tumor, amiodarone drug reaction and Niemann-Pick disease.

LUNG ABSCESS

Lung abscess is a focal suppurative process within the lung characterized by necrosis of lung parenchyma. It is most often caused by Staphylococcus, streptococci, Pseudomonas, Klebsiella, or Proteus, often in combination with anaerobic organisms.

- **Pathogenesis:** Lung abscess most often occurs due to aspiration of oropharyngeal and gastric material, superior segment, right lower lobe is most common site for aspiration. Other causes of lung abscess include bronchial obstruction (often by tumor), or complication of bacterial pneumonias, septicemias and penetrating lung injury. Microbial pathogens causing lung abscess are given in Table 18.9.

Table 18.9 Microbial pathogens causing lung abscess

Primary Lung Abscess (Uusually with Risk Factors for Aspiration)
▪ Anaerobes (e.g. *Streptococcus milleri*) ▪ Microaerophilic streptococci
Secondary Lung Abscess (Most Often with Underlying Immunocompromising State)
▪ *Staphylococcus aureus* ▪ *Pseudomonas aeruginosa* ▪ Enterobacteriaceae ▪ *Nocardia* species ▪ *Aspergillus* species ▪ *Pneumocystis jiroveci* ▪ *Cryptococcus* species ▪ Legionella
Infective Embolic Lesions in Lung
▪ *Staphylococcus aureus* (most often from infective endocarditis) ▪ *Fusobacterium necrophorum* (recurrent acute sore throats, peritonsillar abscess, meninigitis and thrombosis of cerebral veins and internal jugular veins)
Endemic Infections (with or without Underlying Immunocompromised State)
▪ *Mycobacterium tuberculosis* ▪ *Mycobacterium avium* ▪ *Mycobacterium kansasii* ▪ *Histoplasma capsulatum* ▪ Blastomyces (blastomycosis) ▪ *Entamoeba histolytica* ▪ *Strongyloides stercoralis*
Miscellaneous Conditions
Staphylococcus aureus after influenza or other viral infections

  - **Aspiration:** Person with decreased cough reflex due to alcohol or drug overdose, general anesthesia or neurological disorders may aspirate infected oropharyngeal material, tonsillitis, sinusitis or gingivodental sepsis, that localize in the lung depending on the posture of patient. Person in sitting or standing posture, aspirated material is located in the posterobasal segment of the right lower lobe. In the supine posture, superior segment of the right lower lobe is affected. In right-sided posture, it is localized in the right middle lobe or the posterior segment of the right upper lobe.
  - **Bronchial obstruction:** It occurs due to centrally located squamous cell lung carcinoma in 10–15% of cases, bronchopulmonary carcinoid tumor, and foreign body.
  - **Pneumonias:** Lung abscess occurs in patients suffering from pneumonias caused by streptococci, *Staphylococcus aureus*, pneumococci, *Klebsiella pneumoniae*, and anaerobic bacteria.
  - **Septicemia:** Septic emboli in case of infective endocarditis, thrombophlebitis and puerperal sepsis by pyogenic organisms seed the lung *via* hematogenous route.
  - **Direct penetrating lung injury:** It may cause lung abscess.
- **Clinical features:** Patient presents with productive cough (foul smelling sputum), chest pain and fever of spiking pattern. Chest radiograph shows cavitation with an air-filled level.
- **Complications:** Lung abscess may spread to pleura, mediastinum, meninges, and bones. Patient may develop amyloidosis and septicemia.

Surgical Pathology: Lung Abscess

Gross Morphology

- Lung abscess varies in size and location depending on underlying cause.
- Aspiration of infected oropharyngeal material is located in the superior segment of right lung due to vertical course of right bronchus.
- Distribution of lung abscess is shown in Fig. 18.11 and Table 18.10.

Light Microscopy

Necrotic material obtained from lung abscess shows inflammatory cells. Necrotic area is surrounded by granulation tissue and fibrosis (Fig. 18.12).

Fig. 18.11: Lung abscess present in apical region (arrow).

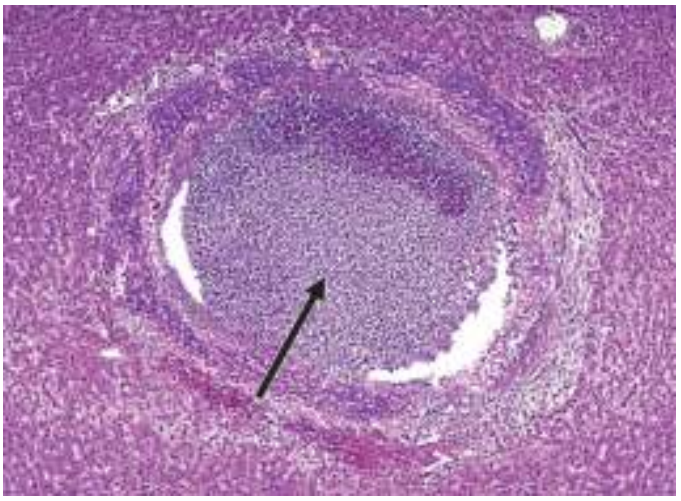

Fig. 18.12: Lung abscess shows collection of neutrophils (arrow) (100X).

Table 18.10 Distribution of lung abscess

Causes of Lung Abscess	Location of Abscess in Lungs
Aspiration sitting or standing posture	Posterobasal segment of the right lower lobe
Aspiration supine posture	Superior segment of the right lower lobe
Aspiration right-sided posture	Right middle lobe or the posterior segment of the right upper lobe
Pneumonia	Multiple lung abscesses
Septic emboli	Multiple lung abscesses
Bronchiectasis	Base of the lung

Treatment

Most acute lung abscesses resolve with appropriate antibiotic therapy (clindamycin) and postural drainage.

In a few cases, imaging guided, tube is inserted to drain the abscess. Bronchoscopy is done if lung abscess does not resolve with antibiotics and postural drainage.

TUBERCULOSIS

PULMONARY AND EXTRAPULMONARY TUBERCULOSIS

Tuberculosis is worldwide health problem caused by Mycobacterium tubercle bacilli (hominis strain). It is transmitted by inhalation of droplets (most common), ingestion of infected milk and skin inoculation (handling infected specimens). It may involve multiple systems.

MYCOBACTERIUM TUBERCLE BACILLUS

- **Acid-fast bacillus:** Mycobacterium tubercle bacillus is strict aerobe. It is acid-fast due to presence of mycolic acid in its cell wall and stained by Ziehl-Neelsen staining (decolorized by 20% sulfuric acid).
- **Composition:** Mycobacterium tubercle bacillus contains large quantity of hydrophobic waxes and fatty acids of high molecular weight, which prevents entry of Gram's stain.
- **Virulence:** Virulence of tubercle bacillus depends on presence of cord factor (a sulfated glycolipid), which prevents fusion of phagosomes with lysosomes and thus favors intracellular survival of AFB in macrophages. If cord factor is extracted, AFB becomes avirulent.
- **Viability:** Tubercle bacillus is viable for months in dry or wet sputum. Single AFB is potentially infective in immunocompromised persons (Table 18.11).

RISK FACTORS

There is increased risk of tuberculosis in person, who is in close contact with a newly diagnosed open

Table 18.11 Four groups of atypical mycobacteria

Group	Example	Pathologic Lesions
Group I: Photochromogens	*Mycobacterium kansasii*	▪ Koch's chest in adults ▪ Cervical lymphadenopathy in children
Group II: Scotochromogens	*Mycobacterium scrofulaceum*	Cervical lymphadenopathy in children, rarely involving lungs
Group III: Nonphotochromogens	▪ *Mycobacterium intracellulare* ▪ *Mycobacterium avium*	▪ Koch's chest in adults ▪ Cervical lymphadenopathy in children ▪ Osteomyelitis may affect any age group
Group IV: Rapid growers	*Mycobacterium fortuitum*	Koch's chest rare (organism present in fresh salty water and swimming pools)

case of pulmonary tuberculosis case (sputum smear positive), history of previous tuberculosis exposure and immunocompromised individuals (AIDS and corticosteroids therapy), history of silicosis, diabetes mellitus, malnutrition, cancer, Hodgkin's disease, or leukemia, gastrectomy, chronic renal failure and alcoholism.

Clinical Pearls: Tubercular Infection and Disease

Tubercular Infection

Tubercular infection refers to positive TB skin test, i.e. Mantoux test or tuberculin test or purified protein derivative (PPD) test with no evidence of active disease. PPD is injected by intradermal route on forearm. Area of induration is demonstrated after 48–72 hours in immunocompetent individuals on exposure to tubercle bacilli after 2–4 weeks. Positive tuberculin test does not distinguish tubercular infection, i.e. inactive disease from active disease.

Tubercular Disease

Tubercular disease refers to cases that have positive acid-fast smear or culture for *Mycobacterium tuberculosis* or radiographic and clinical presentation of tuberculosis. Children below 2 years of age are more susceptible. Patient with silicosis and immunosuppression is more susceptible to tuberculosis.

PATHOGENESIS

Mycobacterium tubercle bacillus antigens play important role in cell-mediated immunity and type IV hypersensitivity reaction. Virulence and bacterial factors in tubercle bacilli are given in Table 18.12.

Pathogenesis of Tuberculosis <3 Weeks Duration

Mycobacterium tubercle bacilli's mannose capped glycolipid (lipoarabinomannan) binds to mannose receptors expressed on alveolar macrophages, which engulf these organisms. Cord factor synthesized by these organisms prevent fusion of phagosomes with lysosomes. Hence, unchecked proliferation of tubercle bacilli continues inside alveolar macrophages.

Pathogenesis of Tuberculosis >3 Weeks Duration

Macrophages are antigen presenting cells, which transmit Mycobacterium tubercle bacilli antigen to CD4+ helper T cells. Macrophages synthesize IL-12, which takes part in differentiation of CD4+ helper T cells in lungs and lymph nodes.

- **Bactericidal activity of immune system:** CD4+ helper T cells synthesize interferon-γ (IFN-γ), which stimulates nitrogen synthase enzyme resulting in synthesis of nitrogen intermediates (NO, NO_2 and

Table 18.12 Virulence and bacterial factors in tubercle bacilli

Characteristics	Name	Functions
Virulence factors	▪ Cord factor composed of glycolipids, mycolic acid and trehalose dimycolate	▪ Cord factor prevents fusion of phagosomes with lysosomes and thus favors intracellular survival of AFB in macrophages. If cord factor is extracted, AFB becomes avirulent. Cord factor can elicit granulomas formation in the tissue
	▪ Catalase-peroxidase	▪ It resists the host cell oxidative response
	▪ Sulfatides and trehalose dimycolate cord factor	▪ These can trigger toxicity in animal models
	▪ Lipoarabinomannan (LAM)	▪ It can induce cytokines and resist host oxidative stress
Bacterial factors	▪ Nonreplicating persistent 1 (NRP1) state	▪ Under aerophilic conditions, it has increased glycine dehydrogenase activity
	▪ Nonreplicating persistent 2 (NRP2) state	▪ Under anaerobic conditions, it has decreased glycine dehydrogenase activity
	▪ A sigma factor	▪ Unknown
	▪ α-Crystallin (αc) like heat shock protein	▪ Unknown

HNO_3) and oxygen-derived free radicals causing oxidative destruction of AFB.

- **Formation of epithelioid cell granulomas:** Macrophages synthesize tumor necrosis factor and chemokines participate in recruitment of monocytes and T cells. This process leads to formation of epithelioid cell granulomas composed of macrophages and surrounded by lymphocytes. Epithelioid cell granulomas prevent spread of infection by confining bacteria within a compact collection of activated macrophages and lymphocytes.
- **Caseous necrosis:** CD8+ cytotoxic T cells cause destruction of macrophages by Fas-dependent mechanism resulting in caseous necrosis.

TISSUE SUSCEPTIBILITY AND DRUG RESISTANCE

Tissue Susceptibility

Most common organs involved in children with tuberculosis include lungs, lymph nodes, spleen and meninges. In adults, most common organs involved comprises lungs, adrenal glands, kidneys, liver, spleen, bone, meninges, serous membranes, fallopian tubes, epididymis and lymph nodes. Lungs are the most common sites of tuberculosis in children and adults. Tissues rarely involved include cardiac and skeletal muscle, stomach, thyroid gland, and pancreas.

Drug Resistance in TB Patients

Patient develops drug resistance due to mutations involving mycolic acid, catalase and peroxidase enzyme. Catalase enzyme is required to activate isoniazid in TB patient.

TUBERCULOSIS: CATEGORIES

Tuberculosis is divided into two categories—pulmonary tuberculosis (85% of cases) and extrapulmonary tuberculosis (15% of cases). Summary of patterns of tuberculous infection of the lungs is given in Table 18.13. Extrapulmonary tuberculosis in order of frequency is given in Table 18.14. Active disease develops in 5–15% of those infected with *Mycobacterium tuberculosis*.

- Pulmonary tuberculosis has two distinct phases, i.e. primary tuberculosis and secondary tuberculosis. Organs involved in primary, secondary and miliary tuberculosis are shown in Fig. 18.13A and B.
- Histologic examination of tubercular lesion shows epithelioid cell granulomas, caseous necrosis and Langhans giant cell (Fig. 18.14).

Table 18.13 Summary of patterns of tuberculous infection of the lungs

Primary Tuberculosis (Ghon's Focus + Lymphatics + Regional Lymph Nodes = Primary Complex)

- Reparative lesion (usually heals by fibrosis and calcification)
- Quiescent lesion (Mycobacterium tubercle bacilli dormant)
- Progressive lesion
  - Pleural involvement
  - Airway dissemination (tuberculous laryngitis, tuberculous bronchopneumonia)
  - Segmental tuberculosis
  - Miliary tuberculosis (hematogenous dissemination to multiple organs)

Post-primary Tuberculosis (Fibrocaseous Apical Cavitation (High Oxygen Tension)

- Reparative lesion (heals by fibrosis and calcification)
- Quiescent lesion (mycobacterium tubercle bacilli dormant)
- Progressive lesion
  - Local extension
  - Pleural involvement
  - Airway dissemination (tuberculous bronchopneumonia)
  - Miliary tuberculosis (hematogenous dissemination to multiple organs)

Nonreactive Tuberculosis (Immunocompromised Persons)

- Tubercular lesion lacks epithelioid cell granulomas
- Ziehl-Neelsen stain demonstrated numerous Mycobacterium tubercle bacilli

Table 18.14 Extrapulmonary tuberculosis in order of frequency

Extrapulmonary Tuberculosis	Mechanism of Involvement	Comments
Tuberculous lymphadenitis	Hematogenous and lymphatic spread	▪ Painless enlarged lymph nodes in cervical and supraclavicular regions ▪ Cervical lymph node may form fistulous tract in skin
Pleural tuberculosis	Pleural tuberculosis can be part of pulmonary tuberculosis	▪ Pleural effusion ▪ Empyema ▪ Pleural fibrosis ▪ Restrictive lung disease
Tuberculosis of the upper respiratory airways	Hematogenous spread	▪ Involvement of the larynx, pharynx and epiglottis in advanced secondary tuberculosis ▪ Symptoms such as hoarseness, productive cough and dysphagia

Contd...

Table 18.14 Extrapulmonary tuberculosis in order of frequency (*Contd...*)

Extrapulmonary Tuberculosis	Mechanism of Involvement	Comments
Genitourinary tuberculosis	Hematogenous spread	▪ Urinary tract infection ▪ Genital tuberculosis in females affects the fallopian tubes and endometrium causing infertility and menstrual abnormalities ▪ Genital tuberculosis in males affects epididymis producing a tender mass that may form a fistulous tract
Skeletal tuberculosis	Hematogenous or lymphatic spread	▪ Weight-bearing joints involved ▪ Spinal tuberculosis (Pott disease) may cause abscess formation that track along muscles and ligaments
Tuberculous meningitis and tuberculoma	Hematogenous spread or rupture of subependymal tubercle	▪ Tuberculous meningitis is more common in children than adults present with headache and altered sensorium and/or paresthesia ▪ Tuberculoma can cause seizures and focal symptoms
Gastrointestinal tuberculosis	Swelling of infected sputum or ingestion of infected milk with *Mycobacterium bovis*	▪ *Mycobacterium bovis* trapped in the lymphoid follicles of intestinal mucosa causing bowel inflammation and ulceration ▪ Ileocaecal mass
Tuberculous pericarditis	Progression of a pericardial focus or rupture of a nearby tubercular lymph node	▪ Pericarditis may progress to constrictive pericarditis ▪ Pericardial effusion
Miliary (disseminated) tuberculosis	Hematogenous spread to multiple organs	▪ Small yellow tubercles that may coalesce forming large areas of consolidation ▪ Nonspecific symptoms such as fever, night sweats and weight loss

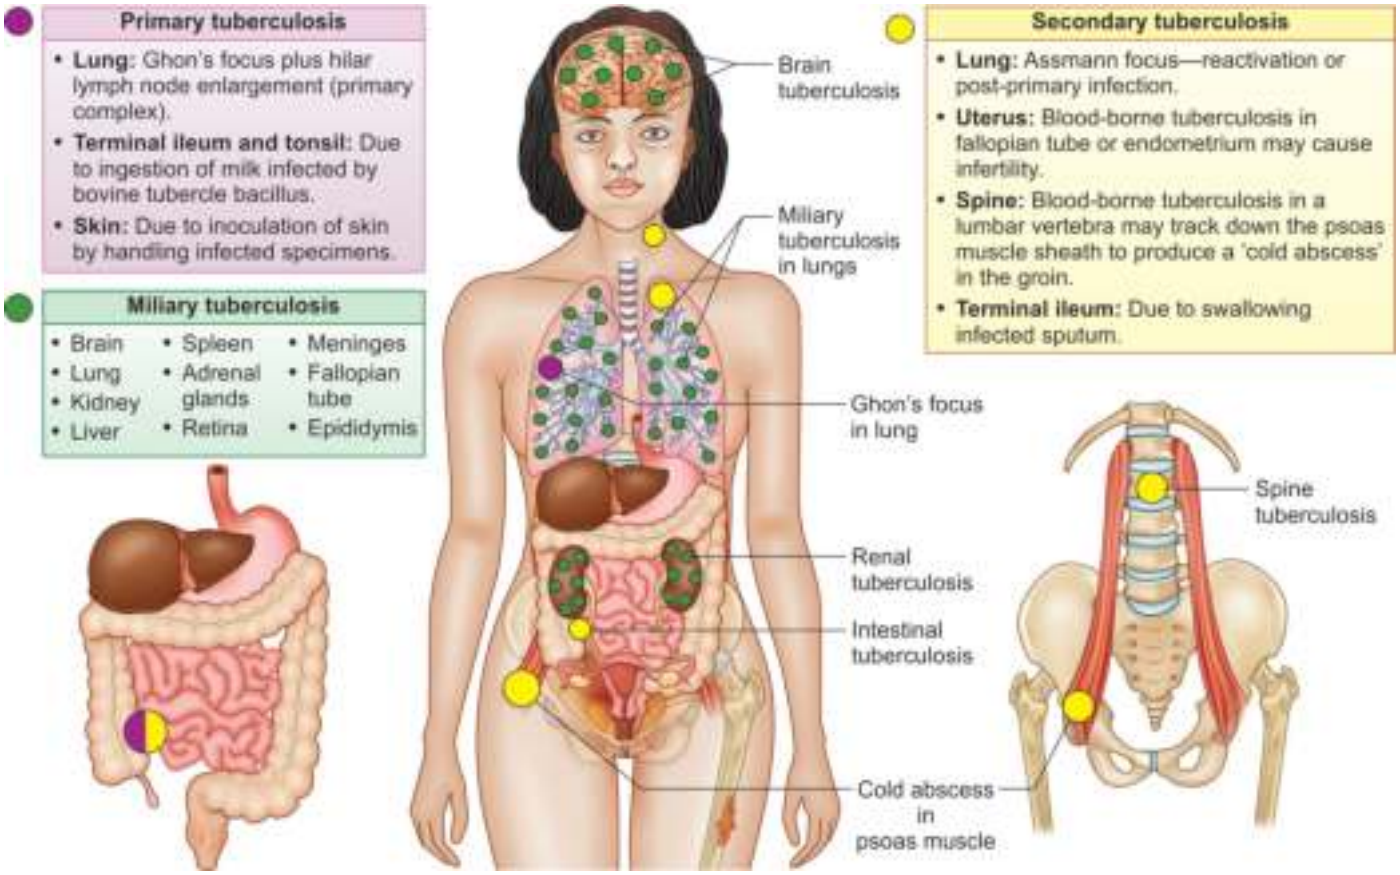

Fig. 18.13A: Organs involved in primary, secondary and miliary tuberculosis. Primary tuberculosis produces a subpleural mid-zone lesion in lung. In secondary tuberculosis, lesion is located in apical region of lung. Miliary tuberculosis shows tubercles in various organs.

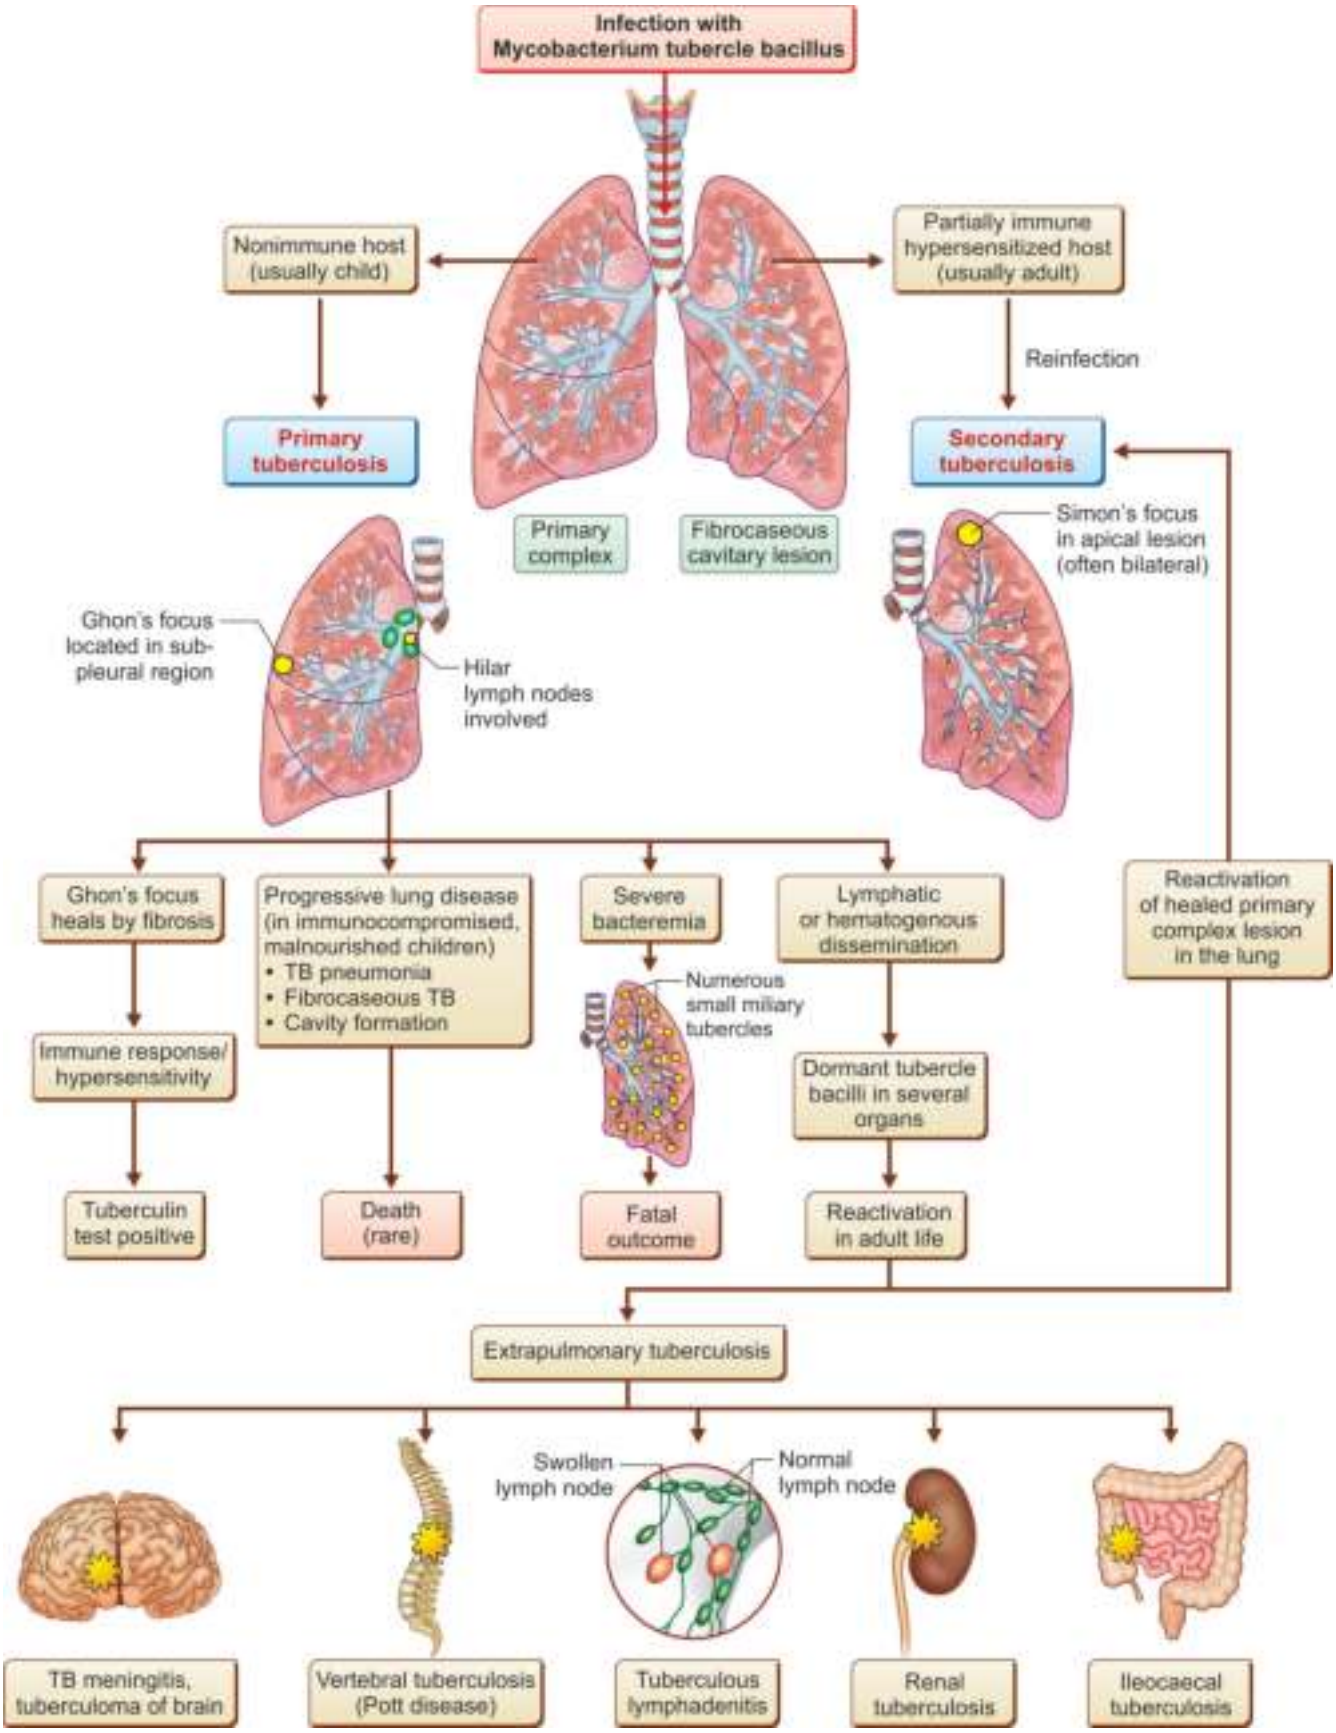

Fig. 18.13B: Pulmonary (primary and secondary) and extrapulmonary manifestations of tuberculosis.

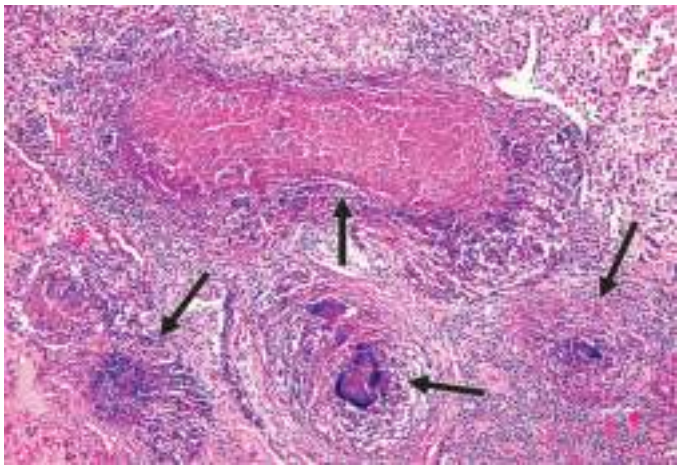

Fig. 18.14: Tuberculosis lung. It shows epithelioid granulomas, Langhans giant cells and caseous necrosis (arrows) (400X).

PRIMARY TUBERCULOSIS (PRIMARY COMPLEX)

Primary tuberculosis is also known as Ghon's focus caused by Mycobacterium tubercle bacillus. It occurs in lung, tonsil, ileocecal region and skin. It usually does not progress to clinically evident disease. Epithelioid cell granuloma in tuberculosis is known as tubercle.

Mode of Transmission

- **Lungs:** Tubercular infection is most common contracted by droplet infection from open case of pulmonary tuberculosis with cavities in lung. Initial exposure to tubercle bacilli produce clinically insignificant nonspecific alveolitis. Patient is asymptomatic at this stage.
- **Tonsils and intestine:** Ingestion of infected milk with Mycobacterium tubercle bacilli produces Ghon's focus in tonsils and ileocecal region. Tubercle bacilli reach the intestine either by ingestion of infected sputum or ingestion of unpasteurized milk and affects terminal ileum and most often ileocecal region. It produces circumferential ulcers perpendicular to long axis of small intestine. Fibrosis in this region is responsible for stricture formation. Histologic examination of intestinal lesion reveals caseating epithelioid cell granulomas with Langhans giant cells. Remember Crohn's disease also produces stricture formation, in which segmental involvement of intestine with skip areas is demonstrated. Thickened wall in Crohn's disease resembles pipe-like and show irregular linear ulcers in the mucosa.
- **Skin inoculation:** Primary cutaneous inoculation of AFB occurs in person handling infected specimens. Patient develops painless nonhealing papule (primary focus) in 2–4 weeks after inoculation, which forms cold abscess resulting in discharging sinuses after several weeks.
- **Vertical transmission:** Placental transmission of tuberculosis from mother to fetus shows lesions in liver and portal lymph nodes seen at birth.

Primary Tuberculosis (Ghon's Complex in Lung)

Ghon's complex consists of Ghon's focus in organs (lung, tonsil, ileocecal region and skin), lymphatic channel and draining lymph nodes involvement.

Ghon's Focus in Lung

- **Location:** Primary tuberculosis produces a small mid-zonal subpleural focus of consolidation near the interlobar fissure with involvement of lymphatic channels and hilar lymph nodes.
- **Dystrophic calcification:** Primary tuberculosis most often heals by fibrosis and dystrophic calcification in 95% of cases. Other lung lesion known as Ranke's complex is often visible on chest radiograph.
- **Lung lesions:** Approximately 5% of immunocompromised children develop symptomatic infection (pulmonary cavities, bronchopneumonia, pleural effusion or miliary tuberculosis).
- **Nidus for secondary tuberculosis:** Because, acid-fast bacilli persisting in dormant form in old necrotic calcified lesions are still capable of initiating lesion, and thus nidus for secondary tuberculosis.

Lymphatic Channels Involvement

Lymphatic channels are laden with Mycobacterium tubercle bacilli without producing lesion.

Draining Lymph Nodes

Lymph nodes draining Ghon's focus show caseous necrosis. Lymph nodes are enlarged in hilar region in pulmonary tuberculosis. Cervical lymphadenopathy occurs in tonsillar tuberculosis. Intestinal tuberculosis involves ileocecal lymph nodes. Cutaneous lymph nodes are involved in skin tuberculosis. Lymph node lesions of tuberculosis take longer time to regress, hence remain a potential source of reactivation (Fig. 18.15).

SECONDARY TUBERCULOSIS

Secondary tuberculosis is also known as post-primary pulmonary tuberculosis or reactivation disease. Lung lesion in secondary tuberculosis is known as **Simon's focus**. It develops during adult life especially in immunocompromised persons. It occurs either due to inhalation of Mycobacterium tubercle bacilli or reactivation of AFB present in dormant lymph node and old calcified healed parenchymal lesion. It causes extensive tissue destruction producing caseous necrosis by the action of cytokines synthesized by memory T cells.

Locations

- Reactivation of tubercular focus produces cavitary lesions in the apical regions or posterior segments

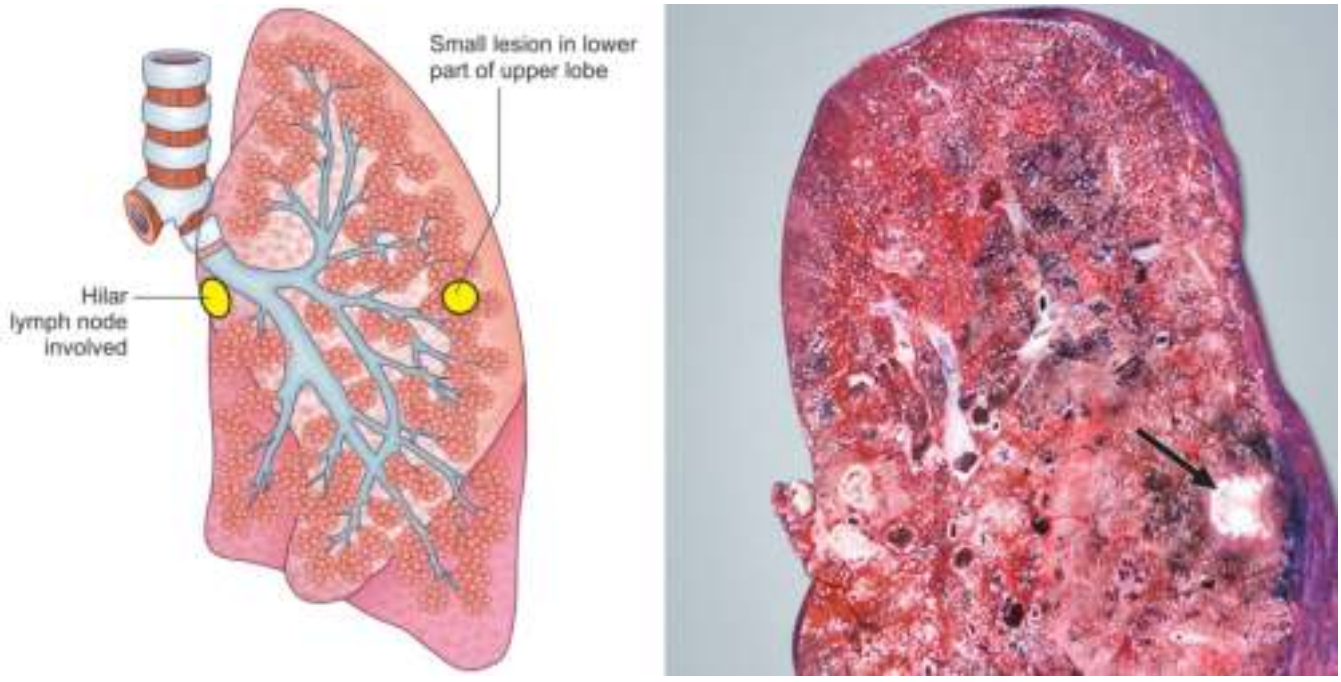

Fig. 18.15: Primary tuberculosis. It shows subpleural mid-zonal Ghon's focus and hilar lymph node enlargement. Gross examination of lung shows subpleural mid-zonal Ghon's focus (arrow).

of the upper lobes either unilateral or bilateral. Hilar lymph node involvement is also common. Apical lesions occur due to high oxygen tension and paucity of macrophages due to decreased blood supply.

- Growth of Mycobacterium tubercle bacilli is inhibited at pH <6.5. Large pulmonary cavities are associated with hemoptysis.
- *Aspergillus* species may also grow in pre-existing cavities caused by tuberculosis. They proliferate to form fungus balls, which are also referred as aspergillomas or mycetomas.

Morphologic Lung Lesions in Tuberculosis

Initially, pulmonary tubercular lesion is 2 cm, solid, gray-white to yellowish, with poorly defined margins and central areas of caseous necrosis. Some patients may develop tubercular cavities, which are highly contagious. The lesion frequently ruptures into the bronchi.

- **Tuberculous cavities:** Caseous material may liquefy resulting in pulmonary cavitary lesions in secondary tuberculosis, but not primary tuberculosis. The cavity is filled with yellow-grayish caseous material more or less surrounded by fibrous tissue. AFB can easily be demonstrated in open pulmonary cavities. Tubercular lesion may erode into airways. Patient may develop empyema and hemoptysis. The sputum becomes positive for AFB.
- **Lung consolidation:** Immunocompromised young children and elderly persons may develop tubercular bronchopneumonia or lobar pneumonia. These patients are very infectious. Patient presents with high-grade fever and productive cough.
- **Tubercular pleuritis and effusion:** These lesions usually develop soon after initial infection. Tuberculous focus located at the edge of the lung ruptures into the pleural space resulting in pleurisy and pleural effusion. Patient with pleurisy presents with dyspnea and sharp chest pain that worsens with a deep breath (pleurisy). Tubercular pleurisy generally resolves without treatment. Morphology of lung in tuberculosis is shown in Fig. 18.16A to F. Differences between primary and secondary tuberculosis are given in Table 18.15. Differences between tuberculosis and sarcoidosis are given in Table 18.16.

Complications of Pulmonary Tuberculosis

Complications of secondary tuberculosis are lung fibrosis, lung cavitation, miliary tuberculosis and other lesions described as under:

- **Lung fibrosis:** Healing of secondary pulmonary TB occurs by fibrosis in favorable conditions.
- **Lung cavitation:** In some patients, tubercular lesion continues to progress for months and years results in further pulmonary damage. It leads to cavity

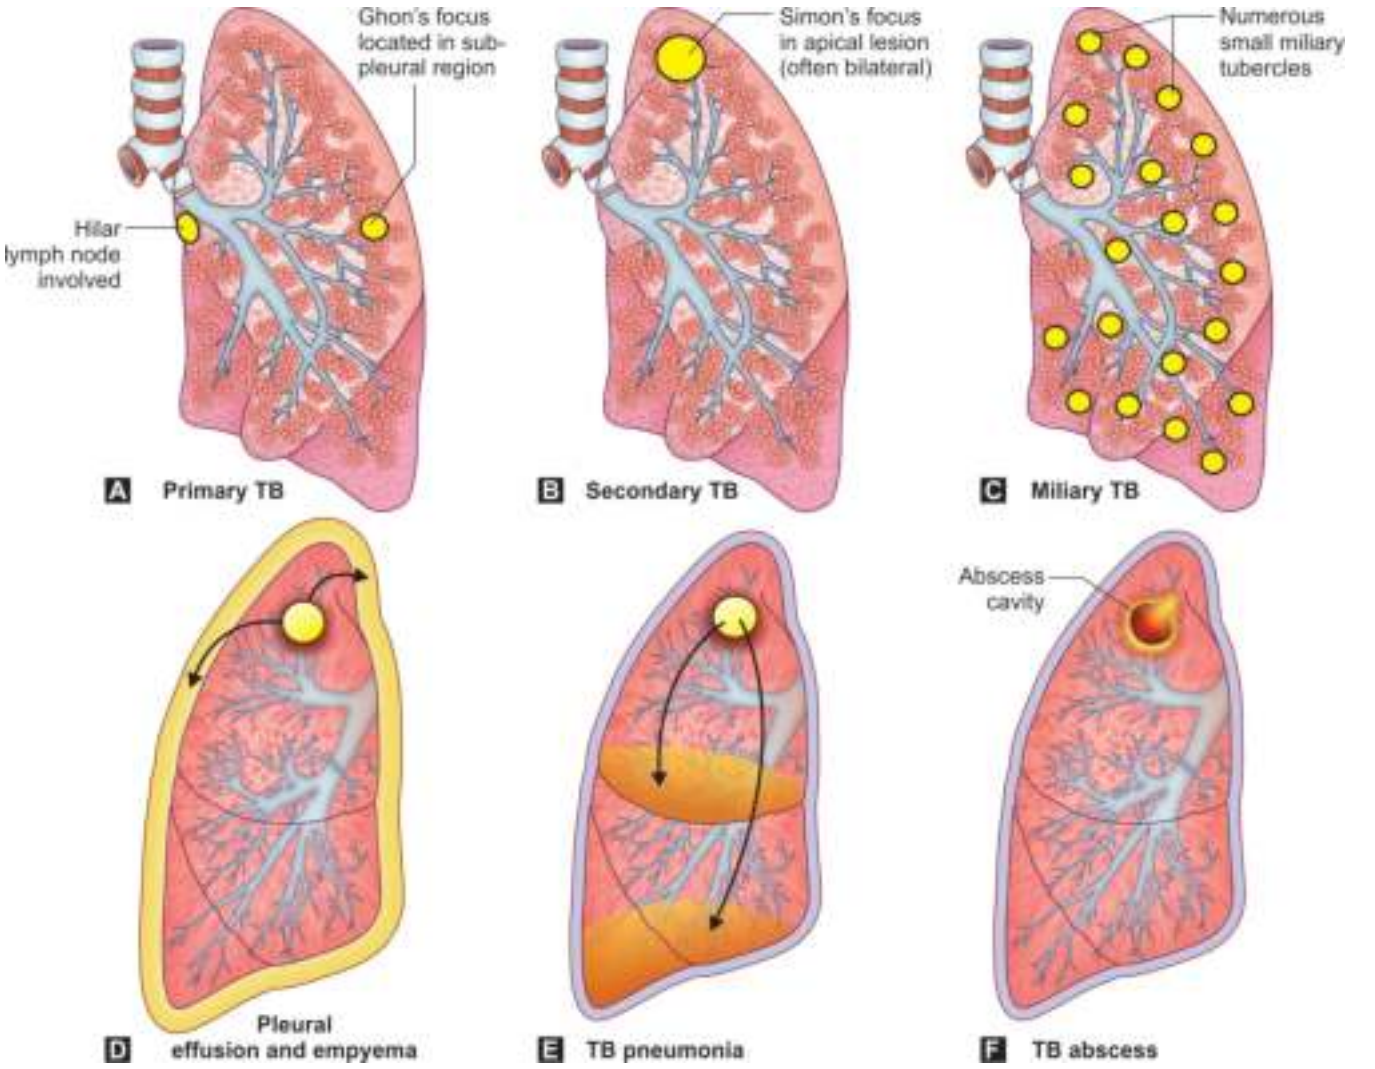

Fig. 18.16: Morphology of lung in tuberculosis. (A) Primary tuberculosis shows subpleural mid-zonal region and lesion hilar lymph node enlargement, (B) apical lesion is seen in secondary tuberculosis, (C) small miliary tubercles are demonstrated in lung, (D to F) pleural effusion, empyema, consolidation (pneumonia) and abscess are complications in tuberculosis.

Table 18.15 Differences between primary and secondary (post-primary) tuberculosis

Parameters	Primary Tuberculosis	Secondary Tuberculosis
Exposure to AFB	First time exposure	Reactivation or reinfection
Age group	Children/younger age group	Any age group
Consolidation	Solitary lesion	Multifocal lesions (poorly defined)
Location	Mid-zone (Ghon's focus in subpleural lesion), other sites (tonsils, ileocecal region, skin)	*Upper lobes (apical region), Simon's focus in lungs:* 2 cm gray-white to yellowish well circumscribed consolidation in apical regions of one or both lungs
Lymphadenopathy	Common	Rare
Severity of lesion	Less severe, healing by fibrosis and dystrophic calcification	More severe progressing to cavitation, lobar pneumonia, extension in lumen of bronchi, trachea, and larynx with vocal cord involvement. Sputum positive for AFB in these persons
Pleural effusion	Common	Empyema
Cavitation	Rare	Common
Miliary tuberculosis	Yes (lung, liver, bone marrow, spleen, adrenal glands, meninges, kidneys, fallopian tubes, epididymis)	Yes (lung, liver, bone marrow, spleen, adrenal glands, meninges, kidneys, fallopian tubes, epididymis)

Table 18.16 Differences between tuberculosis and sarcoidosis

Characteristics	Tuberculosis	Sarcoidosis
Etiological agent	Mycobacterium tubercle bacilli	Unknown etiology
Granuloma	Caseating granuloma	Noncaseating granulomas
Cytoplasmic inclusions in giant cells	Absence of Schaumann bodies, asteroid bodies and birefringent crystals	Presence of Schaumann bodies, asteroid bodies and birefringent crystals
Steroid therapy	Worsens the disease	Improves the patient
Diagnosis	Acid-fast bacilli demonstration	Excluding causes of granulomatous lesions

formation, lobar tubercular pneumonia, fibrocaseous tuberculosis and miliary tuberculosis (Fig. 18.17).

- **Airways involvement:** Endobronchial or endotracheal spread of tuberculosis may cause laryngeal tuberculosis with involvement of vocal cords. Erosion of airways reveals AFB in sputum.
- **Miliary tuberculosis:** Tuberculosis may disseminate via hematogenous route resulting in innumerable small millet seed-like tubercular granulomas known as miliary tuberculosis. Mycobacterium tubercle bacilli may disseminate via systemic circulation to seed distant organs such as bone marrow, liver, spleen, adrenal glands, retina, meninges, kidneys, fallopian tubes, and epididymis. Mycobacterium tubercle bacilli reach the lungs via pulmonary arteries. Chest radiograph reveals very small nodules throughout the lungs that look like millet seeds. Miliary tuberculosis occurs shortly after primary infection in immunocompromised persons (Fig. 18.18).
- **Other complications:** Patient may also develop tubercular laryngitis, bronchopleural fistula, bronchiectasis, vertebral tuberculosis, i.e. Pott's disease, amyloidosis, scar carcinoma of lung and granulomatous hepatitis.

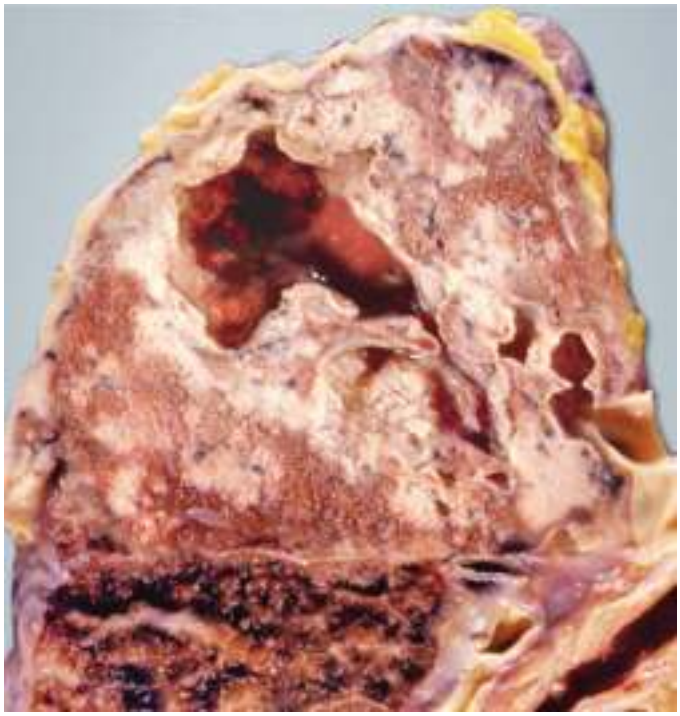

Fig. 18.17: Lung shows cavity in the upper lobe in a case of secondary tuberculosis.

Clinical Features

Patient presents with cough, expectoration, hemoptysis (blood-tinged sputum), night sweats, evening rise of temperature, anorexia, loss of weight, lassitude, and chest pain.

- Fever is probably caused by the absorption of toxic products from the site of infection and synthesis of cytokines (TNF-α and IL-1) by macrophages.
- On clinical examination, percussion note is dull over the affected area. On auscultation, one can hear bronchial breath sounds, crepitant crackles and wheeze. Sound is heard through stethoscope, when the patient whispers, it is known as **whispered pectoriloquy**.

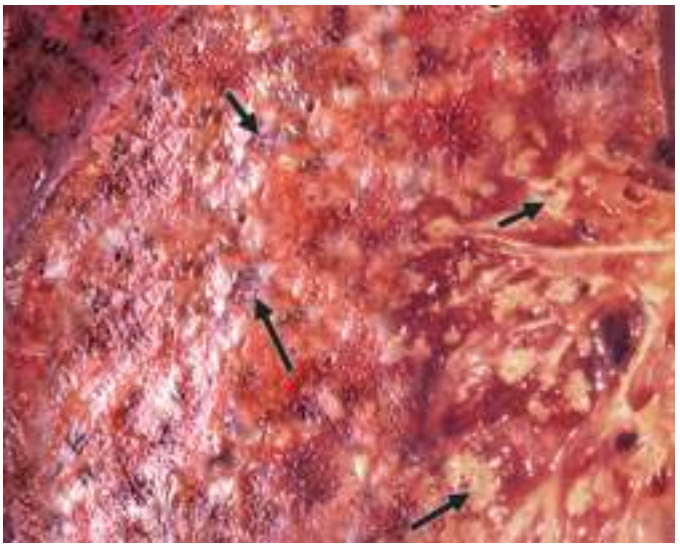

Fig. 18.18: Miliary tuberculosis. Lung shows millet-like seedlings of tuberculosis (arrows).

TUBERCULOSIS IN HIV CASES

Mycobacterium avium–intracellulare (MAI) infection is a progressive systemic disorder, often occurring in patients, who have AIDS. Approximately 33% of all patients develop overt disease due to depletion of CD4+ helper T cells.

CD4+ Helper T Cells Count <200/cu mm

- Immunosuppression is more severe. Consolidation occurs in lower and middle lobe of lungs. Lymphadenopathy occurs in 50% of cases. This pneumonia is characterized by an extensive infiltrate of macrophages.
- Tubercular lesions range from epithelioid granulomas containing a few organisms to loose aggregates of foamy macrophages.
- Clinical presentation associated with *Mycobacterium avium–intracellulare* resembles that of tuberculosis.

CD4+ Helper T Cells Count >300/cu mm

Immunosuppression is less severe. Apical regions of lungs are affected. Extrapulmonary organs involvement occurs in 15% of cases.

CHRONIC OBSTRUCTIVE PULMONARY DISEASES (COPDs)

COPDs: OVERVIEW AND EXAMPLES

Chronic obstructive pulmonary diseases (COPDs), or airway diseases are characterized by chronic obstruction of airflow (partial or complete obstruction). Examples of COPDs are chronic bronchitis, bronchiectasis, emphysema, and bronchial asthma. On the other hand, restrictive pulmonary diseases caused by interstitial or infiltrative lesion of lung and skeletal abnormalities like kyphoscoliosis is characterized by decrease in both FEV1 and FVC resulting in a normal FEV1:FVC ratio.

- **Obstruction of air respiratory passages:** There is increased resistance to airflow from the trachea and large bronchi to the terminal and respiratory bronchioles due to increased luminal secretions in cystic fibrosis or tobacco smokers, thickening of airway wall (edema or hypertrophy), or loss of the elastic recoil of the airway (parenchymal destruction).
- **Respiratory volumes:** Patients show a marked decrease in the forced expiratory volume 1 (FEV1) and an increased or normal forced vital capacity resulting in a decreased FEV1:FVC ratio.

Differences between obstructive and restrictive lung diseases are given in Table 18.17.

Chronic Obstructive Pulmonary Disease: Categories

- **Local obstructive pulmonary disease:** Obstruction due to tumor or inhalation of foreign body causes distal lung collapse. It may be complicated by lipid pneumonia or lobar pneumonia. Pulmonary function tests are normal.
- **Diffuse chronic obstructive pulmonary disease:** Obstruction occurs in bronchi and bronchioles. Pulmonary function tests are abnormal revealing obstructive pathology. Chronic obstructive pulmonary disease is caused by chronic bronchitis, emphysema, bronchiectasis, and bronchial asthma. Spectrum of chronic obstructive pulmonary diseases is given in Table 18.18.

CHRONIC BRONCHITIS

Chronic bronchitis is an inflammation of bronchi caused by prolonged inhalation of tobacco smoke (most common) and air pollutants. It is characterized by persistent cough with sputum production for at least 3 months for 2 consecutive years in the absence of identifiable cause. Productive cough occurs due to hyperplasia and hypersecretion of bronchial submucosal

Table 18.17 Differences between obstructive and restrictive lung diseases

Characteristics	Chronic Obstructive Pulmonary Diseases	Restrictive Pulmonary Diseases
Definition	Increased resistance to airway owing to partial or complete obstruction at any level from trachea, large bronchi to terminal bronchioles	Reduced lung capacity (expansion) of lung either due to chest wall or skeletal abnormality or infiltrative parenchymal diseases
FEV1	Decreased	Decreased
FVC	Increased	Decreased
FEV1:FVC ratio	Decreased	Normal
Associated with disorders	Chronic bronchitis, bronchiectasis, emphysema and bronchial asthma	Chest wall disorders (kyphoscoliosis) and acute respiratory distress syndrome

Table 18.18 Spectrum of chronic obstructive pulmonary diseases

Clinical Entity	Anatomic Site	Age Group	Pathologic Changes	Etiology	Clinical Manifestations
Chronic bronchitis	Bronchi	Adults	Mucous gland hyperplasia, hypersecretion and increased Reid index, bronchial wall thickened	Tobacco smoke, air pollutants causing impaired mucociliary apparatus	Cough, sputum production for at least 3 months for 2 consecutive years
Bronchiectasis	Bronchi	Adults	Abnormal permanent dilation of bronchi associated with scarring	Bronchial obstruction, persistent infections, α_1-antitrypsin (antiprotease) deficiency damaging bronchi	Cough, copious foul smelling sputum and fever
Bronchial asthma	Bronchi	Adults and children	Smooth muscle hyperplasia, increased mucus, inflammation, mucus plugs in bronchioles	Immunological mechanism (IgE-sensitized mast cells) and undefined etiology causing bronchospasm	Episodic wheezing, cough and dyspnea
Emphysema	Acinus	Adults	Enlargement of airspaces along with destruction of alveolar walls	Tobacco smoke and α_1-antitrypsin (antiprotease) deficiency	Severe progressive exertional dyspnea, crackles and wheezing
Bronchiolitis (small airways disease)	Bronchiole	Children	Decreased synthesis of surfactant, occluded bronchiole	Viral infections and pollutants	Cough and breathlessness

glands. These patients are called **blue bloaters** due to decreased O_2 saturation from hypoxemia.

Pathogenesis

Chronic bronchitis is caused by tobacco smoke (90%), pollen grains, cotton, silica dust, air pollution and infectious agents such as bacteria and viruses.

Surgical Pathology: Chronic Bronchitis

Gross Morphology

Bronchi are hyperemic and swollen. Bronchial lumen shows mucinous or mucopurulent secretions.

Light Microscopy

Pathological changes include hyperplasia of bronchial submucosal glands, leading to increased Reid index, i.e. ratio of the thickness of the gland layer to that of the bronchial wall.

- **Bronchi:** Bronchi show chronic inflammation with lymphocytic infiltrate), squamous metaplasia, goblet cell hyperplasia, fibrosis and loss of cilia resulting in narrowing of bronchi.
- **Bronchial submucosal glands:** These undergo hyperplasia and hypertrophy and secrete abundant mucus responsible for sputum overproduction and retention in air passages.
- **Reid index:** Reid index is increased in chronic bronchitis. Increase in size of the mucosal gland layer is assessed by Reid index. Ratio of thickness of mucous gland layer to the thickness of bronchial wall (epithelium to cartilage) is called Reid index. Normal Reid index is 0.4 (Fig. 18.19).

Consequences

- **Chronic obstructive airway disease:** Patient develops wheezing due to narrowing of the terminal bronchioles by mucus plugs. Resistance to airflow in the small airways leads to severe ventilation–perfusion imbalance and decreased arterial oxygenation.
- **Cor pulmonale and heart failure:** Patient develops exertional dyspnea, cyanosis and cor pulmonale. The combination of cyanosis and edema secondary to cor pulmonale has led to the label **blue bloaters** (cyanosis) for such patients. Hypoxia-induced erythropoiesis by erythropoietin increases hemoglobin.
- **Cyanosis:** Though the amount of hemoglobin is high, yet oxygenation low, therefore, cyanosis is evident. Patient may develop respiratory acidosis.
- **Dysplastic change:** Respiratory epithelium may undergo dysplasia or metaplasia.

Chest Radiograph

Chest radiograph shows prominent blood vessels with an enlarged horizontally oriented heart and increased bronchial markings.

Clinical Features

Patient presents with productive cough, dyspnea in late cases, cyanosis of skin and mucous membranes, hypoxemia due to decreased O_2 saturation, expiratory wheezing, sibilant rhonchi, and cor pulmonale. Comparison of chronic bronchitis and bronchial asthma is given in Table 18.19.

Complications

Complications of chronic bronchitis include cor pulmonale, bronchiectasis, bronchopneumonia and bronchogenic carcinoma.

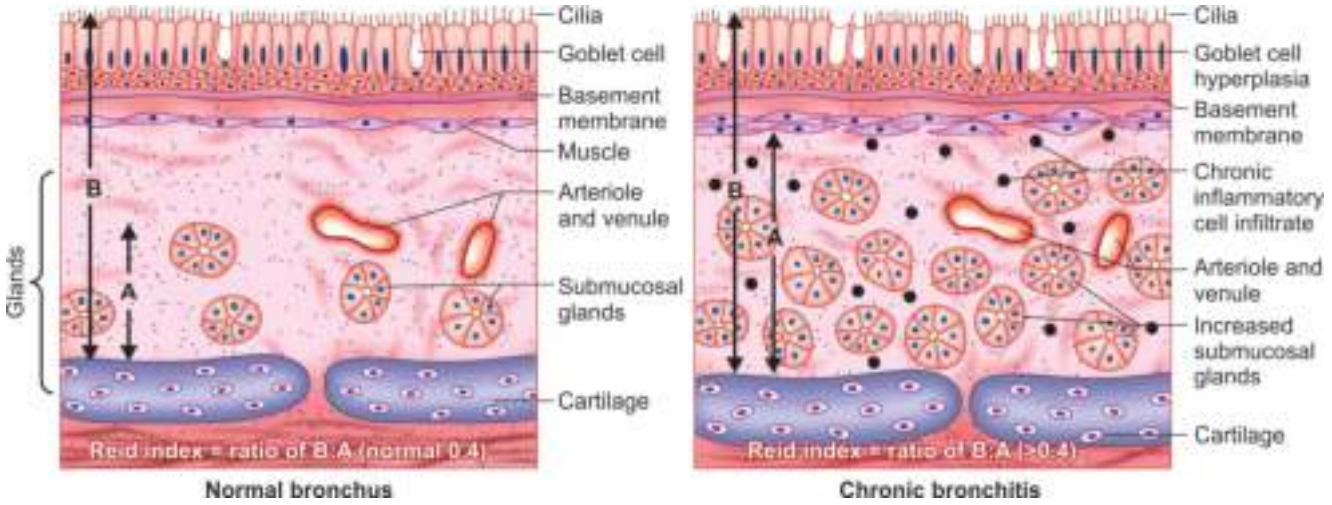

Fig. 18.19: Chronic bronchitis. The lumen of the bronchus shows marked thickening of the mucous glands approximately twice the normal. Squamous metaplasia of epithelium may also occur. Reid index is defined as ratio between the thickness of the submucosal mucus secreting glands and the thickness between the epithelium and cartilage that covers the bronchi under microscope (normal Reid index is 0.4).

Table 18.19 Comparison of chronic bronchitis and bronchial asthma

Features	Chronic Bronchitis	Bronchial Asthma
Clinical history		
Age group	<35 years	Children and adults
Tobacco smoking	Almost invariable	Possible
History of cough	Persistent and productive	Intermittent and nonproductive
History of breathlessness	Progressive and persistent	Intermittent and variable
Nocturnal symptoms	Uncommon	Common
Family history	Uncommon	Common
Concomitant allergic rhinitis or eczema	Uncommon	Common
Airflow obstruction	Fixed and irreversible	Variable and reversible
Sputum examination		
Sputum examination	Macrophages and neutrophils	Eosinophils, Charcot-Leyden crystals, creola bodies, Cruschmann's spirals
Airway muscles	Hypertrophy	Hypertrophy
Histologic features		
Airway congestion and edema	Present	Present
Airway inflammation	CD8+ cytotoxic T cells, neutrophils periodically	CD4+ helper T cells, eosinophils, mast cells
Airway epithelium	Intact, goblet cell hyperplasia and squamous metaplasia	Fragile with stripping, goblet cell hyperplasia and squamous cell metaplasia
Basement membrane reticular layer thickening	Mild-to-moderate	Marked
Bronchial glands	Marked enlargement of the mucous acini	Moderate enlargement of both mucous and serous acini
Histochemistry		
Shift from neutral mucin to acidic mucin; sialo-acidic mucin to sulpho-acidic mucin	Present	Unchanged
Major complications		
Examples	Cor pulmonale	Allergic bronchopulmonary aspergillosis

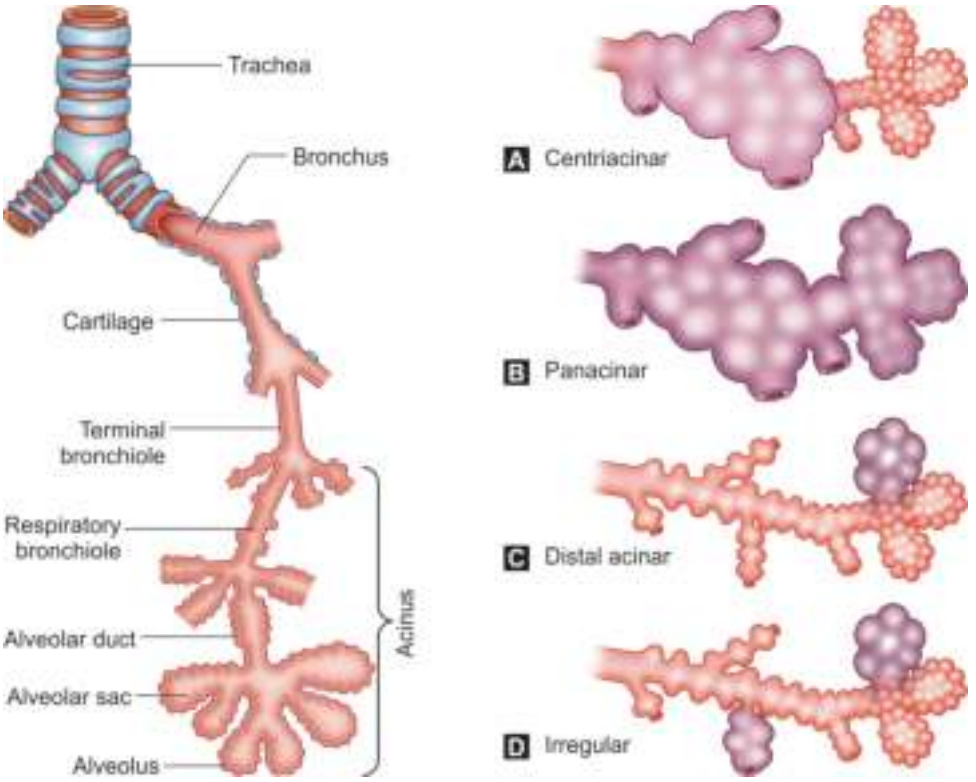

Fig. 18.20: Types of emphysema (centriacinar, panacinar, distal acinar, irregular).

EMPHYSEMA

Emphysema is a chronic lung disease characterized by abnormal permanent enlargement of the airspaces, i.e. respiratory bronchioles, alveolar ducts and alveoli distal to the terminal bronchiole associated with destruction of the alveolar walls without obvious fibrosis and inflammation. Patient develops dyspnea due to impaired oxygen–carbon dioxide gaseous exchange.

Emphysema: Types

Centriacinar and panacinar emphysemas are most common. Paraseptal emphysema may result in spontaneous pneumothorax. Irregular emphysema may be associated with fibrosis. Centriacinar and panacinar emphysemas cause clinically significant airflow obstruction (Fig. 18.20).

Etiopathogenesis

Emphysema occurs as a consequence of protease–antiprotease; and oxidant–antioxidant imbalances. Tobacco smoking is most common cause of emphysema followed by α_1-antitrypsin deficiency (Fig. 18.21).

- **α_1-Antitrypsin (antiprotease):** Normally, α_1-antitrypsin (antiprotease) inhibits elastases activity. The α_1-antitrypsin is a protein encoded on the protease inhibitor (Pi) locus on chromosome 14.
  - Normal amounts of α_1-antitrypsin are synthesized by liver in normal genotype persons (PiMM phenotype). It is a major inhibitor of variety of proteases including elastase, and responsible for 90% of antiprotease activity in the blood.
  - Homozygous PiZZ genotype has decreased synthesis of α_1-antitrypsin. Serum electrophoresis reveals absence of α_1-globulin peak. Most patients with clinically diagnosed emphysema, who are younger than 40 years of age have α_1-antitrypsin (PiZZ phenotype) deficiency.

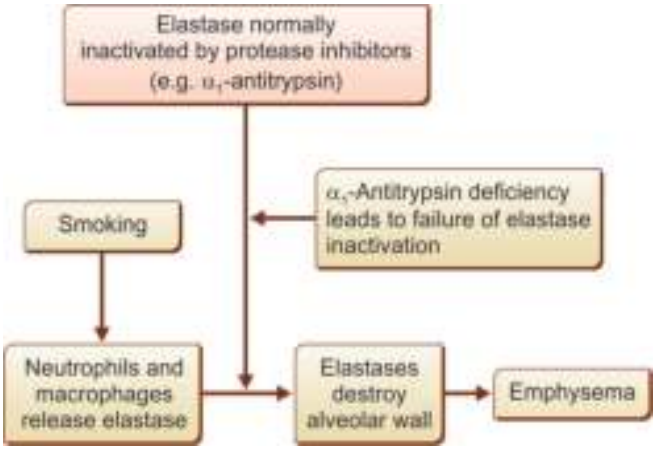

Fig. 18.21: Pathogenesis of emphysema. Under physiologic state, proteases synthesized by inflammatory cells are inactivated by extracellular proteases especially α_1-antitrypsin. If proteases are not inactivated, these cause destruction of lung parenchyma. Imbalance of activity of proteases and protease inhibitors is responsible for emphysema.

- Intravenous purified pooled human plasma is recommended to enhance α_1-antitrypsin levels in these patients.

- **Tobacco smoking:** Tobacco smoke inhibits synthesis of α_1-antitrypsin, and increases the activity of the macrophage's elastases resulting in destruction of alveolar walls. Tobacco smoke induces tissue damage as a result of synthesis of oxygen-derived free radicals, which antagonise antioxidant mechanisms.

Classification of Emphysema

Classification of emphysema includes centriacinar, panacinar, distal acinar (paraseptal), irregular and interstitial types. Differences between centriacinar emphysema and panacinar emphysema are given in Table 18.20.

Centriacinar Emphysema

- Centriacinar emphysema occurs predominantly in heavy tobacco smokers, often in association with chronic bronchitis. It initially affects the respiratory bronchioles and then involve central portion of acinus. The lesions are more common and severe in the upper lobes especially in apical segments (i.e. upper two-thirds of the lungs).
- Tobacco smoke induces an inflammatory reaction as a result of synthesis of serine elastase and oxygen-derived free radicals synthesized by neutrophils and macrophages.
- Elastases cause destruction of the walls of respiratory unit, by promoting splitting peptide bond hydrolysis.
- Oxygen-derived free radicals inactivate α_1-antitrypsin (antiprotease) and antioxidant glutathione leading to destruction of walls of respiratory unit.

Panacinar Emphysema

- Panacinar emphysema initially affects peripheral structures of acinus (i.e. the alveolus and alveolar duct), and then extends to involve the respiratory bronchioles. It tends to occur more commonly in the lower zones as well as anterior margins of the lung.
- The acini are uniformly distended from the level of the respiratory bronchiole to the terminal bronchiole. It is usually more severe at the base of the lungs. It affects equally both men and women.

Distal Acinar (Paraseptal) Emphysema

- In distal acinar (paraseptal) emphysema, the proximal portion of the acinus is normal, but the dilatation predominantly involves distal part of the respiratory unit, i.e. alveoli and alveolar ducts in subpleural region and interlobar septa.
- The morphologic findings include multiple, continuous enlarged airspaces measuring <0.5 cm to >2 cm in diameter sometimes forming cyst-like structures (bullae) in subpleural region due to focal destruction of alveolar walls with confluence of multiple alveoli.
- There is increased risk for spontaneous pneumothorax as a result of rupture of bullae.

Irregular Emphysema

- The acinus is irregularly involved. It is almost invariably associated with scars from healed inflammatory process.
- Irregular emphysema is most common form of emphysema. Patients are asymptomatic and clinically insignificant.

Interstitial Emphysema

Interstitial emphysema occurs as a result of entrance of air into the connective tissue of lung, subcutaneous tissue or mediastinum in settings of penetrating chest injury, chronic bronchitis, and obstruction to airflow. Children with whooping cough are prone to interstitial emphysema. Differences between emphysema and chronic bronchitis are given in Table 18.21.

Table 18.20 Differences between centriacinar emphysema and panacinar emphysema

Characteristics	Centriacinar (Centrilobular) Emphysema	Panacinar (Panlobular) Emphysema
Sites involved	Targeting destruction of the distal terminal bronchioles and respiratory bronchioles (proximal or central part of the acini of respiratory unit)	Targeting destruction of terminal bronchioles and the entire respiratory unit
Frequency	More common	Less common
Lobes affected	Apical segments of upper lobes	Basal parts of lower lobes
Risk factors	Tobacco smoking or coal workers pneumoconiosis	Patients with α_1-antitrypsin deficiency (an autosomal dominant disorder)
Mechanism	Destruction of the distal terminal bronchioles and respiratory bronchioles	Destruction of terminal bronchioles and the entire respiratory unit
Gross morphology	Not significant	Voluminous lungs overlapping heart and hiding it

Table 18.21 Differences between emphysema and chronic bronchitis

Parameters	Emphysema	Chronic Bronchitis
Age group	50–75 years	15–40 years
Onset and severity of dyspnea	Early onset and severe	Late onset but mild
Cough	Late but scanty sputum	Early and copious sputum
Infections	Occasional	Common
Respiratory insufficiency	Terminal event	Repeated events
Cor pulmonale	Rare and in terminal stage	Common
Airway resistance	Normal or slightly increased	Increased
Elastic recoil	Low	Normal
Chest radiograph	Hyperinflation of lungs with small heart	Prominent blood vessels and large heart
Clinical appearance	Pink puffer	Blue bloater

Surgical Pathology: Emphysema

Gross Morphology

- In centriacinar emphysema, upper two-thirds of the lungs are more severely affected than the lower lungs.
- In panacinar emphysema, lungs are pale and voluminous obscuring heart.
- Distal acinar emphysema shows bullae in subpleural region due to focal destruction of alveolar walls with confluence of multiple alveoli leading to spontaneous pneumothorax (Figs 18.22 to 18.24).

Light Microscopy

- In all types of emphysema, alveolar walls show thinning and destruction. Adjacent alveoli become confluent, creating large airspaces.
- There is loss of elastic tissue in the surrounding alveolar septate. Number of alveolar capillaries is diminished.
- Ischemia is probably a factor in rupture of alveoli. Special stains show loss of elastic tissue in lungs (Fig. 18.25).

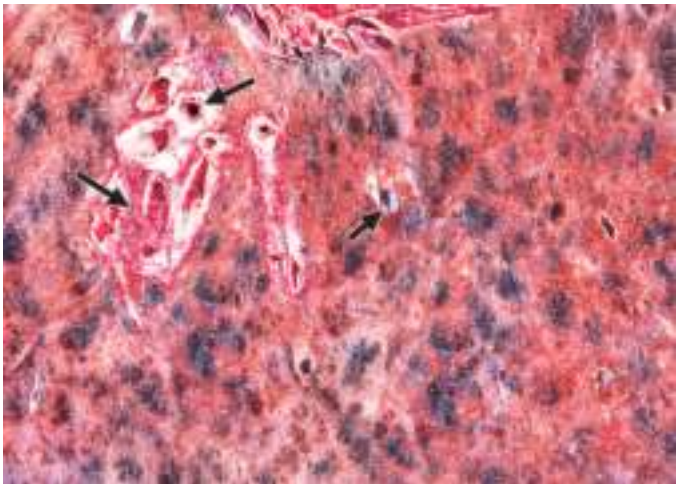

Fig. 18.22: Centriacinar emphysema. Central areas show marked emphysematous damage (arrows), surrounded by relatively spared alveolar spaces.

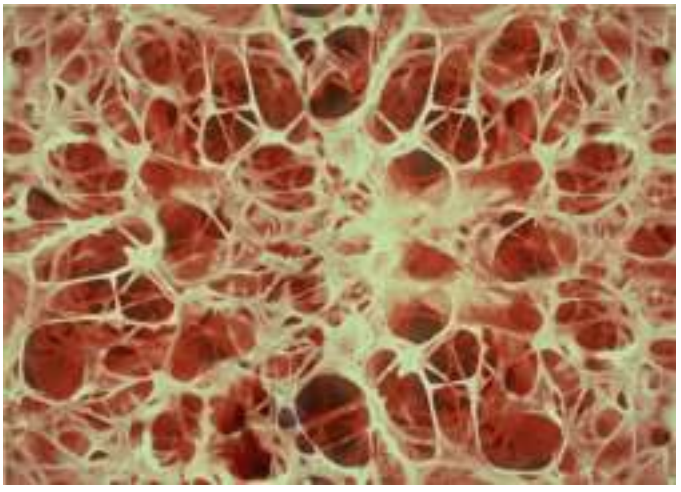

Fig. 18.23: Panacinar (panlobular) emphysematous lung. Cut surface shows dilated airspaces in all lung fields. Panacinar emphysema occurs with loss of all portions of the acinus from the respiratory bronchiole to the alveoli. This pattern is typical for α_1-antitrypsin deficiency. On the other hand, centrilobular (centriacinar) involves primarily the upper lobes and occurs with loss of the respiratory bronchioles in the proximal portion of the acinus, with sparing of distal alveoli especially in smokers.

Clinical Features

Classic presentation of emphysema (centriacinar or panacinar) is pink puffer who develops tachypnea, severe progressive exertional dyspnea and prolonged forced expiration, cough, crackles and wheezing on inspiration and barrel-shaped chest. Breath sounds are diminished due to hyperinflation.

- Chest expansion is decreased. Tactile fremitus is decreased. Centriacinar emphysema frequently coexists with chronic bronchitis.
- Cor pulmonale is uncommon. Pulmonary function tests reveal reduction of ratio of FEV1 to FCV.

Chest Radiograph

Chest radiograph in emphysema shows hyperlucent lung fields, increased anteroposterior diameter

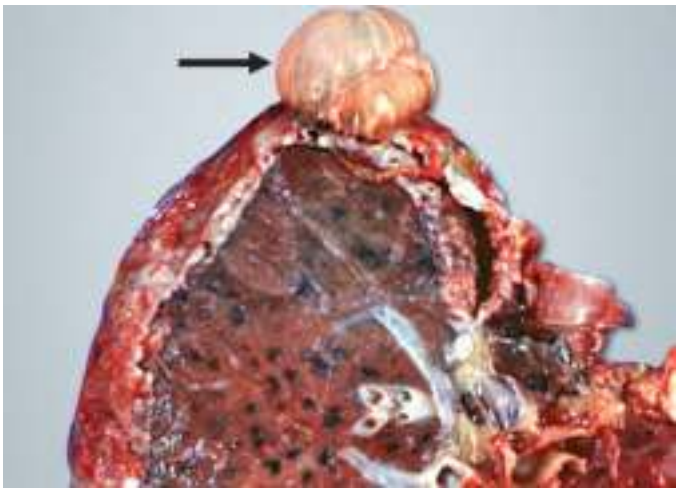

Fig. 18.24: Distal (paraseptal) emphysema. The characteristics of morphological findings include multiple, continuous enlarged airspaces measuring <0.5 cm to >2 cm in diameter sometimes forming cyst-like structures (bullae) in subpleural region due to focal destruction of alveolar walls with confluence of multiple alveoli. There is increased risk of spontaneous pneumothorax as a result of rupture of bullae. Large bullous is seen on subpleural region (arrow).

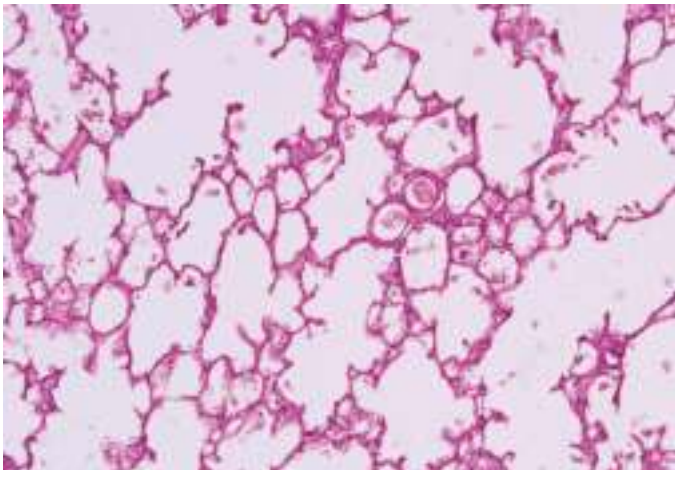

Fig. 18.25: Pulmonary emphysema. There is marked enlargement of airspaces with thinning and destruction of alveolar septa. Tobacco smoking and α_1-antitrypsin antiprotease are important predisposing risk factors (400X).

producing barrel-shaped chest, vertically oriented heart and depressed diaphragms due to hyperinflated lungs.

Complications

The complications of emphysema are interstitial emphysema, pneumothorax, cor pulmonale, respiratory acidosis, and coma. Expansion of emphysema into the interstitial tissues of the chest wall occurs as a result of acute overinflation of the lungs with rupture and perforation in multiple airspaces in interstitial fibrous septa.

Pathology Pearls: Functional Effects of Emphysema

These are categorized into two groups depending on tolerance to hypoxia or not.

- **Blue bloaters tolerate hypoxia:** Patient develops severe hypoxemia, hypercapnea, right ventricular hypertrophy, cor pulmonale with peripheral edema, and secondary polycythemia.
- **Pink puffers do not tolerate hypoxia:** Patient develops severe dyspnea, hyperventilation, and relatively normal blood gases.

BRONCHIECTASIS

Bronchiectasis is abnormal permanent (irreversible) dilation of bronchi and bronchioles caused by chronic necrotizing infections resulting in destruction of cartilage and elastic tissue. The bronchi and bronchioles are filled with mucus and neutrophils. Cough and expectoration of copious amounts of purulent sputum are characteristic findings. Obstruction and infection result in bronchiectasis. It more frequently affects young persons than adults.

Salient Features

- Normally, airways cannot be traced beyond 2–3 cm from pleural surface. Bronchiectasis is more common in vertical airways especially distal bronchi or bronchioles of lower lobes extending up to pleural surface. It is worth mentioning that upper lobes are affected in pulmonary tuberculosis.
- These airways undergo four times dilation than normal size, and lumen is filled with suppurative exudates.
- The dilatation of bronchi and bronchioles is permanent. It should not be confused with a transient mild cylindrical dilatation, which occurs in viral or bacterial pneumonia or collapsed lung; in which the changes become reversible within six weeks.
- *Aspergillus* species may also grow in pre-existing cavities caused by bronchiectasis. They proliferate to form fungus balls, which are also referred to aspergillomas or mycetomas.

Pathogenesis

Obstruction and chronic persistent infection cause damage to bronchial walls leading to weakening and permanent dilation of bronchial tree. Obstructive secretions and inflammation are present throughout the wall of bronchi. Major causes of bronchiectasis and proposed workup of patients are given in Table 18.22.

Genetic and Congenital Disorders

Genetic and congenital disorders play role in pathogenesis of bronchiectasis. These patients are asymptomatic and superadded infections appear late in life.

Table 18.22 Major causes of bronchiectasis and proposed workup of patients

Focal and Diffuse Lung Involvement Categories	Workup of Patients
Focal lung involvement	
Obstruction of bronchi (aspirated foreign body, tumor mass or compression of bronchi by adjacent lymphadenopathy)	Chest imaging (conventional chest radiograph, chest CT scan, bronchoscopy)
Diffuse lung involvement	
Infection (bacterial, nontubercular mycobacterium)	Sputum smear examination by Gram stain/sputum culture for acid-fast bacilli and fungi. If no pathogen is demonstrated, bronchoscopy and bronchoalveolar lavage should be considered
Immunodeficiency state (hypoglobulinemia, human immunodeficiency virus infection, bronchiolitis obliterans after lung transplantation)	Complete blood counts, differential blood counts, immunoglobulin analysis, HIV testing
Genetic causes (Kartagener's syndrome, cystic fibrosis, α_1-antitrypsin deficiency)	Analysis of nasal or respiratory tract brush/biopsy for dyskinesis/immotile cilia syndrome; measurement of chloride levels in sweat and CFTr genetic testing for cystic fibrosis; and α_1-antitrypsin level for α_1-antitrypsin deficiency. Genetic testing is performed to diagnose these disorders
William-Campbell syndrome	Absence of cartilage in the bronchi
Autoimmune disorders (rheumatoid arthritis, Sjögren's disease, inflammatory bowel disease) and immune-mediated disease (allergic bronchopulmonary aspergillosis)	Clinical examination with joint involvement and serologic testing (rheumatoid factor) is done for rheumatoid arthritis; complete workup for allergic bronchopulmonary aspergillosis especially in patients with refractory asthma
Recurrent aspiration in bronchi	Testing of swallowing function and general neuromuscular strength
Miscellaneous disorders (traction bronchiectasis from post-radiation fibrosis or idiopathic pulmonary fibrosis)	Guided by the clinician
Idiopathic	Exclusion of other causes

- **Kartagener's syndrome:** It is autosomal recessive disorder characterized by sinusitis, bronchiectasis and situs inversus, sometimes with male sterility and hearing loss. Structural defect occurs in the dynein arms known as primary ciliary dyskinesis. Impaired ciliary activity predisposes to infection in the sinuses and bronchi resulting in bronchiectasis. Male infertility is an important manifestation of ciliary dyskinesia.
- **Cystic fibrosis:** It is autosomal recessive disorder of exocrine glands characterized by synthesis of thick secretions in their ducts. It is also known as mucoviscidosis of pancreas linked to bronchiectasis. Normally, transmembrane conductance regulator (CFTr) gene located on long arm of chromosome 7 codes for a membrane protein that participates in the movement of chloride and other ions across membranes. Mutation of CFTr gene causes malfunction of exocrine glands and results in increased viscosity of mucus and chloride concentration in sweat and tears. Systemic manifestations of cystic fibrosis are given in Table 18.23.
- **Chronic granulomatous disease of childhood:** It is X-linked disorder with defect in NADPH oxidase activity in neutrophils. It leads to failure of synthesis of superoxide anion and hydrogen peroxide during phagocytosis. Phagocytic cells are unable to kill certain microorganisms and cause bronchiectasis.
- **α_1-Antitrypsin deficiency:** α_1-Antitrypsin synthesized by liver in normal genotype persons (PiMM phenotype) is a major inhibitor of a variety of proteases, including elastase. The α_1-antitrypsin is a protein encoded on the protease inhibitor (Pi) locus on chromosome 14. Its deficiency may be associated with bronchiectasis.
- **Williams-Campbell syndrome:** It is characterized by bronchial cartilage deficiency resulting in bronchiectasis.

Acquired Causes

Bronchial obstruction (partial or complete) and post-inflammation play an important role in pathogenesis of bronchiectasis.

Table 18.23 Systemic manifestations of cystic fibrosis

Organs	Secondary Effects
Skin	▪ Salty sweat results in hyponatremia ▪ Acrodermatitis ▪ Dilation of eccrine and apocrine glands
Gastrointestinal tract (distal region)	Meconium ileus resulting in obstruction, perforation, peritonitis, rectal prolapse
Pancreas	▪ Pancreatic duct obstruction causes pancreatic insufficiency (steatorrhea) ▪ Chronic pancreatitis ▪ Failure to thrive ▪ Diabetes mellitus
Liver	▪ Hepatic duct obstruction causes biliary cirrhosis resulting in esophageal varices ▪ Sclerosing cholangitis
Gall bladder	Cholecystitis
Kidney	▪ Nephrolithiasis ▪ Diabetic glomerulopathy ▪ Immune complex-mediated glomerulonephritis
Respiratory system	▪ Bronchiectasis ▪ Recurrent infections ▪ Atelectasis ▪ Allergic bronchopneumonia ▪ Aspergillosis
Heart	▪ Cor pulmonale ▪ Left ventricular fibrosis ▪ Carotid bodies enlarged
Male genital system	Male infertility (obstructive aspermia due to vas deferens atresia in 6% and male infertility in 1–2%)
Female genital system	▪ Multiple ovarian follicular cysts ▪ Cervicitis ▪ Reduced fertility
Musculoskeletal system	▪ Osteoporosis ▪ Muscle wasting ▪ Hypertrophic pulmonary arthropathy ▪ Clubbing
General manifestations	▪ Malnutrition ▪ Vitamin deficiencies (vitamin B_{12}, vitamin K*) ▪ Amyloidosis

Vitamin K deficiency at birth may lead to bleeding.

- **Bronchial obstruction:** It occurs due to neoplasm, foreign body, aspiration and compression by lymph node leading to bronchiectasis.
- **Post-inflammation (nonobstruction):** Bronchiectasis results from repeated episodes of pneumonia especially during first two decades of life. Patient with immunodeficiency states may develop superadded infection due to *Haemophilus influenzae* (most common), measles, whooping cough, tuberculosis and allergic bronchopulmonary aspergillosis. Traction bronchiectasis occurs from pulmonary fibrosis.

Surgical Pathology: Bronchiectasis

Gross Morphology

- Bronchiectasis most commonly affects pulmonary lower lobes.
- Bronchi and bronchioles reveal destruction of wall with replacement by scar tissue.
- Dilated airways may take various shapes, i.e. cylindrical, fusiform, varicose (numerous constriction and dilation) and saccular (bead-like bulge on one side).
- Dilated airways are easily visible up to <3 mm from the pleural surface. Normally, bronchi are traceable up to 2–3 cm from the pleural surface.
- Bronchi and bronchioles are dilated and filled with pus, which impairs normal inflow of O_2 in lungs and outflow of CO_2 (Fig. 18.26).

Light Microscopy

- **Intense inflammation:** The walls of bronchi and bronchioles are infiltrated by acute and chronic inflammatory cells, composed of neutrophils, lymphocytes, plasma cells and macrophages. Mature lymphoid follicles may also be present.
- **Desquamation of lining epithelium:** Mucosa of airways shows extensive areas of necrotizing ulceration. Remaining lining epithelium may show squamous metaplasia.
- **Granulation tissue:** In more advanced cases, there is presence of granulation tissue and fragmentation of cartilage. Mucous glands persist longer than other structures.
- **Fibrosis:** Fibrosis occurs in bronchi and bronchioles walls. Peribronchial fibrosis is also evident (Fig. 18.27).

Clinical Features

Patient presents with constant cough, foul smelling sputum, hemoptysis (in some cases), wheezing, shortness of breath, fever, digital clubbing and cor pulmonale. Some patients may develop pneumonia. On auscultation, moist crackling noises may be heard in the chest.

Complications

Patient with bronchiectasis may develop lung abscess, pneumonia, bronchopleural fistula, cor pulmonale, necrotising brain abscess, meningitis, amyloidosis and squamous cell lung carcinoma.

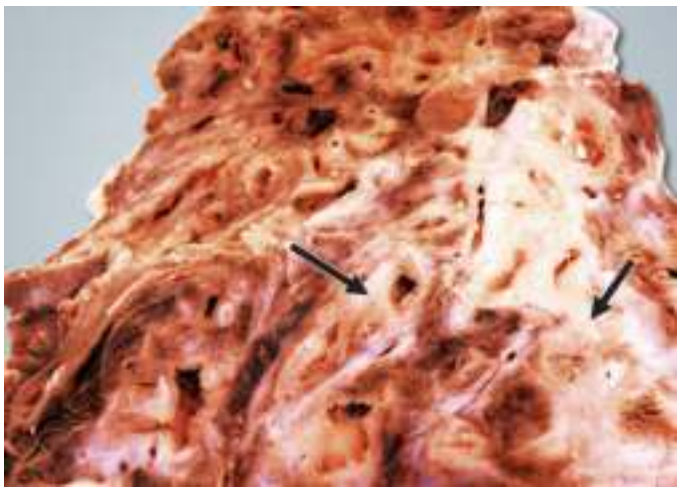

Fig. 18.26: Bronchiectasis. It shows abnormal permanent dilatation of bronchi of variable sizes filled with pus (arrows).

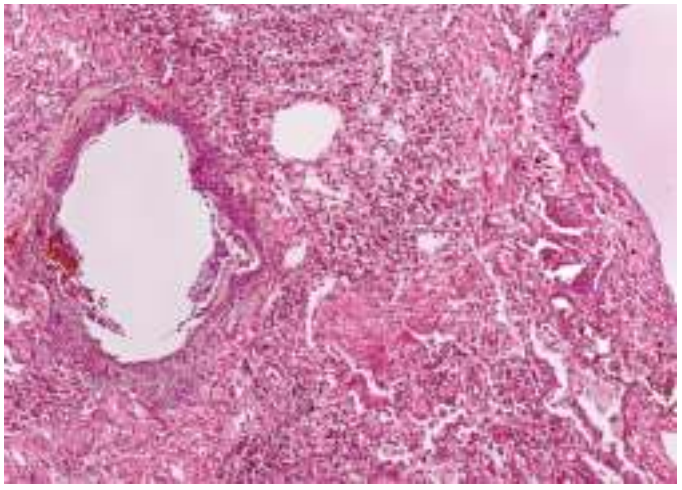

Fig. 18.27: Bronchiectasis. Bronchial wall is infiltrated by acute and chronic inflammatory cells (400X).

Diagnosis

A complete medical history and physical examination by a physician is necessary.

- **Imaging techniques:** Chest X-ray, bronchography, and CT may reveal evidence of bronchiectasis.
- **Sputum examination:** Sputum needs to be collected and cultured (grown in a laboratory dish), in order to examine it microscopically for the specific type of organism responsible for infection.
- **Pulmonary function tests:** These are performed to determine the presence and severity of abnormal airflow out of the lungs.
- **Diagnostic techniques:** A careful search for other underlying diseases is important, looking in particular for ciliary abnormalities, cystic fibrosis, or immunoglobulin deficiencies.

BRONCHIAL ASTHMA

Bronchial asthma is a chronic relapsing disorder resulting from bronchospasm of bronchi and terminal bronchioles. Airways are obstructed due to increased mucus secretion and mucosal edema. It is mediated by type 1 hypersensitivity reaction or undefined causes. Patient presents with episodic reversible wheezing, cough, dyspnea and respiratory alkalosis.

- Bronchial asthma can occur by intrinsic or extrinsic mechanisms.
- Atopy is the strongest risk factor. Atopy refers to the genetic tendency to develop allergic rhinitis and bronchial asthma associated with heightened immune response to allergens, drugs and food.

Etiology

Bronchial asthma occurs due to air-pollutants, viral-induced respiratory infections, i.e. rhinovirus, para-influenza virus, and respiratory syncytial virus, aspirin sensitivity, stress, cigarette smoke and fungal spores of *Aspergillus flavus.*

Pathogenesis

Bronchial asthma occurs by two mechanisms: extrinsic asthma is typically a childhood disease, whereas intrinsic asthma usually begins in adults.

- **Extrinsic (immune) asthma:** Bronchial asthma is mediated by type 1 hypersensitivity reaction involving IgE bound to mast cells. It occurs due to exposure to allergens. Disease starts in childhood. There is family history of allergy.
- **Intrinsic (nonimmune) asthma:** Bronchial asthma is associated with chronic bronchitis, exercise or cold-induced asthma. Disease most often begins in adult life. There is no family history of allergy.

Age Group

Bronchial asthma is most common chronic respiratory disease in children (<10 years) in 50% of cases than adults. Adult males and females are equally affected.

Pathologic Changes

Pathologic changes in bronchial asthma include bronchial smooth muscle hypertrophy, hyperplasia of bronchial submucosal glands and goblet cells, airways plugged by viscid mucus containing, Curschmann spirals, eosinophils, and Charcot-Leyden crystals in sputum.

Pathogenesis

There are early and late phase reactions in pathogenesis of bronchial asthma. Late phase reactions occur 4–8 hours after a symptom-free period.

Early Phase Reactions in Bronchial Asthma

- **First exposure to allergen:** Allergen may enter through nose by inhalation (most common) and ingestion. It is absorbed in the tissues and triggering immune response. CD4+ helper T cells release interleukins (IL-4 and IL-5). IL-4 stimulates B cells to synthesize IgE, which binds to the mast cells on the mucosal surfaces.
- **Second exposure to allergen:** Allergen re-enters nose and mouth. Inhaled antigens cross-link IgE antibodies on mast cells on mucosal surfaces. It triggers mast cells to release histamine and leukotrienes. These chemical mediators cause bronchospasm, increased mucus secretion, smooth muscle contraction, deposition of plasma proteins in the bronchial submucosa due to increased vascular permeability, and influx of leukocytes (LTB4).

Late Phase Reactions in Bronchial Asthma

- **Chemokine (eotaxin) synthesis:** Eotaxin synthesized by leukocytes participates in emigration of eosinophils in the tissues.
- **Leukotrienes synthesis:** Synthesis of leukotrienes (LTC_4, LTD_4, and LTE_4) by mast cells cause prolonged bronchoconstriction. Acetylcholine synthesis further causes bronchospasm (Fig. 18.28).

Surgical Pathology: Bronchial Asthma

Light Microscopy

- **Bronchi/bronchiole changes:** These include bronchial smooth muscle hypertrophy, hyperplasia of goblet cells, thickening and hyalinization of basement membranes.
- **Bronchial wall:** It is infiltrated by eosinophils, mast cells, macrophages and lymphocytes.
- **Bronchial lumen:** Bronchial mucosa shows edema, focal ulceration. Bronchial lumen is occluded with mucus plugs containing whorl-like accumulations of epithelial cells.
- **Curschmann spirals and crystalloids:** Eosinophils derived major basic protein and cationic proteins coalesce to form Charcot-Leyden crystals demonstrated in the sputum of bronchial asthma patients.

Clinical Features

Patient presents with widespread high-pitched wheeze rhonchi. Barrel-shaped chest occurs in severe chronic bronchial asthma. Widespread rhonchi are heard on auscultation. Disease can be controlled by administration of β-agonists, theophylline, corticosteroids and leukotriene receptor agonists. Acute severe bronchial asthma can be life-threatening. Patient requires immediate oxygen, nebulization, β-agonists, anticholinergic drugs and systemic corticosteroid therapy.

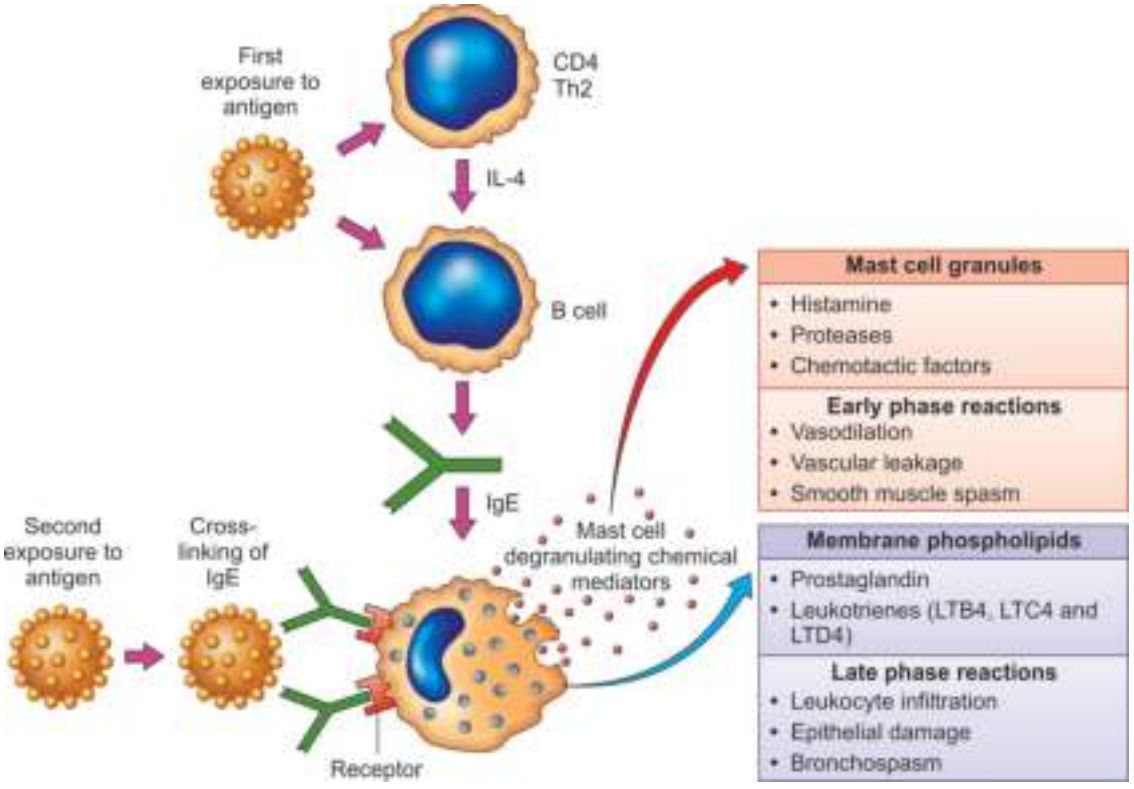

Fig. 18.28: Type 1 hypersensitivity reaction. The antigen stimulates B cells to produce IgE. IgE binds to mast cells or basophils *via* its Fc fragment, causing them to be sensitized. Further exposure to antigen causes cross-linking of bound IgE on mast cells, resulting in degranulation.

- **Breathlessness:** Bronchial asthma attack may last for hours or even days. Due to narrowing of airways, patient presents with sudden dyspnea, episodic expiratory wheezing, i.e. inspiratory in severe cases, tightness in the chest, nocturnal coughing, and tachypnea with use of accessory muscles for breathing.
- **Prolonged coughing:** After the bronchial asthmatic attack is over, there is prolonged coughing up of tenacious secretions. Anteroposterior diameter of chest is increased due to air trapping and increased residual volume. Initially, patient develops respiratory alkalosis. If bronchospasm is not relieved, patient may develop respiratory acidosis. Such patients need tracheal intubation and mechanical ventilation.

Complications

Patient may develop pneumothorax, pneumomediastinum, status asthmaticus and fatal outcome. When severe acute bronchial asthma is unresponsive to therapy, it is referred to as status asthmaticus. Light microscopy of lung in status asthmaticus often shows a bronchus containing luminal mucous plug, submucosal gland hyperplasia, smooth muscle hyperplasia, basement membrane thickening, and increased numbers of eosinophils (Table 18.24).

Table 18.24 Comparison of extrinsic and intrinsic bronchial asthma

Characteristics	Extrinsic Bronchial Asthma	Intrinsic Bronchial Asthma
Definition	Extrinsic asthma is caused by type 1 hypersensitivity reaction induced by exposure to an extrinsic antigen	Intrinsic asthma is caused by diverse non-immune mechanisms as a result of intrinsic stimuli
Age of clinical presentation	Childhood	Adult
Family history	Present	Absent
Preceding allergic reactions	Present in the form of rhinitis, urticaria, and eczema	Absent
Drug hypersensitivity	Absent	Present
Serum IgE level	Increased	Normal
Skin test	Positive skin test	Negative skin test
Emphysema	Unusual	Common
Associated chronic bronchitis	Absent	Present
Examples	▪ Atopic/allergic asthma ▪ Occupational asthma ▪ Allergic bronchopulmonary aspergillosis	Aspirin ingestion, pulmonary infection especially viral, cold, inhaled irritants, stress, exercise

RESTRICTIVE PULMONARY DISEASES

Restrictive pulmonary diseases comprise group of disorders characterized by reduced lung expansion and total lung capacity. There is decrease in both forced expiratory volume 1 (FEV1) and forced vital capacity (FVC) resulting in a normal FEV1:FVC ratio.

- Restrictive pulmonary diseases restrict lungs expansion and often interfere with respiratory gaseous exchange. Causes of restrictive pulmonary diseases are given in Table 18.25.
- Gas exchange barrier consists of alveolar epithelial cells, capillary endothelial cells, basement membrane and interstitial tissue.
- Initial lung injury occurs to capillary endothelial and alveolar epithelial cells leading to interstitial fibrosis and dyspnea. Damage to alveolar epithelium and capillaries leads to impaired ventilation–perfusion leading to hypoxia, cyanosis and cor pulmonale.

ACUTE RESTRICTIVE PULMONARY DISEASES

ADULT RESPIRATORY DISTRESS SYNDROME

Adult respiratory distress syndrome (ARDS) is characterized by pulmonary edema (noncardiogenic) resulting from acute alveolar–capillary damage. It is also known as shock lung. It can quickly lead to acute respiratory failure with fatal outcome within 48 hours in 50–70% of cases. Highest rate of mortality occurs due to aspiration of gastric contents, bacteremia and pneumonia.

- Normally, pulmonary surfactant reduces tension in alveoli and keeps alveoli open. Decrease in synthesis of surfactant by type 2 pneumocytes causes acute respiratory distress syndrome.
- Patient develops a clinical syndrome characterized by refractory hypoxemia not responsive to oxygen

Table 18.25 Causes of restrictive pulmonary diseases

Etiology	Disorders
Chest wall abnormality	▪ Deformities (kyphoscoliosis) ▪ Neuromuscular disorder
Acute primary lung disease	Acute respiratory distress syndrome
Chronic primary lung disease	▪ *Occupational lung diseases:* Asbestosis, silicosis, coal worker's pneumoconiosis ▪ Interstitial lung disease (interstitial pneumonia), idiopathic pulmonary fibrosis ▪ *Immune diseases:* Sarcoidosis, systemic lupus erythematosus, rheumatoid arthritis, Wegener's granulomatosis and Goodpasture syndrome ▪ *Physical injury:* Radiation-induced injury ▪ *Drugs:* Chemotherapeutic agents, methotrexate

therapy, reduction in lung compliance, normal oncotic pressure, normal capillary pulmonary wedge pressure and chest radiograph suggestive of bilateral pulmonary edema.

Etiopathogenesis

Adult respiratory distress syndrome may follow direct or indirect lung injury. Sepsis is most common cause of acute respiratory distress syndrome (ARDS). Other causes include pulmonary contusions, severe trauma and shock. Etiology of acute respiratory distress syndrome in adults is given in Table 18.26.

- **Direct lung injury:** Hantavirus, oxygen toxicity, inhalation of chemical irritants (chlorine), smoke inhalation, pneumonia, aspiration of gastric contents and post-lung transplant cause acute alveolar capillary damage in >30% of cases. Coronavirus destroys type 2 pneumocytes and causes diffuse alveolar damage.
- **Indirect lung injury:** Various systemic disorders cause indirect alveolar–capillary damage. Examples are septicemia (40% cases), severe trauma with shock (20% cases), acute hemorrhagic pancreatitis, therapeutic drug (bleomycin), overdose with street drug (heroin), multiple blood transfusions, cardiopulmonary bypass, disseminated intravascular coagulation, fat embolism, complicated abdominal surgery, and radiation injury.

Table 18.26 Etiology of acute respiratory distress syndrome in adults

Lung Damage	Disorders
Primary lung damage	▪ Aspiration of gastric contents (35%) ▪ Bacterial and viral pneumonias (12%) ▪ Inhalation of smoke and chlorine ▪ Oxygen toxicity ▪ Radiation-induced injury ▪ Drug-induced lung injury (salicylates, bleomycin) ▪ Paraquat poison
Secondary lung damage	▪ Disseminated intravascular coagulation (22%) ▪ Traumatic shock (5%) ▪ Multiple blood transfusions (5%) ▪ Extensive burns ▪ Septicemia (4%) ▪ Acute pancreatitis

Highest prevalence of acute respiratory distress syndrome in decreasing frequency occurs due to aspiration of gastric contents, disseminated intravascular coagulation, pneumonias, traumatic injury, and multiple blood transfusions.
Highest rates of mortality are aspiration of gastric contents, bacteremia and pneumonia.

Pathogenesis

Following alveolar–capillary damage, alveolar macrophages synthesize IL-1, IL-8, TNF-α and macrophage inhibiting factor (MIF).

- Chemical mediators IL-1, IL-8, and TNF-α cause sequestration of neutrophils into the alveolar spaces, and aggregation of platelets.
- Activation of the coagulation system cascade is suggested by the presence of microemboli containing aggregate of platelets in alveolar capillaries. Pathogenesis of acute respiratory distress syndrome in adults is shown in Fig. 18.29.

Exudative Phase of ARDS

Lung becomes dark, red and firm within 7 days. Histamine released by platelets increases the pulmonary capillary permeability resulting in pulmonary edema.

- Neutrophils synthesize chemical mediators like leukotrienes, oxidants, proteases and platelet-activating factor, resulting in damage to type 1 and type 2 pneumocytes.
- Damage to type 2 pneumocytes leads to inactivation of pulmonary surfactant (lecithin-rich surface-

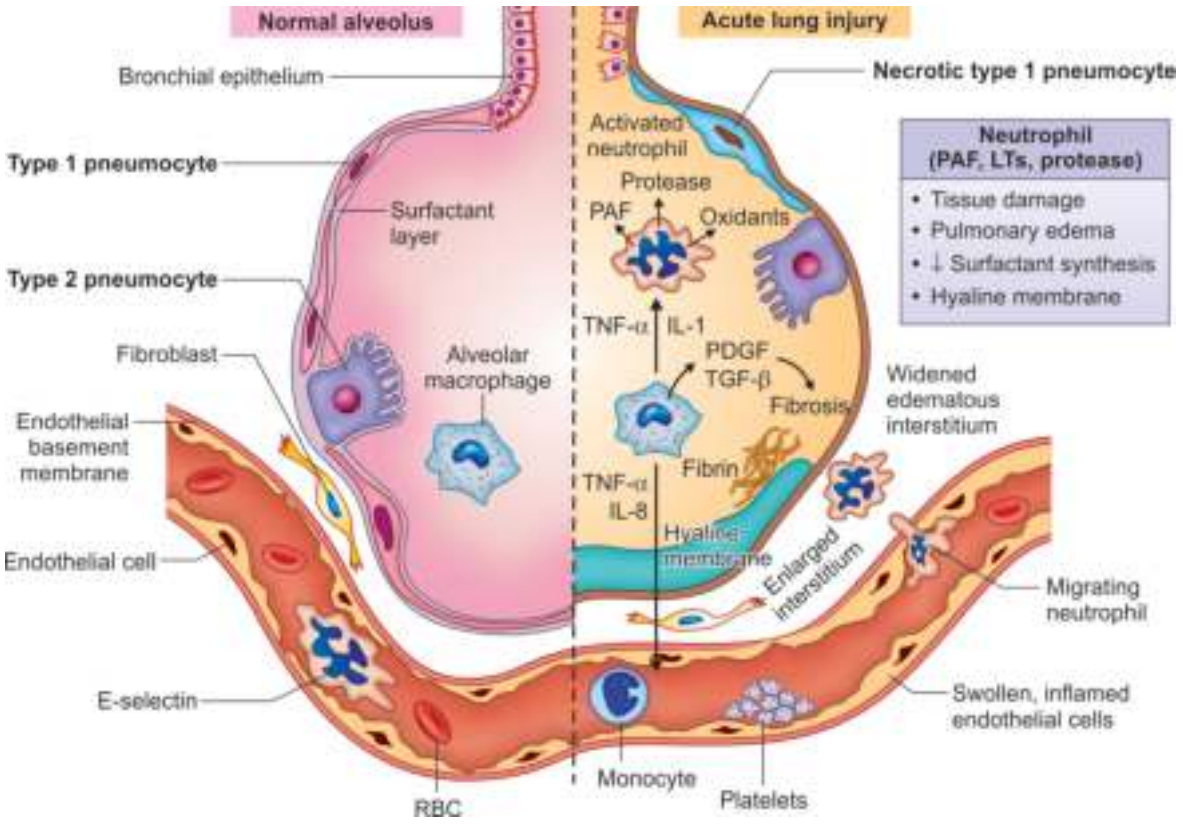

Fig. 18.29: Pathogenesis of acute respiratory distress syndrome. Normal alveolus is seen on left half of figure. Synthesis of IL-8 and TNF-α by macrophages and neutrophils occurs in the alveoli. Leukotrienes, oxidants, proteases, and platelet-activating factor (PAF) synthesized by neutrophils produce local tissue damage, pulmonary edema, surfactant inactivation, and hyaline membrane formation. Fibrogenic factors (PDGF and TGF-β) synthesized by macrophages stimulate fibroblast growth and collagen deposition associated with the healing phase of injury.

active lipid) resulting in atelectasis (collapse of alveoli).

- Exudative phase of ARDS leads to pulmonary edema and fibrinous exudation. Fibrinous exudates form hyaline membranes lining alveoli, which appear bright, pink in hematoxylin and eosin stained tissue sections.
- Macrophage inhibitory factor (MIF) released into the local milieu sustains the ongoing pro-inflammatory response. These pathologic changes result in impairment of respiratory gaseous exchange with consequent severe hypoxia.

Proliferative Phase of ARDS

Proliferative phase of ARDS begins about one week after the initial injury. It is marked by the proliferation of macrophage within alveolar walls.

- Alveolar macrophages digest the remnant of hyaline membranes and other cellular debris.
- TGF-β and PDGF synthesized by macrophages cause proliferation of fibroblasts leading to mild fibrosis that resolves in adult respiratory distress syndrome.

Fibrotic Phase of ARDS

In severe cases, it may progress to restructuring of the pulmonary parenchyma and cyst formation. Alveolar walls are thickened. Progressive pulmonary fibrosis may produce honeycomb appearance in rare cases.

Surgical Pathology: Adult Respiratory Distress Syndrome
Gross Morphology
Lungs are heavy, diffusely firm, solid, dark red and rubbery due to diffuse alveolar damage.
Light Microscopy
▪ **Acute exudative phase:** Lungs show congestion of capillaries, interstitial edema, and fibrinous exudates in alveoli. The alveolar walls are lined by hyaline membranes. ▪ **Proliferative/fibrotic phase:** Proliferative phase is marked by the proliferation of macrophage within alveolar walls. Fibrinous exudate undergoes organization leading to alveolar fibrosis and thickening of the alveolar septa. There may be superimposed bronchopneumonia in fatal cases. Histology of diffuse alveolar damage is shown in Fig. 18.30.

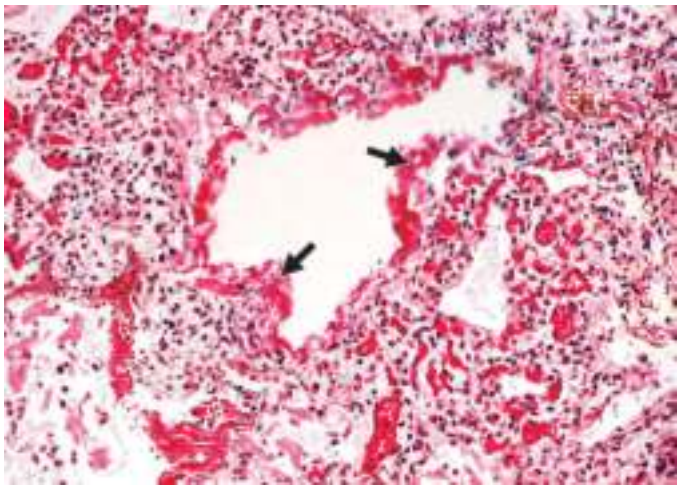

Fig. 18.30: Diffuse alveolar damage. Acute exudative phase shows protein-rich hyaline membranes, interstitial edema and inflammation (arrows).

Chest Radiograph

Initially, chest radiograph shows bilateral interstitial infiltrates followed by extensive pulmonary consolidation in 80% of cases.

Clinical Features

- **Respiratory system:** Patient develops rapid, shallow breathing, dyspnea, intercostal and suprasternal retraction crackles, rhonchi, respiratory and metabolic acidosis, and sometimes respiratory failure. Pulmonary edema in acute respiratory distress syndrome does not resolve, however, it resolves in cases of congestive heart failure.
- **Cardiovascular system:** Patient develops arterial hypoxemia refractory to oxygen therapy, cyanosis, tachycardia, and hypotension.
- **Central nervous system:** Patient develops restlessness, apprehension, mental sluggishness, and motor dysfunction.
- **Urinary system:** Patient has decreased urinary output (oliguria).

Prognosis

Patient with adult respiratory distress syndrome has frequently fatal outcome in 60% of cases. Approximately 30–40% of cases with good intensive care may survive. High concentration of oxygen therapy may further cause alveolar–capillary damage due to oxygen toxicity. Old age, multi-system failure and high levels of IL-1 indicate poor prognosis.

NEONATAL RESPIRATORY DISTRESS SYNDROME

The pathogenesis of neonatal respiratory distress syndrome is intimately linked to deficiency of surfactant. It leads to collapse of the alveoli followed by leakage of fibrin-rich fluid into the alveoli from injured vascular bed resulting in respiratory failure in newborn.

- Normally surfactant, lecithin-rich lipid synthesized by pneumocytes 2 prevents lung collapse (atelectasis) of the alveoli during expiration by lowering the surface tension of the alveoli at low lung volumes and keeps alveoli open.
- Cortisol increases the synthesis of surfactant, while insulin inhibits its synthesis. Pulmonary surfactant composition, surfactant-specific proteins (A, B, C, D apoproteins), their surface activity and functions; and surfactant dysfunction disorders are given in Tables 18.27 to 18.29.

Clinical Features

The first symptom of neonatal respiratory distress syndrome usually appearing within an hour of birth is cyanosis, increased respiratory effort, with forceful intercostal retraction and the use of accessory neck muscles in newborn. Despite advances in neonatal intensive care, the overall mortality of ARDS is about 15%, and 33% of infants born before 30 weeks of gestational age die of this disorder.

Predisposing Factors

Predisposing factors include prematurity, maternal diabetes mellitus, neonatal amniotic fluid aspiration and birth by cesarean section.

- **Premature newborn:** Premature newborn is unable to synthesize pulmonary surfactant. To reduce the potential for developing respiratory distress syndrome in newborn, woman is administered glucocorticoids to enhance fetal surfactant synthesis.
- **Maternal diabetes mellitus:** Fetal hyperglycemia increases the insulin release. Good blood sugar control of maternal diabetes mellitus by insulin

Table 18.27 Pulmonary surfactant composition

Composition	Constituents Percentage
Saturated phosphatidylcholine	50%
Unsaturated lipids	17%
Phosphatidylglycerol	7%
Phosphatidylethanolamine, phosphatidylinositol, sphingomyelin, other phospholipids and lipids	16%
Serum proteins	8%
Surfactant-specific proteins (A, B, C, D apoproteins)	2%

Table 18.28 Surfactant-specific proteins (A, B, C, D apoproteins), their surface activity and functions

Features	Surfactant Apoprotein A	Surfactant Apoprotein B	Surfactant Apoprotein C	Surfactant Apoprotein D
Molecular weight	26–38 kDa	9 kDa	4 kDa	43 kDa
Hydrophilic or hydrophobic in nature	Hydrophilic nature	Hydrophobic nature	Hydrophobic nature	Hydrophilic nature
Lowering alveolar surface activity	None surface activity	High surface activity	Very high surface activity	None surface activity
Main functions	Acts as opsonin, promotes phagocytosis and regulates surfactant secretion by unwinding lamellar bodies	Optimizes alveolar surface activity	Optimizes alveolar surface activity	Acts as opsonin, promotes phagocytosis and regulates surfactant secretion by unwinding lamellar bodies

Hydrophilic surfactant apoproteins A and D act as opsonins and participate in phagocytosis. These are involved indirectly in lowering alveolar surface activity. Hydrophobic surfactant apoproteins B and C optimize alveolar surface activity in conjunction with surfactant phospholipids.

Table 18.29 Surfactant dysfunction disorders

Features	Surfactant Apoprotein B	Surfactant Apoprotein C	Surfactant Apoproteins A, B, C, A3
Genetic inheritance	Autosomal recessive	Autosomal dominant, sporadic	Autosomal recessive
Chromosomal abnormality	2p12–11.2	8p21	16p13.3
Age distribution	Neonates	Infants, children	Neonates, infants
Clinical features	Respiratory failure and death	Respiratory failure	Respiratory failure
Lung histologic features	Alveolar type 2 cell hyperplasia, alveolar proteinosis, interstitial inflammation and fibrosis	Desquamative pattern or nonspecific interstitial pneumonia	Alveolar type II cell hyperplasia, alveolar proteinosis, and accumulation of macrophages

Unexplained neonatal or infantile respiratory may occur. Lung histology shows endogenous lipid pneumonia, cholesterol pneumonitis, alveolar proteinosis, chronic pneumonitis of infancy, desquamative interstitial pneumonia or nonspecific interstitial pneumonia.

administration reduces the risk of respiratory distress syndrome in newborn.

- **Neonatal amniotic fluid aspiration:** Amniotic fluid aspiration in newborn causes severe damage to alveolar–capillary membrane resulting in impaired respiratory gaseous exchange.

Pathogenesis

There is decreased synthesis of pulmonary surfactant in the immature lungs of premature newborn infants. Immature lungs and decreased pulmonary surfactant cause decreased lung compliance, atelectasis and hypoxia.

- Hypoxia produces neonatal respiratory distress syndrome by causing vasoconstriction of pulmonary vasculature leading to pulmonary hypertension and decreased pulmonary perfusion.
- Hypoxia simultaneously increases pulmonary capillary permeability leading to alveolar exudation and formation of hyaline membrane. Pathogenesis of neonatal respiratory distress syndrome is shown in Fig. 18.31.

Surgical Pathology: Neonatal Respiratory Distress Syndrome

Gross Morphology

Lungs are dark red, airless heavier than usual, with areas of atelectasis alternating with occasional dilated alveoli or alveolar ducts.

Light Microscopy

- The alveolar ducts and alveoli are lined by conspicuous, eosinophilic, fibrin-rich, amorphous material, termed hyaline membranes.
- Pulmonary capillaries are congested.

Complications

Intraventricular hemorrhage in brain is a major complication of neonatal respiratory distress syndrome. Thin-walled veins in the periventricular germinal matrix are dilated as a result of anoxia resulting in rupture. Intraventricular hemorrhage reflects anoxic injury to the periventricular capillaries, dilation of thin-walled veins, thrombosis and impaired autoregulation.

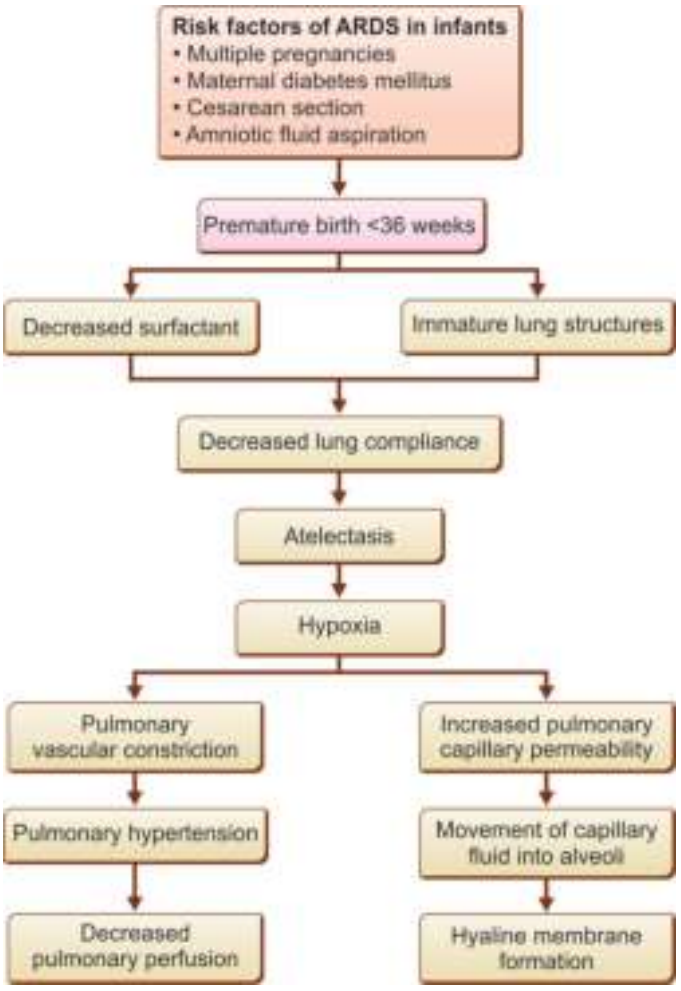

Fig. 18.31: Pathogenesis of neonatal respiratory distress syndrome.

Diagnostic Tools

Examination of amniotic fluid by flow cytometry and immunofluorescence polarizing microscopy is used to assess fetal pulmonary maturity.

- Previously, lecithin to sphingomyelin ratio greater than 2:1 in amniotic fluid analysis indicated fetal maturity.
- Currently, phosphatidylglycerol concentration is estimated in amniotic fluid and blood, because it is reliable diagnostic tool in spite of meconium contamination.

SEVERE RESPIRATORY DISTRESS SYNDROME

Severe respiratory distress syndrome is a viral respiratory tract infection caused by coronavirus that can progress to pneumonia and, eventually, death. Incubation of severe respiratory distress syndrome is 2–10 days.

Mode of Transmission

Coronavirus is transmitted by respiratory droplets produced when an infected person coughs or sneezes. Infected droplets are inhaled by the nearby person and get deposited on the mucous membranes of the mouth, nose, or eyes. It is also transmitted by using viral contaminated objects on mouth, nose, or eyes.

Risk Factors

Severe respiratory distress syndrome occurs due to close contact with an infected person, exhaled droplets and body secretions, and traveling to endemic areas.

Pathogenesis

Coronavirus attaches to receptors on the host cell membrane. It then releases enzymes and weakens the cell membrane. It then penetrates the cell membrane, and removes the protein coating that protects its genetic material resulting in replication and maturation. It then escapes from the cell by budding from the plasma membrane. The infection then can spread to other host cells (*refer* to Chapter 7 for SARS-CoV-2).

Clinical Features

Patient initially presents with fever, fatigue, headache, chills, myalgia, malaise, anorexia, and diarrhea. Later, patient develops dry cough, dyspnea, progressive and hypoxemia, and respiratory failure.

DIFFUSE ALVEOLAR DAMAGE

Diffuse alveolar damage (DAD) is nonspecific injury to alveolar epithelial and endothelial cells caused by variety of acute insults.

- The injurious agents include respiratory infections, sepsis, shock, aspiration of gastric contents, inhalation of toxic gases, near-drowning, radiation pneumonitis, and a large assortment of drugs and other chemical agents.
- The clinical counterpart of severe DAD is acute respiratory distress syndrome. In this disorder, a patient with apparently normal lungs sustains pulmonary damage and then develops rapid progressive respiratory failure (Table 18.30).

Table 18.30 Etiology of diffuse alveolar damage (DAD)

Category	Selected Agents
Infectious agents	Viruses, Mycoplasma, opportunistic infections in immunocompromised persons
Inhaled toxins	Oxygen toxicity, smoke
Therapeutic agents	Chemotherapeutic drugs, amiodarone, nitrofurantoin
Shock	Traumatic, cardiogenic shock
Sepsis	Any pathogen
Miscellaneous conditions	Radiation, burns, cardiopulmonary bypass, pancreatitis

CHRONIC RESTRICTIVE PULMONARY DISEASES

PNEUMOCONIOSIS

Pneumoconiosis refers to inhalation of mineral dust into the lungs. Dust particles are phagocytozed by alveolar macrophages, which then collect and drain into peribronchial lymphatic channels and hilar lymph nodes.

- Mineral dusts include coal dust, silica, asbestos and beryllium. These account for 25% of cases of chronic interstitial lung disease. Some dusts are apparently inert and cause a little or no damage. Certain dusts are antigenic and cause damage through immunological reactions. Exposure to asbestos may predispose to tuberculosis or neoplasia. Occupational causes of the pneumoconiosis are given in Table 18.31. Categories of occupational exposure and associated respiratory disorders are given in Table 18.32. Pulmonary reactions to mineral dust are given in Table 18.33.
- Radiologic findings in pneumoconiosis are related to the degree of associated pulmonary fibrosis. Highest atomic number (56) of the mineral dust gives a denser opacities on chest radiograph than least atomic number (12) of carbon, given the same amount of mineral particles inhaled.
- Predisposing factors which determine the extent of lung damage caused by an inhaled dust, its size, shape, solubility, concentration, and duration of exposure, effectiveness of mucociliary mechanism and co-existence of other lung diseases.

Table 18.31 Occupational causes of pneumoconiosis

Occupation	Agent	Disease
Mining	Coal dust	Pneumoconiosis
Quarrying (stone crushing)	Silica dust	Silicosis
Foundry work	Silica dust	Silicosis
Asbestos (mining, heating, building, demolition)	Asbestos fibers	Asbestosis—mesothelioma, lung carcinoma
Farming	Actinomycetes	Alveolitis
Paint spraying	Isocyanates	Bronchial asthma
Plastics manufacture	Isocyanates	Bronchial asthma
Soldering	Colonophony	Bronchial asthma

Table 18.32 Categories of occupational exposure and associated respiratory disorders

Occupational Exposures	Nature of Respiratory Responses	Comments
Inorganic dust		
Asbestos: Mining, processing, construction, ship repair	Asbestosis (pulmonary diffuse fibrosis), pleural plaques, mesothelioma, lung carcinoma	Virtually all new mining and construction with asbestos done in developing countries
Silica, mining, stone cutting, sandblasting, quarrying	Acute silicosis (alveolar lipoproteinosis), silicosis (nodular or massive pulmonary fibrosis), progressive massive fibrosis (PMF), chronic obstructive pulmonary disease (COPD), tuberculosis, lung carcinoma	Persistent risk of silicosis in developing countries
Coal dust: Mining	Coal worker pneumoconiosis (nodules formation), primary pulmonary fibrosis (PMF), COPD	Risk of coal worker pneumoconiosis persists in developing and developed countries
Beryllium: Processing alloys for high-tech industries	Chronic granulomatous disease of lung, lung carcinoma (high suspect), acute pneumonitis (rare)	Risk of berylliosis persists in high-tech industries
Other metals: Aluminum, chromium, cobalt, nickel, uranium, tungsten carbide, or hard metal (containing cobalt)	Acute pneumonitis, lung carcinoma, bronchial asthma, aluminum pneumoconiosis (nodular or massive fibrosis)	New pulmonary diseases appear with new process development

Contd...

Table 18.32 Categories of occupational exposure and associated respiratory disorders (*Contd...*)

Occupational Exposures	Nature of Respiratory Responses	Comments
Organic dust		
Cotton dust: Milling, processing	Byssinosis (an asthma-like syndrome), COPD, chronic bronchitis	Increasing risk of byssinosis in developing countries
Other agricultural dusts: Fungal spores, vegetable products, insect fragments, animal dander, bird and rodents faeces, endotoxins, microorganisms, pollens	Hypersensitivity pneumonitis (farmer's lung), bronchial asthma, COPD	Other agricultural dusts are important in migrant labor and also in-home exposure
Toxic chemicals: Wide variety of industries such as acid anhydrates, H_2SO_4 fumes, HNO_3 fumes, cadmium fumes, ammonia, formaldehyde, halides and acid salts (chloride, bromide, fluoride), nitrogen oxide, ozone, sulphur dioxide, hydrogen sulfide, acrolein and other aldehydes	Bronchial asthma, chronic bronchitis, COPD	Increased risk to exposure to toxic elements in developing countries
Other environmental agents		
Uranium, radon, passive tobacco smoke, biomass smoke, polycyclic aromatic hydrocarbons, welding fumes, diesel exhaust, wood finishing	Occupational exposures estimated to contribute to COPD, ≤10% of lung carcinomas, chronic bronchitis, COPD and pulmonary fibrosis	Occupational exposures to in-home environmental agents are increased in developing countries. Biomass smoke is a major risk factor for COPD among women

Table 18.33 Pulmonary reactions to mineral dust

Pulmonary Reaction to Mineral Dust	Mineral Dust
Macrophage accumulation with little deposition of reticulin fibers in lung	▪ Anthracosis (prolonged exposure to coal dust) ▪ Siderosis (prolonged exposure to iron) ▪ Stannosis (prolonged exposure to tin oxides) ▪ Baritosis (prolonged exposure to barium dust) ▪ Coal worker's pneumoconiosis (macules), coal dust (carbon and silica) ▪ Aluminum pneumoconiosis (granular aluminum)
Nodular or massive fibrosis of lung	▪ Silicosis (silica duct) glasswork, common material of masonry construction ▪ Coal worker's pneumoconiosis (nodules) ▪ Mixed dust pneumoconiosis
Diffuse fibrosis of lung	▪ Asbestosis (old insulation) ▪ Hard metal pneumoconiosis ▪ Aluminum pneumoconiosis
Epithelioid granulomas and giant cells	Chronic berylliosis
Alveolar lipoproteinosis	Acute silicosis
Small airway disease	Various dusts

- **Size of dust particle:** It determines site of deposition in lung alveoli. Dust particles measuring 1–5 micron are most dangerous, which reach alveoli and cause lung damage. Dust particles measuring <1.00 micron are suspended in respiratory tract and exhaled. Dust particles measuring >5 micron trapped in the mucus of nasopharynx, trachea, and bronchi are cleared by mucociliary apparatus.
- **Shape of dust particle:** Long and thin fibers of asbestos may reach the alveoli and cause lung damage.
- **Solubility of dust particle:** Finely divided dust may induce exudative reactions. Large dust particles resist dissolution, hence may persist within lung parenchyma for years together and produce fibrosis in lungs.

- **Concentration of dust particle:** Increased concentration of dust particles produces more lung damage.
- **Duration of exposure to dust particle:** Prolonged exposure to dust particles in mine workers increases risk of lung damage.
- **Mucociliary mechanism:** Normally, mucus secretion and mucociliary apparatus participate in clearance of dust particles. Damage to mucociliary apparatus by cigarette smoking predisposes to the accumulation of mineral dusts in lungs resulting in lung damage.

Coal Worker's Pneumoconiosis

Deposition of coal dust, i.e. anthracotic pigment derived from coal mines and tobacco smoke in the interstitial tissue of lungs and hilar nodes is known as coal worker's pneumoconiosis. Alveolar macrophages laden with anthracotic pigment are called dust cells. Pathologic lesions depend upon duration of exposure and magnitude of coal dust.

- **Forms of coal dust:** Coal dust exists in various forms—anthracite (most fibrogenic) and least fibrogenic bituminous, sub-bituminous. There is no study on lignite.
- **Pathogenesis:** Inhalation of massive amount of coal dust is engulfed by alveolar macrophages. These macrophages transmit the dust to interstitium of the lung and form aggregates around respiratory bronchioles. Coal worker's pneumoconiosis in lung is shown in Fig. 18.32.

Clinical Features

- **Asymptomatic anthracosis:** Coal dust is deposited in connective tissue along lymphatic channels and draining hilar lymph nodes without perceptible cellular reaction.

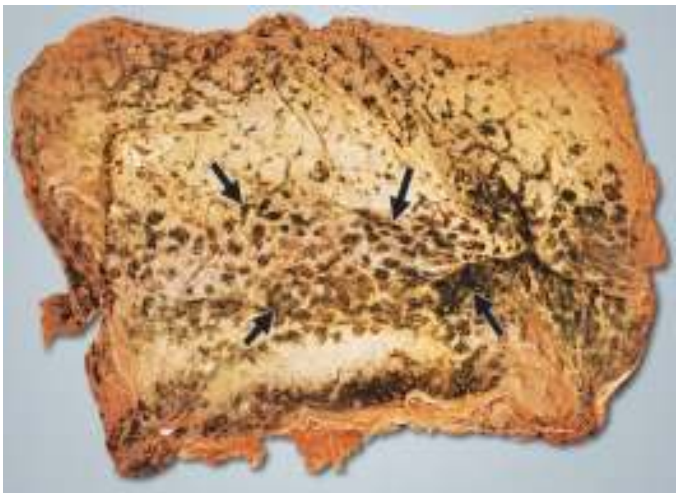

Fig. 18.32: Coal worker's pneumoconiosis. It shows deposition of coal dusts in lung (arrows).

- **Simple coal worker's pneumoconiosis:** Deposition of coal dust produces fibrotic opacities measuring <1.00 cm in upper lobes and upper region of lower lobes. Accumulation of coal dust near respiratory bronchioles produces centrilobular emphysema.
- **Complicated coal worker's pneumoconiosis:** It is also known as pulmonary progressive massive fibrosis (PMF) or black lung disease. Accumulation of coal dust produces fibrotic opacities measuring ≥1–2 cm with or without necrotic centers in posterior region of pulmonary upper lobes and upper segment of lower lobes. Patients may develop cor pulmonale. There is no increased risk of tuberculosis or lung cancer. Patient may develop Caplan syndrome characterized by coal worker's pneumoconiosis forming large cavities in lungs and rheumatoid arthritis (Table 18.34).

Table 18.34 Features of simple and complicated coal worker's pneumoconiosis

Lesions	Simple Coal Worker's Pneumoconiosis	Complicated Coal Worker's Pneumoconiosis
Fibrosis	Absent	Present
Size of lesion	<1.0 cm (macules 1–2 mm) and nodules <5 mm	Nodules >2.0 cm (usually 5–10 cm)
Region of lung	Upper region	▪ Upper lobe (posterior region) ▪ Lower lobe (upper segment)
Pulmonary functions	Normal	Impaired
Emphysema	Focal	Centriacinar or panacinar emphysema
Pulmonary vessels	Normal	Thickened
Chronic bronchitis	Absent	Present
Cor pulmonale	Absent	Present
Cavitation	Absent	Present (containing inky fluid)

Silicosis

Deposition of silica dust in lung parenchyma producing silicotic nodular opacities is known as silicosis.

- The greater the degree of exposure to silica and increasing length of exposure determine the amount of silicotic nodule formation and the degree of restrictive pulmonary disease.
- Silicosis is most common occupational disease across world. An occupational history is of importance in establishing the diagnosis. In silicosis, pulmonary opacities contain collagen and quartz.

Silica: Forms

Silica exists in three forms, i.e. crystalline, cristocrystalline and amorphous silica.

- **Crystalline silica:** Examples of crystalline silica are quartz, tridymite and cristobalite. Quartz is derived from foundries, i.e. casting material, sandblasting and mines. At higher temperature (800–1400°C), quartz gets converted into tridymite and cristobalite. Inhalation of tridymite and cristobalite is more potent than quartz in producing pulmonary fibrosis in upper lobes.
- **Cristocrystalline silica:** It contains minute crystals of flint, chert, opal, chalcedony. Higher temperature converts cristocrystalline silica into tridymite, which is potent mineral dust in producing lung fibrosis.
- **Amorphous silica:** It comprises glass, kaolin and diatomite. Repeated exposure to amorphous silica can cause lung fibrosis.

Pathogenesis

- **Pronged exposure to quartz:** It results in formation of silicotic nodule in lung composed of concentric layers of collagen with or without central cavitation. There is minimal inflammatory reaction. Quartz polarizes in the nodules. Egg shell dystrophic calcification is present in hilar nodes.
- **Prolonged exposure to tridymite and cristobalite:** It causes activation and cytolysis of alveolar macrophages, releasing cytokines, which stimulate pulmonary fibrosis. Chest radiograph in early phase reveals fine nodularity imparting snowstorm appearance; and later diffuse pulmonary fibrosis with irregular emphysema (Fig. 18.33A to D).

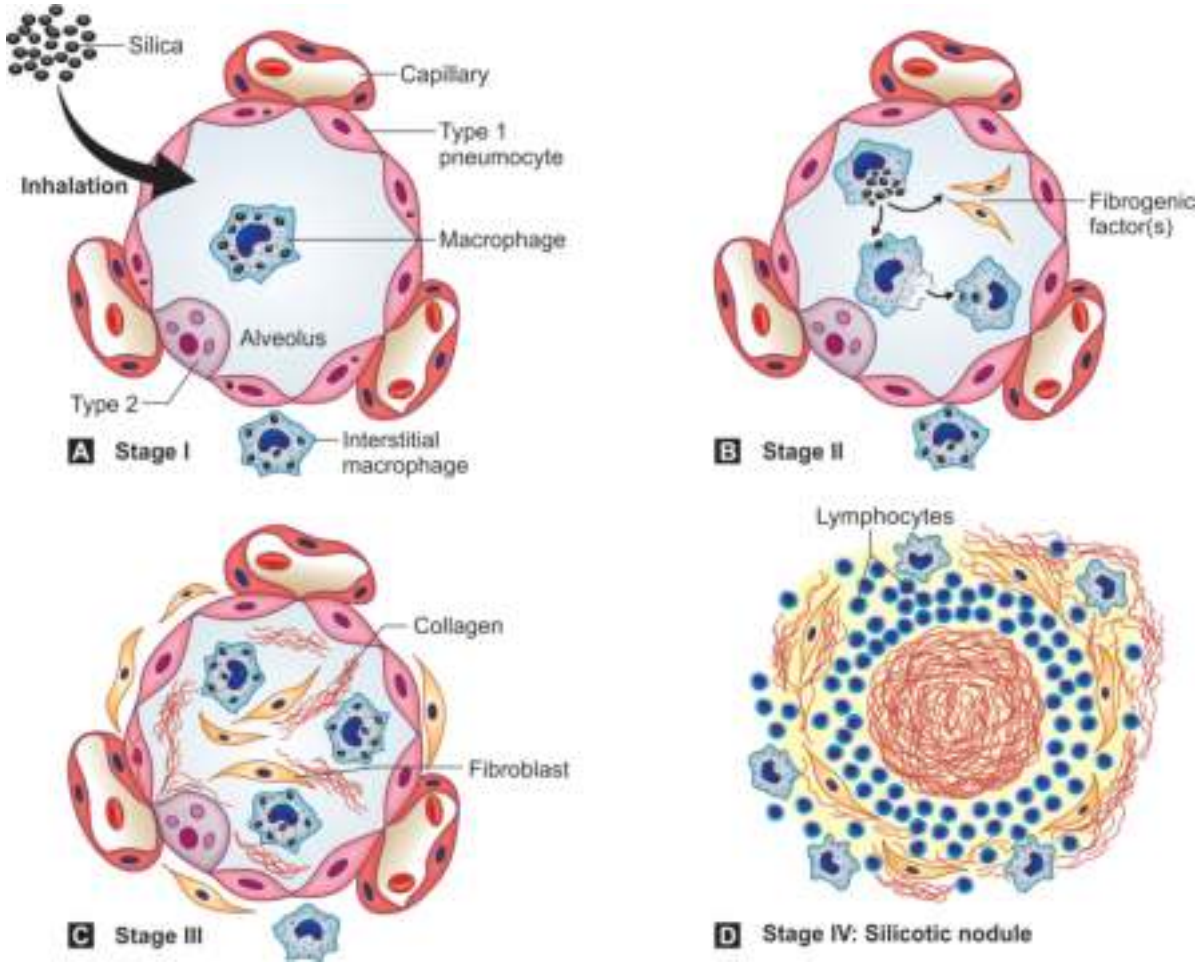

Fig. 18.33A to D: Pathogenesis of pneumoconiosis by silicosis. Inhaled silica particles are toxic to the alveolar macrophages, which die and release a fibrogenic factor. The released silica is again engulfed by alveolar macrophages. The process leads to formation of silicotic nodule.

Clinical Features

Clinical features depend on lesions present in simple or complicated silicosis. Patients may develop cor pulmonale and Caplan syndrome. There is increased risk for developing lung carcinoma and tuberculosis.

Asbestosis

Deposition of asbestos fibers in the respiratory unit, i.e. respiratory bronchioles, alveolar ducts and alveoli is known as asbestosis.

- Occupational hazards occur due to asbestos and its products after a prolonged exposure of 10 years. Lower lobes of lungs are severely affected.
- Asbestos occurs as silica compounds throughout earth. It is widely used in flooring, roofing materials, insulating conduits (i.e. sewer, water), brake linings, and clutch castings as well as a fire retardant. It is inconsumable air and water pollutant.

Asbestos Fibers: Types

Asbestos fibers measure 5–300 micron in length and 0.25–0.5 micron in width. There are two types of asbestos fibers, i.e. serpentine fibers and amphibole fibers (most dangerous). Types of asbestos fibers are given in Table 18.35 and grading of asbestosis is given in Table 18.36.

- **Serpentine asbestos fibers:** These are composed of **chrysolite fibers** (white asbestos). These are curly and flexible fibers, which reach the upper respiratory tract without fragmentation. These do not produce lung fibrosis.
- **Amphibole asbestos fibers:** These are composed of crosidolite fibers (blue asbestos) and amosite fibers (brown asbestos). These are straight and rigid fibers, which undergo fragmentation and reach the alveoli. These fibers are most dangerous responsible for pathologic lesions in lungs.

Pathogenesis

Straight and rigid amphibole fibers undergo fragmentation and reach the alveoli resulting in recurrent pleural effusions, pleural plaques, mesothelioma, bronchogenic carcinoma, other cancers (GIT, larynx), emphysema, bronchiectasis and pulmonary hypertension. Pathogenesis of asbestosis lung is shown in Fig. 18.34A to D.

Pathologic Lesions

Serpentine fibers of asbestos coated with ferritin and proteins are phagocytozed by macrophages and form golden brown beaded ferruginous bodies; demonstrated in sputum or in distal, small airways. Amphiboles asbestos fibers have been associated with cancerous and noncancerous lung diseases.

Table 18.35 Types of asbestos fibers

Characteristics	Serpentine Fibers	Amphibole Fibers
Composition	Chrysolite fibers (white asbestos)	▪ Crosidolite fibers (blue asbestos) ▪ Amosite fibers (brown asbestos)
Fibers shape	Curled fibers	Straight fibers
Fibers texture	Flexible textue	Stiff texture
Fragmentation	No fragmentation	Fragmentation occurs
Site of deposition	Upper respiratory tract (alveoli spared)	Respiratory unit (terminal bronchioles, acini and alveoli)
Lesions	These do not produce lung lesions	▪ Pleural effusion (recurrent) ▪ Pleural plaques ▪ Lung extensive fibrosis ▪ Mesotheliomas ▪ Lung cancer (adenocarcinoma and squamous cell lung carcinoma) ▪ Cancers of gastrointestinal tract and larynx ▪ Other lesions such as emphysema, bronchiectasis and pulmonary hypertension

Table 18.36 Grading of asbestosis

Criteria	Grade
Amount of lung parenchyma involved	▪ A: Lung parenchyma not involved ▪ B: <25% of lung parenchyma involved ▪ C: 25–50% of lung parenchyma involved
Severity of fibrosis and distortion of lung parenchyma	0–4: Zero (no fibrosis) and 4 (severe fibrosis)

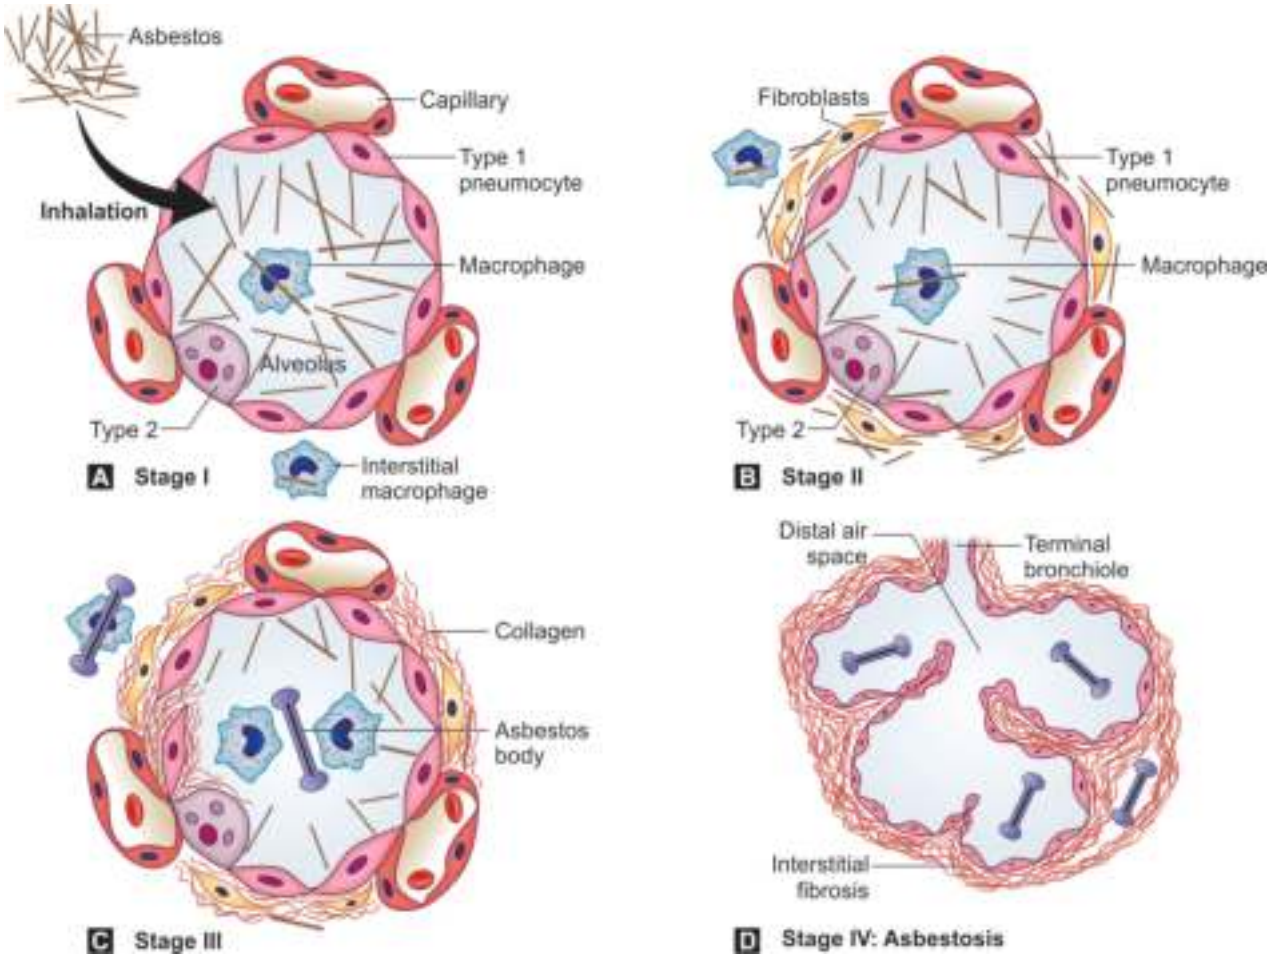

Fig. 18.34A to D: Pathogenesis of pneumoconiosis by asbestos fibers. Asbestosis is characterized by inhalation of small amount of dust producing extensive pulmonary fibrosis.

Asbestos-related Pulmonary and Extrapulmonary Lesions

- **Pleural effusion:** Patient exposed to asbestosis develops recurrent and bilateral pleural effusion.
- **Pleural plaques:** Benign pleural plaques are most common lesions in asbestosis. These are well circumscribed tan-white benign pleural plaques containing calcium over the domes of diaphragm and costophrenic angles. They do not contain asbestos bodies.
- **Mesothelioma:** Mesothelioma arises from visceral layer of pleura and peritoneum. It occurs in 5–10% of cases, 25–40 years after first exposure. Tumor is dense white bulky filling pleural cavity. Patient presents with dyspnea, pain and effusion. Malignant mesothelioma arises from serosa of pleura encasing the lung.
- **Lung cancer:** Bronchogenic carcinoma is most common asbestos-related lung cancer such as adenocarcinoma (most common) and squamous cell lung carcinoma. Cigarette smoking increases the risk for developing lung carcinoma manifold.
- **Other malignancies:** There is increased risk for cancer of gastrointestinal tract, larynx and lymph nodes.
- **Other respiratory tract lesions:** Patients may develop emphysema, bronchiectasis and pulmonary hypertension.

Berylliosis

Deposition of beryllium (mineral dust, fumes) in the lungs is known as berylliosis. There is increased risk of cor pulmonale and lung cancer.

Source of Beryllium

Grinding, heating, melting of beryllium metal and alloys produce dangerous dust particles in the form of beryllium oxide. These are inhaled and producing two types of lesions in respiratory tract.

Pathologic Lesions

On prolonged inhalation of beryllium oxide, patient develops acute nonspecific chemical tracheo-bronchopneumonia. Later, the patient develops diffuse interstitial pulmonary fibrosis and noncaseating epithelioid cell granuloma entrapping birefringent crystals. These may become 50 micrometer in size called **Schaumann bodies** similar demonstrated sarcoidosis. In biopsy, other causes of noncaseating epithelioid cell granulomatous disorders must be excluded.

DRUG-INDUCED INTERSTITIAL PULMONARY FIBROSIS

Prolonged administration of amiodarone, bleomycin, busulfan, cyclophosphamide, methotrexate, methysergide, nitrosourea and nitrofurantoin cause chronic interstitial pulmonary fibrosis. Pulmonary manifestations of drug reactions include diffuse interstitial pneumonia, diffuse alveolar damage, bronchiolitis obliterans, organizing pneumonia, eosinophilic pneumonia, pulmonary hemorrhage, pulmonary venoocclusive disease and large and small vessel vasculitis.

RADIATION-INDUCED INTERSTITIAL PULMONARY FIBROSIS

Acute pneumonitis may occur 1–6 months after radiotherapy. Patient presents with fever, dyspnea, pleural effusions. Some patients develop chronic radiation-induced pneumonitis, that can be demonstrated on chest radiograph.

IDIOPATHIC PULMONARY FIBROSIS

Idiopathic pulmonary fibrosis accounts for 15% of cases of chronic interstitial pulmonary diseases. Men are more affected than women in 40–70 years of age group.

Pathogenesis

Unknown agent triggers repeated cycles of alveolitis resulting in alveolar fibrosis and proximal dilation of the small airways. IL-8, FGF, TGF-β, PDGF synthesized by macrophages stimulate fibroblasts resulting in alveolar fibrosis. Lung exhibits '**honeycomb appearance**'.

Clinical Features

Patient presents with fever, breathlessness, chronic nonproductive cough, late inspiratory crackles, hypoxemia and cyanosis. Patient has poor prognosis with mean survival of 4–6 years.

Surgical Pathology: Idiopathic Pulmonary Fibrosis

Gross Morphology

- Normal architecture of lungs is impaired showing extensive fibrosis.
- Gross morphology of lung is shown in Fig. 18.35.

Light Microscopy

- Histologic examination reveals interstitial pulmonary fibrosis, interstitial pneumonia, desquamative pneumonia, bronchiolitis obliterans and organizing pneumonia.
- Alveolar septa are thickened by fibrosis.
- Capillaries are diminished. Interalveolar septa are infiltrated by chronic inflammatory cells (Fig. 18.36).

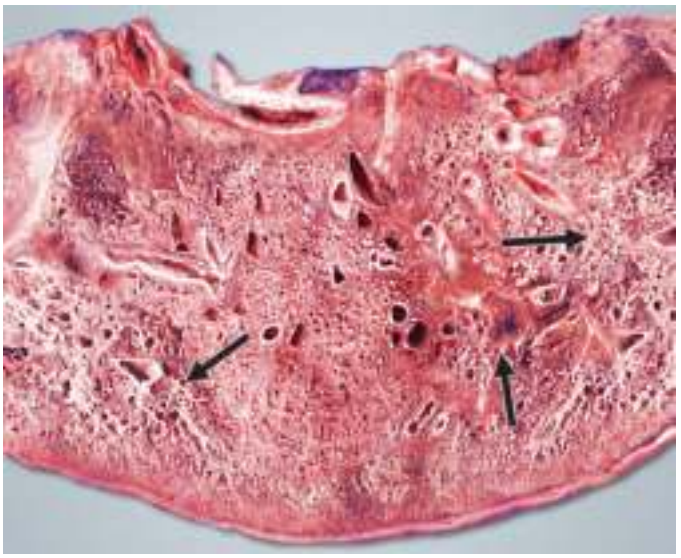

Fig. 18.35: Idiopathic pulmonary fibrosis. Lung shows extensive fibrosis in a patient with idiopathic pulmonary fibrosis (arrows).

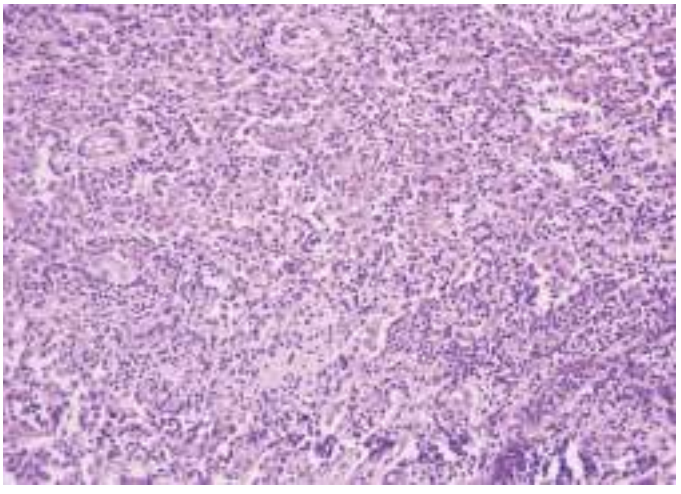

Fig. 18.36: Idiopathic pulmonary fibrosis. It shows desquamative pneumonia. Alveolar septa are thickened by fibrosis. Capillaries are diminished. Interalveolar septa are infiltrated by chronic inflammatory cells (100X).

SARCOIDOSIS

Sarcoidosis is a noncaseating granulomatous disease of unknown etiology. It becomes clinically apparent in teenagers and young adults. It is more common in women than men.

Pathology Pearls: Organs Involved in Sarcoidosis

Noncaseating granulomas are seen in lymph nodes, bone marrow, spleen and skin.

- **Lung lesion:** It shows interstitial pulmonary fibrosis and respiratory failure. Symptoms of pulmonary disease include dyspnea, cough, and wheezing.
- **Skin lesion:** Patient develops rashes on the nose and cheeks (lupus pernio), lateral painful nodules on extremities, i.e. erythema nodosum and inflammation of subcutaneous fat.

- **Anterior uveitis:** It results in blurred vision, glaucoma and corneal opacities. Angiotensin-converting enzyme (ACE) synthesized by epithelioid macrophages is elevated in the blood.
- **Liver lesion:** Patient develops granulomatous hepatitis.

Chest Radiograph

Chest radiograph reveals bilateral hilar lymphadenopathy and interstitial pulmonary disease manifesting as diffuse reticular densities.

Laboratory Diagnosis

Tuberculin test is negative. Blood γ-globulins and calcium levels are raised with hypercalciuria. Definitive diagnosis requires biopsy demonstrating noncaseating granulomas, laminated calcium concretions, i.e. Schaumann bodies and star-shaped inclusions called *asteroid bodies*.

COLLAGEN VASCULAR DISEASE

Collagen vascular diseases (i.e. scleroderma and systemic lupus erythematosus) account for 10% of chronic interstitial pulmonary fibrosis. Approximately 50% of patients with systemic lupus erythematosus produce chronic interstitial pulmonary fibrosis, pleuritis and pleural effusions.

RHEUMATOID ARTHRITIS

Rheumatoid arthritis may produce interstitial pulmonary fibrosis, nodules undergoing cavitation, pleuritis and pleural effusion. Caplan syndrome comprises rheumatoid nodules and pneumoconiosis.

EOSINOPHILIC GRANULOMA

Eosinophilic granuloma of lung is characterized by localized proliferation of histiocytes closely related to the Langerhans' cells of the skin. These histiocytes contain Birbeck granules resembling tennis rackets. Histiocytes are admixed with lymphocytes and eosinophils. Patient develops pneumonitis. Eosinophilic granuloma most often occurs in the lung or ribs.

EOSINOPHILIC PNEUMONIA

Eosinophilic pneumonia refers to accumulation of eosinophils and macrophages in alveolar spaces due to allergens. The alveolar septa are thickened by the presence of numerous eosinophils and formation of hyaline membranes. Eosinophilic pneumonia is classified as either idiopathic or secondary to an underlying illness. Patient with acute eosinophilic pneumonia responds dramatically to corticosteroids than chronic eosinophilic pneumonia.

HYPERSENSITIVITY PNEUMONITIS

Extrinsic allergic alveolitis (hypersensitivity pneumonitis) is associated with exposure to a known inhaled thermophilic Actinomyces, i.e. *Saccharopolyspora rectivirgula* antigen in moldy hay. Patient develops farmer's lung.

Pathogenesis

On first exposure to thermophilic Actinomyces antigen, patient's blood IgG antibodies level is increased.

- On subsequent exposure to antigen, antigen–antibody complexes are formed resulting in inflammatory reaction in lung tissue due to type III hypersensitivity response.
- Later, patient develops granulomatous inflammation of lungs due to type IV hypersensitivity reaction.
- Persons handling moldy hay should use facial mask. These patients respond well to corticosteroid therapy.

GOODPASTURE SYNDROME

Goodpasture syndrome is an autoimmune disorder, i.e. *in situ* immune complex-mediated disorder involving kidneys and lungs.

- Hemorrhagic pneumonitis and glomerulonephritis are caused by antibodies (IgG) directed against glomerular basement membrane, i.e. noncollagenous domain of type IV collagen.
- Local complement activation results in the recruitment of neutrophils, tissue injury, pulmonary hemorrhage, and glomerulonephritis.
- Patient presents with hematuria due to glomerular involvement and hemoptysis as a result of pulmonary hemorrhage.

BYSSINOSIS

Exposure to bacterial endotoxin from gram-negative bacteria growing on the cotton, linen or hemp products in textile factories produces byssinosis in occupational workers in textile factories. Patient presents with breathlessness due to pulmonary involvement.

SILO-FILLER'S DISEASE

Inhalation of wheat weevil protein causes Silo-filler's disease due to immediate hypersensitivity reaction resulting in dyspnea. Patient responds to corticosteroid therapy.

LYMPHANGIOLEIOMYOMATOSIS

Lymphangioleiomyomatosis is a rare interstitial pulmonary disease that occurs in women of childbearing age.

- Patient develops widespread abnormal proliferation of smooth muscle in the lung, mediastinal and retroperitoneal lymph nodes, and the major lymphatic ducts.
- The lungs show bilateral, diffuse enlargement, with extensive cystic changes resembling those of emphysema.
- Hormonal ablation through oophorectomy and antiestrogen and progesterone therapy has shown some promise in the management of patients.

PULMONARY ALVEOLAR PROTEINOSIS

Pulmonary alveolar proteinosis (PAP) is also termed lipoproteinosis. It is an uncommon disease of unknown etiology, in which the alveoli are filled with a granular, proteinaceous and eosinophilic amorphous material, which are PAS positive-diastase resistant, and rich in lipids. This material sometimes appears to be pulmonary surfactant.

Acquired Pulmonary Alveolar Proteinosis

Recent studies have revealed that acquired pulmonary alveolar proteinosis is associated with immunocompromised state, leukemia and lymphoma, respiratory infections, and exposure to environmental inorganic dusts. Histologic examination shows homogenous, agranular precipitate within the alveoli producing focal to confluent consolidation with minimal inflammation. The patients are treated by repeated bronchoalveolar lavage that may halt progression of the disease.

Congenital Pulmonary Alveolar Proteinosis (PAP)

Congenital PAP is a rare cause of immediate-onset neonatal respiratory distress syndrome. It has a fatal outcome shortly after birth. Without lung transplantation, death occurs within 3–6 months.

PNEUMOTHORAX AND ATELECTASIS LUNG

PNEUMOTHORAX

Pneumothorax is the presence of air outside the lung, within the pleural space. It leads to partial or complete pulmonary collapse. It may be due to traumatic perforation of the pleura or may be spontaneous.

- Spontaneous pneumothorax occurs when the visceral pleura ruptures without an external traumatic injury or iatrogenic etiology.
- Pneumothorax causes pulmonary collapse of a previously expanded lung, a condition that is termed atelectasis. The most common types of pneumothorax are open, closed, and tension.

OPEN PNEUMOTHORAX

In open pneumothorax, there is loss of negative intrathoracic pressure. In spontaneous pneumothorax, trachea deviates to side of spontaneous pneumothorax (Fig. 18.37).

Etiopathogenesis

- Penetrating wounds or rib fracture results in open pneumothorax. Due to penetrating injury, atmospheric air flows directly into the pleural cavity due to negative intrapleural pressure. As the air pressure in the pleural cavity becomes positive, the lung collapses on the affected side resulting in

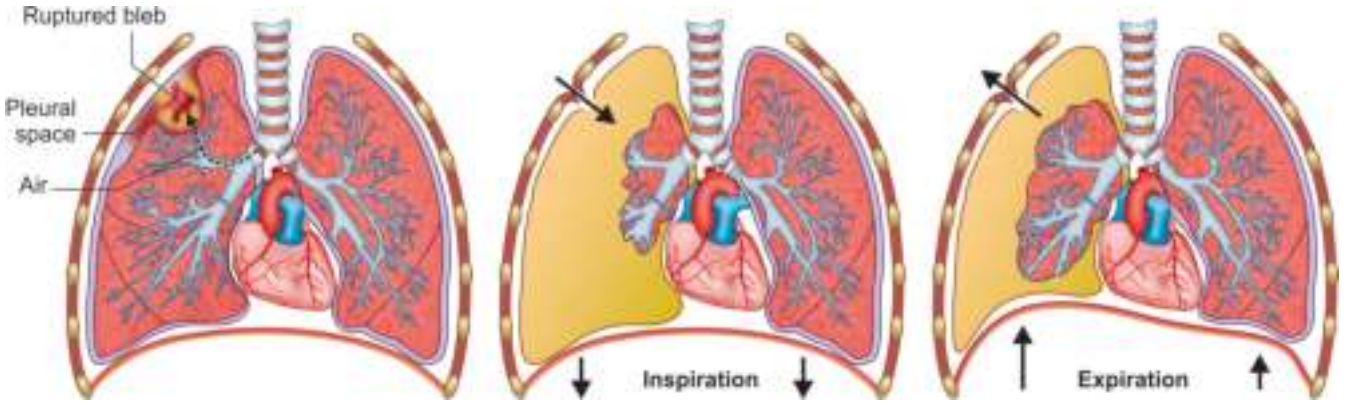

Fig. 18.37: Open pneumothorax. Air enters into the pleural cavity leading to lung collapse.

decreased total lung capacity, vital capacity, and lung compliance.
- Iatrogenic induced open pneumothorax occurs as a result of aspiration of pleural fluid (thoracocentesis) or pleural and transbronchial lung biopsies.

Clinical Features

Patient presents with chest pain (90%), dyspnea (80%), hypotension and tachycardia. On clinical examination, breath sounds are absent on affected side of pneumothorax. Chest rigidity is seen on affected side. Crackling lung sounds are observed beneath skin on palpation.

CLOSED PNEUMOTHORAX

Closed pneumothorax develops in a spontaneous manner especially in tobacco smokers in adults of 30–40 years of age. It is more common in men than women. It may recur in the opposite lung in 25% of cases within a span of two years.

Pneumothorax: Types

- **Primary pneumothorax:** It occurs in young age group. The condition runs in families. Rupture of paraseptal emphysema is the most common cause of closed pneumothorax. It may also occur due to rupture of apical subpleural bleb. Patient presents with sharp pleuritic pain and breathlessness. Clinical course is self-limited. Chest drain is not required, in patient not having respiratory distress.
- **Secondary pneumothorax:** It occurs as a result of visceral pleural leakage in tuberculosis, necrotizing malignant tumors and lung diseases with cavities.

Clinical Features

Patient presents with shortness of breath, respiratory distress, cyanosis and sudden onset severe pleuritic pain enhanced by coughing, breathing, and chest movement. On clinical examination, there is asymmetrical chest wall movement. Percussion note is hyperresonant. Trachea deviates to same side of spontaneous pneumothorax due to loss of negative intrathoracic pressure.

Chest Radiograph

Chest radiograph reveals white visceral pleural line and absence of vessel markings in the peripheral region of visceral pleural line.

TENSION PNEUMOTHORAX

There is an increase in pleural cavity pressure in tension pneumothorax. Trachea deviates to contralateral side of tension pneumothorax (Fig. 18.38).

Pathogenesis

Tension pneumothorax occurs as a result of trauma to pleura in mechanically ventilated patients. Each inspiration results in rushing out of air from alveoli and enters the pleural space through punctured site.
- Tension pneumothorax acts as a one-way check valve, but cannot escape as the rupture site closes on expiration. Each inspiration keeps on increasing intrapleural pressure resulting in pulmonary collapse. It forces mediastinal structures, i.e. heart, trachea, esophagus, and great vessels to opposite side.
- Heart and opposite lung are compressed resulting in impairment of venous return. Trachea deviates

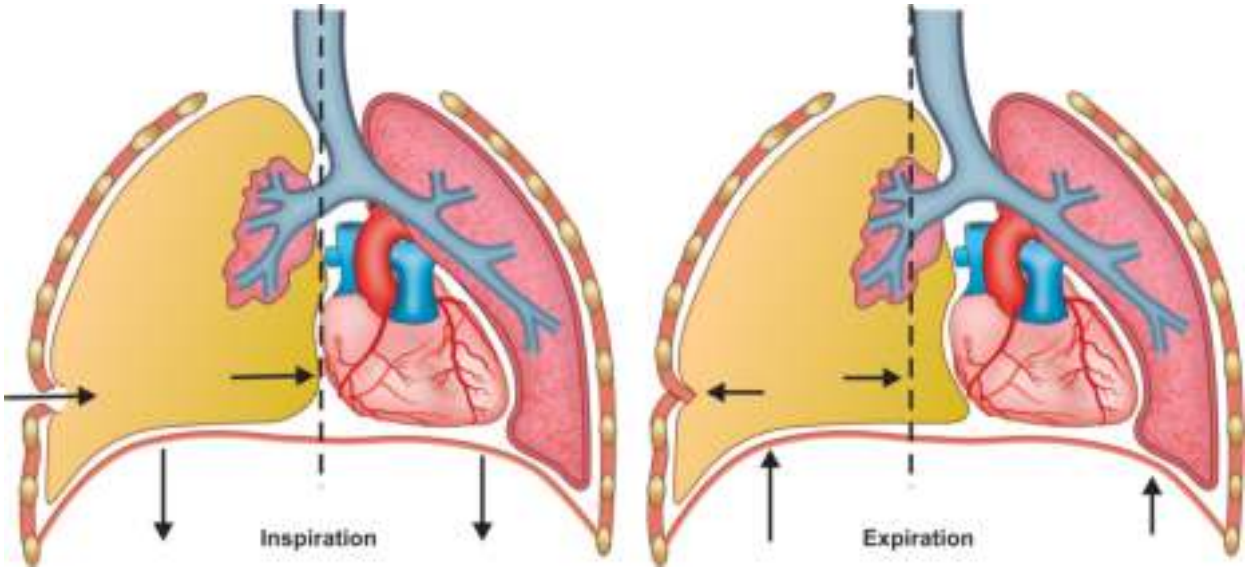

Fig. 18.38: Tension pneumothorax. Each inspiration results in rushing out of air from alveoli and enters the pleural space through punctured site. It acts as a one-way check valve, but cannot escape as the rupture site closes on expiration (arrows).

to opposite side of pneumothorax due to increase in pleural cavity pressure. The diaphragm is flattened.

Clinical Features

Patient presents with sudden onset of severe dyspnea, pleuritic chest pain, hypotension, decreased cardiac output and cardiac arrest. On auscultation, breath sounds are absent. Percussion note is resonant due to presence of air in the pleural cavity on the affected side of pneumothorax.

Treatment

Pressure of air in pleural cavity is relieved by inserting a needle into the second intercostal space on the mid-clavicular line or putting a chest tube.

ATELECTASIS OF LUNG (PULMONARY COLLAPSE)

Atelectasis refers to incomplete expansion of the lungs or the pulmonary collapse of previously inflated lung. Severe atelectasis significantly reduces oxygenation and predisposes to infection. Obstruction of airways causes resorption atelectasis, while air or fluid in pleural cavity under increased pressure results in compression atelectasis.

ETIOPATHOGENESIS

Acquired Atelectasis of Lung

Acquired atelectasis is generally encountered in adults. It may be divided into following categories: obstructive or resorption atelectasis, compression atelectasis, patchy atelectasis and contraction atelectasis. Atelectasis is a reversible disorder except that is caused by contraction.

Atelectasis Neonatorum of Lung

Atelectasis neonatorum is failure of alveolar spaces to expand adequately at birth. Primary atelectasis is failure of initial aeration of the lungs at birth. The alveoli remain collapsed and respiration is never fully established. It is associated with premature birth and intrauterine hypoxia.

- Secondary neonatal atelectasis is collapse of previously aerated lungs.
- Atelectasis neonatorum occurs due to deficient synthesis of pulmonary surfactant phosphatidylcholine (lecithin) synthesized by type 2 pneumocytes and stored in lamellar bodies. Surfactant reduces surface tension in the small airways. Synthesis of pulmonary surfactant begins in 28th week of gestation.
- Cortisol and thyroxine increase its synthesis while decreased by insulin.

ATELECTASIS: TYPES

Obstructive Atelectasis of Lung

Obstructive atelectasis involves regions of the lung distal to an obstruction in cases of aspiration of foreign bodies, centrally located bronchogenic carcinoma, and mucopurulent plugs after postoperative states, bronchial asthma, chronic bronchitis, and bronchiectasis. Airway obstruction by thick secretions prevents air from reaching the alveoli. It occurs due to obstruction of bronchi, segmental bronchi, or terminal bronchioles.

Compressive Atelectasis of Lung

Compressive atelectasis usually involves the entire lung. The pleural space is filled with fluid compressing the lung, which has retracted lung towards the hilus.

- Similar findings can be produced by pneumothorax, because of entry of air into the pleural space.
- Collapse of lung occurs due to lack of air and distal resorption of pre-existing air through the pores of Kohn in the alveolar walls, involving whole or part of a lung.
- Air or fluid in the pleural cavity under increased pressure induce collapse of small airways beneath the pleura. In tension pneumothorax, air compresses the lung. Accumulation of fluid in the pleural cavity compresses the lung.

Patchy Atelectasis of Lung

Patchy atelectasis is characterized by the presence of airless irregular patches in small segments of both lungs. It occurs in neonatal and adult acute respiratory distress syndrome.

Contraction Atelectasis of Lung

Contraction atelectasis occurs when local or generalized fibrotic changes in the lungs or pleura prevent full expansion of the lung parenchyma, especially in subpleural regions.

- Patient presents with fever and dyspnea, both usually occur within 24–36 hours of collapse. Percussion note is dull due to collapse of alveoli. Breath sounds are absent.
- There is ipsilateral elevation of the diaphragm and tracheal deviation. Collapsed lung does not expand on inspiration, i.e. inspiratory lag.

PULMONARY VASCULAR DISORDERS

Bronchial arteries originate from thoracic aorta and intercostal arteries; protect lungs from infarction. A pulmonary embolus produces a hemorrhagic infarction in 10% of cases.

Patient with decreased blood flow in bronchial artery as well as obstructive lung disease will likely to result in a hemorrhagic pulmonary infarct, hence increases the risk of morbidity and mortality.

PULMONARY THROMBOEMBOLISM

Pulmonary thromboembolism is a potentially fatal disorder. It is an obstruction of the pulmonary arterial bed by a dislodged thrombus. Patient presents with abrupt onset of pleuritic pain, shortness of breath and hypoxia. Bronchial arteries protect lungs from infarction. Dyspnea and tachypnea are common symptoms in cases of pulmonary infarction.

PATHOGENESIS

Most pulmonary emboli arise from the thrombi deep veins of the lower extremities in 50% of cases. It may originate in femoral and pelvic veins in many cases.

- Rarely, it can be due to nonthrombotic particulate material such as fat, amniotic fluid, clumps of tumor cells or bone marrow, or foreign matter, such as bullet fragments.
- Predisposing factors for developing pulmonary thromboembolism include stasis of venous blood flow, prolonged bed rest or immobilization, thrombophlebitis, varicose veins, hypercoagulable states, due to use of hormonal contraceptives, and pregnancy.

CONSEQUENCES

- The size of the embolus determines large-, medium- and small-sized pulmonary vessel that is occluded.

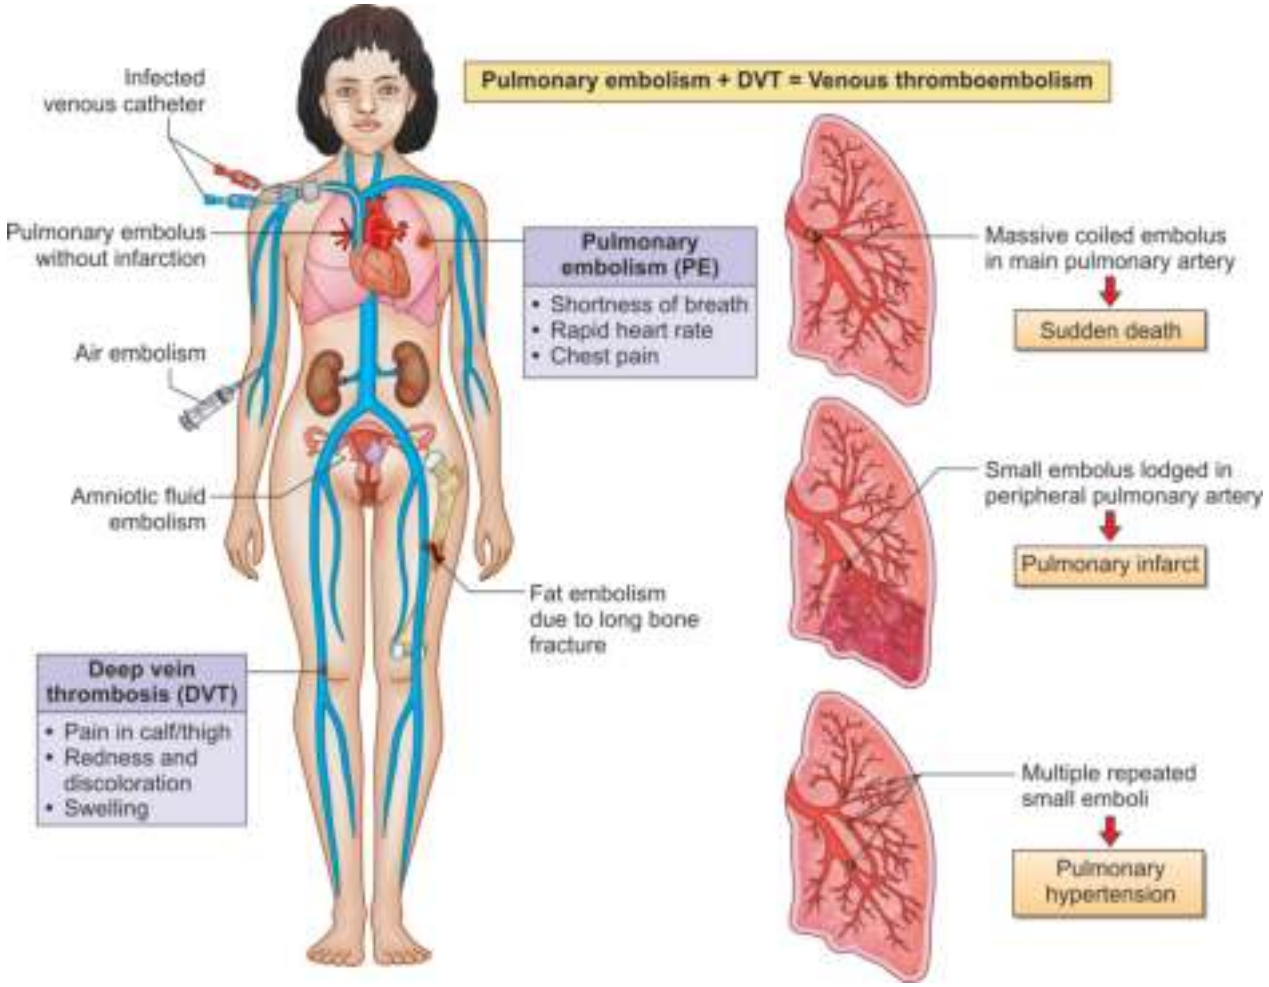

Fig. 18.39: Pathogenesis and consequences of pulmonary thromboembolism. Massive embolus in main pulmonary artery leading to sudden death. Small embolus in peripheral branches of pulmonary artery causes pulmonary hemorrhagic infarct. Multiple repeated small emboli lead to pulmonary hypertension.

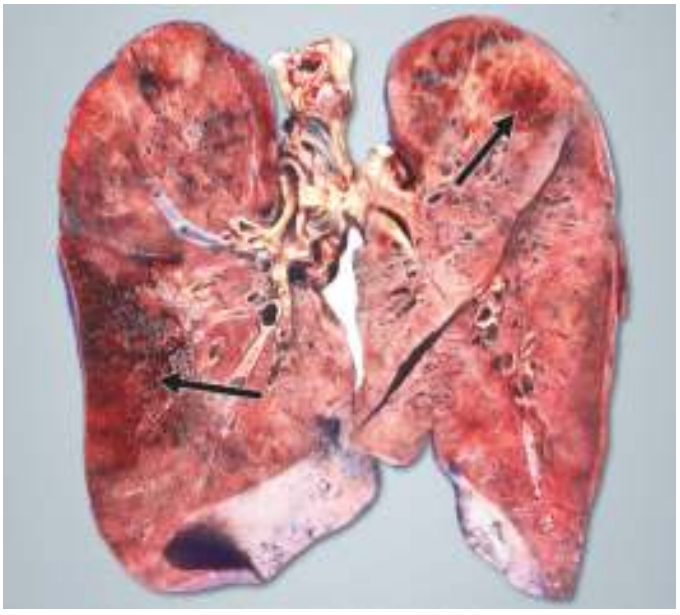

Fig. 18.40: Pulmonary hemorrhagic infarct (arrows).

- Large embolus occluding the major pulmonary vessels is known as '**saddle embolus**'.
- Small emboli occlude medium-sized and small-sized pulmonary arteries.
- Occlusion of pulmonary artery decreases the perfusion of lung parenchyma and resulting in hemorrhagic pulmonary infarction with fatal outcome (Fig. 18.39).
- Hemorrhagic pulmonary infarct is raised, wedge-shaped area with red blue discoloration that extends to the pleural surface. Majority of presons have hemorrhagic pulmonary infarct located in the lower lobes. Perfusion is greater than ventilation in the lower lobes (Fig. 18.40).

CLINICAL FEATURES

Approximately 50% of patients with mild pulmonary thromboembolism are asymptomatic. But in rest 50% of cases, massive pulmonary thromboembolism results in obstruction of pulmonary arterial circulation.

- Patient develops dyspnea or pleuritic chest pain on inspiration, expiratory wheezing, tachycardia, productive cough, blood-tinged sputum, low-grade fever and pleural effusion with fibrinous exudate.
- Overall survival rate in pulmonary thromboembolism patients is 80%. Hemorrhagic pulmonary infarct resolves without treatment in 60% of cases. In 90% of cases, the hemorrhagic pulmonary infarct resolves with treatment.

Imaging Diagnostic Techniques: Pulmonary Thromboembolism

- **Chest radiograph:** It shows pleural effusion; cut-off sign of one or more pulmonary arteries. Hypovascularity is demonstrated beyond the blocked blood vessel. Wedge-shaped area of lung consolidation seen is known as Hampton's hump.
- **Radionuclide scan:** It shows abnormal perfusion radionuclide scan. Ventilation scan is normal, but the perfusion scan is abnormal.
- **Pulmonary angiogram:** It is gold standard confirmatory test. It is expensive and not readily available in smaller hospitals.
- **Spiral (helical) CT:** It is excellent diagnostic technique if pre-existing lung disease present.
- **Positive D-dimer:** It is usually performed in conjunction with ventilation/perfusion scan or spiral CT.

FAT EMBOLISM SYNDROME

Fat embolism syndrome is a rare but potentially fatal problem. Pulmonary, cerebral, and cutaneous manifestations occur within 24–48 hours after a traumatic injury of long bone. Fat emboli comprise fat microglobules in the circulation. Grud and Wilson diagnostic criteria for fat embolism syndrome and clinical and laboratory findings are given in Table 18.37.

Table 18.37 Grud and Wilson diagnostic criteria for fat embolism syndrome and clinical and laboratory findings

Major Diagnostic Criteria
Skin (petechial hemorrhages)
Respiratory symptoms (tachypnea, dyspnea, bilateral inspiratory crepitations, hemoptysis, bilateral diffuse patchy shadowing on chest radiograph)
Neurological signs (confusion, drowsiness, coma)
Minor Diagnostic Criteria
Tachycardia (heart rate >120 per minute)
Pyrexia >38.5°C
Retinal petechial hemorrhages and fat emboli
Renal changes (anuria or oliguria)
Jaundice
Unexplained thrombocytopenia and low hemoglobin level
Erythrocyte sedimentation rate increased
Fat macroglobulinemia
Fat globules in urine
Fat globules in sputum

Etiopathogenesis

Fat embolism syndrome most often occurs as a consequence of severe trauma to long bone fractures such as femur with abundant fatty marrow. It can also be seen with extensive trauma to fat laden tissues, burns, and very rarely with orthopedic procedures.

- Following long bone fracture, bone marrow fatty globules enter the circulation, lodge in small blood vessels of the lung, skin, kidneys, brain and other organs producing ischemia and hemorrhage leading to clinical manifestations.
- Fat microglobules are converted into fatty acids, which damage vascular endothelium resulting in formation of platelet thrombi in areas of injury.
- Capillary permeability is increased allowing protein-rich fluid to leak into the alveoli, resulting in pulmonary edema.

CLINICAL FEATURES

Patient develops pulmonary fat embolism syndrome within 24–72 hours. It is characterized by pulmonary distress, cutaneous petechial hemorrhages, and various neurologic manifestations associated with fatal outcome.

- **Pulmonary manifestations:** Patient develops dyspnea and tachypnea due to presence of fat microglobules in pulmonary capillaries causing hypoxemia.
- **Petechial hemorrhage:** Patient develops petechial hemorrhage over the chest and upper extremities resulting from thrombocytopenia due to platelets adhesion to microglobules of fat.
- **Neurologic manifestations:** Numerous petechial hemorrhages are produced by fat emboli in the brain, particularly in white matter known as '**brain purpura**'. Patient develops neurologic manifestations such as loss of consciousness, cerebral edema and herniation within a week in <10% of cases with fatal outcome (Fig. 18.41).

LABORATORY DIAGNOSIS

Fatty acids released from fat emboli are taken up by alveolar macrophages. Bronchoalveolar lavage is performed in suspected cases of fat embolism syndrome. Smears are stained with fat stains (Sudan III, Sudan IV, Sudan black and Oil red O). Positivity of smears with fat stains is suggestive of fat embolism syndrome.

PULMONARY HYPERTENSION

Primary pulmonary hypertension is a rare disorder of unknown etiology that arises in the absence of heart or lung disease associated with poor prognosis. It is characterized by thickening of the media of pulmonary muscular arteries. As pulmonary hypertension becomes more severe, there is extensive intimal fibrosis and muscle thickening within arteries and arterioles, which may be occlusive.

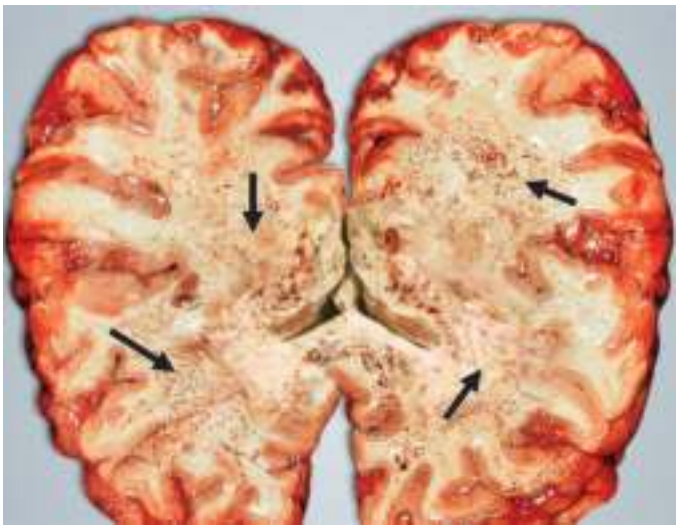

Fig. 18.41: Fat embolus. The patient was in a motorcycle accident and sustained multiple fractures of both legs. The fat emboli caused petechial hemorrhages in the white matter throughout the brain, resulting in coma and death. The macroscopic appearance of cerebral malaria is identical to this (arrows).

ETIOPATHOGENESIS

- **Primary pulmonary hypertension:** It is characterized by mean pulmonary artery pressure >25 mm Hg at rest and >30 mm Hg with exercise. It most common affects in young women. Gene mutation is associated with increased synthesis of transforming growth factor (TGF) which causes proliferation of smooth muscle cells of pulmonary artery.
- **Secondary pulmonary hypertension:** It is more common than primary pulmonary hypertension. Hypoxemia and respiratory acidosis stimulate vasoconstriction of pulmonary arteries. Hypoxemia occurs in chronic obstructive pulmonary disease (COPD), congenital left-to-right shunt, mitral stenosis, recurrent pulmonary thromboembolism and increased blood viscosity from polycythemia. Vasoconstriction is caused by increased synthesis of endothelin vasoconstrictor and loss of nitric oxide vasodilator.

PATHOLOGY

Pulmonary hypertension imposes an increased overload on the right ventricle resulting in right ventricular hypertrophy. Histologic changes in muscular arteries in pulmonary hypertension may show media hypertrophy, cellular intimal proliferation, plexiform, angiomatous and necrotizing lesions. Changes seen in muscular arteries in the lung in pulmonary hypertension are

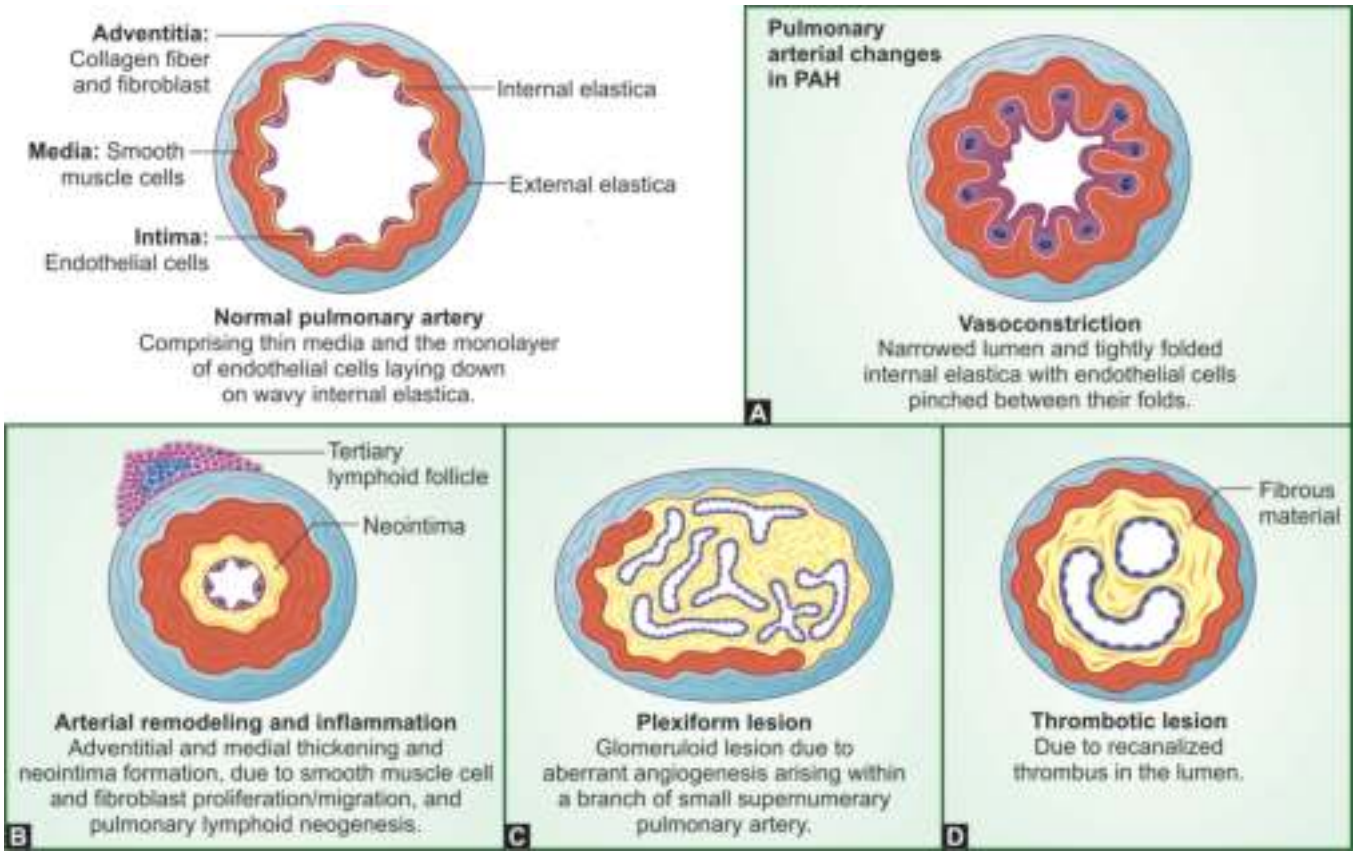

Fig. 18.42A to D: Changes seen in muscular arteries of the lung in pulmonary hypertension.

shown in Fig. 18.42A to D. Grading of pulmonary vascular lesions is given in Table 18.38.

CLINICAL FEATURES

Patient with pulmonary hypertension presents with dyspnea on exertion, chest pain and left parasternal heave, sign of right ventricular hypertrophy.

- On auscultation, there is accentuation of P2 as a result of pulmonary hypertension. Features of right-sided heart failure occur due to cor pulmonale.
- Chest radiograph shows enlargement of main pulmonary arteries and tapering of the distal vessels.
- Catheterization is done to measure mean pulmonary artery pressures at rest and after exercise.

Table 18.38 Grading of pulmonary vascular lesions

Grade	Pathologic Lesions
Grade 1	Vascular media hypertrophy
Grade 2	Grade 1 + intimal cell proliferation
Grade 3	Grade 2 + intimal fibrosis
Grade 4	Grade 3 + plexiform vascular lesion
Grade 5	Grade 4 + vascular dilatation (angiomatous) lesions
Grade 6	Grade 5 + necrotizing vascular lesions

PULMONARY EDEMA

Pulmonary capillary blood and alveolar gases are separated by the alveolar–capillary membrane, which consists of three different layers: (a) the capillary endothelium, (b) the interstitial space, which may contain connective tissue, fibroblasts, and macrophages; and (c) the alveolar epithelium.

- Exchange of fluid normally occurs between the vascular bed and the interstitium.
- Pulmonary edema is fluid accumulation in the interstitial tissue and air spaces. It leads to impaired gaseous exchange and may cause respiratory failure.
- Depending on the cause, pulmonary symptoms may appear suddenly or develop over time.
- Patient can have mild to extreme breathing difficulty, cough, chest pain and fatigue and other symptoms.

PATHOPHYSIOLOGY

Pulmonary edema can be caused by the following major pathophysiologic mechanisms: (a) imbalance of Starling forces, i.e. increased pulmonary capillary pressure, decreased plasma oncotic pressure, increased

negative interstitial pressure; (b) damaged to the alveolar–capillary barrier; and (c) impaired lymphatic drainage.

- The lymphatics play an important role in maintaining adequate fluid balance in the lungs by removing solutes, colloid and liquid from the interstitial space at a rate of 10–20 ml/hour. An acute elevation of pulmonary arterial capillary pressure to >18 mm Hg can increase filtration of the fluid into the pulmonary interstitium, but the removal of fluid by lymphatic channels does not increase correspondingly. In contrast, in the presence of sustained elevated left atrial pressure, the rate of removal of fluid by lymphatic channels can be as high as 200 ml/hour, which protects the lungs from pulmonary edema.
- Acute pulmonary edema can lead to fatal respiratory distress or cardiac arrest due to hypoxia. It is a cardinal feature of congestive heart failure. The most common cause of pulmonary edema is congestive heart failure (CHF). Heart failure happens when the heart can no longer pump out blood properly throughout the body. This creates a backup of pressure in the small blood vessels of the lungs, which causes the small blood vessels to leak fluid in the interstitial tissue and air spaces (alveoli). The alveoli are filled with smooth or floccular pink material. Alveolar capillaries are congested and containing red blood cells. Clinical manifestations of congestive heart failure are shown in Fig. 18.43. Histologic examination of pulmonary edema is shown in Fig. 18.44.

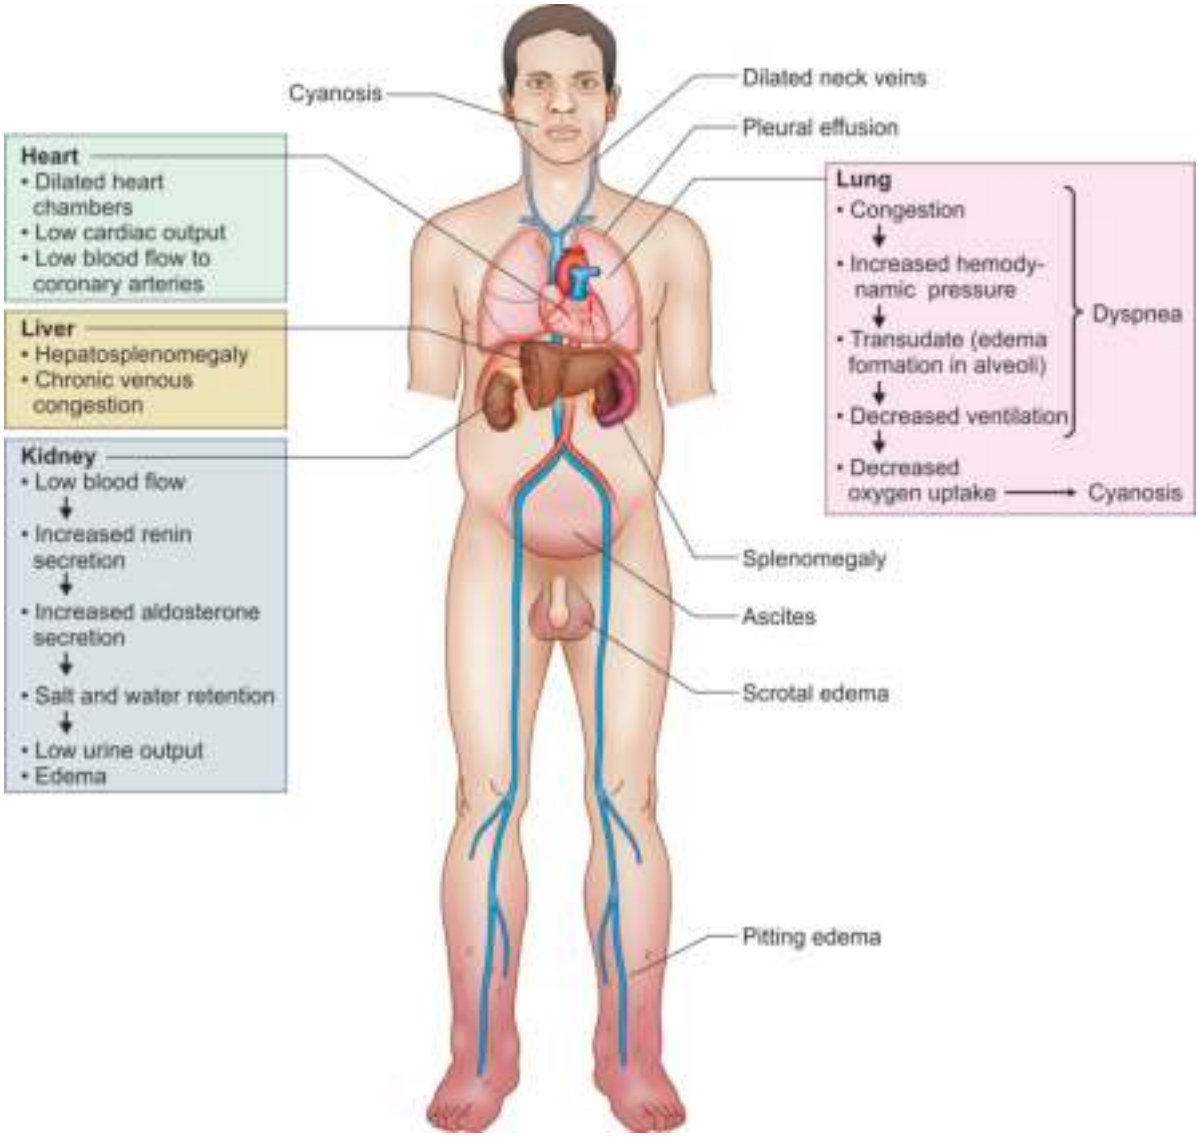

Fig. 18.43: Clinical manifestations in heart failure. Left heart failure is associated with retention of salt and water, pulmonary congestion, dyspnea, cyanosis, generalized edema, ascites, hydrothorax and scrotal edema. Right heart failure is associated with systemic venous congestion, peripheral pitting edema over ankles and hepatosplenomegaly.

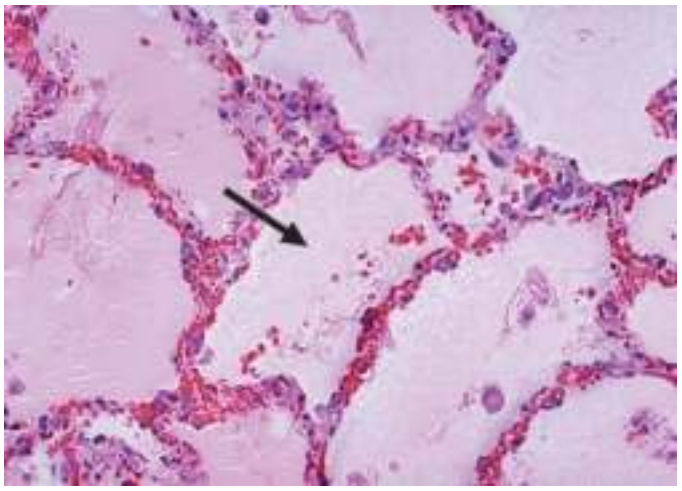

Fig. 18.44: Pulmonary edema. The alveoli in this lung are filled with a smooth to slightly floccular pink material. Alveolar capillaries are congested (arrow) (400X).

Cardiogenic Pulmonary Edema

Cardiogenic pulmonary edema is most common and potentially fatal cause of acute respiratory distress. It usually occurs due to acute decompensated heart failure, i.e. left ventricular systolic or diastolic dysfunction.

- Elevated left atrial pressure increases pulmonary venous pressure and hydrostatic pressure in the lung microvasculature resulting in fluid accumulation in interstitial tissue and alveolar spaces. Decreased breath sounds, dull percussion note, crackles on auscultation and orthopnea are clinical findings.
- Left atrial outflow obstruction can occur due to mitral stenosis, atrial myxoma and thrombosis of a prosthetic valve. Left ventricle systolic dysfunction is a common cause of cardiogenic pulmonary edema resulting from decreased myocardial contractility, that reduces cardiac output. The fall in the cardiac output stimulates sympathetic activity and blood volume expansion by activating the renin-angiotensin system resulting in retention of sodium and water, which further causes deterioration by decreasing left ventricular filling time and increasing capillary hydrostatic pressure.
- Causes of acute exacerbations of cardiogenic pulmonary edema include acute myocardial infarction, myocarditis, cardiomyopathies, aortic stenosis, aortic valve regurgitation and mitral valve regurgitation.

Noncardiogenic Pulmonary Edema

Noncardiogenic pulmonary edema is a distinct clinical syndrome associated with diffuse filling of the alveolar spaces in the absence of elevated pulmonary capillary wedge pressure.

- Adult respiratory distress syndrome is characterized by noncardiogenic pulmonary edema resulting from acute alveolar–capillary damage induced by toxins. There is leakage of fibrin-rich fluid into the alveoli resulting from injured vascular bed. It is also known as shock lung.
- Patient develops a clinical syndrome characterized by refractory hypoxemia not responsive to oxygen therapy and reduction in lung compliance.
- In infants, noncardiogenic pulmonary edema is linked to a deficiency of surfactant (a lecithin-rich lipid synthesized by pneumocytes II), that normally prevents alveolar collapse during expiration by lowering surface tension. Deficient pulmonary surfactant results in leakage of fibrin-rich fluid into the alveoli, that is not responsive to oxygen therapy. Clinical history, physical examination, electrocardiogram, echocardiography, laboratory investigations and direct measurement of pulmonary capillary wedge pressure can be done to distinguish cardiogenic from noncardiogenic pulmonary edema causing respiratory distress.

CLINICAL FEATURES

Patient presents with frothy pink or white sputum and breathlessness especially on lying down position. Clinical examination reveals weak pulse and cool and moist extremities. On auscultation, crackles and wheeze breath sounds are heard.

PULMONARY VASCULITIS

Patient with pulmonary vasculitis and related lesions often presents with alveolar hemorrhages resulting from Goodpasture syndrome, idiopathic rapidly progressive glomerulonephritis, Wegener's granulomatosis, microscopic polyarteritis, systemic lupus erythematosus and toxins. Patient may develop pulmonary hemorrhagic syndromes as given in Table 18.39.

Table 18.39 Pulmonary hemorrhagic syndromes

Syndrome	Inflammation of Capillaries	Immunofluorescence Study
Goodpasture syndrome	+/–	Linear staining
Idiopathic rapidly progressive glomerulonephritis	+	Granular staining
Wegener's granulomatosis	+	–
Microscopic polyarteritis	+	–
Collagen vascular disease, e.g. SLE	+	Granular staining
Toxins	–	–

NEOPLASTIC DISORDERS OF LUNG

Many benign and malignant tumors originate in the lungs. Approximately 90–95% are malignant tumors, 5% carcinoid tumors and 2–5% mesenchymal and tumor-like disorders.

- Cigarette smoking remains the most important risk factor for the development of lung cancer across world. Other risk factors for lung cancer include asbestos exposure, radiation, chemicals, heavy metals, fibrosing lung disorders, immunosuppression and genetic syndromes.
- Most common types of lung cancer in clinical practice include small cell lung carcinoma, squamous cell lung carcinoma, adenocarcinoma, bronchioloalveolar carcinoma and large cell lung carcinoma.
- Pulmonary Langerhans cell histocytosis is considered a malignant disorder. Tumor is composed of cells with nuclear groove and slightly eosinophilic cytoplasm. Tumor cells are positive for CD1a. Electron microscopy shows granules with a pentalaminar configuration and bulbous ends.

BENIGN TUMORS OF LUNG

Benign tumors of lung include bronchial adenoma and hamartomas (most common). These are relatively uncommon. Size of tumor remains constant for >2 years, but may exhibit dystrophic calcification on chest radiograph. Patient with tumor in peripheral region is usually asymptomatic, until it becomes large in size. But centrally located benign tumor may present with hemoptysis and signs of bronchial obstruction.

PULMONARY HAMARTOMA

Pulmonary hamartoma is disorganized benign mature tissue with altered architecture found in their normal anatomic location.

Age and Sex Predilection

Pulmonary hamartoma affects adults over 40 years of age, with a peak in the sixth decade of life.

Molecular Genetic Alterations

Chromosomal anomalies such as rearrangements of 12q14–15 or 6p21 suggest that pulmonary hamartoma is a neoplastic process.

- Pulmonary hamartoma has a high frequency of chromosomal translocation t(3; 12)(q27–28; q14–15), resulting in gene fusion of the high mobility group protein gene HMGA2 and the LPP gene.
- The HMGA2–LPP fusion gene usually consists of exons 1–3 of HMGA2 and exons 9–11 of LPP and seems to be expressed in pulmonary hamartoma with this chromosomal translocation.

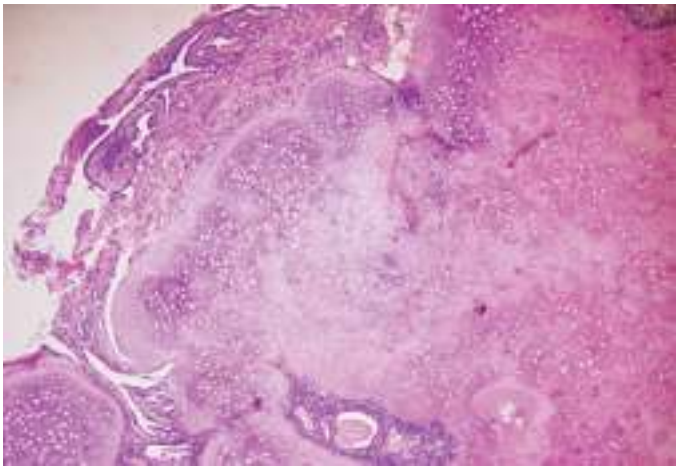

Fig. 18.45: Pulmonary hamartoma is composed of cartilage, bronchial epithelium, and smooth muscle cells (100X).

Imaging Technique

Pulmonary hamartoma accounts for 10% of coin lesion discovered incidentally on chest radiograph. A characteristic popcorn pattern of calcification is often seen on chest radiograph.

Surgical Pathology: Pulmonary Hamartoma
Light Microscopy
▪ Pulmonary hamartoma is composed of cartilage, bronchial epithelium, and smooth muscle cells. ▪ Myxoid components with spindle and stellate cells are often present at the periphery of pulmonary hamartoma (Fig. 18.45).
Immunohistochemistry Technique
Smooth muscle actin and S-100 are expressed in spindle cells. In males, the cells express ER, PR and androgen receptors.

BRONCHOPULMONARY CARCINOIDS

Bronchopulmonary carcinoid tumors of lung are derived from pluripotent neuroendocrine cells of major bronchial epithelium constituting up to 2% of primary lung tumors. These are not associated with cigarette smoking.

- Carcinoid tumors contain neuroendocrine granules, but the tumor cells are arranged in a distinctive pattern.
- Cushing's syndrome is often encountered in patients with small cell lung carcinoma, but not in bronchopulmonary carcinoids.

Clinical Behavior

Bronchopulmonary carcinoid tumors are slow growing highly vascular tumors. About 85% tumors are benign in nature. These tumors do not metastasize but may spread by direct extension. In approximately 15% of cases, metastasis may occur in distant organs.

Age Group

Bronchopulmonary carcinoid tumor is most common solitary primary tumor in children but may affect elderly persons.

Location of Tumor

Bronchopulmonary carcinoid tumor may be located in central, peripheral and midportion of lung. Centrally located carcinoid tumor appears as fleshy, smooth polypoid growth protruding into bronchial lumen, which obstructs bronchial lumen resulting in pneumonia.

Clinical Features

Patient with bronchopulmonary carcinoid tumor confined to lung presents with hemoptysis (most common), cough, and carcinoid syndrome associated with synthesis of neuropeptide in <1% in cases. Regional lymph node metastases occur in 20% of patients.

Surgical Pathology: Bronchopulmonary Carcinoids

Light Microscopy

Histologic variants of bronchopulmonary carcinoid tumors include classic and atypical variants. Comparison of typical carcinoid, atypical carcinoid, large cell neuroendocrine carcinoma and small cell lung carcinoma is given in Table 18.40. Comparison of atypical carcinoid tumor and neuroendocrine large cell lung carcinoma is given in Table 18.41.

- **Classic carcinoid tumor:** It is slow-growing tumor that does not metastasize and has excellent prognosis with appropriate surgery (5-year survival in 90%). Tumor is composed of monomorphic round to oval cells with **salt and pepper nuclei** and eosinophilic granular cytoplasm. The tumor cells are arranged in small groups or nests, cords or tubular structures separated by thin fibrous septa (Fig. 18.46).
- **Atypical carcinoid tumor:** Presently atypical carcinoid tumor is reclassified alongside small cell lung carcinoma as part of the spectrum of neuroendocrine carcinoma. On histologic examination, tumor shows 5–10 mitotic figures per 10 high power fields, pleomorphism with hyperchromatic nuclei and tumor necrosis.

Histochemistry

Silver stain shows black granules in the cytoplasm, which may be argentaphilic or argyrophilic in nature.

- **Argentaffin cells:** These cells reduce silver salts to metallic silver (black color) without the help of reducing agent.
- **Argyrophil cells:** These cells reduce silver salts to metallic silver (black color) only after addition of a reducing agent.

Immunohistochemistry Technique

Panel of immunomarkers is used to analyze expression in bronchopulmonary carcinoid on histologic sections.

Markers	Expression
▪ Neuron-specific enolase (NSE)	▪ Positive
▪ Chromogranin (neural marker)	▪ Positive
▪ Synaptophysin (neural marker)	▪ Positive
▪ Cytokeratin	▪ Positive
▪ CDX2*	▪ Negative

**CDX2 is positive in GIT carcinoids*

Table 18.40 Comparison of bronchopulmonary typical carcinoid, atypical carcinoid, large cell neuroendocrine carcinoma and small cell lung carcinoma

Feature	Typical Carcinoid	Atypical Carcinoid	Large Cell Neuroendocrine Carcinoma	Small Cell Lung Carcinoma
Etiology				
Role of tobacco smoking	None	Weak association	Strong association	Strong association
Male:female ratio	0.8:1	2:1	2.5:1	Declining
Mean age	50 years	56 years	63 years	62 years
Histologic features				
Architecture	Well organized	Focal loss	Moderate loss	Poor
Pleomorphism	Usually absent	Moderate	Marked	Mild
Mitoses	<2 per 10 high power field	2–10 per 10 high power fields	>10 per 10 high power field	>10 per 10 high power field
Necrosis	None	Focal necrosis	Abundant necrosis	Abundant necrosis
Argyrophilia	Common	Variable	Absent	Rare
DNA deposition on blood vessels (Azzopardi effect)	None	None	None	Frequent
Immunohistochemistry				
Neuroendocrine markers	Common, diffuse ++	Common, diffuse ++	Common often patchy +	Common often patchy +
Electron microscopy				
Granule numbers	Many	Moderate number	Nil	Scanty in number

Contd...

Table 18.40 Comparison of bronchopulmonary typical carcinoid, atypical carcinoid, large cell neuroendocrine carcinoma and small cell lung carcinoma (*Contd...*)

Feature	Typical Carcinoid	Atypical Carcinoid	Large Cell Neuroendocrine Carcinoma	Small Cell Lung Carcinoma
Granule size	15–250 nm	80–140 nm	Nil	80–140 nm
Clinical behavior				
Local invasion	Present	Present	Present	Present
Lymphatic route metastasis	Occasional	Not frequent	Frequent	Usual
Hematogenous route distant metastasis	Rare	45–70%	>50%	90–100%
Five-year survival	95%	60%	27–35%	2%

Neuroendocrine markers are synaptophysin (SYN) cytoplasmic marker, chromogranin A (CHG-A) cytoplasmic marker, neuron-specific enolase (NSE) cytoplasmic marker and CD56 (neuronal cell adhesion molecule) membranous marker.

Table 18.41 Comparison of atypical carcinoid tumor and neuroendocrine large cell lung carcinoma

Feature	Atypical Carcinoid Tumor	Neuroendocrine Large cell lung carcinoma
Cell size	Medium size cell	Large cell
Cells arrangement	Small cells arranged in groups in a trabecular or mosaic pattern	Large cells arranged in groups in well circumscribed manner with peripheral palisading
Nuclear/cytoplasmic ratio	Moderate nucleocytoplasmic (N/C) ratio	Low nucleocytoplasmic (N/C) ratio
Nuclear chromatin	Fine chromatin	Coarse chromatin
Nucleoli	Indistinct nucleoli	Prominent nucleoli
Nuclear atypia	Moderate atypia	Prominent atypia
Mitoses	≥2 per high power fields	≥10 per high power fields
Necrosis	Necrosis present usually confined to the centers of the cell groups	Necrosis present in large areas of tumor
Neuroendocrine stains	Optional (positive)	Essential (positive)

Neuroendocrine markers are synaptophysin (SYN) cytoplasmic marker, chromogranin A (CHG-A) cytoplasmic marker, neuron-specific enolase (NSE) cytoplasmic marker and CD56 (neuronal cell adhesion molecule) membranous marker.

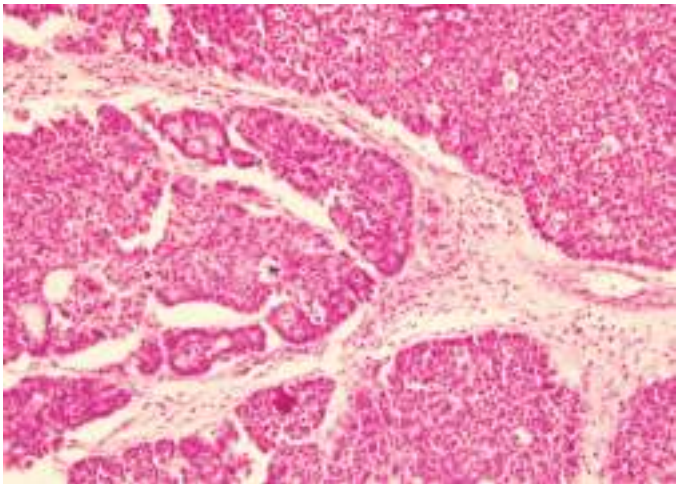

Fig.18.46: Bronchopulmonary carcinoid is composed of monomorphic round to oval cells with salt and pepper nuclei and abundant eosinophilic granular cytoplasm arranged in small groups or nests, cords or tubular structures and separated by thin fibrous septa (100X).

PRIMARY MALIGNANT TUMORS OF LUNG: OVERVIEW

Lung cancer is the most common fatal malignancy in both men and women in the age group above 50 years. Lung cancers are rare under age of 30 years. Surgical excision has limited role in management, as majority of cases report to hospital very late with locally advanced disease or wide dissemination (Fig. 18.47).

RISK FACTORS

Occupational exposure to various agents and their risk in development of lung cancers is given in Table 18.42.

- **Tobacco smoking:** Tobacco smoking accounts for 80–90% of lung cancers. Lung cancer correlates with duration and cumulative amount of exposure and depth of inhalation of tobacco smoke. Neutral fraction of tobacco smoke contains polycyclic hydrocarbons,

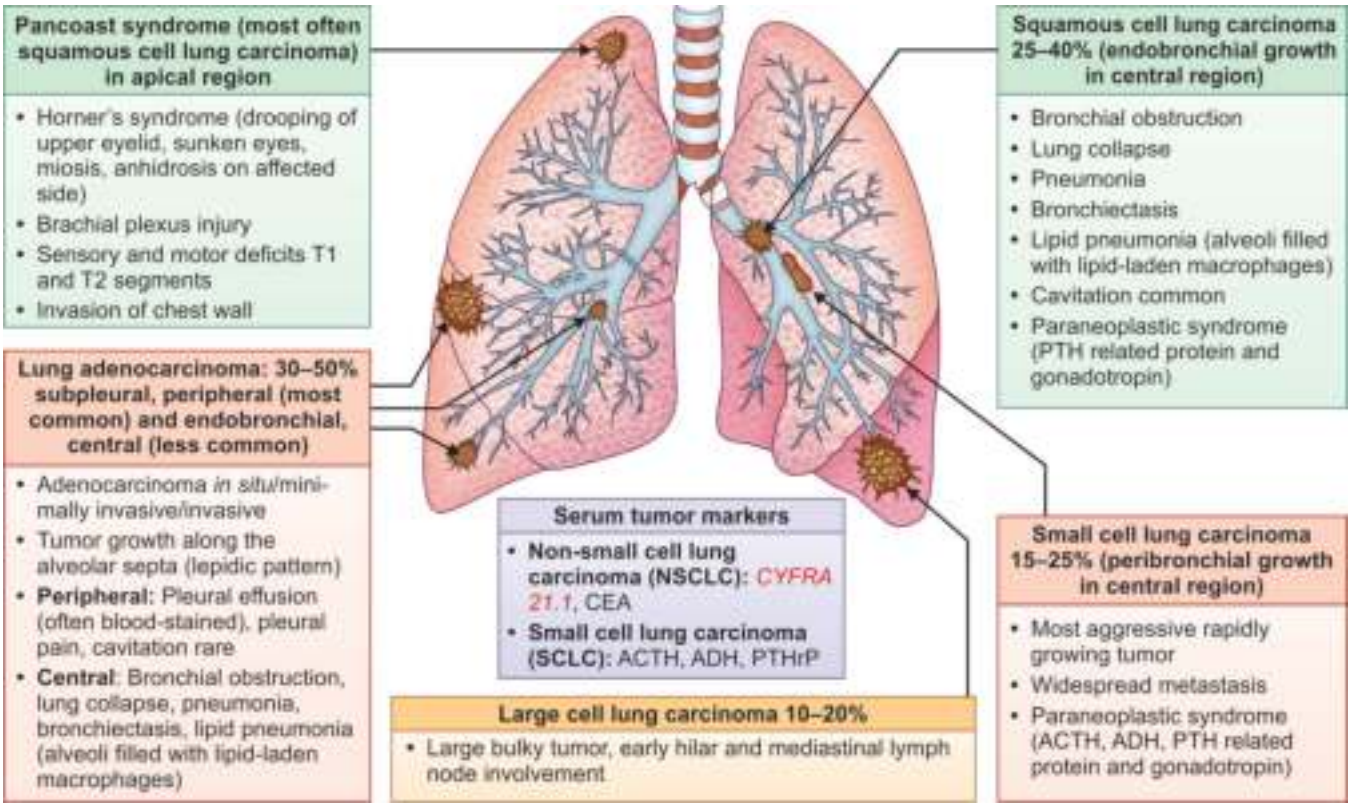

Fig. 18.47: Histologic variants of primary lung cancers. Clinical features of lung cancer depend on site of lesion, invasion of neighboring structures and extent of metastases.

Table 18.42 Occupational exposure to various agents and their risk in development of lung cancers

Occupational Agents	Main Industrial use
Asbestos	Insulation, filters, textiles
Arsenic and arsenic compounds	Glasses, metals, pesticides
Beryllium and beryllium compounds	Aerospace industry
Bis (chloromethyl) ether and chloromethyl methyl ether	Chemical intermediates
Cadmium and cadmium compounds	Dyes/paints
Chromium hexavalent compounds	Pigments (for textile dyes, paints, plastics), metal industry, chrome plating
Coal-indoor emissions from household combustion	Fuel for heating, cooking
Coal tars	Fuel
Coal tar-pitch	Construction, electrodes
Dioxin (2, 3, 7, 8-tetrachlorodibenzo-p-dioxin)	Chemical industry
Engine exhaust, diesel	Fuel
MOPP chemotherapy (a mixture of vincristine, prednisone, nitrogen mustard and procainamide)	Treatment fo Hodgkin disease
Nickel compounds	Metallurgy, alloys, catalyst
Outdoor air pollution	Pollutants in atmosphere
Particulate matter in outdoor air pollution	Particulate matter in atmosphere
Lutonium-239	Nuclear plants
Polycyclic aromatic compounds	Petrochemical industries

Contd...

Table 18.42 Occupational exposure to various agents and their risk in development of lung cancers (*Contd...*)

Occupational Agents	Main Industrial use
Radon-222 and its decay products	Mining
Silica, crystalline	Stone cutting, mining, glass, paper
Soot	Pigments
Sulphur mustard	Chemical warfare
Talc containing asbestiform fibers	Paper, paints
Tobacco smoke, second hand	Exposure to passive tobacco smoke
Tobacco smoking	Exposure to active tobacco smoke
X-rays and γ-radiation	Medical, nuclear

Exposure circumstances include aluminum production, coal gasification, coal-tar pitch, coke production, hematite mining (underground) with exposure to radon, iron and steal founding, painter (occupational exposure) and occupational exposures in the rubber production industry.

which bind to nuclear DNA and exert mutagenic effect. Acidic fraction of tobacco smoke contains tumor promoting benzopyrene compound. Well differentiated squamous cell lung carcinoma, small cell lung carcinoma, large cell lung carcinoma and to some extent lung adenocarcinoma all demonstrate an increased incidence with increasing tobacco smoke inhalation. Approximately 25% of lung cancers in nonsmokers have been attributed to passive tobacco smoke inhalation. Many genetic alterations are caused by tobacco smoking. Major carcinogens of tobacco smoke are given in Table 18.43.

- **Occupational exposure to organ dust:** Occupational exposure to pollutants during metal refining and smelting processes such as arsenic, nickel, iron oxides, chromium, asbestos, beryllium, cadmium, mustard gas, pesticides, and uranium increases the risk of lung cancer in 10% of cases. Asbestos exposure is the best recognized occupational risk factor of lung cancer. Tobacco smoking is synergistic risk factor in asbestos-exposed persons to manyfolds in the development of lung cancers such as lung adenocarcinoma (most common) and squamous cell lung carcinoma. Asbestos fibers act as promoter and cigarette smoke as initiator as well as promoter of carcinogenesis. Incidence of lung cancer is increased in uranium workers. Uranium exposure emits particulate products and radon gas. Patient develops lung cancer after 17 years of exposure to uranium.
- **Exposure to ionizing radiation:** It can cause DNA mutations and chromosomal abnormalities resulting in lung cancer. Japanese are at increased risk for lung cancers, i.e. squamous cell lung carcinoma, lung adenocarcinoma and small cell lung carcinoma after atom bomb explosion in Hiroshima and Nagasaki.
- **Exposure to chemical agents:** Chloromethyl ether is a potent carcinogen that causes small cell lung carcinoma. Combustion of coal and other fossils releases polycyclic aromatic hydrocarbon benzopyrene, which increases risk for lung cancer.
- **Diffuse pulmonary fibrosis:** Diffuse pulmonary fibrosis in tuberculosis has been associated with increased risk of lung cancer.
- **Chronic obstructive pulmonary disease:** Risk for lung cancer increases in chronic bronchitis and diffuse pulmonary fibrosis. Proposed mechanisms of increased risk include decreased clearance of inhaled carcinogens and epithelial metaplasia.
- **Genetic predisposition:** In general, relatives of persons with lung cancer have higher risk for development of lung cancer. Defects in specific oncogenes, specific HLA antigens, and tumor suppressor genes increase the risk for development of lung cancer.

Table 18.43 Major carcinogens of tobacco smoke

Particulate Phase	Vapor Phase
Neutral fraction (e.g. benzpyrene, dibenzanthracene, benzofluoranthene)	Nickel carbonyl
Basic fraction (e.g. nitrosamine)	Hydrazine
Residual fraction (e.g. nickel, cadmium, polonium-210)	▪ Vinyl chloride ▪ Nitrogen oxides ▪ Nitrosodimethylamine

Mutation of TP53 tumor suppressor gene is common in both small cell lung carcinoma (70% of cases) and non-small cell lung carcinoma (30% of cases).

PRECURSOR LUNG LESIONS

The 'term' precursor lesion does not imply that it definitely progresses to lung carcinoma. Four types of epithelial precursor lesions are squamous dysplasia and carcinoma *in situ*, atypical adenomatous hyperplasia, adenocarcinoma *in situ* and diffuse idiopathic pulmonary neuroendocrine cell hyperplasia.

WHO CLASSIFICATION OF LUNG TUMORS

Lung carcinoma is categorized into two main histologic groups: small cell lung carcinomas (SCLCs) and non-small cell lung carcinomas (NSCLCs) constituting 15% and 85% of lung carcinomas respectively. NSCLCs are usually categorized into squamous cell lung carcinoma (25–40%), adenocarcinoma (30–50%) and large cell lung carcinoma (10–20%). Ratio of occurrence SCLCs and NSCLCs is 1 : 4. The 2024 WHO classification of tumors of the lung is given in Table 18.44.

Small Cell Lung Carcinoma

Small cell lung carcinoma (SCLC) is most aggressive tumor having peribronchial growth pattern associated with paraneoplastic syndromes. It usually metastasizes to distant organs before the tumor mass attains large size and resulting in bronchial obstruction and lung collapse. It is usually treated by chemotherapy rather with radiotherapy and surgical resection. SCLC is associated with poor prognosis.

Non-small Cell Lung Carcinoma

Non-small cell lung carcinomas (NSCLCs) (e.g. squamous cell lung carcinoma, lung adenocarcinoma and anaplastic lung carcinoma) invade stroma and surrounding structures. Histopathologic characteristics of NSCLCs are less significant, but pathologic staging is critical for treatment and prognostic outcome. NSCLCs confined to lung are treated by surgical excision. Bronchoalveolar carcinoma and histologic variant of adenocarcinoma characterized by spreading of tumor along the alveolar septa in 'lepidic pattern' without invading stroma and pre-existing structures.

Uncommon Malignant Tumors

Uncommon primary malignant lung tumors include bronchopulmonary carcinoids, mucoepidermoid carcinoma, adenoid cystic carcinoma, angiosarcoma, hemangioendothelioma and lymphomas.

LUNG CARCINOMAS: ORIGIN

Lung carcinomas arise from cells present in the lower respiratory tract, that are capable of cell division, e.g. neuroendocrine cells in bronchoalveolar region (small cell lung carcinoma), basal cells in major bronchi (squamous cell lung carcinoma), mucinous cells in terminal bronchioles (adenocarcinoma) and clara cells (bronchoalveolar carcinoma replaced by adenocarcinoma *in situ*). Cell of origin and histologic variants of lung carcinomas are given in Table 18.45.

Four types of precursor lesions of lung include squamous dysplasia and carcinoma *in situ*, atypical adenomatous hyperplasia and adenocarcinoma *in situ*; and idiopathic neuroendocrine hyperplasia. It is not essential that precursor lesions progress to development of lung carcinoma in all cases.

MOLECULAR CARCINOGENESIS

Lung cancer is the leading cause of cancer-related mortality due to late diagnosis and limited treatment interventions. Malignant tumors of lung are

Table 18.45 Cell of origin and histologic variants of lung carcinomas

Cell of Origin of Lung Carcinoma	Histologic Variants of Lung Carcinoma
Neuroendocrine cells (also known as Kulchitsky cells) in broncho-pulmonary region	Small cell lung carcinoma
Basal cells in major bronchi (lobar or segmental)	Squamous cell lung carcinoma
Mucous cells in terminal bronchioles	Lung adenocarcinoma
Clara cell in terminal bronchoalveolar region	Bronchoalveolar carcinoma, histologic variant of adenocarcinoma

categorized into two main histologic groups: small cell lung carcinomas (SCLCs) and non-small cell lung carcinomas (NSCLCs) constituting 15% and 85% of lung cancers respectively. NSCLCs are usually categorized into squamous cell lung carcinoma (25–40%), lung adenocarcinoma (30–50%) and large cell lung carcinoma (10–20%). Ratio of occurrence of SCLCs and NSCLCs is 1:4. Lung tumors are clinically and genetically distinct; and varying in primary site, invasion, mode of spread and biological behavior. Oncogenes and tumor suppressor gene mutations associated with lung cancers and other cancers (Table 18.46).

- Recently, comprehensive molecular profiles of lung carcinoma and different subtypes at the levels of DNA alterations, DNA methylation, mRNA expression, microRNA expression and protein expression have been identified. These novel characteristics have increased the understanding of the molecular carcinogenesis of lung carcinoma and molecular targeted therapies. Major genetic changes in small cell lung carcinoma, squamous cell lung carcinoma and lung adenocarcinoma are given in Table 18.47. Gene mutations in small cell lung carcinoma, squamous cell lung carcinoma and lung adenocarcinoma are given in Table 18.48.
- In addition to complete molecular profile, an increasing number of tumor-related cytokines, which affect blood vessel formation, tumor growth, invasion and metastasis have been identified. Vascular endothelial growth factor (VEGF), and basic fibroblast growth factor (β-FGF) are among the most important angiogenic factors. Based on available literature, mechanisms of angiogenesis and its prognostic significance in NSCLCs are estimated by microvessel density (MVD) and β-FGF in the tumor from NSCLC patients.

Table 18.46 Oncogenes and tumor suppressor gene mutations associated with lung cancers and other cancers

Category	Proto-oncogenes	Mode of Action	Associated Cancers
Growth factor receptors			
EGFR receptor	ERBB1 (EGFR) Erb-B2 (avian erythroblastosis)	Amplification	*Lung adenocarcinoma*
ALK receptor	ALK	Point mutation	*Lung adenocarcinoma*
Signal-transduction proteins			
GTP-binding proteins	K-RAS	Point mutation	▪ *Lung carcinoma* ▪ Colon carcinoma ▪ Pancreatic carcinoma
Cell cycle progression inhibitors (tumor suppressor gene)			
RB gene (locus 13p14)	RB gene codes for pRB protein inhibiting G1 to S of cell cycle and nuclear transcription factor (mutation by deletion and nonsense)	Familial cancers ▪ Retinoblastoma ▪ Osteosarcoma	Associated sporadic cancers ▪ *Lung carcinoma* ▪ Retinoblastoma and osteosarcoma ▪ Breast carcinoma ▪ Colon carcinoma ▪ Prostatic carcinoma ▪ Urinary bladder carcinoma

Table 18.48 Gene mutations in small cell lung carcinoma, squamous cell lung carcinoma and lung adenocarcinoma

Lung Carcinoma and Genes Involved	Comments
Small cell lung carcinoma	
TP53 tumor suppressor gene	TP53 is located on short arm of chromosome 17(17p13.1). In human, a common polymorphism involves the substitution of an arginine for proline at codon position 72. It is linked with small cell lung carcinoma susceptibility.
RB1 tumor suppressor gene	RB1 gene is located on the long arm of chromosome 13(13q14.1-q14.2). It provides instructions for making a protein called pRB. RB1 gene mutation is linked with SCLC susceptibility
TP73 tumor suppressor gene	TP73 is located on long arm of chromosome 1(1p73). It induces apoptosis of cancer stem cells and may act as a tumor suppressor gene overlapping its functions with TP53. Loss of heterozygosity of TP73 contributes to human SCLC.
NOTCH family of genes	NOTCH signaling plays an essential role in development and homeostasis of multiple organs. Dysregulation of NOTCH signaling has been implicated in various diseases including small cell lung carcinoma.
Gastrin releasing peptide (GRP)	Human small cell lung carcinomas synthesize regulatory gastrin releasing peptide (GRP), that selectively stimulates small cell lung carcinoma clonal growth.
Squamous cell lung carcinoma	
TP53 gene (90%)	TP53 is located on short arm of chromosome 17(17p13.1). In human, a common polymorphism involves the substitution of an arginine for proline at codon position 72. TP53 gene mutation is linked with squamous cell lung carcinoma susceptibility
CDKN2A tumor suppressor gene	▪ Cyclin-dependent kinase inhibitor 2A (CDKN-2A) gene resides on chromosome 9 at the band 9p21 and contains 8 exons. The gene codes for two proteins including the NK4 family member p16 (INK4A) and p14 (ARF) proteins with different amino acid sequences. Both function as tumor suppressors by regulating the cell cycle. ▪ The p16 (INK4A) inhibits cyclin-dependent kinases 4 and 9 (CDK 4 and 9) and thereby activates the retinoblastoma (RB) family of proteins. CDKN-2A gene is the second most commonly inactivated gene in cancer after TP53. ▪ Germline CDKN-2A mutation is also associated with lung carcinoma, familial melanoma, glioblastoma and pancreatic cancer. ▪ The CDKN-2A gene also contains one of 27 SNPs associated with increased risk of coronary artery disease.
PTEN tumor suppressor gene	PTEN gene resides on long arm of chromosome 10q23. It acts as tumor suppressor gene, that codes for phosphatase and tensin homolog protein (PTEN) involved in the regulation of the cell cycle, preventing the cells from growing and dividing too rapidly. Somatic deletions of PTEN gene affect phosphatase domain of the protein and linked to squamous cell lung carcinoma.

Table 18.48 Gene mutations in small cell lung carcinoma, squamous cell lung carcinoma and lung adenocarcinoma (*Contd...*)

Lung Carcinoma and Genes Involved	Comments
PIK3CA gene	PIK3CA (phosphatidylinositol-4,5-bisphosphatase 3-kinase catalytic subunit α) gene is integral part of P13 pathway, that has been described as an oncogene. PIK3CA gene amplification and/or point mutations have been demonstrated in several human cancers.
KEAP1 tumor suppressor gene	KEAP1 gene codes for a protein containing Kelch-like ECH-associated protein 1. Under quiescent conditions, NRF1 is anchored in the cytoplasm through binding to KEAP1. KEAP1 interacts with NRF2, a master regulator of the antioxidant response. KEAP1 is not only a tumor suppressor gene but also a metastasis suppressor gene.
NFE2L2 gene	NFE2L2 (nuclear factor, erythroid 2 like 2) gene encodes a transcription factor which is member of a small family of basic leucine zipper (pZIP) proteins, that binds to antioxidant response (ARE). Recurrent loss of NFE2L2 exon 2 is a mechanism for NRF pathway activation in lung carcinoma and head and neck cancers.
MLL2 gene	MLL2 (myeloid/lymphoid or mixed-lineage leukemia) gene is located on chromosome 11q23 that has partial synteny with chromosome 19q. It encodes a regulator of homeotic gene expression. Mutation of cancer driver MLL2 results in transcription stress and genome stability.
NOTCH1 gene	NOTCH signaling plays an essential role in development and homeostasis of multiple organs. Dysregulation of NOTCH signaling has been implicated in various diseases including small cell lung carcinoma.
RB-1 tumor suppressor gene	RB1 gene is located on the long arm of chromosome 13 (13q14.1-q14.2). It provides instructions for making a protein called pRB. RB1 gene mutation is linked with cancer susceptibility.
SOX2 gene	▪ SOX2 gene resides on 3q26. 3-q27 and codes for transcriptional factor. It is a regulator of foregut development and an embryonic stem cell factor cooperating during induction of pluripotency in a terminally differentiated somatic cells. ▪ SOX2 gene regulates the transcriptional network of oncogenes and affects tumorigenesis of human lung cancer stem cells. ▪ SOX2 amplification and upregulation are frequent events in squamous cell lung carcinomas and are associated with indicators of good prognosis.
TP63 gene	▪ TP63 is a member of the TP53 gene family. In contrast to TP53 gene, TP63 gene is frequently not inactivated. ▪ TP63 gene codes for p63 protein, that regulates differentiation and morphogenesis in epithelial and mesenchymal tissues. ▪ Amplification of TP63 is demonstrated in 25% of squamous cell lung carcinomas.
Vascular endothelial growth factor (VEGF)	VEGF is a tumor-related angiogenic cytokine, that affects vessel formation, tumor growth, invasion and metastasis in NSCLCs.
Basic fibroblast growth factor (β-FGF)	Basic fibroblastic growth factor is a tumor-related angiogenic cytokine, that affects vessel formation, tumor growth, invasion and metastasis in NSCLCs.
Insulin-like growth factors I and II (IGF-1, IGF-II)	Insulin-like growth factors I and II (IGF-1, IGF-II) stimulate the proliferation of a variety of cancer cells including those from lung cancer.
Endothelin 1 (ET-1)	Endothelin, a potent vasoconstrictor enhances proliferation of cancer stem cells in lung carcinoma by increasing intracellular free calcium.
Lung adenocarcinoma	
K-RAS oncogene	▪ Oncogenic K-RAS decouples glucose and glutamine metabolism by enhanced glycolytic activity and increased utilization of glutathione for anabolic synthesis to support cancer cell growth in some non-small cell lung carcinomas (NSCLCs). ▪ Recent studies indicate that patients with mutant K-RAS tumors fail to benefit from adjuvant chemotherapy and associated with short survival.
EGFR	▪ Some non-small cell lung carcinomas (NSCLCs) harbor mutated oncogene in lung carcinoma encodes for epidermal growth factor receptor. ▪ EGFR mutations are highly specific for lung adenocarcinoma especially in cases with lepidic and papillary growth and associated with TTF-1 positivity. ▪ Families with germline mutations of EGFR T790M mutations have high risk for development of lung adenocarcinoma.

Contd...

Table 18.48 Gene mutations in small cell lung carcinoma, squamous cell lung carcinoma and lung adenocarcinoma (*Contd...*)

Lung Carcinoma and Genes Involved	Comments
BRAF gene	Oncogenic BRAF gene codes for BRAF protein serine/threonine kinase, that induces senescence and apoptosis through pathways mediated by the secreted protein IGFBP7. Analysis of BRAF sequence revealed mutations in adenocarcinomas, one in exon 11 (G465V), and a second in exon 15 (L596R)
ALK rearrangement	▪ EML4-ALK fusion accounts for >90% ALK rearrangements in lung adenocarcinomas ▪ Other less commonly ALK fusion partners include KIF5B-ALK, LKC1-ALK and TFG-ALK
MET exon 14 skipping	Recently, MET exon 14 skipping has been identified as a potential driver mutation in lung and colon cancers. Strikingly, NSCLC patients have shown remarkable responses to MET inhibitor (crizotinib or cabozatinib)
ERBB2 kinase (HER2/neu)	Gene codes transmembrane protein tyrosine kinase ERRB2 (also known as HER2/neu). Functional analysis of transmembrane receptor tyrosine kinase mutations in lung adenocarcinoma identifies oncogenic extracellular domain mutations of EBBR2. The patients harboring EBBR2 mutations could benefit from EBBR2 directed therapy
ROS1 fusion gene	Chromosomal rearrangement of the gene encoding ROS1 proto-oncogene receptor tyrosine kinase defines a distinct molecular subgroup of non-small cell lung carcinomas (NSCLCs) that may be susceptible to therapeutic ROS1 kinase inhibition
MAK2K1 gene	Dysregulation of miRNAs-449a contributes to carcinogenesis of the human non-small cell lung carcinoma (NSCLC). The miRNAs-449a suppresses cell invasion by inhibiting NSCLC
RET fusion gene	Rearrangement of RET gene generates fusion transcript, that encodes the tyrosine kinase domain. RET fusion gene is a new targetable driver gene in lung adenocarcinoma. Patients are treated by inhibitors of RET tyrosine kinase
MET gene	MET gene alteration is linked to non-small cell lung carcinoma
NF1 gene	NF1 gene resides on chromosome 17p11 and codes for neurofibronin 1. Reduced NF1 expression confers resistance to EGFR inhibition in lung adenocarcinoma
RIT1 gene	▪ RIT1 is a driver oncogene in a subset of lung carcinomas, that suggests P13K and MEK inhibition as a potent therapeutic strategy in RIT1-mutated tumors ▪ Somatic mutation in the small GTPase gene RIT1 is demonstrated in 2% of lung adenocarcinomas
Vascular endothelial growth factor (VEGF)	VEGF is a tumor-related angiogenic cytokine, that affects vessel formation, tumor growth, invasion and metastasis in NSCLCs
Basic fibroblast growth factor (β-FGF)	Basic fibroblastic growth factor is a tumor-related angiogenic cytokine, that affects vessel formation, tumor growth, invasion and metastasis in NSCLCs
Epidermal growth factor receptor (EGFR)	▪ Recently, it has been reported that mutations in the tyrosine kinase domain of the epidermal growth factor receptor (EGFR) gene occur in a subset of patients with NSCLC especially in well to moderately differentiated adenocarcinoma ▪ Approximately 10% of patients with adenocarcinoma have a rapid response to the tyrosine kinase inhibitor gefitinib, which targets the epidermal growth factor receptor (EGFR)
Insulin-like growth factors I and II (IGF-1, IGF-II)	Insulin-like growth factors I and II (IGF-1, IGF-II) stimulate the proliferation of a variety of cancer cells including those from lung cancer
Endothelin 1 (ET-1)	Endothelin 1, a potent vasoconstrictor enhances proliferation of neoplastic cells in lung carcinoma by increasing intracellular free calcium

- Recently, it has been reported that mutations in receptor tyrosine kinase (RTK) domain of the epidermal growth factor receptor (EGFR) gene occur in a subset of patients with NSCLC especially in well-to-moderately differentiated adenocarcinoma. Approximately 10% of patients with lung adenocarcinoma have a rapid response to receptor tyrosine kinase inhibitor gefitinib, which targets the EGFR. Insulin-like growth factors I and II (IGF-I, IGF-II) stimulate the proliferation of cancer stem cells leading to lung cancer growth. Endothelin 1, a potent vasoconstrictor enhances proliferation of cancer stem cells in lung carcinoma by increasing intracellular free calcium. Human small cell lung carcinomas synthesize regulatory gastrin releasing peptide (GRP), that selectively stimulates small cell lung carcinoma clonal growth. Growth factors involved in pulmonary carcinogenesis are given in Table 18.49. Molecular pathogenesis of bronchial carcinoma is shown in Fig. 18.48.

Table 18.49 Growth factors involved in pulmonary carcinogenesis

Epidermal growth factor receptor (EGFR)
Basic transforming growth factor (β-TGF)
Vascular endothelium growth factor (VEGF)
Gastrin-releasing peptide (GRP)
Transferrin
Insulin-like growth factor
Endothelin 1

Small Cell Lung Carcinoma

Small cell lung carcinoma is characterized by highly complex genomic alterations such as biallelic inactivation of TP53 and RB1 tumor suppressor genes. Other tumor suppressor gene alterations have been observed in TP73 as a result of rearrangement of TP73. In small cell lung carcinoma, inactivating mutations of NOTCH family of genes have also been demonstrated; that suppress neuroendocrine differentiation via regulation of ASCL1 expression in 25% of cases.

- **Messenger RNA profiling:** Based on messenger RNA (mRNA) profiling, small cell lung carcinomas are divided into two groups: Group 2 and group 1. Group 2 is characterized by higher expressions of CHGA, GRP, ASCL1, and DLK1 genes. Group 1 shows lower expressions of CHGA, GRP, ASCL1, and DLK1 genes.
- **MicroRNAs and SCLC:** Small cell lung carcinoma is a neuroendocrine tumor. It demonstrates ASCL1 transcription factor that promotes neuroendocrine differentiation. ASCL1 also promotes miR-375 in small cell lung carcinoma. The miR-375 may reduce the YAP1-associated proliferative arrest by inhibiting YAP1. Serum miR-92a-2 analysis is a potential non-invasive method for SCLC diagnosis. High expression of miR-34a may be associated with atypical carcinoids.

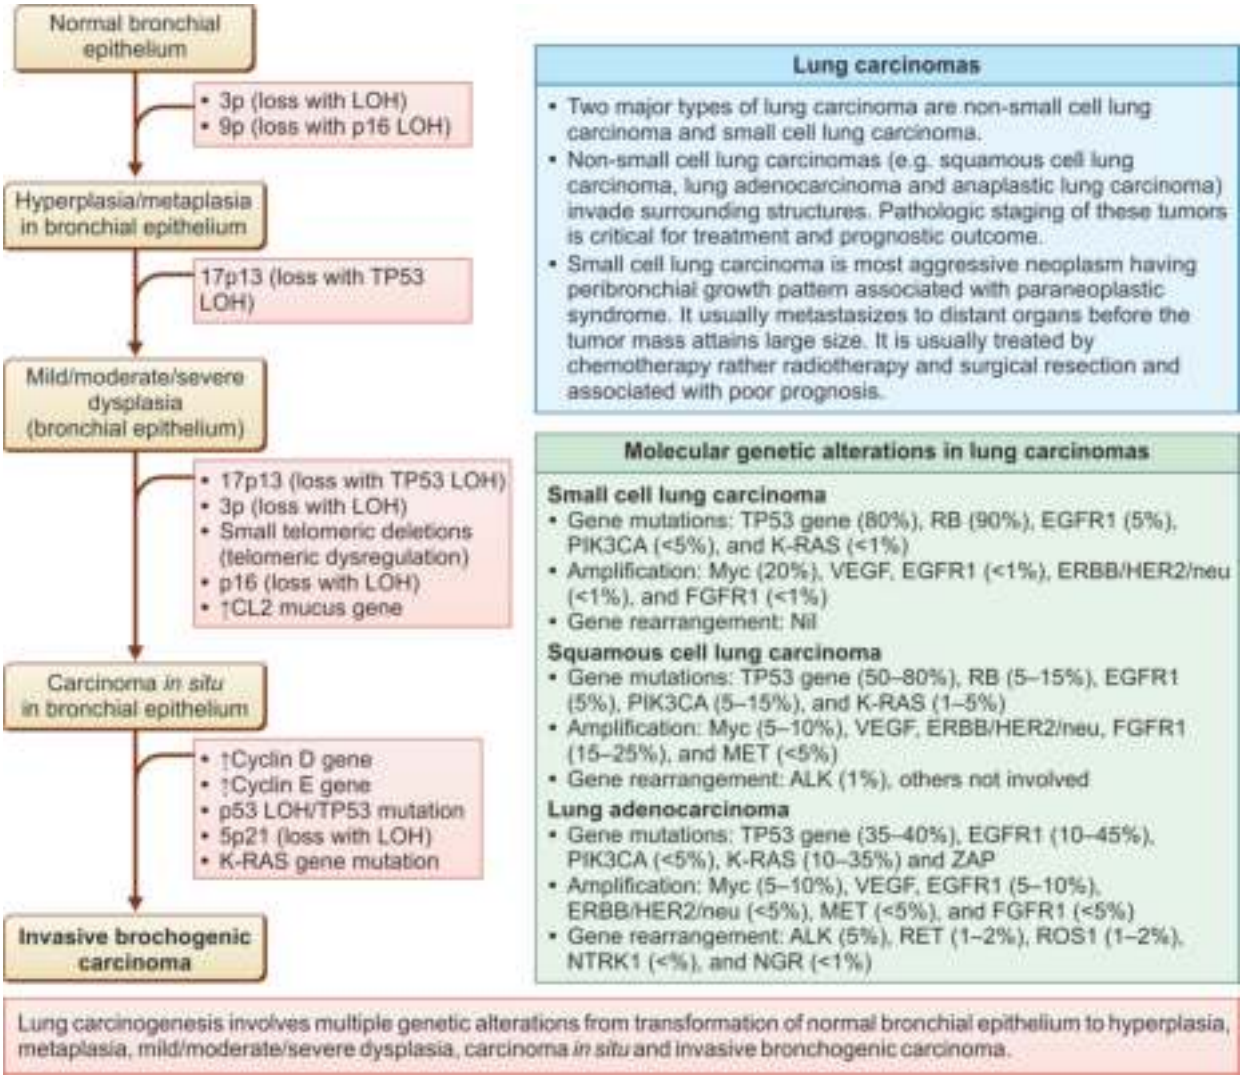

Fig. 18.48: Molecular pathogenesis of bronchogenic carcinoma.

Squamous Cell Lung Carcinoma

In the 2024 WHO classification of lung tumors, squamous cell lung carcinomas are classified into keratinizing, non-keratinizing and basaloid variants. However, basaloid squamous cell lung carcinoma immunohistochemically demonstrates positivity for p40, CK5, CK6, and p53, hence categorized under squamous cell lung carcinoma.

- **Gene mutations and affected signaling pathways:** The complete molecular profiling of squamous cell lung carcinoma has demonstrated statistically significant genomic alterations: TP53, CDKN2A, PTEN, PIK3CA, KEAP1, NFE2L2, MLL2, HLA-1, NOTCH1, RB1, and PDYN (promoter of the human prodynorphin gene).
- **TP53 gene mutation:** It has been demonstrated in 90% of squamous cell lung carcinomas. Oxidative damage causes mutations of KEAP1 and NFE2L2 in 35% of cases. Squamous cell differentiation pathway including overexpression of SOX2 and TP63; and P13K/AKT pathway occur in 45% of cases. CDKN2A gene mutation is demonstrated in 70% of cases.
- **Messenger RNA (mRNA) profiling:** Based on the messenger RNA profiling, squamous cell lung carcinomas have been divided into four subtypes: classical, basal, secretory and primitive subtypes. Classical subtype of squamous cell lung carcinoma demonstrates hypermethylation, chromosomal instability and genetic alterations of PTEN, KEAP1 and NFE2L2. The basal subtype of squamous cell lung carcinoma shows NF1 gene alterations. The primitive subtype of squamous cell lung carcinoma demonstrates RB1 and PTEN gene alterations.
- **MicroRNA profiling:** Based on the microRNA (miRNA) profiling, squamous cell lung carcinomas have been categorized into four subtypes. DNA methylation profiling also divided squamous cell lung carcinoma into four subtypes (methylation cluster 1–4). Methylation cluster 4 demonstrates little DNA hypermethylation and includes most of the primitive mRNA subtype. Cluster 3 is predominantly composed of the classical mRNA subtype and enriched for NFE2L2 mutations. Clutter 3 and cluster 2 demonstrate the highest levels of DNA. Cluster 1 demonstrates intermediate DNA hypermethylation levels.

Lung Adenocarcinoma

Significant molecular genetic alterations in lung adenocarcinoma reported in the recently published literature include TP53, K-RAS, KEAP1, STK11, EGFR, NF1, BRAF, SETD2, RBM10. MGA, MET, ARID1A, PIK3, SMARCA4, RB1, CDKN2A, U2AF1 and RIT1, in decreasing frequency. Characteristics of ALK gene fusions and EGFR mutations in lung adenocarcinoma are given in Tables 18.50 and 18.51. RAS family of genes associated lung adenocarcinoma is given in Table 18.52.

- **RTK/RAS/RAF aberrant signaling pathway:** About 75% of the lung adenocarcinomas harboring genetic alterations promote RTK/RAS/RAF signaling pathway include K-RAS, EGFR, BRAF. Other genetic alterations that promote RTK/RAS/RAF signaling

Table 18.50 Characteristics of ALK gene fusions in lung adenocarcinoma

Although ALK fusions are common in anaplastic large cell lymphoma and inflammatory myoblastic tumor, yet the specific EML4-ALK fusion is almost demonstrated in lung adenocarcinomas
ALK rearrangement is strongly associated with lung adenocarcinoma histology, in particular with acinar and/or solid growth pattern, or cellular features of signet cell carcinoma
EML4-ALK fusion accounts for >90% ALK rearrangements in lung adenocarcinomas. Other less commonly ALK fusion partners include KIF5B-ALK, LKC1-ALK and TFG-ALK
ALK rearrangement is frequent in lung adenocarcinoma in non-smokers, but less associated with female sex
ALK positive lung adenocarcinoma constitutes 4–5% on NSCLCs and ethnic differences have not been reported, unlike EGFR mutations
ALK rearrangement in lung adenocarcinoma is predictive of response to ALK inhibitor, but it is not a prognostic factor

Table 18.51 Characteristics of EGFR mutations in lung adenocarcinoma

EGFR mutations occur in the receptor tyrosine kinase domain and lead to constitutive activation of downstream signaling without ligand
Two most common EGFR mutations: Point mutation at codon 858 (L858) and the in-frame deletions in exon-19 accounts for >90% of cases, although other mutations at codon G719 and in-frame insertions in exon 20 in lung adenocarcinoma
EGFR mutations are highly specific for lung adenocarcinoma especially in cases with lepidic and papillary growth and associated with TTF-1 positivity
Families with germline mutations of EGFR T790M mutations have high risk for development of lung adenocarcinoma
EGFR mutations in lung adenocarcinoma demonstrate ethinin differences with prevalence ranges of 10–15% in Caucasians and 30–40% in Asians
Patients with EGFR mutations are treated by EGFR tyrosine kinase inhibitor treatment
Mutations in EGFR exon 20, in-frame insertions and rarely EGFR T790M mutations in lung adenocarcinoma are associated with primary resistance to EGFR tyrosine kinase inhibitors. Acquisition of an additional TT/790M mutation is the most common cause of secondary resistance to EGHR tyrosine kinase inhibitor

Table 18.52 RAS family of genes associated with lung adenocarcinoma

RAS gene family is a part of the RAS superfamily including RAS (K-RAS, H-RAS, N-RAS), RAL, RAC, RHO, RAP and RAB gene families. RAS gene mutation is linked to lung adenocarcinoma
K-RAS (Kirsten rat sarcoma 2 viral) oncogene resides on 12p12.1. The oncogene encodes a small GTPase transducer protein called K-RAS protein, that acts as an on/off switch in cell signaling. When K-RAS gene mutated, aberrant p21 proteins produced by mutated gene have the potential to transform normal cells to cancer stem cells and increased resistance to chemotherapy and biological therapies targeting EGFR in lung adenocarcinoma
RAS gene mutations have been demonstrated in 20–25% of human cancers. Frequency of K-RAS mutations in various cancers include pancreas (80–90%), colon and rectum (25–60%), lung (25–60%), prostate (0–25%), skin (0–25%), thyroid (0–60%), liver (50%), ovary (0–50%), endometrium (10–40%), kidney (0–15%), brain (0–15%), seminoma testis (10–45%), acute nonlymphocytic leukemia and myelodysplasia (5–15%), urinary bladder (5%), head and neck (10%); and breast (10%)

pathway include MET exon 14 splice skipping, ERBB2 (HER2/neu), ROS fusion, MAK2K1 mutation, RET fusion, N-RAS and H-RAS mutations. Analysis of the DNA copy number without driver genetic alterations promotes RTK/RAS/RAF signaling pathway include amplification of ERBB2 and MET. Other genetic alterations that activate RTK/RAS/RAF signaling pathway include NF1 and RIT1 mutations.

- **EGFR mutation:** EGFR mutation is one of the common driver mutations in lung adenocarcinoma. Pathologically, EGFR-mutated lung adenocarcinoma typically demonstrates nuclear TTF-1 (NKX21) immunostaining. Lung adenocarcinoma with a micropapillary pattern demonstrates high frequency of EGFR mutations than adenocarcinoma without micropapillary pattern. Fusion genes have been recently identified as oncogene driver genes. Lung adenocarcinoma demonstrates rearranged genes such as ALK, ROS1, RET, NTRK1 and NRG1. Lung adenocarcinomas with these rearranged genes show a good clinical response to molecular-targeted therapeutic drugs.
- **ALK (anaplastic lymphoma kinase) rearrangement:** It is characterized by a TTF-1 cell lineage, an acinar structure with mucin/signet-ring pattern without or light tobacco smoking affecting young persons. Adenocarcinomas with rearranged ROS1 and RET genes have similar morphologic features demonstrated in ALK-rearranged adenocarcinoma such as mucinous cribriform pattern or solid signet-ring cell pattern.
- **NTRK1 rearrangement:** It responds to molecular TRKA kinase inhibitors. Five oncogenic fusions demonstrated in lung adenocarcinoma include CD74-NRG1, SLC3A2-NRG1, EZR-ERBB4, TRIM24-BRAF, and KIAA1468-RET. These are potential molecular targets in clinical practice.
- **K-RAS mutation:** It is usually demonstrated in lung adenocarcinomas in tobacco smokers. On the other hand, EGFR, ALK, ROS1 and RET are frequently demonstrated in non-tobacco smokers. Asians have high frequency of EGFR mutations in 50% cases of lung adenocarcinoma and low frequency of K-RAS mutations.

LUNG CARCINOMAS: LOCATION

- **Central region:** Squamous cell lung carcinoma and small cell lung carcinoma are centrally located. Squamous cell lung carcinoma shows endobronchial growth. Small cell lung carcinoma shows peribronchial growth.
- **Peripheral region:** Lung adenocarcinoma, bronchioloalveolar carcinoma and large cell lung carcinoma are located in peripheral region.
- **Central or peripheral region:** Some patients with lung adenocarcinoma may develop tumor in the central portion of lung that grows as endobronchial growth invading bronchial cartilage. Local and systemic manifestations of lung carcinoma are given in Table 18.53.

Table 18.53 Underlying cause and clinicopathological features of lung carcinoma

Clinicopathological Features	Underlying Cause and Mechanism
Pulmonary involvement by lung carcinoma	
Cough (75%)	Infection distal to airway blocked by lung carcinoma
Hemoptysis (<50%)	Ulceration of squamous cell lung carcinoma
Chest pain (40%)	Involvement of pleura or chest wall by lung carcinoma
Wheeze (15%)	Narrowing of airways by lung carcinoma
Systemic features (anorexia, loss of weight, malaise, fever)	General systemic manifestations in lung carcinoma

Contd...

Table 18.53 Underlying cause and clinicopathological features of lung carcinoma (*Contd...*)

Clinicopathological Features	Underlying Cause and Mechanism
Obstructive pneumonia (with or without cavitation)	Obstruction of respiratory tract by lung carcinoma
Pleural effusion	Involvement of pleura by lung carcinoma
Paraneoplastic syndrome	Synthesis of hormones by primary lung carcinoma
Extension of lung cancer to mediastinal structures	
Hoarseness of voice	Direct invasion of recurrent laryngeal nerve hooking below arch of aorta especially by squamous cell lung carcinoma
Paralysis of diaphragm and dyspnea	Invasion of phrenic nerve by lung carcinoma
Horner's syndrome	Direct invasion of cervical sympathetic ganglion by lung carcinoma and characterized by ptosis, sunken eyes, miosis and loss of sweating on the affected side
Brachial plexopathy	Direct invasion of brachial plexus by lung carcinoma arising in superior sulcus
Superior vena cava syndrome	Compression/obstruction of superior vena cava by lung carcinoma
Pain in T1 dermatome and wasting of intrinsic hand muscles	Direct invasion of brachial plexus by apical pancoast lung carcinoma
Pericarditis/pericardial hemorrhagic effusion	Direct invasion in pericardium by lung carcinoma may result in cardiac tamponade
Pleural effusion	Direct invasion in pleura by lung carcinoma
Rib destruction	Direct invasion and destruction of rib by lung carcinoma
Dysphagia	Compression of esophagus by lung carcinoma
Pneumonia, lung abscess, lung collapse	Obstruction of airways by lung carcinoma
Lipid pneumonia	Accumulation of cellular lipid in foamy macrophages due to airway obstruction by lung carcinoma
Metastatic spread of lung carcinoma	
Pathologic fracture	Lung carcinoma metastasis to bone
Hepatomegaly and/or jaundice	Lung carcinoma metastasis to liver
Central nervous system symptoms	Lung carcinoma metastasis to brain
Non-metastatic extrapulmonary syndromes	
Endocrinal manifestations	
Hyponatremia, high osmolality in serum and urine, confusion, weakness and seizures	Inappropriate antidiuretic hormone synthesis by small cell lung carcinoma
Hypercalcemia	Parathormone-like peptide synthesis by squamous cell lung carcinoma
Atypical Cushing syndrome	Adrenocorticotropic hormone (ACTH) synthesis by small cell lung carcinoma
Gynecomastia and testicular atrophy	Gonadotropin-like peptide synthesis by squamous cell lung carcinoma, small cell lung carcinoma, lung adenocarcinoma and large cell lung carcinoma
Skin pigmentation	Melanocyte-stimulating hormone synthesis by lung carcinoma
Carcinoid syndrome	Serotonin synthesis by lung carcinoma
Serum growth hormone level high	Growth hormone synthesis by lung carcinoma
Serum prolactin level high	Prolactin hormone synthesis by metastatic non-small cell lung carcinoma
Diarrhea	Vasoactive intestinal polypeptide by lung carcinoma

Contd...

Table 18.53 Underlying cause and clinicopathological features of lung carcinoma (*Contd...*)

Clinicopathological Features	Underlying Cause and Mechanism
Neurological syndromes	
Eaton-Lambert syndrome (weakness of pelvic girdles, proximal limbs and trunk)	Production of IgG autoantibodies against calcium channels in motor nerve terminals resulting in non-release of acetylcholine in small cell lung carcinoma
Peripheral neuropathy (motor, sensory or mixed)	Production of IgG autoantibodies against anterior and lateral horns of spinal cord in small cell lung carcinoma
Gastrointestinal tract and urinary bladder disturbances; and postural hypotension	Invasion of autonomic nervous system by lung carcinoma
Cerebral degeneration (ataxia, vertigo and dysarthria, i.e. difficulty in speech)	Production of IgG autoantibodies synthesis against cerebellum in small cell lung carcinoma
Weakness of proximal region of body associated with pain tenderness, purple facial rash, arthralgia, dysphagia and Raynaud phenomenon	Polymyositis and dermatomyositis occur in lung carcinoma
Flaccid paraparesis (partial paralysis of lower limbs) associated with sensory loss and sphincters malfunction	Acute transverse myelopathy occurs in lung carcinoma
Hypertrophic osteoarthropathy	
Hypertrophic osteoarthropathy (clubbing of fingers, swelling of wrists and ankles with periosteal new bone formation)	Hypertrophic osteoarthropathy occurs in 2–3% of squamous cell lung carcinoma and lung adenocarcinoma
Skin manifestations	
Acanthosis nigricans, dermatomyositis and tylosis (marked hyperkeratosis of palms and soles)	Skin manifestations in lung carcinoma (unknown mechanism)
Hematological/coagulation and vascular manifestations	
Disseminated intravascular coagulation (DIC)	Thrombotic occlusion and ischemia in non-small cell lung carcinoma
Thrombophlebitis migrans (migratory thrombophlebitis with tender clot beneath skin)	Inflammation, pain, redness and swelling in lung carcinoma
Nonbacterial thrombotic endocarditis	Nonbacterial thrombotic endocarditis in lung carcinoma
Venous thromboembolism	Venous thromboembolism phenomenon in lung carcinoma
Anemia, dysproteinemia, granulocytosis, eosinophilia, leukoerythroblastosis, bone marrow plasmacytosis and thrombocytopenia	Hematological abnormalities in patient with lung carcinoma
Miscellaneous (very rare) manifestations	
Henoch-Schönlein purpura, glomerulonephritis (nephrotic syndrome), systemic lupus erythematosus, lactic acidosis, hyperuricemia, amyloidosis	Miscellaneous manifestations rarely occur in patient with lung carcinoma

IMAGING TECHNIQUES

- Primary lung carcinomas are poorly circumscribed, solitary undergoing cavitation and dystrophic calcification.
- Tumors metastasizing to lung are sharply circumscribed and multiple. These usually lack cavitation and dystrophic calcification. Presence of calcification in the tumor indicates metastases from osteosarcoma and chondrosarcoma.

THERAPEUTIC RESPONSE

Small cell lung carcinoma (SCLC) initially responds to chemotherapy. Non-small cell lung carcinoma (NSCLC) confined to lung is curable by surgery. Small cell lung carcinoma is most often metastatic than non-small cell lung carcinoma.

PARANEOPLASTIC SYNDROME

Paraneoplastic syndromes occur in small cell lung carcinoma, squamous cell lung carcinoma, lung adenocarcinoma and large cell lung carcinoma. Paraneoplastic syndromes in lung carcinoma are given in Table 18.54.

Neuromuscular Manifestations

Nonmetastatic neuromuscular abnormalities associated with lung carcinoma are given in Table 18.55.

Intrathoracic Manifestations

Intrathoracic manifestations of bronchial carcinoma are given in Table 18.56.

Table 18.54 Paraneoplastic syndromes in lung carcinoma

System	Clinical Manifestations
Neuroendocrine manifestations	
General symptoms	Weight loss, fever and anorexia
Skin manifestations	Acanthosis nigricans, dermatomyositis, tylosis (marked hyperkeratosis of palms and soles)
Vascular manifestations	Thrombophlebitis migrans, noninfective thrombotic endocarditis, disseminated intravascular coagulation
Skeletal system	Hypertrophic osteodystrophy, clubbing of fingers
Nervous system	Myasthenia-like syndrome, peripheral neuropathies, cerebellar degeneration, myositis, and encephalopathy
Endocrine manifestations	
ACTH-like synthesis in small cell lung carcinoma	Atypical Cushing's syndrome (facial edema, cachexia, low serum potassium and alkalosis)
ADH-like synthesis in small cell lung carcinoma	Inappropriate secretion of antidiuretic syndrome (high urine osmolality and low serum sodium, confusion, weakness and seizures (if extreme)
Parathormone-like effects in squamous cell lung carcinoma	Serum calcium high, weakness, polyuria, polydipsia, constipation, abdominal pain and coma (if extreme)
Gonadotropin-like effects due to estrogens in squamous cell lung carcinoma, adenocarcinoma, small cell lung carcinoma and large cell lung carcinoma	Gynecomastia and testicular atrophy

Endocrine and neuroendocrine products of lung cancers: These include ACTH, calcitonin, parathormone-related peptide, melanocyte-stimulating hormone, growth hormone, chorionic gonadotropin, insulin, gastrin, renin, glucagon, estradiol, erythropoietin, histaminase, DOPA-decarboxylase, carcinoembryonic antigen, α-fetoprotein, bombesin and neuron-specific enolase.

Table 18.55 Nonmetastatic neuromuscular abnormalities associated with lung carcinoma

Neuromuscular Abnormalities	Clinical Manifestations
Peripheral neuropathy (motor, sensory or mixed)	Muscle weakness, muscle wasting, loss of tendon reflexes, glove and stocking type of loss of sensation
Autonomic neuropathy	Gastrointestinal and urinary bladder disturbances, and or postural hypotension
Cerebellar ataxia	Nystagmus, dysarthria, impaired coordination
Eaton-Lambert syndrome	Differs from myasthenia gravis in muscle function with improvement due to repeated effort monitored by electromyography
Polymyositis–dermatomyositis	Weakness of proximal region with pain and tenderness, purple facial rash, arthralgia, dysphagia and Raynaud's phenomenon
Acute transverse myelopathy	Flaccid paraparesis with sensory loss, sphincter functional loss

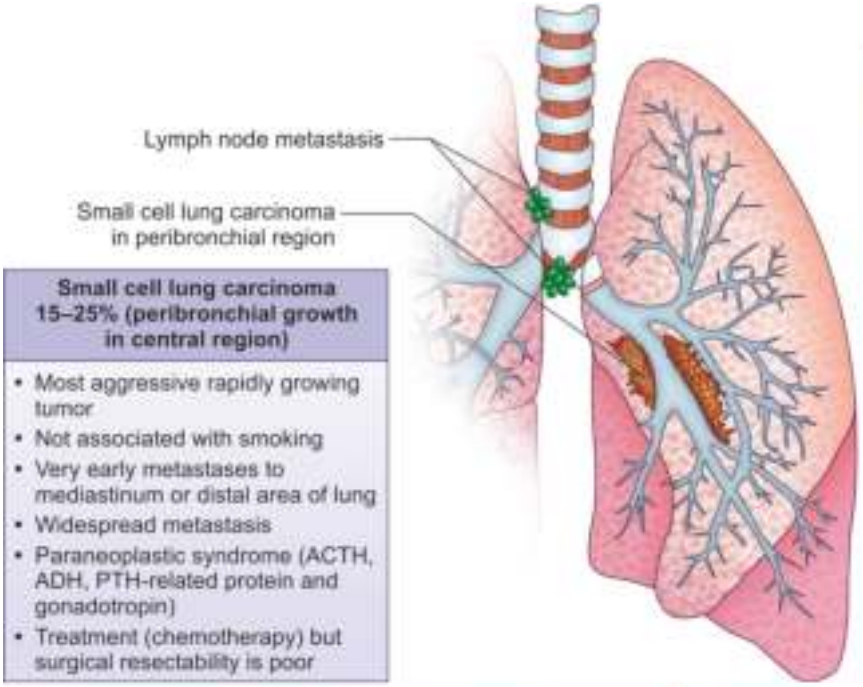
Table 18.56 Intrathoracic manifestations of bronchial carcinoma

Location	Clinical Manifestations	
Apical region	▪ Pancoast syndrome ▪ Horner's syndrome	▪ Sensory and motor deficits of T1 and T2 segments
Peripheral region	Pleural effusion (often blood stained), pleural pain	
Central region	▪ Bronchial obstruction ▪ Lung collapse ▪ Pneumonia	▪ Bronchiectasis ▪ Lipid pneumonia (alveoli filled with lipid-laden macrophages)

PRIMARY LUNG CARCINOMAS

SMALL CELL LUNG CARCINOMA

Small cell lung carcinoma (previously referred to as oat cell carcinoma) is rapidly growing highly malignant epithelial tumor of lung that exhibits neuroendocrine features. It constitutes 15–25% of lung cancers.



- Small cell lung carcinoma (SCLC) is strongly associated with cigarette smoking. It is more common in men than women. It is commonly associated with paraneoplastic syndrome.
- Patient develops SCLC in hilar or parahilar region. Extensive peribronchial growth causes bronchial narrowing. Lymph node metastasis is demonstrated in >90% of cases at diagnosis.
- Tumor causes extensive peribronchial invasion in the hilar or parahilar region.
- Bronchial narrowing, marked mediastinal lymphadenopathy and early widespread metastases are demonstrated in >90% of cases at diagnosis. It is a common cause of superior vena cava syndrome. Prognosis of SCLC is very poor.
- The tumor is responsive to chemotherapy. The median survival is measured in months. Small cell lung carcinoma shows risk factors, gene mutations, clinical manifestations, immunohistochemistry and metastases (Fig. 18.49).
- Desmoplastic small round cell tumor is a rare variant of small cell lung carcinoma. Patient presents with a solitary mass arising from pulmonary parenchyma. It is indolent neoplasm associated with good prognosis. The tumor cells are positive for cytokeratin (AE1/AE3) and desmin.

SCLC: Origin

Small cell lung carcinoma arises from neuroendocrine argentaffin cells (Kulchitsky cells) near central portion of chest. It accounts for 20% of all lung cancers.

Molecular Genetic Alterations

Small cell lung carcinoma exhibits mutations of both c-Myc oncogene and tumor suppressor gene, i.e. RB gene (80–100%), p53 gene (50–80%) and 3p deletion. There is increased expression of anti-apoptotic BCL-2 gene in 90% of cases. There is low expression of pro-apoptotic BAX gene in small cell lung carcinoma.

Small cell lung carcinoma 15–25% (peribronchial growth in central region)

- Most aggressive rapidly growing tumor
- Not associated with smoking
- Very early metastases to mediastinum or distal area of lung
- Widespread metastasis
- Paraneoplastic syndrome (ACTH, ADH, PTH-related protein and gonadotropin)
- Treatment (chemotherapy) but surgical resectability is poor

Paraneoplastic syndrome in small cell lung carcinoma

- **Lambert-Eaton myasthenic syndrome:** IgG autoantibodies against calcium channel in motor nerve terminals, weakness of pelvic girdles, proximal limbs and trunk (acetylcholine not released)
- **Peripheral neuropathy:** IgG autoantibodies against anterior and lateral horns of CNS
- **Cerebellar degeneration:** IgG autoantibodies against cerebellum leading to ataxia, vertigo and dysarthria
- **Corticotropic-like effects:** Facial edema, decreased serum potassium and alkalosis
- **ADH-like effects:** Increased urine osmolality, low serum potassium and weakness
- **Parathormone-like effects:** Increased serum calcium
- **Gonadotropic-like effects:** Gynecomastia and testicular atrophy

Gene mutations in small cell lung carcinoma

Oncogene	c-Myc oncogene
Tumor suppressor gene	RB gene (80–100%)
	p53 gene (50–80%)
Anti-apoptotic gene	BCL-2 gene (90%)

Immunohistochemistry of small cell lung carcinoma

Markers	Expression
Chromogranin	Positive
Synaptophysin	Positive
Leu7 (CD57)	Positive
Nonspecific esterase (specific marker)	Positive
CD56	Positive

Fig. 18.49: Small cell lung carcinoma shows risk factors, gene mutations, clinical manifestations, immunohistochemistry and metastases.

Small Cell Lung Carcinoma: Paraneoplastic Syndrome

Paraneoplastic syndrome most often occurs in small cell lung carcinoma (SCLC). The tumor synthesizes polypeptide hormones such as ACTH, ADH, parathormone-like peptide, gonadotropins, insulin-like growth factor and calcitonin.

- **Eaton-Lambert syndrome:** It is characterized by muscular weakness of pelvic girdles, skeletal muscle wasting, and fatigability of the proximal limbs and trunk. It is usually associated with small cell lung carcinoma in 65% of cases. Under physiologic state, calcium channels are necessary for release of acetylcholine. The pathogenic IgG autoantibodies are formed against voltage-sensitive calcium channels in motor nerve terminals. The calcium channels are greatly reduced in the presynaptic membrane in these patients, thereby interfering with neuromuscular transmission.
- **Peripheral neuropathy:** IgG autoantibodies against anterior and lateral horns of central nervous system cause motor and sensory loss resulting in peripheral neuropathy.
- **Cerebellar degeneration:** Autoantibodies cause subacute cerebellar degeneration, which presents with severe ataxia, vertigo and dysarthria.
- **Corticotropic effects:** ACTH synthesized by SCLC stimulates adrenal gland to produce corticosteroid hormones. Patient presents with atypical Cushing's syndrome, facial edema and cachexia. Serum calcium is decreased.
- **ADH effects:** Small cell lung carcinoma synthesizes ADH, which acts on renal collecting ducts and produces high urine osmolarity and low serum osmolarity resulting in decreased serum sodium level. Patient becomes irritable and develops convulsions and seizures.
- **PTH-related protein:** SCLC ectopically secretes PTH-related protein resulting in hypercalcemia. Patient presents with constipation, abdominal pain, polyuria and polydipsia.
- **Gonadotropic substances:** Small cell lung carcinoma ectopically synthesizes estrogens which cause development of gynecomastia and testicular atrophy.

Surgical Pathology: Small Cell Lung Carcinoma

Gross Morphology

Tumor is lobulated and soft in consistency. Cut surface of this tumor has a white to tan appearance (Fig. 18.50).

Light Microscopy

- **Tumor cell morphology:** Tumor is composed of small anaplastic oval to spindle cells with scanty cytoplasm and ill-defined borders, nuclear moulding and inconspicuous nuclei. Nuclear chromatin is finely granular exhibiting salt and pepper pattern. It shows 6–7 mitoses per high power fields.
- **Tumor cells arrangement:** Tumor cells are arranged in sheets, cords, or small aggregates that exhibit neither squamous nor glandular differentiation.
- **Tumor necrosis:** Extensive necrosis is often seen in small cell lung carcinoma.
- **Azzopardi effect of tumor:** It refers to the presence of cellular DNA in necrotic venules in small cell lung carcinoma. Necosis of venules results in release of cellular DNA, which adheres in patches in the walls of venules showing an intensely basophilic material on hematoxylin and eosin stain (Fig. 18.51A to C). Comparison of small cell lung carcinoma and large cell lung carcinoma is given in Table 18.57.

Immunohistochemistry Technique

Panel of immunomarkers is used to analyze expression in small cell lung carcinoma on histologic sections. These include chromogranin, synaptophysin, CD56, CD57 (HNK-1/Leu-7), neuron-specific enolase, cytokeratins (AE1/AE3) and TTF-1.

Markers	Expression
Chromogranin	Positive
Synaptophysin	Positive
CD56	Positive
CD57 (HNK-1/Leu-7)	Positive
Neuron-specific enolase (NSE)	Positive
Cytokeratins (AE1/AE3)	Positive
TTF-1	Positive

Electron Microscopy

- Dense-core neurosecretory granules (100 nm) are present in tumor cells in 66% of SCLC cases. The granules are similar to those found in the neuroendocrine Kulchitsky cells scattered along the bronchial epithelium particularly in fetus and neonates. These neurosecretory granules synthesize ectopic polypeptide hormones.
- Low-grade neuroendocrine tumor, e.g. typical carcinoid tumor has prominent neurosecretory dense-core granules on electron microscopy.
- High-grade neuroendocrine tumor, e.g. small cell lung carcinoma has fewer dense-core granules on electron microscopy.

Mode of Spread

- **Direct spread:** SCLC appears as a perihilar mass that spreads along the bronchi in the circumferential manner. Hence, it does not obstruct the bronchus lumen. On reaching a large size, it may cause bronchial obstruction and lung collapse.
- **Lymphatic route:** SCLC spreads to hilar tracheobronchial lymph nodes with extension to mediastinal lymph nodes in >50% of cases. It may also involve cervical lymph nodes.
- **Hematogenous spread:** Approximately 66% of SCLC cases have metastasized to extranodal location at time of diagnosis. It metastasizes to adrenal gland, liver, brain, bone, spinal cord, kidneys, and pancreas. Adrenal gland involvement is usually asymptomatic (Table 18.58).

Fig. 18.50: Small cell lung carcinoma. This most aggressive tumor arises centrally, spreads extensively along the bronchi. It often metastasizes widely before the primary tumor mass in the lung reaches a large size leading to bronchial obstruction and lung collapse. The cut surface of this tumor has a soft, lobulated, and white to tan appearance. Black rounded areas represent hilar lymph nodes with metastatic carcinoma. It is usually treated by chemotherapy rather than radiotherapy or surgery. Prognosis is very poor.

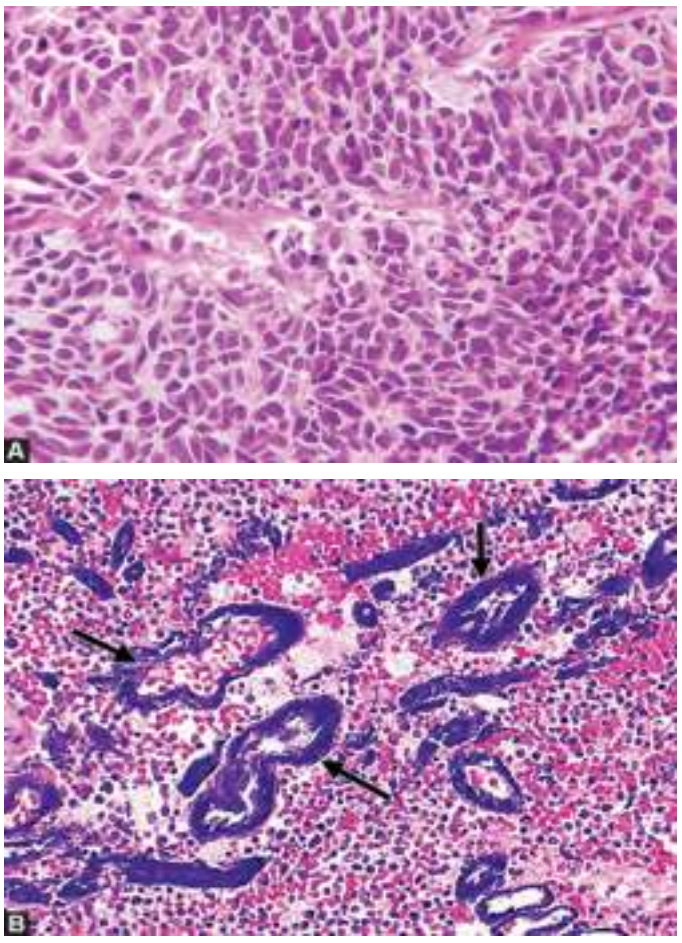


Fig. 18.51: Small cell lung carcinoma. (A) Tumor is composed of small dark blue cells with minimal cytoplasm, (B) Azzopardi effect encrusting of nuclear material on blood vessel wall is known as Azzopardi effect (arrows) (400X).

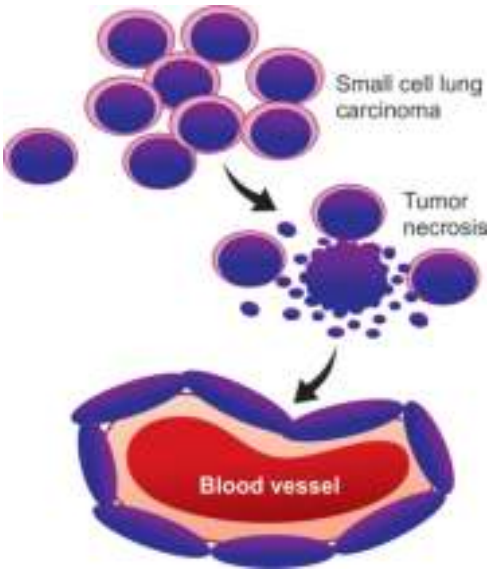

Fig. 18.51C: Azzopardi effect in small cell lung carcinoma. Encrusting of nuclear material on blood vessel wall is known as Azzopardi effect.

Therapeutic Response and Prognosis

Small cell lung carcinoma grows rapidly and metastasizes. It is very sensitive to chemotherapy and radiotherapy. Radiotherapy alone is rarely curative. Surgical excision of the tumor is not effective treatment.

- Combination of chemotherapy involves intravenous administration of cyclophosphamide, doxorubicin and vincristine in cycles lasting for three weeks each of these chemotherapeutic drugs.
- Disease is usually extensive at diagnosis, hence has poor prognosis associated with fatal outcome without treatment within 12 weeks.
- Treatment relieves symptoms, e.g. pain and superior vena cava syndrome due to invasion of chest wall by the tumor.

SQUAMOUS CELL LUNG CARCINOMA

Squamous cell lung carcinoma is the most common variant of lung cancer also known as epidermoid carcinoma affecting 55–75 years of age group. It accounts for 25–40% of cases. It is strongly associated with tobacco smoking. Squamous dysplasia is precursor lesion for squamous cell lung carcinoma.

- **Origin:** Tumor arises from basal cell of major bronchi in majority of cases in hilar region of chest; and bronchioles in a few patients.
- **Growth invasion:** Endobronchial growth causes bronchial obstruction and then invades bronchial wall and adjacent lung parenchyma or blood vessels. Atelectasis, bronchiectasis and consolidation are common in these cases. Tumor appears as solitary hilar mass. Central necrosis and cavitation in lungs are more common in SCLC than other cell types.

Table 18.57 Comparison of small cell lung carcinoma and large cell lung carcinoma

Histologic Features	Small Cell Lung Carcinoma	Large Cell Lung Carcinoma
Cell size	Small cell	Large cell
Cell shape	Fusiform	Polygonal
Nuclear/cytoplasmic ratio	High	Low
Nuclear chromatin	Fine chromatin	Coarse chromatin
Nucleoli	Indistinct	Prominent
DNA staining of blood vessels (Azzopardi phenomenon)	Frequent Azzopardi phenomenon	Rare

Table 18.58 Sites of metastases from lung cancers

Location	Frequency
Hilar tracheobronchial lymph nodes	80%
Extrathoracic lymph nodes (mediastinum and cervical region)	66%
Liver	50%
Adrenal glands (asymptomatic)	50%
Bone	30%
Kidney	25%
Brain	20%
Spinal cord	Uncommon
Pancreas	Uncommon

- **Signs and symptoms:** Endobronchial growth of tumor causes early symptoms. Tumor is detected on sputum cytological examination before being radiographically visible. It metastasizes late, hence has relatively good prognosis. Risk factors, gene mutations, clinical manifestations, immunohistochemistry and metastases of squamous cell lung carcinoma are shown in Fig. 18.52.

Risk Factors

- **Cigarette smoking:** Cigarette smoking is important cause of lung cancers, i.e. small cell lung carcinoma and squamous cell lung carcinoma.
- **Asbestosis:** Lung adenocarcinoma (most common) and squamous cell lung carcinoma are asbestos-related lung cancers in 34% of cigarette smokers. Asbestos fibers act as promoter in pulmonary carcinogenesis.

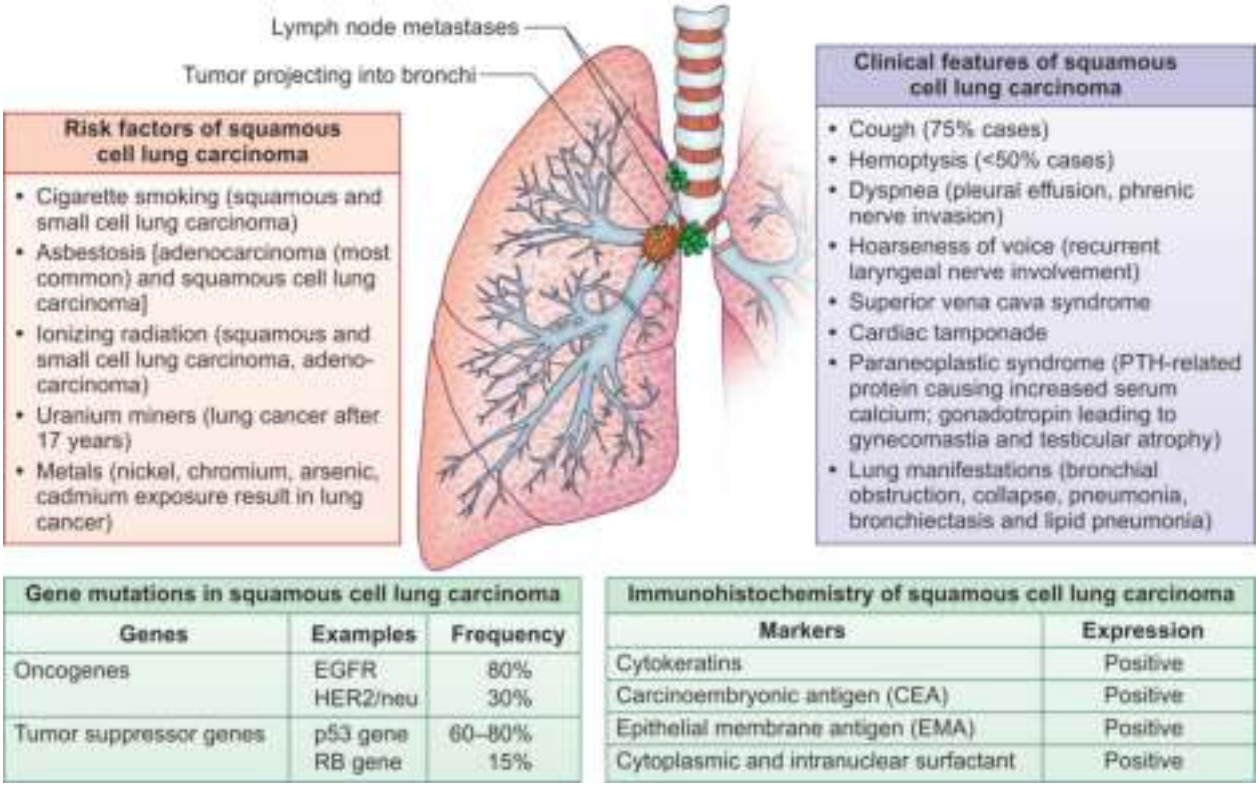

Fig. 18.52: Squamous cell lung carcinoma shows risk factors, gene mutations, clinical manifestations, immunohistochemistry and metastases.

- **Ionizing radiation:** Japanese are at higher risk for lung cancers, i.e. squamous cell lung carcinoma, lung adenocarcinoma and small cell lung carcinoma after atom bomb explosion in Hiroshima and Nagasaki.
- **Uranium miners:** Uranium exposure emits particulate products and radon gas. Inhalation of uranium particulate products may cause lung carcinoma after 17 years of exposure.
- **Metals exposure:** Metal refining and smelting processes of nickel, chromium, arsenic and cadmium exposure can result in lung carcinoma.

Molecular Genetic Alterations

Proto-oncogenes participate in normal cellular growth and development. Tumor suppressor genes inhibit this process.

- When proto-oncogenes undergo mutations, these are referred as oncogenes.
- Tobacco smoking harbors genetic abnormalities, i.e. chromosomal deletions involving tumor suppressor loci of 3p, 9p and 17p, which cause SCLC.
- Chromosome 3p and 9p deletions involving site of CDKN2A gene is demonstrated in 65% cases of squmous cell lung carcinoma.
- Chromosome 17p deletion involves TP53 gene. TP53 gene mutation is demonstrated in squamous dysplasia in 10–50% of cases and squamous cell lung carcinoma in 60–80% of cases.
- FGFR1 gene encoding fibroblast growth factor receptor tyrosine kinase is overexpressed in squamous cell lung carcinoma.
- HER2/neu is overexpressed in 30% of squamous cell lung carcinoma cases. Gene mutations in squamous cell lung carcinoma (*see* Fig. 18.52).

Surgical Pathology: Squamous Cell Lung Carcinoma

Gross Morphology

- Tumor is solid with cut surface pale white to tan, firm in consistency. Large tumor is necrotic, granular giving cheesy appearance as seen in tuberculosis.
- Hilar tumor is solid and located in central region of lungs.
- Peripheral tumor is small, far away from pleura and showing cavitation.

Light Microscopy

- Well-differentiated squamous cell lung carcinoma variant is composed of polygonal cells forming nests with hyperchromatic angular nuclei, pink cytoplasm with distinct cell borders.
- Keratinizing squamous cell lung carcinoma variant displays intercellular bridging and keratin pearls, which appear as a small round nest of brightly eosinophilic aggregates of keratin surrounded by concentric (onion skin) layers of squamous cells (Figs 18.53 and 18.54).
- Basaloid variant of squamous cell lung carcinoma has been associated with poor prognosis.

Fig. 18.53: Squamous cell lung carcinoma. It is arising centrally and obstructing the left main bronchus. The neoplasm is very firm and has a pale white to tan cut surface (arrows).

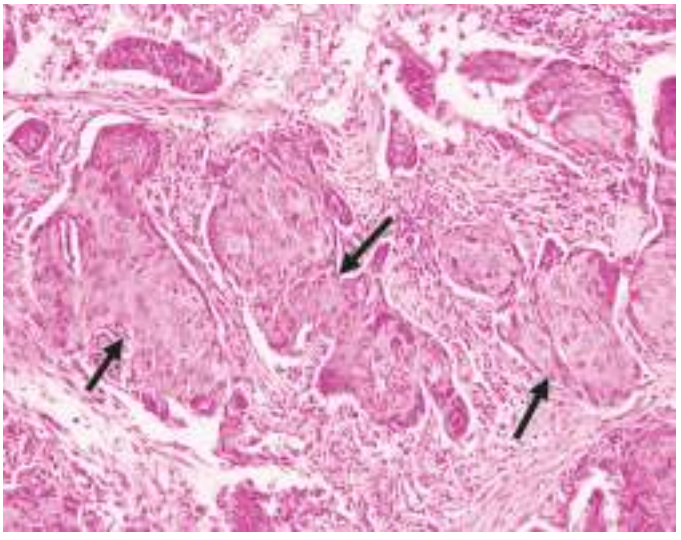

Fig. 18.54: Squamous cell lung carcinoma shows well differentiated polygonal tumor cells with pink cytoplasm with distinct cell borders and intercellular bridges. The nuclei are hyperchromatic and angular with many mitoses (arrows) (400X).

Immunohistochemistry Technique

Panel of immunomarkers is used to analyze expression in squamous cell lung carcinoma on histopathologic sections (*see* Fig. 18.52).

Markers	Expression
p53	Positive
p40	Positive
Cytokeratin (5, 6)	Positive
Epithelial membrane antigen (EMA)	Positive
Carcinoembryonic antigen (CEA)	Positive
Cytoplasmic and intranuclear surfactant	Positive

Table 18.59 Causes of hemoptysis

Etiology	Disorders
Inflammatory lesions	▪ Tuberculosis* ▪ Bronchiectasis* ▪ Pneumonias*
Neoplastic lesions	▪ Primary lung cancers* ▪ Metastatic lung cancers* ▪ Bronchopulmonary adenoma
Other lesions	▪ Pulmonary embolism and infarction* ▪ Mitral stenosis ▪ Left ventricular failure ▪ Anticoagulant therapy ▪ Bronchial adenoma ▪ Idiopathic pulmonary hemosiderosis

**Most common causes of hemoptysis are tuberculosis, bronchiectasis, pneumonias, bronchogenic carcinoma, pulmonary embolism and infarction.*

Clinical Features

Patient with squamous cell lung carcinoma presents with history of cough (75%), hemoptysis (<50%), severe chest pain (40%), dyspnea (20%) wheeze, stridor, hoarseness of voice, weight loss, paraneoplastic syndrome (ectopically secretes PTH-related protein resulting in hypercalcemia).

- **Cough:** It is common presentation in 75% cases of squamous cell lung carcinoma involving central airways.
- **Hemoptysis:** It occurs in <50% patients of squamous cell lung carcinoma at initial presentation (Table 18.59). It occurs due to hemorrhage from a tumor located in central airways.
- **Severe chest pain:** It suggests invasion of chest wall with intercostal nerves by tumor. Brachial plexus is involved in pancoast tumor located in apical portion.
- **Dyspnea:** Patient develops dyspnea due to loss of functioning lung parenchyma, invasion of lymphatics and pleura (massive pleural effusion). Hemorrhagic pleural effusion indicates invasion of pleura by tumor.
- **Digital clubbing:** It occurs due to reactive periosteal changes in the underlying bones in non-small cell lung cancers (e.g. squamous cell carcinoma, lung adenocarcinoma, and large cell lung carcinoma). Mechanism of digital clubbing is unknown. It may resolve with excision of the primary lesion.
- **Invasion of mediastinum:** Patient may develop hoarseness of voice due to involvement of recurrent laryngeal nerve supplying vocal cords, dysphagia due to invasion of esophagus or extrinsic pressure on esophagus and superior vena cava syndrome. Obstruction of the superior vena cava by tumor leads to venous congestion in head and neck.
- **Difficulty in respiration:** Phrenic nerve invasion causes paralysis of diaphragm.
- **Cardiac tamponade:** Tumor may cause erosion of major blood vessels and produce massive bleeding in pericardial cavity.
- **Lung lesions:** Patient with squamous cell lung carcinoma obstructing the bronchial lumen becomes symptomatic earlier. Complete bronchial obstruction by tumor may lead to pneumonia, bronchiectasis, lung collapse and lung abscess. Partial bronchial obstruction results in emphysema. Lipid pneumonia occurs due to accumulation of cellular lipid in foamy macrophages especially obstruction caused by lung carcinoma.
- **Paraneoplastic syndrome:** Tumor ectopically secretes PTH-related protein resulting to hypercalcemia. Patient presents with constipation, abdominal pain, polyuria and polydipsia. Serum calcium levels are increased. Gonadotropin synthesized by tumor leads to development of gynecomastia and testicular atrophy in male patients.

Clinical Manifestations: Pancoast Lung Tumor

Apical primary lung cancer (usually squamous cell lung carcinoma) is known as **Pancoast tumor** can involve structures of the neck. It may invade cervical sympathetic chain (Horner's syndrome), brachial plexus and ribs.

- **Horner's syndrome:** Involvement of the cervical sympathetic chain causes Horner's syndrome is characterized by ptosis-drooping of upper eyelid, enophthalmos (sunken eyes), miosis (constriction of pupil), and anhidrosis (loss of sweating) on the affected side.
- **Brachial plexus injury:** Apical tumor in superior sulcus may destroy brachial plexus.
- **Chest wall invasion:** Apical tumor in superior sulcus may destroy neighboring ribs.

Mode of Spread

- **Direct spread:** Tumor appears as a perihilar mass that spreads along the bronchi in the circumferential manner. Hence, it does not obstruct the bronchus lumen. On reaching a large size, it may cause bronchial obstruction and lung collapse.
- **Lymphatic route:** It spreads to hilar tracheobronchial lymph nodes with extension to mediastinal lymph nodes in >50% of cases. It may also involve cervical lymph nodes.
- **Hematogenous spread:** Approximately 66% of cases have metastasis in extranodal location at time of diagnosis. Tumor metastasizes to adrenal gland,

liver, brain, bone, spinal cord, kidneys, and pancreas. Adrenal gland involvement is usually asymptomatic.

Therapeutic Response

Most often, squamous cell lung carcinoma is treated surgically. It responds to radiotherapy.

LUNG ADENOCARCINOMA

Lung adenocarcinoma is the most common tumor in elderly women. Its association with tobacco smoking is relatively weak. It accounts for 30–50% of all lung cancers. It is most common lung cancer in the United States. Early metastases are common. Tumor is present in peripheral region of lung most often in upper lobe in 75% of cases. Speculated appearance of the tumor is demonstrated on radiograph.

- **Origin:** Lung adenocarcinoma is thought to arise from bronchial or alveolar epithelium and characterized by glandular differentiation with presence of mucin in the tumor cells.
- **Cell population:** Cell population of tumor may comprise columnar cells, goblet cells, Clara cells or mucous glands. Tumor shows glandular differentiation with presence of mucin in the tumor cells.
- **Invasion:** Invasion of lung parenchyma by tumor is most often present.
- **Metastases:** Early metastasis lung adenocarcinoma is more common than squamous cell lung carcinoma especially to central nervous system and adrenal glands.

Revised 2024 WHO Classification of Lung Adenocarcinoma

Based on revised 2024 WHO classification of lung tumors, the previously designated bronchoalveolar carcinoma has now been replaced with adenocarcinoma *in situ*.

Preinvasive Lesions of Lung

- Atypical adenomatous hyperplasia
- Adenocarcinoma *in situ* replacing bronchoalveolar carcinoma

Invasive Lung Adenocarcinomas

- Minimally invasive adenocarcinoma
- Lepidic predominant adenocarcinoma
- Invasive mucinous adenocarcinoma
- Invasive nonmucinous adenocarcinoma
- Solid predominant adenocarcinoma
- Acinar adenocarcinoma
- Papillary adenocarcinoma
- Micropapillary adenocarcinoma
- Colloid adenocarcinoma
- Fetal adenocarcinoma
- Enteric adenocarcinoma

Table 18.60 Molecular genetic abnormalities in lung adenocarcinoma

Molecular Genetic Abnormalities	Frequency
K-RAS	32%
EFGR	22%
BRAF	6%
ALK	3.9%
MET	2%
ERBB1	1.5%
ROS-1	1.5%
RET	1%
Other genes	30%

Location

Lung adenocarcinoma is a slow-growing irregular tumor measuring <4.0 cm in diameter in peripheral or central regions of lung. Large tumor may completely replace the entire lobe of the lung. It is often associated with pulmonary fibrosis. It may arise in relation to preexisting pulmonary fibrosis.

- **Peripheral subpleural mass:** Approximately 75% of patients present with peripheral subpleural solitary nodule in peripheral region. It is often associated with pleural fibrosis and subpleural scars, now recognized as desmoplastic response to tumor.
- **Central endobronchial growth:** In a few cases, lung adenocarcinoma originates within major bronchi in the central region of upper lobes. Tumor grows as endobronchial growth invading bronchial cartilage.

Risk Factors

Ionizing radiation may cause lung cancer. Japanese are at higher risk for lung cancers (squamous cell lung carcinoma, lung adenocarcinoma and small cell lung carcinoma) after atom bomb explosion in Hiroshima and Nagasaki.

Molecular Genetic Alterations

Molecular genetic abnormalities in lung adenocarcinoma are given in Table 18.60. Estimation of gene mutation prevalence is based on targeted next generation sequencing of lung adenocarcinoma.

Surgical Pathology: Lung Adenocarcinoma

Gross Morphology

Tumor measures 2–5 cm in diameter. Cut surface of tumor is gray white and glistening depending on amount of mucin production (Fig. 18.55).

Light Microscopy

Atypical adenomatous hyperplasia of lung

It refers to ≤5 mm lesion due to atypical proliferation of pneumocytes type II lining centriacinar alveoli with minimal widening of septa.

Lung adenocarcinoma *in situ*

- It replaces former designated bronchoalveolar carcinoma.
- It is characterized by tumor growth ≥5 mm to ≤3 cm.
- Tumor cells are growing along existing alveolar walls in a lepidic growth pattern.
- Alveolar septae show widening.
- There is no evidence of lymphovascular invasion, lung parenchyma and pleura.
- Patient has 5 years disease-free interval. Tumor cells express p53.

Minimal invasive lung adenocarcinoma

- It refers to formation of tumor growth measuring <3 cm with lepidic pattern with more than one foci of invasion in pulmonary parenchyma measuring <5 mm.
- There is no evidence of invasion of lymphovascular and pleura.
- Tumor necrosis is absent.
- On histologic examination, tumor is composed of angulated tumor cells arranged in nests and acini with desmoplasic stroma.
- Patient has 5 years disease-free survival.

Invasive mucinous lung adenocarcinoma

- It replaces former bronchoalveolar carcinoma.
- Tumor cells express mutation of K-RAS and EML-4 ALK translocation.
- Tumor is mistaken for metastatic disease.
- Most tumors are well differentiated composed of goblet cells along the framework of alveolar septa and projecting like papillary formation into the alveolar spaces.
- This pattern resembles butterfly sitting on fence, i.e. lepidic pattern.
- Tumor cells show mucin in cytoplasm and minimal atypia (Fig. 18.56).

Invasive nonmucinous lung adenocarcinoma

- This histologic variant constitutes 66% cases of adenocarcinoma.

Lepidic predominance lung adenocarcinoma

- It refers to ≥3 cm tumor growth invading pulmonary parenchyma, lymphovascular and pleura.
- Tumor shows areas of necrosis.
- About 90% of patients have 5-year survival with stage 1 disease (Fig. 18.57).
- Tumor is composed of clara cells and pneumocytes type II growing along the alveolar walls.

Solid predominance lung adenocarcinoma

- Tumor is composed of cells without glandular differentiation arranged in nests and cords.
- It should be differentiated from nonkeratinizing squamous cell lung carcinoma and large cell lung carcinoma.
- Histochemistry and immunohistochemistry help in establishing diagnosis.
- Tumor cells show presence of mucin.

Acinar lung adenocarcinoma

- It is an invasive tumor composed of cells forming glandular structures with visible lumina.
- Tumor cells are closely packed or back to back arrangement. These cells may invade desmoplastic stroma.

Papillary lung adenocarcinoma

It is an invasive tumor composed of papillary structure and fibrovascular cores. Its prognosis is similar to acinar adenocarcinoma.

Micropapillary lung adenocarcinoma

This histologic variant is composed of intra-alveolar detached papillae and tufts of tumor cells lacking fibrovascular core lymphovascular by tumor is often widespread at the time of diagnosis.

Colloid lung adenocarcinoma

- This histologic variant is composed of extracellular mucin lakes that expand and destroy alveolar spaces.
- The alveolar spaces are lined by mucinous epithelial goblet or columar cells.

Fetal lung adenocarcinoma

- This histologic variant is composed of columnar cells forming tubular and cribriform structures.
- It occurs in young age group.
- It is associated with mutation of β-catenin. There may be presence of morula metaplasia and endometrioid carcinoma.

Enteric lung adenocarcinoma

This histologic variant is characterized by the presence of enteric differentiation with acinar architecture and intracinar necrosis in at least 50% of the tumor.

Histochemistry

Mucin production presents in tumor cells may be demonstrated by mucicarmine, Alcian blue and periodic Schiff stain.

Immunohistochemistry Technique

Panel of immunomarkers is used to analyze expression in lung adenocarcinoma on histopathologic sections.

Markers	Expression
Cytokeratin 7 (CK 7)	Positive
Epithelial membrane antigen	Positive
Napsin A	Positive
TTF-1 (thyroid transcription factor 1)	Positive
Carcinoembryonic antigen (CEA)	Positive
B72.3 monoclonal antibody reacts with tumor-associated glycoprotein 72 (TAG-72)	Positive
Ber-EP4 monoclonal antibody reacts with glycoproteins of tumor cells	Positive
CD15 (Leu-M1) monoclonal antibody reacts with tumor cells	Positive

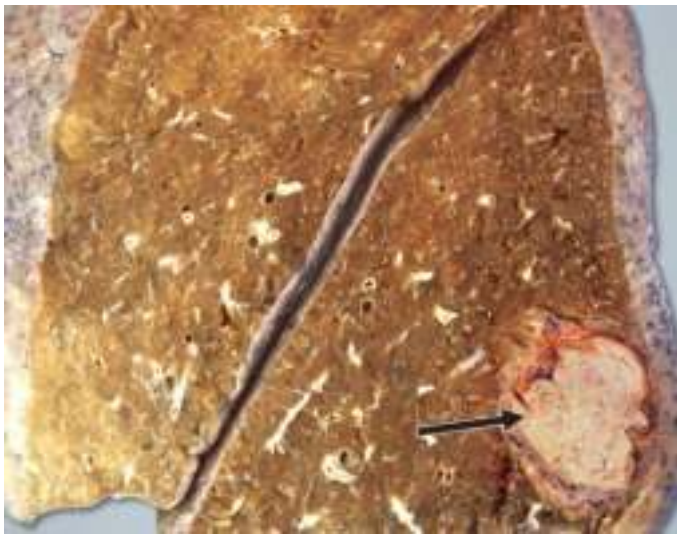

Fig. 18.55: Peripheral lung adenocarcinoma. It tends to occur more peripherally in lung. It occurs more often in nonsmokers and in smokers who have quit. Resection would have a greater chance for cure. The solitary appearance of this neoplasm suggests that the tumor is primary rather than metastatic (arrow).

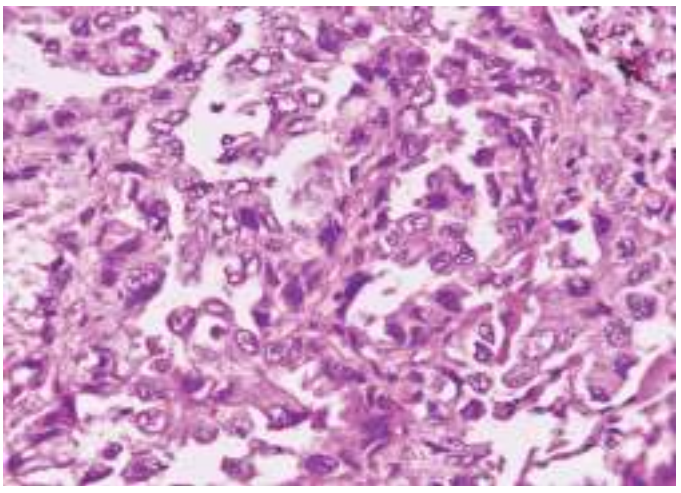

Fig. 18.56: Lung adenocarcinoma is showing well differentiated adenocarcinoma (400X).

Mode of Spread

Early metastasis of lung adenocarcinoma is more common than squamous cell lung carcinoma histologic variant. The metastatic deposits are especially demonstrated in nervous system and adrenal glands.

- **Lymphatic route:** Tumor spreads by lymphatic route to hilar tracheobronchial lymph nodes and extrathoracic lymph nodes of mediastinum and cervical region.
- **Hematogenous route:** Approximately 66% of cases metastases via hematogenous route are demonstrated in adrenal glands, liver, spinal cord, kidneys and pancreas at the time of diagnosis.

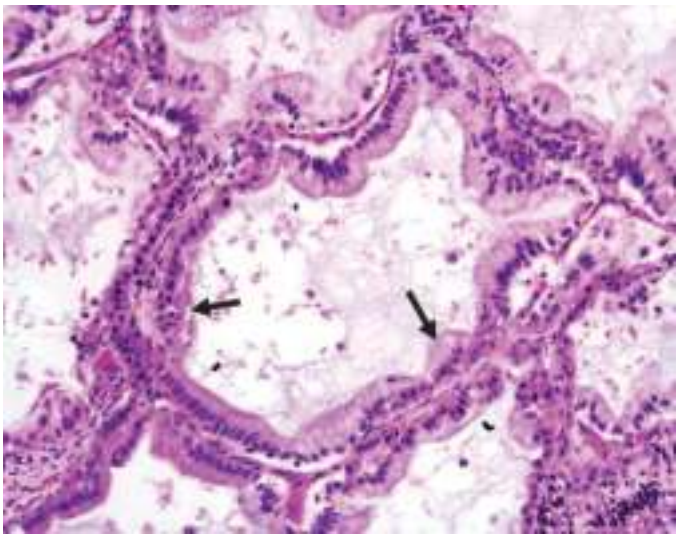

Fig. 18.57: Lepidic predominance adenocarcinoma. It is composed of columnar cells that proliferate along the framework of alveolar septa. The cells are well differentiated. It has a better prognosis than most other primary lung cancers (arrows) (400X).

Tumor Growth and Therapeutic Correlation

Patient with stage I adenocarcinoma confined to lung, who undergoes complete surgical excision has a 5-year survival in 50–80% of cases. Differences between squamous cell lung carcinoma and lung adenocarcinoma are given in Table 18.61.

There is no relationship to tobacco smoking. It affects patients of both sexes in all ages from the 20s to the advanced years of life. Noninvasive tumor characterized by lepidic growth has good prognosis. Diffuse or patchy ill-defined tumor showing consolidation has poor prognosis.

- **Noninvasive tumor growth:** Tumor tends to occur in peripheral region of lung. Tumor spreads as a thin layer of cells using the alveoli or bronchial walls as a framework or scaffold in lepidic pattern. This pattern of growth does not invade lung parenchyma, pleura or blood vessels. It has excellent prognosis when localized associated with 5-year survival rate approaching 100%.
- **Invasive tumor growth:** The growth most often invades and destroys lung parenchyma. Prognosis is poor. Differences between invasive mucinous adenocarcinoma and nonmucinous adenocarcinoma *in situ* (AIS)/minimally invasive adenocarcinoma (MIA)/lepidic adenocarcinoma are given in Table 18.62.

Comparison of lepidic-predominant lung adenocarcinoma and atypical alveolar hyperplasia is given in Table 18.63.

Table 18.61 Differences between squamous cell lung carcinoma and lung adenocarcinoma

Characteristics	Squamous Cell Lung Carcinoma	Lung Adenocarcinoma
Sex	Male	Female
History of tobacco smoking	Associated with tobacco smoking	Not associated with tobacco smoking
Location	Larger tumor, more centrally located	Tend to be more peripherally located
Growth rate	Rapid growth	Slow growth
Local spread	Predominant	Uncommon
Molecular genetics	FGFR 1 (80%), ERBB2 (*HER2/neu*) (30%), TP53 (60–80%), RB gene (15%), p16 and CDKN2K gene	K-RAS, FGFR 1, ALK, ROS, MET and RET genes
Distant metastases	Later stage	Early stage
Light microscopy	Well-differentiated carcinoma showing keratin pearls and intercellular bridges. May be poorly differentiated	Bronchial derived and bronchioloalveolar carcinoma
Immunohisto-chemistry	Cytokeratins, carcinoembryonic antigen (CEA), epithelial membrane antigen (EMA) and cytoplasmic and intranuclear surfactant	Cytokeratins, carcinoembryonic antigen (CEA), epithelial membrane antigen (EMA) and cytoplasmic, intranuclear surfactant, TTF-1 and CD15 (Leu-M1)
Size	Large tumor	Small tumor
Scarring	Absent	May be present

Table 18.62 Differences between invasive mucinous adenocarcinoma and nonmucinous adenocarcinoma *in situ* (AIS)/minimally invasive adenocarcinoma (MIA)/ lepidic adenocarcinoma

Characteristics	Invasive Mucinous Adenocarcinoma (Formerly Mucinous Bronchioloalveolar Carcinoma)	Nonmucinous Adenocarcinoma *in situ* (AIS)/Minimally Invasive Adenocarcinoma (MIA)/Lepidic Adenocarcinoma
General considerations		
Frequency	40%	60%
Female gender	60%	70%
Tobacco smokers	45%	45%
Invasion of lung, pleura and blood vessels	Present	Absent
Prognosis	Poor	Excellent
Radiological features		
Conventional radiographs	Majority of tumors demonstrate consolidation, air bronchogram, frequently multifocal and multilobar presentation	Majority of tumors with ground glass attenuation
Histologic features		
Cell type	Mucin-filled, columnar, and/or goblet cells	Type II pneumocytes and/or Clara cells
Immunophenotype		
CK7	90%	95%
CK20	50%	5%
TTF-1	15%	65%
Genotype		
K-RAS mutation	75%	15%
EGFR mutation	<5%	45%

Table 18.63 Comparison of lepidic-predominant lung adenocarcinoma and atypical alveolar hyperplasia

Parameters	Lepidic-predominant Lung Adenocarcinoma	Atypical Alveolar Hyperplasia
Size of lesion	>5 mm to ≤3 cm	Small usually <5 mm
Clinical features	Gross lesion demonstrated on radiographs	Often unsuspected. Atypical hyperplasia may be found in histologic sections of grossly normal lungs
Morphology of cells	Monomorphic cells with mild atypical features along alveolar walls in lepidic pattern	Polymorphic cells with mild atypical features

Clinical Features

Patient presents with copious watery sputum termed **bronchorrhea** as a result of extensive mucin production, cough, and pain. Atelectasis and emphysema are infrequent.

Imaging Technique

Lung adenocarcinoma is discovered as a single nodule or multiple nodules or pneumonia-like diffuse infiltrate (ground glass opacities) on the radiograph. Diffuse tumor may involve several lobes of lung or even bilateral associated with poor prognosis. After resection, tumor can appear in another lobe or opposite side lung.

Prognosis

Patient with solitary tumor (i.e. lung adenocarcinoma) in stage I has excellent prognosis with 5-year survival after surgical excision. Patient with tumor exhibiting diffuse pattern has poor outcome.

LARGE CELL LUNG CARCINOMA

Large cell lung carcinoma is peripherally located and accounts for about 10–20% of all lung cancers. It is characteristically aggressive and metastasizes early with fatal outcome. It is strongly associated with cigarette smoking. Patient presents with a mass >4 cm in diameter in peripheral region of lung in 60% of cases with early metastasis and poor prognosis.

Imaging Techniques

Radiologic appearance of large cell lung carcinoma is similar to adenocarcinoma except for its large size.

Surgical Pathology: Large Cell Lung Carcinoma

Gross Morphology

- Large cell lung carcinoma is usually peripheral and unifocal tumor measuring >4 cm in diameter with well-defined borders.
- Cut surface shows bulging lobulated homogenous gray-white 'fleshy' tumor mass with areas of hemorrhage and necrosis.

Light Microscopy

- **Classic variant of large cell lung carcinoma:** Tumor is composed of large cells with hyperchromatic nuclei and prominent nucleoli. There is minimal squamous or glandular differentiation. It does not express cytokeratin.
- **Tumor with neuroendocrine differentiation of large cell lung carcinoma:** Tumor is composed of tumor cells arranged in nests, trabecular, forming rosettes and palisading pattern. It suggests neuroendocrine differentiation on histochemical staining and electron microscopy.
- **Adenosquamous variant of large cell lung carcinoma:** Tumor has mixed histologic features of both lung adenocarcinoma and squamous cell lung carcinoma in 33% of cases. Patient presents with mass in the lung periphery and indistinguishable from adenocarcinoma or large cell lung carcinoma. Metastases are common. It has aggressive behavior with poor prognosis.

Differences between various histopathologic variants of lung cancers are given in Table 18.64.

ADENOSQUAMOUS LUNG CARCINOMA

Adenosquamous lung carcinoma shows admixture of adenocarcinoma and squamous cell lung carcinoma components. Each component should be >10% in the tumor.

PLEOMORPHIC LUNG CARCINOMA

Pleomorphic lung carcinoma is composed of any type of non-small cell lung carcinoma containing ≥10% spindle and/or giant cells.

CARCINOSARCOMA OF LUNG

Carcinosarcoma of lung consists of a mixture of non-small cell lung carcinoma and sarcoma containing heterologous elements, i.e. chondrosarcoma, osteosarcoma and rhabdomyosarcoma.

TUMORS METASTASIZING TO LUNGS

Pulmonary metastases are more common than primary lung carcinoma. In one-third of all fatal cancers, pulmonary metastases are evident at autopsy (Figs 18.58 and 18.59). Patterns of secondary tumor growth in the lungs are given in Table 18.65.

Table 18.64 Differences between various histopathologic variants of lung cancers

Parameters	Small Cell Lung Carcinoma (Neuroendocrine Carcinoma)	Squamous Cell Lung Carcinoma	Lung Adenocarcinoma	Adenocarcinoma *in situ*	Large Cell Lung Carcinoma
Frequency	15–25%	25–40%	30–50%	10%	10–20%
Cell of origin	Neuroendocrine tumor (Kulchitsky cells)	Basal cells of major bronchi	Mucus producing glands near previous scar	Clara cells (nonciliated epithelium) of terminal bronchiole	Epithelial tumor with squamous and glandular differentiation on EM
Location in lung	Central region	Central region	Peripheral region (75%), central region (25%)	Peripheral region	Peripheral region (65%)
Tobacco smoking	Strong association	Strong association	Weak association	No association	Strong association
Growth rate	Very rapid	Slow	Slow to moderate	Slow	Rapid
Metastasis	Very early to mediastinum or distal area of lung and widespread metastases	▪ Localized metastasis not common or occurs late ▪ Usually to hilar lymph nodes, adrenals, liver	Early metastasis throughout lung and brain or to other organs	Late metastasis	Early and widespread metastasis to kidney, liver and adrenals
Molecular genetics	▪ c-Myc gene ▪ RB gene (80–100%) ▪ p53 gene (50–80%)	▪ EGFR gene (80%) ▪ ERBB2 (*HER2/neu*) gene (30%) ▪ TP53 (60–80%) ▪ RB gene (15%)	▪ K-RAS gene ▪ EGFR gene ▪ ERBB2 (*HER2/neu*) ▪ p53 gene ▪ RB gene ▪ p16 gene	▪ K-RAS gene ▪ EGFR gene ▪ ERBB2 (*HER2/neu*) ▪ p53 gene ▪ RB gene ▪ p16 gene	▪ RB gene ▪ p16 gene
Light microscopy	Small cells, scanty cytoplasm, hyperchromic nuclei (EM showing neurosecretory granules)	Well differentiated SCC with keratin	Tumor cells forming glandular pattern	Lepidic growth pattern or diffuse pattern	Anaplastic or neuroendocrine differentiation or adenosquamous variants
Immunohistochemistry	▪ Chromogranin ▪ Synaptophysin ▪ CD56 ▪ CD57 (HNK-1 Leu-7) ▪ Neuron-specific enolase (NSE) ▪ Cytokeratin (AE 1/AE 3) ▪ TTF-1	▪ p63 ▪ p40 ▪ Cytokeratins (5, 6) ▪ Epithelial membrane antigen (EMA) ▪ Carcinoembryonic antigen (CEA) ▪ Cytoplasmic and nuclear surfactant	▪ TTF-1 (70–75%) ▪ Napsin A (80%) ▪ CK 7 ▪ Carcinoembryonic antigen ▪ B72.3 monoclonal antibody reacts with tumor associated glycoproteins in tumor cells ▪ MOC 31 ▪ CD15 (Leu-M1) monoclonal antibody reacts with tumor cells ▪ Ber EP4	–	–
Paraneoplastic syndrome	ACTH, ADH parathormone-related protein, gonadotropin	Parathormone-related protein, gonadotropin	Gonadotropin	Absent	Gonadotropin

Contd...

Table 18.64 Differences between various histopathologic variants of lung cancers (*Contd...*)

Parameters	Small Cell Lung Carcinoma (Neuroendocrine Carcinoma)	Squamous Cell Lung Carcinoma	Lung Adenocarcinoma	Adenocarcinoma *in situ*	Large Cell Lung Carcinoma
Clinical behavior	Most aggressive wide distant metastasis at diagnosis	Rapidly growing tumor with cavitation with late metastasis, lung collapse, consolidation	Cavitation rare	Solitary coin lesion or diffuse mimicking lobar consolidation	Large bulky tumor <4 cm in diameter
Treatment	Combination chemotherapy, surgical resectability is poor	Surgical resectability is good, if stage I or II	Surgical resectability is good, if stage I or II; chemotherapy, radiation and surgery may be combined for stage III	Chemotherapy and surgical resection or lung	Radiotherapy is palliative but chemotherapy is of limited use

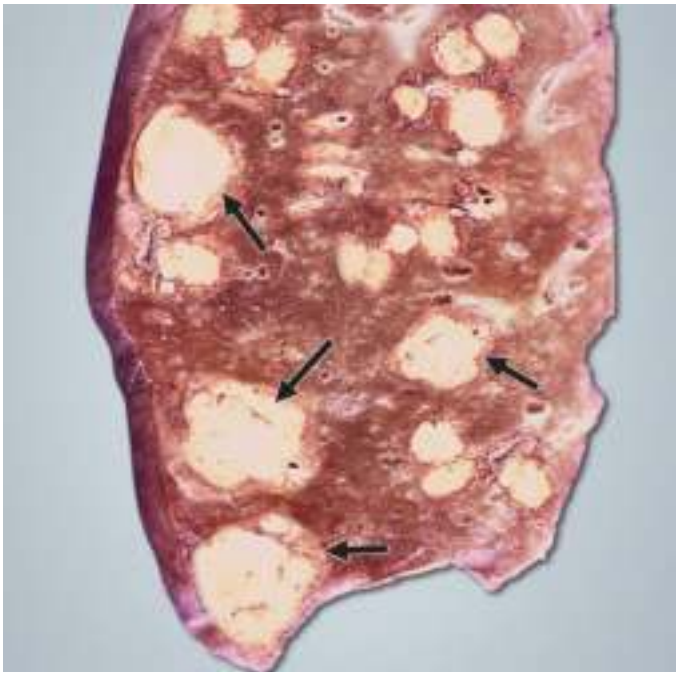

Fig. 18.58: Metastases in lung shows variable sized nodules (arrows).

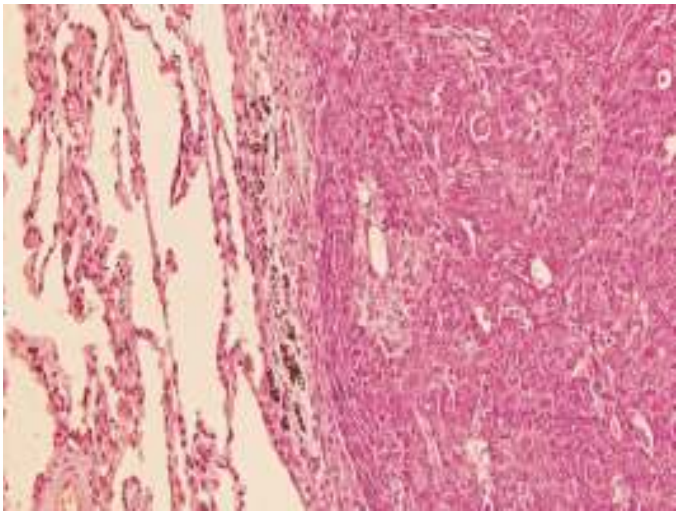

Fig. 18.59: Lung shows metastatic deposit from carcinoma (100X).

- Metastases are seen in lung parenchyma (most common), pleural cavity and lymphatics. Lymphatics may be diffusely involved, leading to the appearance of lymphangitis carcinomatosa.

Table 18.65 Patterns of secondary tumor growth in the lungs

Blood-borne Metastases in Lungs

- Solitary well-circumscribed nodule
- Multiple well-circumscribed nodules
- Massive tumor embolism (e.g. renal cell carcinoma, hepatocellular carcinoma invading systemic veins)
- Microscopic tumor microangiopathy (carcinomatous thrombotic microangiopathy) refers to presence of neoplastic cells occluding small muscular pulmonary arteries and arterioles. Breast carcinoma and gastric carcinoma produce microscopic tumor microangiopathy. This pattern may also be demonstrated in tumors of liver and placenta

Diffuse Lymphatic Permeation (Lymphangitis Carcinomatosa) in Lungs

- Entire lymphatic system of lungs demonstrates pale thread of tumor cells filling these vessels present on visceral pleura and broncho-arterial bundles
- Lymphangitis carcinomatosa may extend to regional lymph nodes

Contd...

Table 18.65 Patterns of secondary tumor growth in the lungs (*Contd...*)

Endobronchial Metastases in Lungs
▪ Tumor cells from intestine, uterine cervix and breast in lymphatic channels of the lung may occlude mucosal lymph channels thereby develop into secondary tumors in the main airways ▪ It is worth mentioning that primary tumors of bronchus with a propensity to grow in this way include carcinosarcomas, carcinoids and bronchial gland tumors
Intra-alveolar Growth Patterns in Lungs
▪ Diffuse air space involvement with compression of alveolar septa are demonstrated in primary lung tumors and some metastatic breast carcinoma and renal cell carcinoma. Prognosis in primary tumor involving diffuse air spaces have relatively favorable prognosis ▪ Lepidic growth refers to spread of neoplastic cells along the surface of alveolar epithelium. It is demonstrated in primary adenocarcinoma *in situ* (formerly known as bronchioloalveolar carcinoma)
Interstitial Metastases in Lungs
Extralymphatic route of tumor spread in the interstitial tissue of alveoli, which get thickened. Air spaces are obliterated.

Table 18.66 Immunohistochemistry of primary tumors metastasizing to lung in adults

Primary Tumors	Immunoprofiles
Breast carcinoma	ER, PR, *HER2/neu*, CK7, GCDFP-15 (gross cystic disease fluid protein 15), mammoglobulin, Ki-67, p53, CK5, NY-BR and E-cadherin
Renal cell carcinoma	Cytokeratin, vimentin
Colon carcinoma	CK20, CDX2
Thyroid carcinoma	TTF-1, thyroglobulin, CA-125 cell surface glycoprotein (monoclonal antibody OC-125)
Osteosarcoma	Vimentin
Ewing's sarcoma	CD99 (MIC2 specific marker), vimentin, nonspecific enolase (NSE), neurofilament and cytokeratin (low molecular weight)
Endometrium carcinoma type 1	p53, ER, PR, PTEN
Prostatic carcinoma	PSA (prostatic specific antigen), PSAP (prostatic specific acid phosphatase), PSMA (prostate specific membrane antigen), NXK3.1 and prostein
Non-Hodgkin's lymphoma B cell	LCA, CD10, CD19 and CD20
Non-Hodgkin's lymphoma T cell	CD3
Choriocarcinoma	Human chorionic gonadotropin (hCG)

Table 18.67 Immunohistochemistry of primary tumors metastasizing to lung in children

Primary Tumors	Immunoprofiles
Rhabdomyosarcoma	Desmin, vimentin, myoglobin and MyoD1

- Breast carcinoma is most common cause of lung metastases followed by colon carcinoma, and renal cell carcinoma. Other cancers metastasizing to lungs are derived from salivary glands, thyroid gland, uterus, ovaries, urinary bladder and prostate.
- Patterns of secondary tumor growths in the lungs are given in Table 18.65. Immunohistochemistry of primary tumors metastasizing to lung in adults and children, and differences between gross morphology of primary and secondary tumors of lungs are given in Tables 18.66 to 18.68.
- Lung metastases demonstrated by imaging techniques may be solitary, cannon balls, poorly differentiated, snow storm and diffuse alveolar patterns. Radiologic appearances of metastatic deposits in lungs are given in Table 18.69.
- Chest radiograph demonstrates solitary pulmonary nodule <5.0 cm or coin lesion in decreased frequency includes tuberculosis, histoplasmosis, primary lung cancer, bronchial hamartomas, amyloid deposits

Table 18.68 Differences between gross morphology of primary and secondary tumors of lungs

Feature	Primary Lung Tumors	Secondary Lung Tumors
Tumor	Usually solitary	Usually multiple
Circumscribed	Poorly circumscribed	Sharply circumscribed
Cavitation	Usual	Unusual
Calcification	Usual	Extremely unusual. If calcification present, then it is indicative of chondrosarcoma and osteosarcoma

Table 18.69 Radiologic appearances of metastatic deposits in lungs

Type of Lesions	Cancers
Solitary lesions	Breast carcinoma,* colon carcinoma, renal cell carcinoma
Cannonball multiple lesions	Breast carcinoma, colon carcinoma, renal cell carcinoma, testicular germ cell tumors, bone (osteosarcoma) and soft tissue sarcoma
Poorly differentiated multiple lesions	Breast carcinoma, choriocarcinoma
Snow storm pattern (multiple small nodules)	Breast carcinoma, thyroid carcinoma, urinary bladder carcinoma, prostatic carcinoma
Diffuse alveolar consolidation	Breast carcinoma, primary lymphomas (differential diagnosis pneumonias)

** On imaging study, breast carcinoma metastases in lung may show solitary multiple cannonballs, and multiple poorly differentiated nodules or diffuse alveolar consolidation. Multiple nodules are also demonstrated in Wegener's granulomatosis, rheumatoid lung disease, histoplasmosis and coccidioidomycosis.*

(pseudotumor), chondroma, lipoma and leiomyoma (*see* Figs 18.58 and 18.59).

DIAGNOSTIC APPROACH OF LUNG TUMORS

IMAGING TECHNIQUES

Imaging techniques are chest radiographs, CT scan, MRI, bone scan and positron emission tomography described as under:

- **Chest X-rays:** A chest radiograph detects most lung carcinomas.
- **Mediastinoscopy:** It is performed in case of involvement of mediastinum by lung carcinoma. It helps in evaluating the extent of the tumor.
- **CT scan:** It is most important imaging technique in detection of suspected lung carcinoma. It helps surgeon to know, whether the lung carcinoma is resectable or not.
  - Draining lymph nodes measuring >2 cm are likely to be involved due to metastases in 70% of cases.
  - Lymph nodes measuring <1 cm are unlikely to be involved.
  - The International Association for the Study of Lung Cancer (IASLC) lymph node map including the proposed grouping of lymph node stations into zones for the purpose of prognostic analysis is given in Table 18.70.
- **MRI technique:** It is essential to evaluate metastases in brain, spinal cord and other organs.
- **Bone scan:** It is done to evaluate bone metastases.
- **Positron emission tomography:** Presence or absence of metastatic deposits in draining lymph nodes and distant organs (liver, adrenal glands and elsewhere) is critical in management of lung cancer.
  - Positron emission tomography with radiolabeled fluorodeoxyglucose (FDG-PET) and biopsy are essential diagnostic tools. The dye is taken up by all cells, but more avidity with cancer stem cells.
  - Dye enters Krebs cycle but cannot complete and accumulates in the malignant cells.
  - A FDG-PET scan shows how well the lungs are functioning.

Table 18.70 The International Association for the Study of Lung Cancer (IASLC) lymph node map including the proposed grouping of lymph node stations into zones for the purpose of prognostic analysis

Study of Lung Cancer Lymph Nodes Map	Proposed Grouping of Lymph Node Stations into Zones	
Supraclavicular lymph nodes	▪ Low cervical lymph nodes ▪ Supraclavicular lymph nodes	▪ Sternal lymph nodes
Superior mediastinal lymph nodes	▪ Upper paratracheal lymph nodes on left side and right side ▪ Prevascular lymph nodes	▪ Retrotracheal lymph nodes ▪ Lower paratracheal lymph nodes on left side and right side
Aortic lymph nodes	▪ Subaortic lymph nodes ▪ Para-aortic lymph nodes	
Inferior mediastinal lymph nodes	▪ Subcarinal zone lymph nodes ▪ Paraesophageal lymph nodes below carina	▪ Pulmonary ligament lymph nodes
N1 nodes	▪ Hilar/interlobar zone of lung • Hilar lymph nodes • Interlobar lymph nodes	▪ Peripheral zones of lung • Lobar lymph nodes • Segmental lymph nodes • Subsegmental lymph nodes

OTHER DIAGNOSTIC MODALITIES

Fiberoptic Bronchoscopy

Fiberoptic bronchoscopy is used to take biopsy from representative area from centrally located lung cancers (squamous cell lung carcinoma and in some cases of small cell lung carcinoma).

Sputum Examination

Sputum cytology may reveal malignant cells in 85% cases of squamous cell lung carcinoma but the false-negative rate is high. Asbestos bodies may be demonstrated in sputum during prolonged exposure to asbestos.

Bronchoalveolar Lavage

Saline is injected into a lung segment down by bronchoscope. Saline is aspirated and examined for cells and organisms.

Bronchopulmonary Biopsy

- **Bronchial biopsy:** Bronchoscope is introduced to take biopsy to diagnose neoplasia, sarcoidosis and allergic aspergillosis.
- **Transbronchial biopsy:** Forceps is advanced to lung periphery down bronchoscope to take biopsy sample. It is done to diagnose infections, diffuse lung disease and transplant monitoring.
- **Ultrasound or CT-guided percutaneous needle lung biopsy:** It is performed to take biopsy from localized mass lesions (lung cancer) under ultrasound/CT-guidance.
- **Open lung biopsy:** It is done in cases of chronic diffuse lung diseases of uncertain origin.

Surgical Pathology: Lung Cancer

Gross Morphology and Light Microscopy

- Biopsy fixed in 10% formalin is processed in tissue processor. Sections are stained with hematoxylin and eosin.
- Diagnostic features to be reported with resected lung carcinomas include tumor margins, histologic type and grade, lymphatic and blood vessel involvement and staging.

Histochemistry

- Alcian blue, mucicarmine and PAS stains are used to demonstrate mucin in adenocarcinoma. Epithelial mucins are stained purple or dark blue color.
- Connective tissue mucins are stained as pale blue with Alcian blue, but it does not stain with PAS.
- Approximately, 75% of lung cancers show positivity with Kreberg's stain.

Immunohistochemistry Technique

Immunohistochemistry technique plays significant role in differential diagnosis of primary lung cancers described as follows:

- **Neuron-specific enolase:** It is specific for neural crest cells of the neuroendocrine series, i.e. small cell lung carcinoma.
- **Cytokeratin:** Squamous cell lung carcinoma shows positivity for cytokeratin.
- **Carcinoembryonic antigen (CEA):** CEA is a glycoprotein of heterogeneous composition normally detected in the glycocalyx of fetal epithelial cells, particularly those of mucin-secreting glandular nature. It is mainly used for the differential diagnosis between lung adenocarcinoma (usually positive) and mesothelioma (usually negative).
- **B72.3 monoclonal antibody:** It is a monoclonal antibody reacts with a high molecular weight glycoprotein that has been named tumor-associated glycoprotein 72 (TAG-72). One of its most common applications is in the differential diagnosis between mesothelioma (in which it is usually negative) and lung adenocarcinoma (usually positive).
- **Ber-EP4 monoclonal antibody:** It is mainly used for the differential diagnosis between lung adenocarcinoma and mesothelioma.
- **Calretinin:** It is a calcium-binding protein. Its main use is in the differential diagnosis between mesothelioma (almost always positive except for the desmoplastic variant) and lung adenocarcinoma (usually but not always negative).
- **Centromere protein H (CENP-H):** This is one of the fundamental components of the human active kinetochore and thought to be associated with tumorigenesis. High CENP-H protein expression has been related to poor outcome in patients with non-small cell lung carcinoma of lung.
- **CD15 (Leu-M1):** CD15 antibody has been found to react with lung adenocarcinoma. Its main use is in the differential diagnosis between lung adenocarcinoma (usually positive) and mesothelioma (usually negative). Immunohistochemistry of primary lung tumors is given in Table 18.71.

Serum Tumor Markers in Primary Lung Cancer

Certain tumors liberate products (e.g. cell surface antigens, cytoplasmic proteins, enzymes and hormones) that can be detected in blood samples, thereby acting as tumor markers. Their utility is to confirm the diagnosis.

Blood biochemistry analysis is done to evaluate biochemical alterations in primary and secondary lung cancers. Serum tumor markers analyzed in diagnosing primary lung cancers are given in Table 18.72.

- **Serum p53:** The TP53 gene alteration is most often demonstrated in human cancers. The p53 protein overexpression is detected by p53 antibodies in 60–70% of lung carcinoma. The p53 can be used as a precocious marker of TP53 gene alteration before clinical manifestations of lung carcinoma.
- **Serum carcinoembryonic antigen (CEA):** Elevated serum CEA level is demonstrated in patients with extrathoracic lung adenocarcinoma and anaplastic lung carcinoma in 23% of cases. Serum CEA is also elevated in carcinoma of colon, pancreas and breast.

Table 18.71 Immunohistochemistry of primary lung tumors

Markers	Expression
Squamous cell lung carcinoma	
p40	Positive
p63	Positive
CK5/6	Positive (diffuse staining)
CK903	Positive (diffuse staining)
CEA (carcinoembryonic antigen)	Positive
Surfactant protein	Positive
CK7	Positive/negative
CK20	Negative
TTF-1	Negative
Napsin A	Negative
Synaptophysin	Negative
Chromogranin A	Negative
NSE (neuron-specific enolase)	Negative
CD56 (neuronal cell adhesion molecule)	Negative
Small cell lung carcinoma	
TTF-1	Positive (90%)
Synaptophysin	Positive
Chromogranin A	Positive
NSE (neuron-specific enolase)	Positive
CD56 (neuronal cell adhesion molecule)	Positive
CAM5.2	Positive (punctate staining)
AE1/AE3	Positive (punctate staining)
CK7	Negative/positive
CK20	Negative
p63	Negative
CK5/6	Negative
CK903	Negative
Napsin A	Negative
Lung adenocarcinoma (mucinous variant)	
TTF-1	Positive (10–20%)
B72.3	Positive (75–100%)
CD15	Positive (60%)
MOC31	Positive
Ber-EP4	Positive
Napsin A	Positive/negative
p63	Positive/negative
CK20	Positive/negative
CK5/6	Positive/negative
CK903	Positive/negative
CDX2	Positive (focal staining)
Synaptophysin	Negative
Chromogranin A	Negative
NSE (neuron-specific enolase)	Negative
CD56 (neuronal cell adhesion molecule)	Negative
Lung adenocarcinoma (nonmucinous variant)	
TTF-1	Positive
Napsin A	Positive
CK7	Positive
p63	Positive/negative
Synaptophysin	Negative
Chromogranin A	Negative
NSE (neuron-specific enolase)	Negative
CD56 (neuronal cell adhesion molecule)	Negative
CK20	Negative
Bronchopulmonary carcinoids	
TTF-1	Positive (50%)
Synaptophysin	Positive
Chromogranin A	Positive
NSE (neuron-specific enolase)	Positive
CD56 (neuronal cell adhesion molecule)	Positive
Napsin A	Negative
CK7	Negative
CK20	Negative
p63	Negative

Contd...

- **Serum TTF-1:** Its concentration is increased in lung adenocarcinoma and thyroid carcinoma.
- **Serum combined NSE + ProGRP:** In the combined analysis of NSE + ProGRP, sensitivity and specificity in the diagnosis of small cell lung carcinoma is demonstrated in >80% of cases.
- **Serum combined TSGF + SCCAg + CYFRA21-1:** In the combined examination of serum levels of TSGF + SCCAg + CYFRA21-1 sensitivity and specificity in the diagnosis of squamous cell lung carcinoma (SCLC) is demonstrated in >80% of cases.

Serum Tumor Markers in Metastatic Lung Cancer

Serum tumor markers analyzed in metastatic lung cancers are given in Table 18.73.

Table 18.72 Serum tumor markers analyzed in diagnosing primary lung cancers

Categories	Serum Tumor Markers	Associated Malignancies
Oncofetal proteins	Carcinoembryonic antigen (CEA)	▪ *Lung carcinoma* (*adenocarcinoma and anaplastic carcinoma*) ▪ Nonseminomatous germ cell testicular tumor ▪ Colon carcinoma ▪ Stomach carcinoma ▪ Pancreatic carcinoma ▪ Breast carcinoma
Hormones	▪ Adrenocorticotropin hormone (ACTH)	▪ *Small cell lung carcinoma* ▪ Pancreatic carcinoma ▪ Neural tumors
	▪ Antidiuretic hormone (ADH) and atrial natriuretic hormone (ANH)	▪ *Small cell lung carcinoma* ▪ Intratracheal neoplasm
	▪ Parathyroid hormone-related protein (PTHrP)	▪ *Small cell lung carcinoma* ▪ Squamous cell lung carcinoma ▪ Breast carcinoma ▪ Ovarian carcinoma ▪ Renal cell carcinoma ▪ Adult T cell lymphoma
	▪ Gonadotropin	▪ *Small cell lung carcinoma* ▪ Squamous cell lung carcinoma ▪ Lung adenocarcinoma
	▪ Insulin ectopic hormone	▪ *Large cell lung carcinoma* ▪ Fibrosarcoma ▪ Mesenchymal sarcoma ▪ Hepatocellular carcinoma ▪ Cerebellar hemangioma ▪ Hepatocellular carcinoma ▪ Multiple myeloma ▪ Malignant lymphoma ▪ Liver carcinoma ▪ Prostatic carcinoma
Isoenzymes	Neuron-specific enolase (NSE)	▪ *Small cell lung carcinoma* ▪ Neuroblastoma
Mucins and glycoproteins	Cytokeratin fragment 21.1 (Cyfra 21.1)	Non-small cell lung carcinoma

Table 18.73 Serum tumor markers analyzed in metastatic lung cancers

Primary Cancers	Immunoprofiles
Breast carcinoma	CA 15.3, CA 27.29, CEA, ER & PR, PS2, HER2/neu. p53, DNA ploidy, S phase and EGFR, BRCA gene, CK7, GCDFP-15 (gross cystic disease fluid protein 15), and mammaglobin
Renal cell carcinoma	Erythropoietin
Colorectal carcinoma	CEA and p53
Thyroid carcinoma	TTF-1, thyroglobulin
Endometrial carcinoma type 1	ER, PR, PTEN
Prostatic carcinoma	PAP, PSA, DNA ploidy and IGFBP 2
Choriocarcinoma	Human chorionic gonadotropin

PLEURAL DISEASES

Serosal membranes are derived from the mesoderm. These serous membranes form the visceral and parietal surfaces of pleural, pericardial and peritoneal cavities including tunica vaginalis.

Parietal layer is perforated by lymphatic lacuna that connect with the lymphatic channels, which drain the enclosed cavities. Maximum quantity of fluid is absorbed into the lymphatic channels.

NON-NEOPLASTIC PLEURAL DISORDERS

PLEURAL EFFUSION

The pleural cavity contains small amount of pleural fluid <10 ml in a 70 kg man. Daily synthesis of pleural fluid is 17 ml. Maximum quantity of fluid is absorbed into the lymphatic channels.

Fluid moves from parietal pleura to pleural space to lungs. Movement depends upon the balance of Starling pressures. Mechanism of formation of pleural fluid is shown in Fig. 18.60.

Causes

Excessive accumulation of fluid in pleural cavity occurs in settings of congestive heart failure, cirrhosis, pneumonia, cancers and coronary artery bypass surgery. Leading causes of pleural effusions are given in Table 18.74. Differential diagnosis of pleural effusions is given in Table 18.75. Incidence of primary cancers causing pleural effusion is given in Table 18.76.

Pathogenesis

Pleuritis may result from the extension of any pulmonary infection to the visceral pleura. Causes of pleuritis include bacterial infections, viral infections, and pulmonary infarction involving the surface of the lung.

- **Pyothorax:** It refers to a turbid effusion containing many neutrophils. Empyema is a variant of pyothorax in which thick pus accumulates within the pleural cavity, often with loculation and fibrosis.
- **Transudative effusions:** Decreased oncotic pressure or increased hydrostatic pressure causes transudative pleural effusions. Transudate is ultrafiltrate of plasma involving disturbances in Starling pressures. Abnormal accumulation of fluid occurs due to

Table 18.74 Leading causes of pleural effusions

Etiology	Exudate	Transudate
Congestive heart failure	No	Yes
Cirrhosis	No	Yes
Pneumonia	Yes	No
Cancer	Yes	No
Viral disease	Yes	No
Coronary artery bypass surgery	Yes	No
Pulmonary embolism	Sometimes	Sometimes

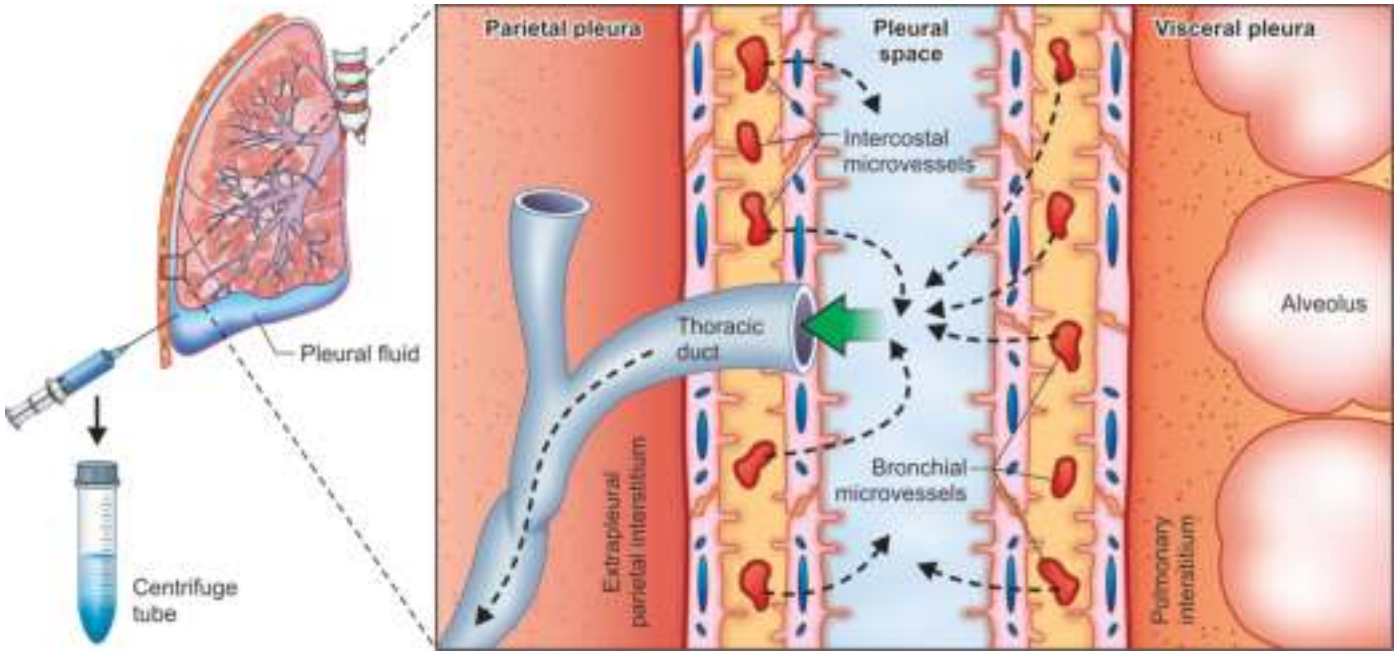

Fig. 18.60: Mechanism of formation of pleural fluid.

Table 18.75 Differential diagnosis of pleural effusions

Congestive heart failure
Nephrotic syndrome
Cirrhosis
Peritoneal dialysis
Superior vena cava syndrome
Myxedema
Urinothorax
Neoplastic diseases ▪ Metastatic disease (breast carcinoma, ovarian carcinoma, gastric carcinoma and lymphomas) ▪ Mesothelioma
Infectious diseases (bacteria including tuberculosis, viruses, fungi, parasites)
Pulmonary thromboembolism
Gastrointestinal disorders ▪ Esophageal perforation ▪ Endoscopic variceal sclerotherapy ▪ Pancreatic disease ▪ Intra-abdominal abscesses ▪ Diaphragmatic hernia ▪ Post-liver transplant cases ▪ Post-abdominal surgery cases
Collagen vascular disorders ▪ Systemic lupus erythematosus ▪ Rheumatoid arthritis ▪ Sjögren syndrome ▪ Wegener granulomatosis ▪ Chrug-Strauss syndrome
Post-coronary artery bypass surgery
Asbestos exposure
Sarcoidosis
Uremia
Meig's syndrome (ovarian fibroma associated with pleural effusion)
Yellow nail syndrome
Drug-induced pleural disease ▪ Nitrofurantoin ▪ Amiodarone ▪ Dantrolene bromocriptine ▪ Dasatinib
Trapped lung
Post-cardiac injury syndrome
Hemothorax
Iatrogenic injury
Ovarian hyperstimulation syndrome
Pericardial disease
Chylothorax

Contd...

Table 18.76 Incidence of primary cancers causing pleural effusion

Primary Neoplasms Causing Pleural Effusion	Frequency
Lung carcinoma	36%
Breast carcinoma	25%
Lymphomas	10%
Ovarian carcinoma	5%
Gastric carcinoma	2%
Unknown	7%

imbalance between hydrostatic pressure and/or reduction in plasma oncotic pressure. The pleura usually remains normal. This is termed transudative pleural effusion. Increased hydrostatic pressure in visceral pleura occurs in congestive heart failure. Nephrotic syndrome leads to decreased oncotic pressure resulting in transudative effusion.

- **Exudative effusions:** It most often results from pathological disorders of pleura resulting in increased vascular permeability and/or impaired fluid reabsorption (e.g. lymphatic obstruction). Increased vascular permeability of visceral pleural capillaries occurs due to pulmonary infarction, pneumonia, tuberculosis and metastatic cancers. Tuberculosis and malignancy are most common causes of pleural exudative effusion. Exudate is rich in proteins and inflammatory cells. Obstruction of lymphatic drainage from the visceral pleura by lung carcinoma also causes pleural effusion.
- **Chylothorax:** Pleural cavity contains milky, lipid-rich turbid lymph fluid as a result of thoracic duct (lymphatic) obstruction or rarely due to lymphomas in the posterior mediastinum. It can be iatrogenic tear during surgery or pathological process. Pleural fluid triglyceride >110 mg/dl is diagnostic of chylous effusion. Repeated thoracocentesis leads to malnutrition and compromised immune system. Chylothorax is treated by pleuroperitoneal shunt, surgical ligation of thoracic duct, radiation therapy and chemical pleurodesis.
- **Pseudochylous effusion:** In rheumatoid lung disease, there is excessive accumulation of milky and turbid fluid in pleural cavity due to inflammatory process and necrotic debris.

- **Hydrothorax:** It refers to transudation of edema fluid into the pleural cavity. The elevation of hydrostatic pressure in patients with congestive heart failure causes transudation of edema fluid into the pleural cavity (i.e. hydrothorax).
- **Hemothorax:** It refers to accumulation of blood in the pleural cavity due to chest trauma.
- **Urinothorax:** Unilateral pleural effusion is caused by ipsilateral obstructive uropathy.

Diagnostic Approach

Diagnostic approach of pleural effusion includes detailed clinical history, physical examination, imaging techniques, pleural fluid analysis and histologic examination.

- Indications of thoracocentesis include significant pleural effusion of unknown etiology and unilateral pleural effusion persisting for three days.
- Investigative parameters of pleural effusions are physical appearance, smell, total proteins content, LDH, microbial analysis, cytology, amylase, cholesterol triglyceride ratio, deaminase and PCR.

Physical parameters of pleural fluid are given in Table 18.77 and differences between pleural fluid exudate and transudate according to Light's criteria are given in Table 18.78.

Pleural Fluid Analysis: Pleural Diseases
Light Microscopy
Smears prepared from centrifuged pleural fluid are examined for inflammatory and malignant cells.

- **Neutrophil predominant exudates:** Exudate-rich in neutrophils is seen in pyothorax.
- **Lymphocyte predominant exudates:** Exudate-rich in predominant lymphocytes include tuberculosis, lymphomas, chylothorax, sarcoidosis, acute lung transplant rejection and coronary artery bypass surgery.
- **Eosinophil predominant pleural effusion:** Eosinophilia is characterized by presence of eosinophil count >10% of total nucleated pleural fluid cells. Etiology of eosinophil-rich pleural effusions is pneumothorax, benign asbestosis pleural disease, parasitic disease, fungal disease, drug-induced and Churg-Strauss syndrome.

PLEURITIS

Acute pleuritis is most often associated with bacterial pneumonia. Gram-positive bacteria are most often isolated. Spontaneous bacterial pleuritis is occasionally seen in a case of cirrhosis. Autoimmune pleuritis may mimic infectious pleuritis.

PLEURAL FIBROSIS

Reactive Pleural Fibrosis

Reactive pleural fibrosis most often occurs as a consequence of prior inflammation or surgery. Pleural fibrosis occurs due to adhesion between parietal and visceral layers of pleura.

Pleural Plaques

Pleural plaques are formed on parietal layer of pleura. Chronic pleural effusions and prolonged exposure to

Table 18.77 Physical parameters of pleural fluid

Parameters	Characteristic Findings	Probable Diagnosis
Color	▪ Pale yellow	▪ Classic paucicellular transudate
	▪ Red (bloody)	▪ Cancers, trauma, benign asbestos effusion, post-cardiac injury syndrome, pulmonary infarction
	▪ Milky white	▪ Chylothorax
	▪ Brown	▪ Amoebic liver abscess rupture, long-standing bloody effusion
	▪ Black	▪ Aspergillosis infection
	▪ Yellow green	▪ Rheumatoid pleurisy
	▪ Green	▪ Biliopleural fistula
Odor	Putrid	Anaerobic empyema

Table 18.78 Differences between pleural fluid exudate and transudate according to Light's criteria

Component	Pleural Exudate	Pleural Transudate
Pleural fluid/serum protein	>0.5	<0.5
Pleural fluid LDH/serum LDH	>0.6	<0.6
Pleural fluid LDH	>200 units/L	<200 units/L

asbestos produces raised, discrete, white to gray bilateral pleural plaques. Histologic examination of pleural plaque shows paucicellular dense collagenous tissue.

Diffuse Fibrosis of Pleural Visceral Layer

Diffuse fibrosis of pleural visceral layer occurs due to silicosis, advanced hypersensitivity reactions, connective tissue disorders and empyema.

Surgical Pathology: Diffuse Fibrosis of Pleural Visceral Layer
Gross Morphology
Diffuse fibrosis of pleural visceral layer is difficult to differentiate from desmoplastic mesothelioma.
Light Microscopy
Diffuse fibrosis of pleural visceral layer does not infiltrate the subjacent soft tissue. On the other hand, mesothelioma invades the subjacent soft tissue.

MALIGNANT PLEURAL TUMORS

MALIGNANT MESOTHELIOMA

Malignant mesothelioma arises from mesothelial cells of pleura. It occurs in occupational workers on prolonged exposure to asbestos for 30–40 years. Oncogenic SV40 virus has also been reported as etiological cause in some cases. Rare cases may be related to therapeutic radiation exposure.Widespread metastases of malignant mesothelioma can occur.

Pathology

Tumor begins as multiple small nodules on the parietal and visceral pleura encasing lung. It then invades the soft tissues of the chest wall and often extends into the mediastinum encasing of the pericardial sac. Disease is lethal and associated with 100% mortality.

Clinical Features

Patient presents with dyspnea, chest pain, and pleural effusion, constitutional symptoms such as weight loss, weakness and fatigue.

Surgical Pathology: Malignant Mesothelioma
Gross Morphology
Pleura exhibits multiple nodules to bulky dense white tumor.
Light Microscopy
▪ **Epithelioid mesothelioma:** Tumor is composed of bland cells with abundant eosinophilic cytoplasm arranged in sheet-like microglandular and tubulopapillary patterns. In some cases, tumor may show more anaplastic features. Psammoma bodies are occasionally seen.
▪ **Sarcomatoid mesothelioma:** Tumor is composed of spindle cells arranged in haphazard pattern. Immunohistochemical analysis shows positivity for cytokeratin 5/6. Tumor shows osteosarcoma and chondrosarcoma differentiation express actin, desmin, vimentin and/or S-100. Sarcomatoid mesothelioma has aggressive behavior.
▪ **Desmoplastic mesothelioma:** Tumor is most often misdiagnosed as organizing pleuritis in small biopsy specimens. Tumor is composed of scattered atypical cells arranged in storiform pattern in >50% of cases. There is presence of dense collagenous fibers in the background of tumor cells.
▪ **Biphasic mesothelioma:** Tumor comprises mixed epithelioid and sarcomatous elements. By definition, each component should comprise at least 10% of the tumor (Figs 18.61 and 18.62).
Immunohistochemistry Technique
Panel of immunomarkers is used to analyze expression in mesothelioma on histologic tissue sections. Immunohistochemistry analysis is done in differential diagnosis of lung adenocarcinoma and mesothelioma (Table 18.79).

Markers	Expression
▪ Calretinin	▪ Positive
▪ WT1	▪ Positive
▪ CK5/CK6	▪ Positive
▪ CK7	▪ Positive
▪ CK903	▪ Positive
▪ Thrombomodulin (CD141)	▪ Positive
▪ HBME-1	▪ Positive
▪ N-cadherin	▪ Positive
▪ D2–40	▪ Positive
▪ Mesothelin	▪ Positive/negative
▪ TTF-1	▪ Negative
▪ Napsin A	▪ Negative
▪ CK20	▪ Negative
▪ p63	▪ Negative
▪ Synaptophysin	▪ Negative
▪ Chromogranin A	▪ Negative
▪ NSE (neuron-specific enolase)	▪ Negative
▪ CD56 (neuronal cell adhesion molecule)	▪ Negative

TTF-1 (thyroid transcription factor 1) is positive in small cell lung carcinoma (90%), adenocarcinoma mucinous (20%) and adenocarcinoma nonmucinous variant, extrapulmonary small cell lung carcinoma (40%); NSE (neuron-specific enolase).

It is difficult to differentiate metastatic adenocarcinoma of pancreas and upper gastrointestinal tract from mucinous lung adenocarcinoma. Both metastatic tumors are CK7 positive, CK20 positive but TTF-1 negative. DPC4 is deleted in 55% cases of adenocarcinoma of pancreas but not lung origin.

Fig. 18.61: Mesothelioma shows bulky dense white tumor arising from visceral pleura most often associated with prolonged asbestos exposure. Asbestos exposure more commonly predisposes to bronchogenic carcinomas. Smoking increases the 10 times risk for lung cancer (arrows).

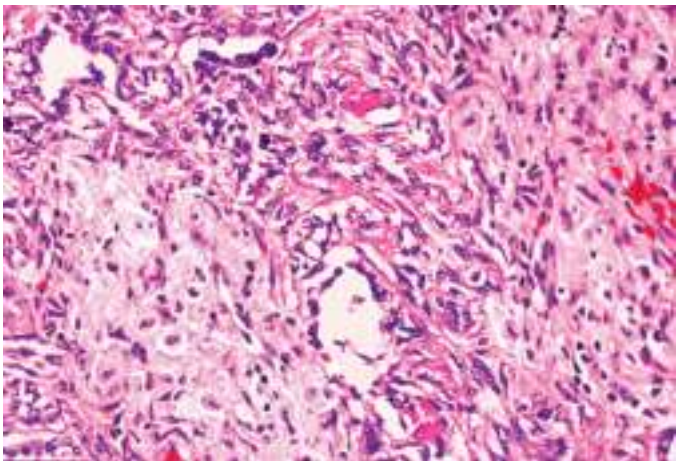

Fig. 18.62: Mesothelioma. Tumor shows plump rounded cells with abundant eosinophilic cytoplasm forming gland-like configurations (400X).

Differential Diagnosis

Mesothelioma should be differentiated from lung adenocarcinoma. Histochemical, electron microscopy and immunohistochemical staining characteristics of mesothelioma and lung adenocarcinoma are given in Table 18.80.

PRIMARY PLEURAL EFFUSION LYMPHOMA

Primary pleural effusion lymphoma presents as pleural effusion without an associated tumor mass.

Table 18.79 Histochemical, electron microscopy and immunohistochemical staining characteristics of malignant mesothelioma and lung adenocarcinoma

Features	Malignant Mesothelioma	Lung Adenocarcinoma
Histochemistry		
Glycogen content in cytoplasm	Present, but no diastase-resistant PAS (periodic acid–Schiff) positive material	Present but small, may demonstrate diastase-resistant PAS (periodic acid–Schiff) positive mucin
Acidophilic hyaluronic acids in glands or on neoplastic cell surface	Present	Absent
Electron microscopy		
Microvilli	Elongated, slender and bushy without glycalyceal bodies and may mingle with collagen fibers	Short and stubby with glycalyceal bodies, generally confined to the luminal surface and seldom mingle with collagen fibrils
Desmosomes	Long and well developed	Short and less developed
Filaments	Perinuclear filaments	Irregularly distributed intermediate filaments
Junctions	Apical tight junctions	Terminal bars near lumen
Mucin granules	Present	May be present
Glycogen	Abundant	Variable
Fat droplets	Scanty	Absent

Thyroid transcription factor 1 (TTF-1)	Negative (100%)	Positive/negative
Napsin A	Negative (100%)	Positive/negative
Ber-EP4	Negative	Positive/negative
Carcinoembryonic antigen monoclonal (mCEA)	Negative/positive	Positive/negative
CD15 (Leu-M1)	Negative	Positive
BG8	Negative/positive	Positive/negative
MOC-31	Negative/positive	Positive/negative
Epithelial markers		
Epithelial membrane antigen (EMA)	Positive/negative (membranous staining)	Positive/negative (membranous staining)
Cytokeratins (AE1/AE3, CAM 5.2)	Positive (perinuclear accentuation)	Positive (membranous accentuation)
Histochemical special stains		
Mucicarmine	Positive	Positive/negative
PAS	Positive	Positive
PAS/diastase	Negative	Positive
Alcian blue	Positive	Positive
Alcian blue/hyaluronidase	Negative	Positive
Electron microscopy		
Length of microvilli	Long (length to breadth ratio >10:1)	Short

Other markers for mesothelioma include p53, EMA, CD146 and GLUT1. Remember GLUT1 is positive in lung carcinoma.
Standard panel of markers for mesothelioma includes calretinin, CK5/CK6.
Standard panel of markers for adenocarcinoma includes TTF-1, napsin A, Ber-EP4.

Table 18.81 Comparison of primary effusion (body cavity-based) pleural lymphoma and pyothorax-associated pleural lymphoma

Features	Primary Effusion (Body Cavity-based) Pleural Lymphoma	Pyothorax-associated Pleural Lymphoma
Gross morphology	Pleural effusion	Pleural mass lesion
Etiology	Immunosuppression, e.g. HIV positive homosexual males	Chronic pleuritis following repeated artificial pneumothorax
HIV (human immunodeficiency virus) status	Positive	Negative
HHV (human herpesvirus)	Positive	Negative
EB virus (Epstein-Barr virus) status	Positive	Positive
Immunohistochemistry	▪ CD20 negative ▪ CD3 negative	▪ CD20 positive/negative ▪ CD3 positive/negative

It is associated with human herpesvirus 8 and acquired immunodeficiency syndrome. Immunohistochemical analysis reveals that primary pleural effusion lymphoma is of null phenotype, although occasional cases express B cell or T cell markers.

Comparison of primary effusion (body cavity-based) pleural lymphoma and pyothorax-associated pleural lymphoma is given in Table 18.81.

PYOTHORAX EFFUSION LYMPHOMA

Pyothorax effusion lymphoma is a diffuse large B cell lymphoma that arises from pleura in elderly persons, who have long-standing history of pyothorax in the settings of tuberculous pleuritis.

- It is strongly associated with EB virus infection.
- Immunohistochemical analysis of tumor shows positivity for B cell markers. CD20 is most often negative.

CHAPTER 19

Oral Cavity, Salivary Glands and Jaw

Vinay Kamal, Anubhav and Vigyat

LEARNING OBJECTIVES

DISORDERS OF ORAL CAVITY

- Congenital and inherited focal disorders: overview
  - Congenital disorders
    - Facial clefts
    - Harelip (cleft lip)
    - Cleft palate
    - Hemifacial hypertrophy
  - Inherited focal disorders
    - Fordyce's granules
    - Congenital lip pits
    - Endogenous melanin pigmentation
    - Congenital epulis
    - White sponge nevus
- Inflammatory disorders
  - Acute necrotizing ulcerative gingivitis (Vincent angina)
  - Ludwig angina
  - Exudative pharyngitis
  - *Candida albicans* (oral thrush)
  - Herpes simplex virus 1 infection
  - Other viral infections
  - Aphthous stomatitis
- Tumors of oral cavity
  - Squamous cell papilloma
  - Squamous cell carcinoma
  - Kaposi sarcoma
  - Epithelial precursor oral lesions
    - Leukoplakia
    - Granuloma pyogenicum

DISORDERS OF SALIVARY GLANDS

- Anatomy of salivary glands
- Inflammatory disorders
  - Acute sialadenitis
  - Viral sialadenitis
  - Autoimmune sialadenitis
  - Chronic obstructive sialadenitis
  - Chronic recurrent parotitis
- Tumors of salivary glands
  - Pleomorphic adenoma
  - Warthin's tumor
  - Oncocytoma
  - Monomorphic adenoma
  - Mucoepidermoid carcinoma
  - Adenoid cystic carcinoma
  - Acinic cell carcinoma
  - Polymorphous low-grade adenocarcinoma
  - Carcinosarcoma
  - Squamous cell carcinoma

DISORDERS OF JAW

- Anatomy of jaw
- Dental and periodontal disorders of jaw
  - Dental caries
  - Periodontal disease
- Cystic lesions of jaw
  - Dentigerous cyst (follicular cyst)
  - Keratocystic odontogenic tumor (odontogenic keratocyst)
  - Lateral periodontal cyst
  - Gingival cyst
  - Calcifying odontogenic cyst
  - Glandular odontogenic cyst
  - Radicular (periapical cyst)
  - Nasopalatine duct cyst
  - Globulomaxillary cyst
  - Median palatal cyst
  - Simple bone cyst
  - Aneurysmal bone cyst
- Odontogenic tumors
  - Adenomatoid odontogenic tumor
  - Calcifying epithelial odontogenic tumor (Pindborg tumor)
  - Squamous odontogenic tumor
  - Ameloblastic fibroma
  - Odontoma
  - Cementoma
  - Odontogenic myxoma, myxofibroma and fibroma
  - Ameloblastoma (adamantinoma)
  - Ameloblastic carcinoma
  - Odontogenic carcinoma
  - Ameloblastic fibrosarcoma
- Nonodontogenic tumors
  - Fibrous dysplasia
  - Fibroma group lesions
  - Central giant cell granuloma
  - Cherubism
  - Brown tumor of hyperparathyroidism

DISORDERS OF ORAL CAVITY

CONGENITAL AND INHERITED FOCAL DISORDERS: OVERVIEW

Oral cavity is lined by stratified squamous epithelium similar to skin. Epithelium of oral cavity varies in respect of keratinization. There are variations in the presence and absence of rete ridges. Rete ridges are absent in the floor of mouth. Rete ridges are well marked in the palate and gums.

CONGENITAL DISORDERS

Facial Clefts

Facial clefts are most common congenital disorders in the oral cavity about 1 per 800 live births. These occur due

to failure of fusion of facial processes at 7th week of gestation. This gap is normally bridged by ectomesenchyme. According to recent studies, abnormalities of growth factors may be linked to formation of facial clefts.

Harelip (Cleft Lip)

Harelip, also known as cleft lip, is the most common congenital defect of upper lip. Normally, on the 35th day of gestation, the frontal prominence fuses with the maxillary process to form the upper lip. Harelip results from failure of fusion of the lower part of the median nasal process with the maxillary process.

- Disturbance in gene expression interferes with proper fusion resulting in cleft lip, with or without cleft palate.
- In addition to multifactorial inheritance, developmental anomalies may occur due to teratogenic effects of rubella infection and anticonvulsants administration involving chromosomes during pregnancy. Harelip is unilateral in 80% of cases. About two-thirds of patients have left-sided harelip.

Cleft Palate

Cleft palate is less common congenital defect than harelip. It occurs in about 1 per 2500 live births. Unlike harelip, isolated cleft palate is more common in females. It occurs due to failure of fusion of facial processes due to multifactorial inheritance in which multiple genes interact with various environmental factors to produce disease.

Cleft palate is more common in Pierre Robin syndrome characterized by small mandible. Backward displacement of chin and displaced small tongue posteriorly cause upper airway obstruction. Cleft palate may occur as part of trisomies 13 and 18.

Hemifacial Hypertrophy

Hemifacial hypertrophy is characterized by rapid growth of both hard and soft tissues on one side of the face. The teeth on the affected side and half of tongue with hypertrophied papillae may occur.

INHERITED FOCAL DISORDERS

Fordyce's Granules

Fordyce's granules are small yellowish-white granules located on the lateral aspect of the vermilion of the upper lip or surface of the buccal mucosa in normal adults without clinical significance. These granules represent ectopic development of sebaceous glands.

Congenital Lip Pits

Congenital lip pits are small fistulae communicating the surface epithelium with underlying mucous glands. These are most often bilateral located on the lower lip. There may be isolated lesions or associated with cleft palate, harelip and agenesis of second premolar teeth. Later defect may be inherited as autosomal disorder.

Endogenous Melanin Pigmentation

Endogenous melanin pigment may be deposited on lips, oral mucosa and circumoral skin in various disorders, which include neurofibromatosis, fibrous dysplasia of bone, Peutz-Jeghers syndrome, hemochromatosis and Addison's disease. Peutz-Jeghers syndrome is characterized by pigmentation of the vermilion of the lips and small intestinal polyps.

Congenital Epulis

Congenital epulis refers non-neoplastic benign lesion of the gingivae especially in females. It is most often a reparative growth rather than a true neoplasm. On histologic examination, lesion is composed of aggregates of large granular cells covered by well differentiated squamous epithelium. Electron microscopy suggests that lesion either originates from fibroblasts or perivascular pericytes. These granular cells are negative for S-100 protein.

White Sponge Nevus

White sponge nevus is an autosomal dominant disorder and characterized by shaggy, white patches on the oral and buccal mucosae. The thickened squamous epithelium becomes edematous that easily desquamate. Histologic examination of lesion shows hyperplastic squamous epithelium, in which there is marked intracellular and extracellular edema.

INFLAMMATORY DISORDERS

Inflammatory disorders of oral cavity are caused by bacteria, viruses or fungi. Oral lesions may occur in various systemic disorders (Table 19.1).

ACUTE NECROTIZING ULCERATIVE GINGIVITIS (VINCENT ANGINA)

Acute necrotizing ulcerative gingivitis also known as Vincent angina, which represents an infection by two symbiotic organisms; one is a fusiform bacillus, and the other is a spirochete (*Borrelia vincentii*) found in oral cavity in normal persons. These organisms multiply under anaerobic conditions and cause tissue breakdown. Malnutrition promotes the risk for development of this disorder.

Clinical Features

Patient develops acute ulcerative necrotizing gingivitis in persons with decreased resistance to infection

Table 19.1 Oral lesions in various systemic disorders

Systemic Disorders	Mechanism	Oral Lesions
Pemphigus vulgaris	*Autoimmune disorder:* IgG antibodies directed against the intercellular area between keratinocytes	Vesicular lesions
Erythema multiforme	Hypersensitivity to sulphonamide drug	Involves oral mucosa
Addison's disease	Adrenal gland disorder	Oral pigmentation
Amyloidosis	Amyloid deposition in tongue	Macroglossia
Lichen planus	Skin disorder	Fine, lacy white lines on the mucosal surface called Wickham's striae
Lead poisoning	Toxic effect	Lead line in oral mucosa

as a result of inadequate nutrition, immunodeficiency, or poor oral hygiene. The ulceration tends to spread and involves all gingival margins, which becomes covered by a necrotic pseudomembrane.

LUDWIG ANGINA

Ludwig angina is potentially life-threatening inflammatory process. It is rapidly spreading cellulitis (phlegmon) in submaxillary or sublingual space. Normal oral bacterial flora is responsible for infection. These microorganisms cause cellulitis following tooth extraction, hairline fractures of lingual cortex of the mandible. By involving the fascial planes, infection may dissect into the parapharyngeal space, and then, into the carotid sheath.

EXUDATIVE PHARYNGITIS

Patient with *Streptococcus pyogenes* develops exudative pharyngitis and tonsillitis in 20–30% of cases. Patient presents with painful exudative lesions in the pharynx and tonsils.

CANDIDA ALBICANS (ORAL THRUSH)

Candida albicans is a common surface inhabitant of the oral cavity, gastrointestinal tract, and vagina. Patient develops oral thrush including tongue with white pseudomembrane consisting of keratinous debris and yeasts. It most commonly occurs in debilitated infants, children, diabetes mellitus and AIDS in 40–90% of cases. About 5–10% of neonates are affected as a result of infection acquired during delivery. In more severe cases, extensive white pseudomembrane formation occurs.

HERPES SIMPLEX VIRUS 1 INFECTION

Herpes simplex virus 1 infection starts with painful inflammation of the affected mucosa, followed shortly by the formation of vesicles due to ballooning degeneration of the epithelial cells. Shallow ulcers are formed as a result of rupture of vesicles. The ulcers heal spontaneously without scar formation. It tends to recur following trauma, sunshine, febrile illnesses or menstruation.

Age Group

Disease due to human simplex virus 1 affects both children and young adults.

Clinical Features

Patient presents with fever, stomatitis involving lips and oral mucosa, blisters on vagina known as herpes viral vaginalis and cold sores due to herpesvirus type 1.

Surgical Pathology: Herpes Simplex Virus 1 Infection

Light Microscopy

- Lesion in herpes simplex virus 1 infection shows intranuclear inclusion bodies in some epithelial cells.
- There is presence of multinucleated epithelial cells with ground glass homogenized nuclei, often exhibiting nuclear molding at the edge of the ulcer.

OTHER VIRAL INFECTIONS

Patient with coxsackievirus A infection develops vesicular lesions in oral cavity, hand and feet. Patient with Epstein-Barr virus infection develops exudative pharyngitis, leukoplakia located on the lateral side of tongue in HIV positive patients.

APHTHOUS STOMATITIS

Patient presents with recurrent painful erosive, solitary or multiple ulcerations in the mouth. It may or may not be associated with systemic disease. Etiology is unknown. Histologic examination shows a shallow ulcer covered by a fibrinopurulent exudate.

TUMORS OF ORAL CAVITY

WHO classification of tumors of the oral cavity is given in Table 19.2.

Table 19.2 WHO classification of tumors of the oral cavity

Epithelial Tumors and Lesions

- Squamous cell carcinoma
- Oral epithelial dysplasia
  - Low-grade dysplasia
  - High-grade dysplasia
- Proliferative verrucous leukoplakia
- Squamous cell papilloma
- Condyloma accuminatum
- Verruca vulgaris
- Multifocal epithelial hyperplasia

Tumors of Uncertain Histogenesis

- Congenital granular cell epulis
- Ectomesenchymal chondromyxoid tumor

Soft Tissue and Neural Tumors

- Granular cell tumor
- Rhabdomyoma
- Lymphangioma
- Hemangioma
- Schwannoma
- Neurofibroma
- Kaposi sarcoma
- Myofibroblastic sarcoma

Oral Mucosal Melanoma Salivary Gland Tumors

- Pleomorphic adenoma
- Mucoepidermoid carcinoma

Hematolymphoid Tumors

- CD30 positive T cell lympho-proliferative disorder
- Plasmablastic lymphoma
- Langerhans cell histiocytosis
- Extramedullary myeloid sarcoma

SQUAMOUS CELL PAPILLOMA

Squamous cell papilloma is the most common benign tumor of oral mucosa, most often seen on the tongue, lips, gingivae, or buccal mucosa.

SQUAMOUS CELL CARCINOMA

Approximately 95% of the cancers of the head and neck are squamous cell carcinomas. These most often occur in the oral cavity in older age group. Biologically, squamous cell carcinoma in oral cavity is similar to elsewhere in head and neck.

Locations

- Squamous cell carcinoma occurs in lower lip, floor of the mouth, tongue, the palatine and lingual tonsils. Ventrolateral surface of tongue and floor of the mouth are the most frequent sites involved accounting for >50% of cases. Least affected sites are dorsum of the tongue and hard palate.
- Oral mucosa with thin nonkeratinized squamous epithelium and poorly developed or absent rete ridges and narrow lamina propria are at higher risk for development of oral cancer. Locations of oral squamous cell carcinoma are shown in Fig. 19.1.

Predisposing Factors

Combined abuse of oral tobacco, snuff-dipping or betel nut chewing and alcohol predispose to oral cancer. Leukoplakia may predispose to oral cancer.

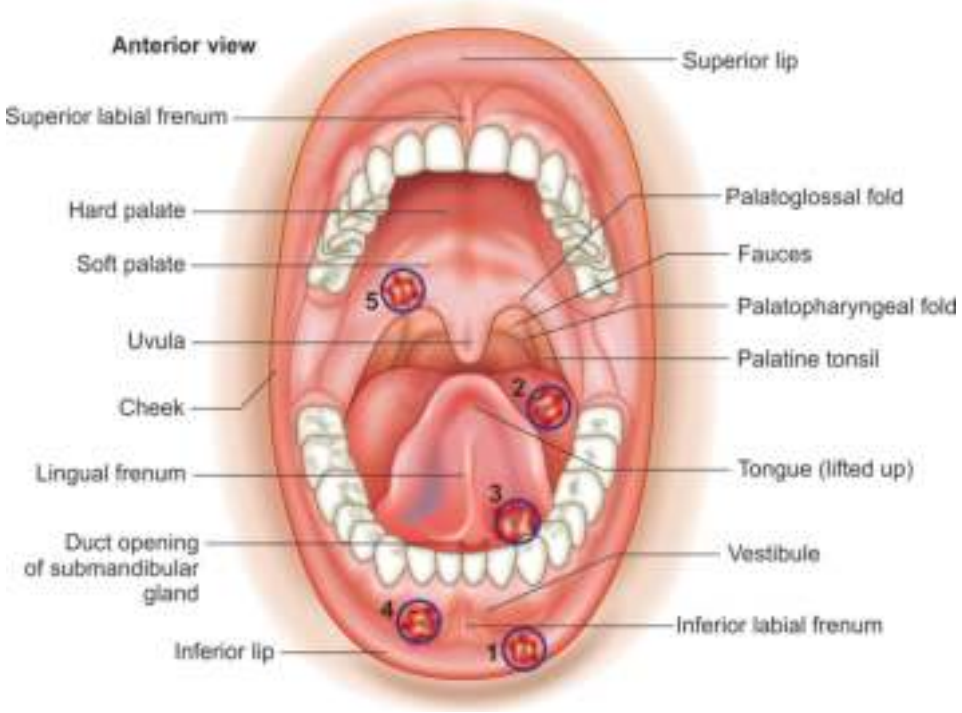

Fig. 19.1: Locations and frequency of oral carcinoma (1–5 most common to least common).

In 50% of cases, human papillomavirus 16 (HPV-16) is the etiological agent in oropharyngeal squamous cell carcinoma.

Molecular Pathogenesis

All cell lines derived from squamous cell carcinoma show multiple loss of chromosomes. Short arms of acrocentric chromosomes (13, 14, 15, 21 and 22) are deleted in 70% of cases. Cytogenetic changes in oral squamous cell carcinoma are given in Table 19.3.

Molecular pathogenesis of squamous cell carcinoma is a multistep process involving the sequential activation of oncogenes and inactivation of tumor suppressor genes in the clonal population of cells. At the molecular level, amplification and overexpression have been observed in epidermal growth factor receptor (EGFR), and apoptosis-inhibiting BCL-2 gene. The high frequency of these aberrations suggests that these genomic alterations play an important role in the pathogenesis of oral squamous cell carcinoma.

- **Transition from normal to hyperplasia:** First change is loss of chromosomal 9p21 and 3p during this process. Hypermethylation and loss of heterozygosity at this locus leads to inactivation of p16, an inhibitor of cyclin-dependent kinase.
- **Mild/moderate dysplasia to severe dysplasia:** Subsequent loss of heterozygosity at 17p with mutation of p53 tumor suppressor gene progresses to severe dysplasia in oral cavity.
- **Severe dysplasia to SCC:** Finally, amplification and overexpression of the cyclin D1 gene located on 11q13 and genomic deletions of 4q, 6p, 8p, 13q and 14q cause progression of severe dysplasia to squamous cell carcinoma in oral cavity.

Table 19.3 Cytogenetic changes in oral squamous cell carcinoma in descending order

Chromosomal Abnormality	Frequency
Chromosome 18q	100%
Chromosome 10p	80%
Chromosome 8p	70%
Chromosome 3p	60%
Chromosome 9p	–
Chromosome 17p	–
Chromosome 4p	–
Chromosome 6p	–
Chromosome 13q	–
Chromosome 14q	–

Surgical Pathology: Squamous Cell Carcinoma in Oral Cavity

Gross Morphology

- Gross morphology of tumor depends on stage of the presentation of oral carcinoma. Initial lesion is either opaque white or irregular warty areas.
- Later, the tumor undergoes ulceration. Ulcer has firm rolled edges and indurated bed.

Light Microscopy

- **Squamous cell carcinoma:** It ranges from well-differentiated keratinizing to poorly differentiated, sometimes shows sarcomatoid to basaloid morphology. Tumor may be slow to rapidly growing invading cervical lymph nodes. Low-grade well-differentiated squamous cell carcinoma is associated with smokeless tobacco (Figs 19.2 and 19.3).
- **Verrucous carcinoma:** It occurs in buccal mucosa and gums of lower jaw. Patient presents with bulky, soft, cauliflower-like growth that becomes infected giving foul smell. Under light microscopy, tumor shows well-differentiated carcinoma. Rete ridges are markedly thickened and growing down into underlying tissues in a characteristically bullous pattern. At a later stage, tumor invades stroma.

Immunohistochemistry Technique

Panel of immunomarkers is used to analyze expression in oral squamous cell carcinoma on histopathological sections.

Markers	Differentiation of Tumor	Expression
Cytokeratin 1,10	Well-differentiated keratinized SCC	Positive
Cytokeratin 4,13	Well-differentiated non-keratinized SCC	Positive
Cytokeratin 8,18	Poorly-differentiated SCC	Positive

Mode of Spread

- **Direct invasion:** Tumor has tendency to invade either deeply or widely within the subepithelial tissue. Invasion of mandible creates obstacle to complete surgical excision.

Fig. 19.2: Squamous cell carcinoma of lower lip (arrow).

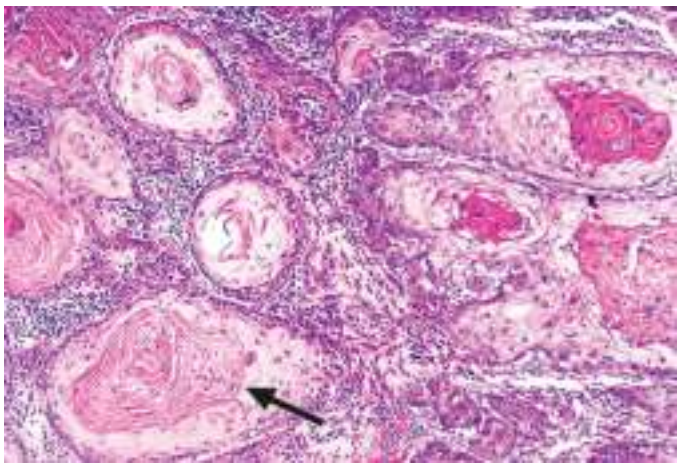

Fig. 19.3: Well differentiated squamous cell carcinoma (arrow) (400X).

- **Lymphatic route:** Lymph node metastases are more often present at the time of clinical presentation in patients with oral carcinoma. Lymph nodes are seen in the submandibular region. At later stage, tumor may metastasize to mediastinal lymph nodes.
- **Hematogenous route:** Oral carcinoma may metastasize to distant organs such as lungs, liver and bones via hematogenous route.

Prognosis

- Prognosis of oral carcinoma depends on location, depth of invasion, stage, histologic grading, desmoplastic reaction, tissue eosinophilia, lymph node metastases and DNA ploidy.
- Presence of florid desmoplastic reaction in squamous cell carcinoma of lip is associated with increased incidence of metastases and associated with aggressive behavior.
- Tumor infiltrated by eosinophils has favorable prognosis.
- Lymph node metastases are used in staging system. Extracapsular spread is an indicator of poor prognosis.
- The nondiploid tumors tend to be clinically more advanced than diploid tumors.
- Overexpression of p16 has favorable prognosis.
- Overexpression of p21 gene and TROP2, loss of H antigen and amplification of 3q26.3 is associated with poor prognosis. Survival rate and staging of oral carcinoma are given in Tables 19.4 and 19.5.

KAPOSI SARCOMA

Kaposi sarcoma occurs due to herpesvirus 8 in the oral cavity. It is most frequently associated with AIDS and located on the palate. It is locally aggressive endothelial tumor.

Surgical Pathology: Kaposi Sarcoma	
Light Microscopy	
Tumor is composed of bizarre-shaped blood vessels with stands of spindle cells and extravasated red blood cells.	
Immunohistochemistry Technique	
Lining cells of vascular structures are positive for CD31, CD34, podoplanin and nuclear expression of HHV8.	
Markers	**Expression**
▪ CD31 ▪ CD34 ▪ Podoplanin ▪ HHV8	▪ Positive ▪ Positive ▪ Positive ▪ Positive

Table 19.4 Overall 5-year survival rate of oral carcinoma

Location	Survival Rate
Lower lip	90%
Anterior aspect of tongue	60%
Posterior part of tongue, floor, tonsil, gum, hard palate	40%
Soft palate	20–30%

Table 19.5 Survival rate and staging of oral carcinoma

Stage	Tumor	Lymph Node Metastases	Distant Metastases	5-Year Survival
Stage 0	*Tis* (Tumor *in situ*)	N0	M0	100%
Stage I	T1 (≤2 cm)	N0	M0	90%
Stage II	T2 (>2 to 4 cm)	N0	M0	77%
Stage III	▪ T1, T2 ▪ T3 (>4 cm)	▪ N1 (≤3 cm) ▪ N0, N1	▪ M0 ▪ M0	61%
Stage IVA	▪ T1, T2, T3 ▪ T4a (advanced invading tissue)	▪ N2 (>3–6 cm single) ▪ N0, N1, N2	▪ M0 ▪ M0	32%
Stage IVB	▪ T4b ▪ Any T	▪ Any N ▪ N3 (>6 cm)	▪ M0 ▪ M0	25%
Stage IVC	Any T	Any N	M1	3.5%

Prognosis

Evolution of Kaposi sarcoma is modified by treatment that includes surgery, radiotherapy and chemotherapy.

EPITHELIAL PRECURSOR ORAL LESIONS

Leukoplakia

Leukoplakia is a clinical term describing irregular white mucosal patches of oral mucosa. On clinical examination, lesion may be homogenous, nodular, erythroplakia or proliferative verrucous leukoplakia. WHO criteria used in diagnosis of dysplasia of oral mucosa are shown in Table 19.6.

- Leukoplakia results from hyperkeratosis, usually secondary to chronic irritation. It is caused by oral tobacco products and excessive alcohol intake.
- Leukoplakia is usually a benign disorder. However, it may represent dysplasia (mild, moderate or severe or carcinoma *in situ*) progressing to squamous cell carcinoma. Oral intraepithelial neoplasia is categorized into grade I (mild dysplasia), grade II (moderate dysplasia) and grade III (severe dysplasia or carcinoma *in situ*). Biopsy is required to rule out squamous dysplasia or squamous cell carcinoma (Fig. 19.4).

Granuloma Pyogenicum

Granuloma pyogenicum is a reactive vascular lesion most commonly seen on tongue, lips, or buccal mucosa especially in pregnant women. Minor trauma to tissues in these regions permits invasion of microorganisms (Fig. 19.5).

Table 19.6 WHO criteria used in diagnosis of dysplasia of oral mucosa

Histologic Architecture
▪ Irregular epithelial stratification ▪ Loss of polarity of basal cells ▪ Drop-shaped rete ridges ▪ Increased number of mitoses ▪ Abnormally superficial mitoses ▪ Premature keratinization in single cells (dyskeratosis) ▪ Keratin pearls within rete ridges
Cytologic Features
▪ Anisocytosis (variation in size) ▪ Cellular and nuclear pleomorphism ▪ Anisonucleosis (abnormal variation in nuclear size) with prominent nucleoli ▪ Increased nucleocytoplasmic ratio ▪ Atypical mitotic figures

Patient presents with small <1.0 cm elevated, red or purple, soft mass, with a smooth, lobulated, ulcerated surface in the oral cavity most frequent on the gingiva.

Surgical Pathology: Granuloma Pyogenicum

Light Microscopy

- Histologic examination shows nodule composed of highly vascular granulation tissue that shows varying degrees of acute and chronic inflammation.
- Granuloma pyogenicum later transforms to less vascular mass resembling fibroma.

Fig. 19.4: Leukoplakia of the oral cavity (arrow).

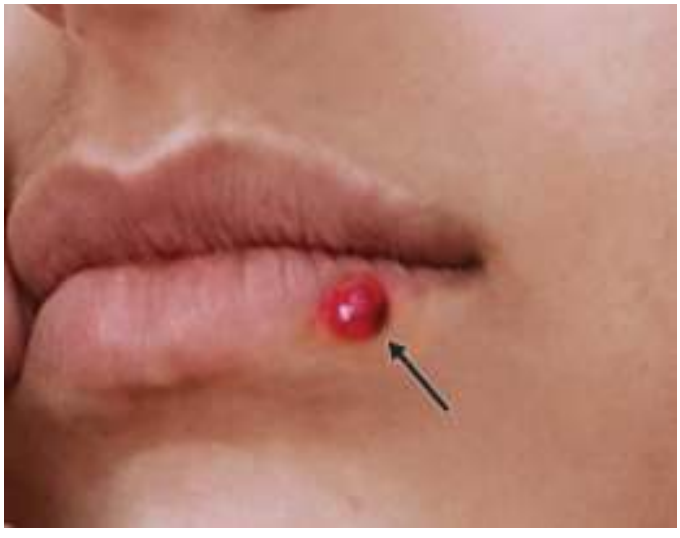

Fig. 19.5: Granuloma pyogenicum on the lip (arrow).

DISORDERS OF SALIVARY GLANDS

ANATOMY OF SALIVARY GLANDS

The salivary gland system comprises three pairs of major glands—parotid, submandibular and sublingual glands. Minor salivary glands are dispersed in the submucosa of oral cavity, lips, gingiva, floor of the mouth, cheek, hard and soft tongue, tonsillar areas and oropharynx (Figs 19.6 and 19.7).

- The functional unit of salivary glands is the secretory acinus and related ducts, and myoepithelial cells. Acini may be serous, mucous or mixed.
- The parotid glands are almost purely serous and the parenchyma is divided into lobules by fibrous septa. Parotid glands are divided into superficial and deep portions by the facial nerve. Each parotid gland drains via Stensen's duct and enters into the mouth.
- The submandibular glands are located in the groove between the lower jaw and tongue. These drain via Wharton's duct into the mouth.
- The sublingual glands are situated in the sublingual tissue of the mandible. Each gland drains via Bartholin's duct into the mouth. In some cases, sublingual gland's main excretory duct joins the main submandibular duct.

INFLAMMATORY DISORDERS

Sialadenitis may be caused by viral or bacterial infection, immune-mediated mechanisms, or occlusion of the salivary ducts by stones (sialolithiasis).

ACUTE SIALADENITIS

Acute sialadenitis is most often caused by bacterial or viral infection. Oral cavity is the source of bacterial

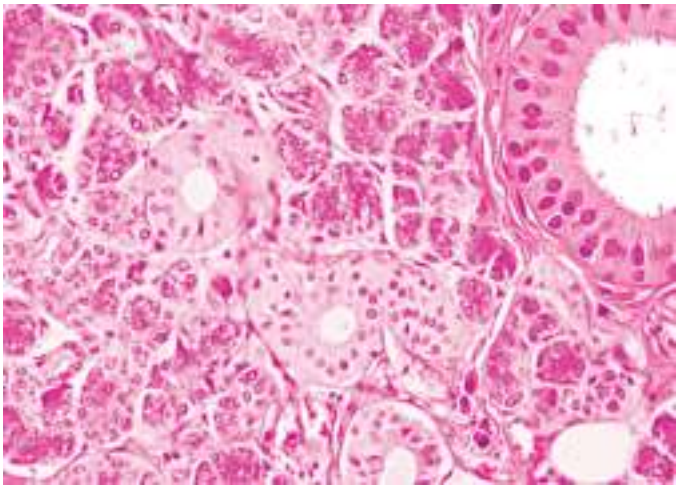

Fig. 19.7: Histology of salivary gland. Salivary gland is made up of secretory acini and ducts (400X).

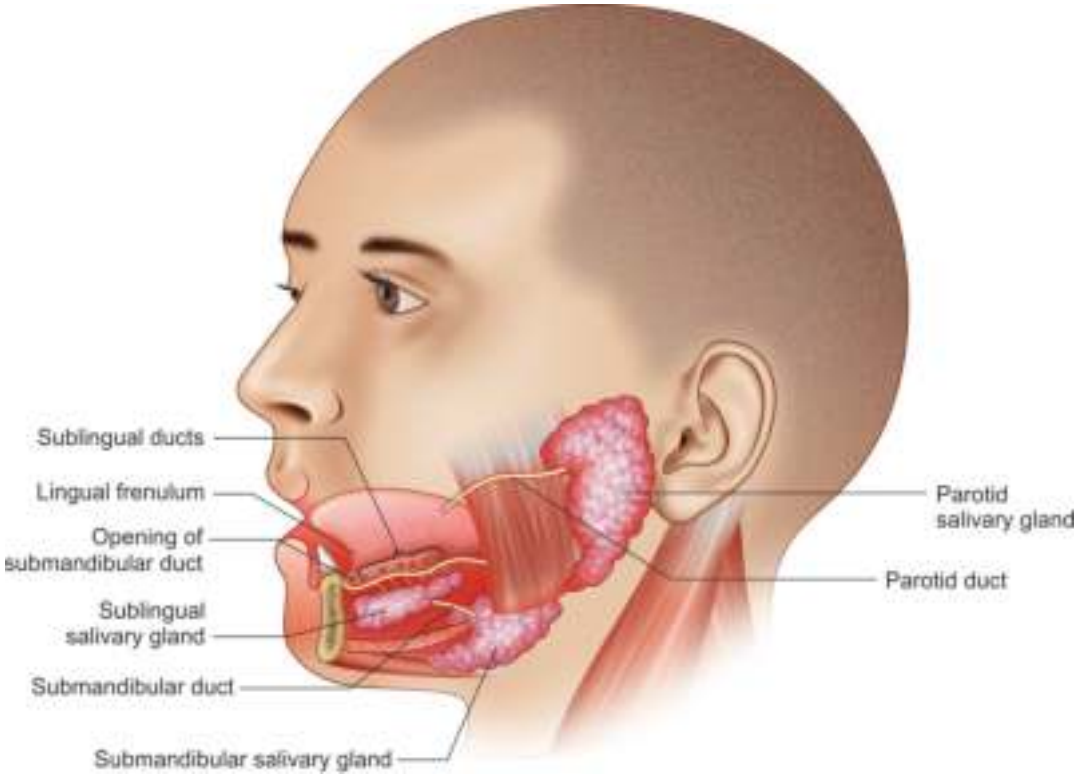

Fig. 19.6: Major salivary glands. These are salivary, submandibular and sublingual glands.

infection. Bacterial sialadenitis occurs when saliva flows through the affected duct is decreased due to salivary calculi. Acute sialadenitis is seen mainly in association with chronic xerostomia. Causative organisms include *Staphylococcus aureus* followed by *Streptococcus viridans*. Salivary gland shows purulent exudate and bacterial colonies. Patient presents with painful enlargement of one or both salivary glands. Examination of the duct orifices may show the presence of pus discharging into the oral cavity. Acute sialadenitis leads to abscess formation in salivary gland.

VIRAL SIALADENITIS

Mumps is the most common cause of deafness in 80% of cases among the postnatal viral infections, which causes bilateral parotitis with increased serum amylase most commonly in children <14 years of age. The incubation period is 16–18 days. Salivary gland shows infiltration by chronic inflammatory cells (Fig. 19.8).

Complications

Complications of viral sialadenitis include orchitis (unilateral; without sterility risk), oophoritis, aseptic meningitis (most common extrasalivary complication) and pancreatitis (increased serum amylase level).

AUTOIMMUNE SIALADENITIS

Autoimmune sialadenitis is relatively common. Sjögren's syndrome is a chronic inflammatory disease of the salivary and lacrimal glands. Sjögren's syndrome is characterized by keratoconjunctivitis sicca (dry eyes), and xerostomia (dry mouth), due to lymphocytic infiltration and parenchymal destruction of the parotid and lacrimal glands. It may be associated with a systemic collagen vascular disease. Malignant lymphoma is a frequent complication of autoimmune sialadenitis.

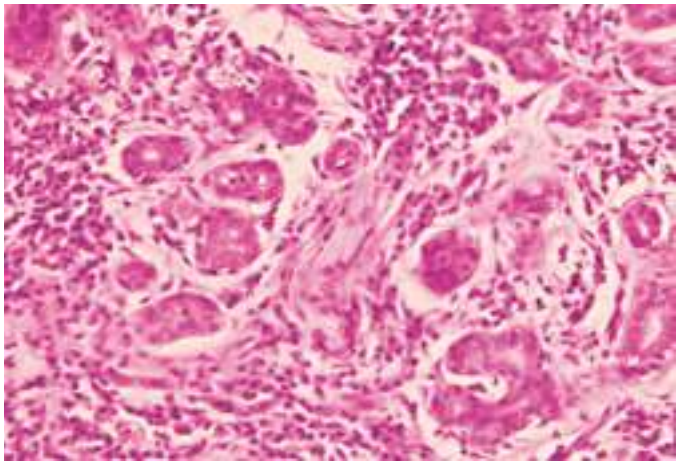

Fig. 19.8: Chronic sialadenitis. It shows infiltration by chronic inflammatory cells (400X).

Surgical Pathology: Autoimmune Sialadenitis

Light Microscopy

- Parotid and lacrimal glands show infiltration by lymphocytes.
- Late on, in the course of the disease, the affected glands become atrophic associated with fibrosis and fatty infiltration of the parenchyma.

Etiopathogenesis

Autoimmune sialadenitis is most likely to autoimmune origin associated with rheumatoid arthritis and Sjögren's syndrome. Autoantibodies demonstrated in Sjögren's syndrome are anti-SS (Ro) and anti-SS (La). Rheumatoid factor and antisalivary gland precipitinin are demonstrated in rheumatoid arthritis.

CHRONIC OBSTRUCTIVE SIALADENITIS

Chronic obstructive sialadenitis most often occurs in submandibular gland, producing a characteristic histologic morphology.

Surgical Pathology: Chronic Obstructive Sialadenitis

Light Microscopy

- Dilated ducts contain eosinophilic glycoproteins.
- Squamous metaplasia is demonstrated in ducts.
- There is expansion of interlobular connective tissue resulting in fibrosis.
- The acini show marked atrophy.
- A mild to moderate chronic inflammatory infiltrate is seen.

CHRONIC RECURRENT PAROTITIS

Chronic recurrent parotitis occurs between the ages of 5–15 years. Girls are more commonly affected than boys. Patient presents with swelling, tenderness over parotid glands, fever and malaise lasting for 7–10 days. Its etiopathogenesis is still not well known.

Surgical Pathology: Chronic Recurrent Parotitis

Light Microscopy

Affected parotid gland shows acinar atrophy and fibrosis.

CYSTIC DISORDERS

Mucocele

Mucocele (cyst-like pool of mucus) lined by granulation tissue, develops near a minor salivary gland. It results from mucus leakage caused by rupture of obstructed or traumatized ducts. Ranula is a large mucocele of salivary gland, characteristically localized to the floor of the mouth.

TUMORS OF SALIVARY GLANDS

Salivary gland tumors have diverse histopathology. These are relatively uncommon constituting 2–6% of all head and neck neoplasms. Their histologic and behavioral diversity as well as their proximity to important head and neck structures that pose considerable management challenges.

- Fine needle aspiration cytology is the popular method for diagnostic evaluation of salivary gland masses due to their superficial nature and easy accessibility for the procedure.
- The majority of tumors of the parotid gland are benign; in contrast, about 50% of the tumors of the submandibular gland are malignant. Pleomorphic adenoma is the most common benign salivary gland tumor. Mucoepidermoid carcinoma is the most common malignant tumor of salivary gland. Recurrence after surgical removal is common, because remnants of tumor may be left behind.
- The majority of salivary gland tumors occur in the parotid gland in 80% of cases overall. Approximately 80% of salivary gland tumors are benign and 20% of tumors are malignant.
- Approximately 15% of tumors occur in submandibular glands. Tumors may be benign in 50% and malignant in 50% of cases. About 5% of salivary gland tumors occur in submandibular glands. Around 40% of tumors are benign and 60% of tumors are malignant.
- Irradiation is only etiologic factor of salivary gland tumors. Adults or children receiving therapeutic irradiation in head and neck are at higher risk for development of salivary gland tumors. An increase in the incidence of salivary gland tumors has also been reported amongst survivors of the nuclear bomb attacks on Hiroshima and Nagasaki in Japanese population.
- A number of viruses have been implicated in the pathogenesis of salivary gland tumors. There is a strong association between Epstein-Barr virus (EBV) and lymphoepithelial carcinomas, but this appears to be largely restricted to Asian patients (Fig. 19.9).

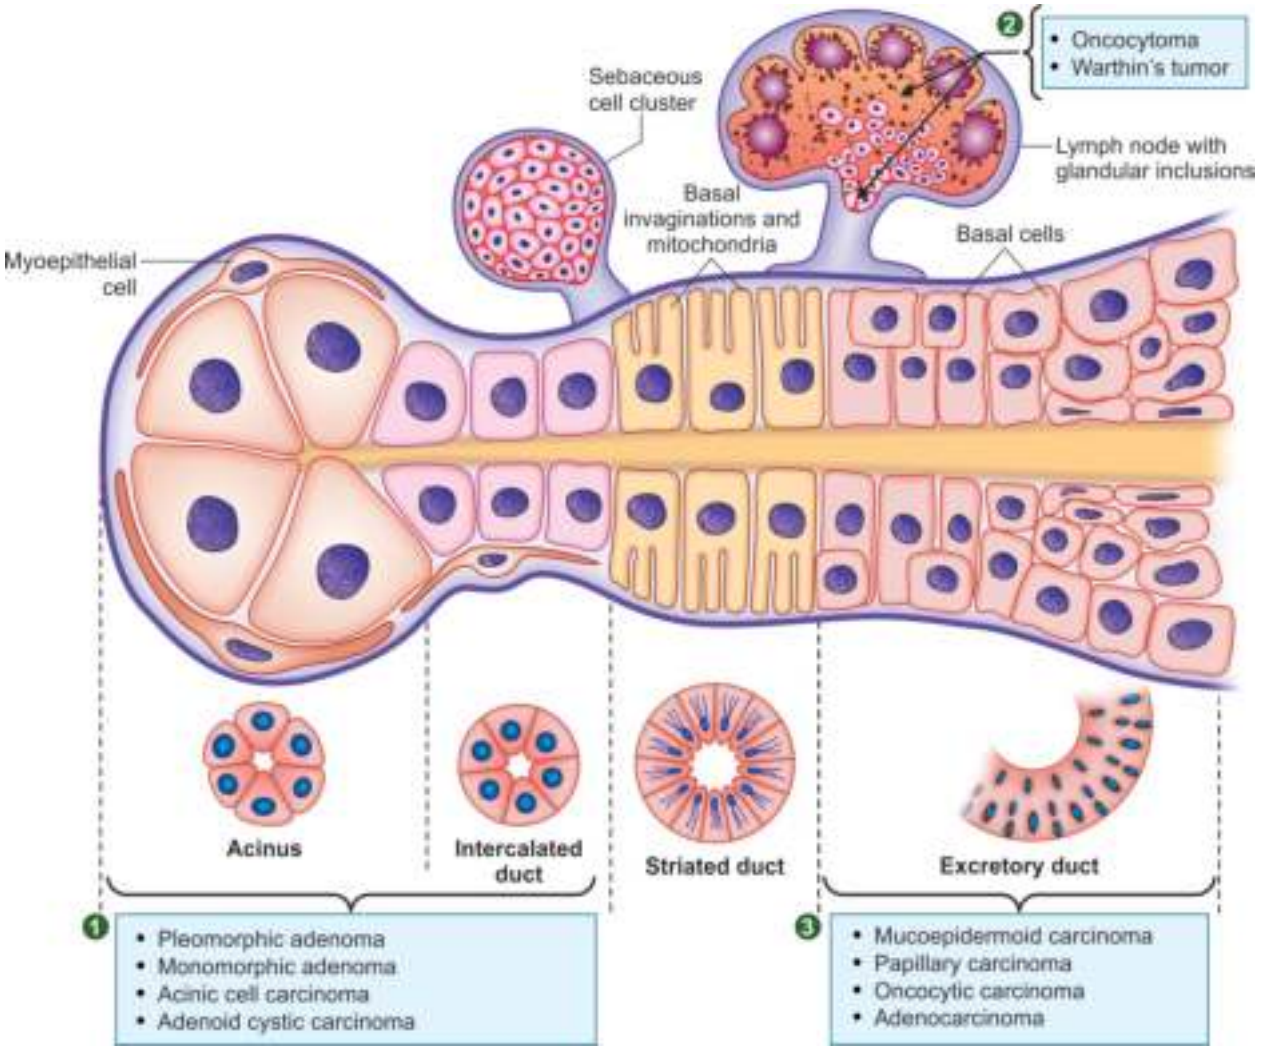

Fig. 19.9: Tumors of salivary glands.

The 2024 WHO classification of salivary gland tumors is given in Table 19.7. Salient features of malignant tumors of salivary glands are given in Table 19.8.

PLEOMORPHIC ADENOMA

Pleomorphic adenoma is commonest benign salivary gland tumor. It is slow-growing painless mass.

Table 19.7 The 2024 WHO classification of salivary gland tumors

Malignant Tumors

- Mucoepidermoid carcinoma
- Adenoid cystic carcinoma
- Acinic cell carcinoma
- Polymorphous adenocarcinoma
- Clear cell carcinoma
- Basal cell adenocarcinoma
- Intraductal carcinoma
- Adenocarcinoma, not otherwise specified
- Salivary duct carcinoma
- Myoepithelial carcinoma
- Epithelial-myoepithelial carcinoma
- Carcinoma ex pleomorphic adenoma
- Secretory carcinoma
- Sebaceous adenocarcinoma
- Carcinosarcoma
- Poorly differentiated carcinoma
  - Undifferentiated carcinoma
  - Large cell neuroendocrine carcinoma
  - Small cell neuroendocrine carcinoma
- Lymphoepithelial carcinoma
- Squamous cell carcinoma
- Oncocytic carcinoma
- Uncertain malignant potential sialoblastoma

Benign Tumors

- Pleomorphic adenoma
- Myoepithelioma
- Basal cell adenoma
- Warthin tumor
- Oncocytoma
- Lymphadenoma
- Cystadenoma
- Sialadenoma papilliferum
- Ductal papillomas
- Sebaceous adenoma
- Canalicular adenoma and other ductal adenomas
- Sclerosing polycystic adenoma
- Keratocytoma
- Intercalated duct adenoma
- Striated duct adenoma

Non-neoplastic Epithelial Lesions

- Sclerosing polycystic hyperplasia
- Nodular oncocytic hyperplasia
- Lymphoepithelial sialadenitis
- Intercalated duct hyperplasia

Benign Soft Tissue Lesions

- Hemangioma
- Lipoma/sialolipoma
- Nodular fasciitis

Hematolymphoid Tumors

Extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT lymphoma).

Contd...

Table 19.8 Salient features of important malignant tumors of salivary glands

Tumor	Sites	Age Group	Molecular Genetics	Features	Light Microscopy	Immunomarkers
Muco-epidermoid carcinoma	Parotid gland and minor salivary glands	Young to elderly	Translocation 11q21, 19p13	Slow growing mass, spreads by direct invasion, lymphatic and hematogenous route	Low- to high-grade	MUC4 positivity better prognosis
Adenoid cystic carcinoma	Submandibular, minor salivary and parotid glands	5th decade	Losses of 12p, 6p23q, 13q21	Tumor invades perineural space	Cribriform or solid pattern	CEA, keratin, S-100 protein, muscle specific actin and Ki-67
Acinic cell carcinoma	Parotid glands	5th decade	–	Clinical course variable, spreads via lymphatic and hematogenous route	Solid or papillary cystic or follicular pattern	The acinic cells show PAS positive diastase resistant granules. These cells are negative for mucin stains
Polymorphous low-grade carcinoma	Minor salivary glands	4th decade	–	Mass in palate	Tumor cells forming glandular structures	Keratin, vimentin, S-100 protein, CEA, GFAP, muscle specific actin, EMA, galectin 3 and BCL-2

Parotid gland is the most common site followed by submandibular gland and minor salivary glands. It was called mixed salivary gland tumor because the stroma is showing areas mimicking cartilaginous differentiation.

Pleomorphic adenoma has a biphasic appearance, which represents an admixture of epithelial and chondromyxoid stromal elements. Mesenchymal chondroid areas occur due to metaplastic changes in pleomorphic adenoma. It rarely becomes malignant.

Age and Sex Distribution

Pleomorphic adenoma affects between 40 and 60 years of age. It is more common in women than men (4:1).

Location

Pleomorphic adenoma most frequently occurs in major salivary gland usually in superficial region of parotid gland above the facial nerve in 90% and deep region of parotid gland below facial nerve in 10% of cases. It also occurs in submandibular gland in 45% of cases and minor salivary glands, e.g. palate, upper lip and mucosa in 45% of cases.

Molecular Genetic Alterations

Chromosomes 3p21, 8q12 and 12q13-15 rearrangements and the PLAG-1 and HMGI-C genes are demonstrated in pleomorphic adenomas.

Clinical Features

Patient presents with slow growing, painless and firm nontender mass in parotid gland. Lateral palate is the most common site in minor salivary gland. In all locations, small tumors are nontender and mobile on palpation but may become fixed with large growth. Facial nerve paralysis in association with pleomorphic adenomas almost never occurs, even with extremely large tumors.

Surgical Pathology: Pleomorphic Adenoma

Gross Morphology

- Pleomorphic adenoma in parotid gland is encapsulated smooth or lobulated tumor, clearly demarcated from the surrounding normal salivary gland.
- The tumor often shows small projections protruding through capsule. If the tumor is enucleated, these projections are left behind resulting in recurrence of tumor after surgical excision.
- Cut surface is solid, rubbery and containing areas of gelatinous myxoid stroma.
- Pleomorphic adenoma arising in minor salivary glands is never encapsulated (Figs 19.10 and 19.11).

Light Microscopy

There is considerable variation in the histologic features within single tumor. Therefore, multiple samples are necessary to study the complete morphology of the tumor. Tumor may be composed of epithelial and stromal component in varying proportions.

- **Epithelial component of pleomorphic adenoma:** Epithelial component is believed to originate from intercalated ducts. Tumor is composed of gland-like epithelial component surrounded by a myxomatous stroma often containing foci of bone or cartilage. Epithelial cells are arranged in nests, solid sheets, some forming duct-like structures.
- **Stromal component of pleomorphic adenoma:** The epithelial cells are embedded in chondromyxoid stroma. The stroma shows accumulation of basophilic material with the staining reaction of connective tissue mucins. The myxoid stroma may be bulky invaded by stromal cells.
- **Other findings in pleomorphic adenoma:** It may show foci of mucinous and squamoid differentiation mimicking mucoepidermoid carcinoma. It may also show adenoid cystic-like pattern.

Fig. 19.10: Pleomorphic adenoma of parotid gland. The multilobulated appearance of this tumor is shown. It must be removed together with some surrounding parotid gland, or else some of the irregular projections around its margins will be left behind and the tumor will recur.

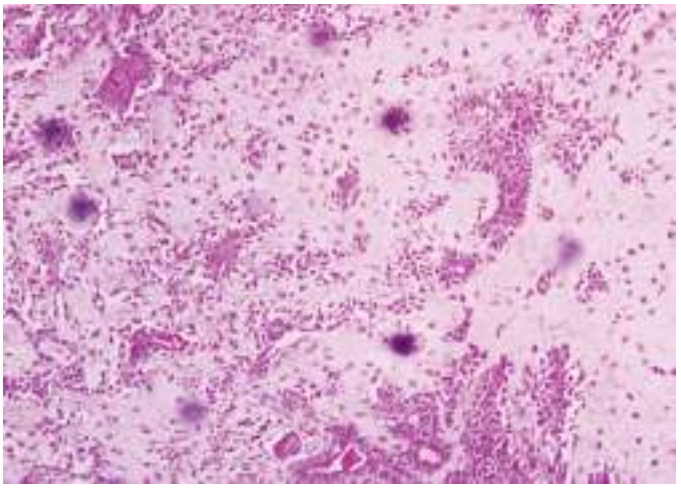

Fig. 19.11: Pleomorphic adenoma of salivary gland. Tumor is composed of mixtures of epithelial component forming duct-like structures, myoepithelial/stromal cells within myxoid stroma, and foci of chondroid/osseous metaplasia (400X).

Malignant Potential

Minimally invasive carcinoma is defined as an extension of <1.5 mm beyond capsule of pleomorphic adenoma and associated with an excellent prognosis. Malignancy in pleomorphic adenoma encompasses these entities: carcinoma ex pleomorphic adenoma and carcinosarcoma. Staining for HER2/neu can be used to detect early development of carcinoma in pleomorphic adenoma. Carcinosarcoma has been associated with poor prognosis.

Metastasizing Pleomorphic Adenoma

Metastasizing pleomorphic adenoma is defined as a histologically benign pleomorphic adenoma that manifests local or distant metastases in multiple organs such as bone, lung, lymph nodes and rarely kidneys.

Surgical Intervention

Often, pleomorphic adenoma is difficult to excise completely because of its proximity to the facial nerve. It is likely to recur after resection due to tumor spillage in the wound. Recurrence of pleomorphic adenoma represents local growth in the form of multiple nodules within fibrous and adipose tissue and does not reflect malignancy.

WARTHIN'S TUMOR

Warthin's tumor accounts for 8% of all tumors in the parotid glands. It is a multicentric tumor, also known as **papillary cystadenoma lymphomatosum** or **adenolymphoma**. The term adenolymphoma should not be confused with any form of lymphoma. Warthin's tumor is monomorphic adenoma with heavy lymphocyte infiltrate in the stroma. Recurrence after excision of tumor is rare. Rarely, squamous cell carcinoma or lymphoma may arise in Warthin's tumor.

Origin

Warthin's tumor most often occurs in parotid glands. It arises from hydrotropic salivary duct epithelium within immediately subjacent lymph node or it may be due to cystic changes of the epithelium in the inflammatory infiltrate.

Age and Sex Predilection

Warthin's tumor is the only tumor of the salivary glands, which is more common in men (especially tobacco smokers) than in women. It generally occurs after the age of 30 years, with most arising after age 50 years. Bilateral tumors occur in 10% of cases.

Molecular Genetic Alterations

Translocations of chromosomes 11q21 and 19p13 are demonstrated in Warthin's tumor.

Clinical Features

Patient presents with slow-growing painless firm or rubbery or nodular mass. A few patients may present with rapidly growing tumor associated with pain or pressure symptoms.

Imaging Technique

Radionuclide scanning (Tc 99m) is helpful in diagnosing patients with Warthin's tumor and oncocytoma.

Surgical Pathology: Warthin's Tumor

Gross Morphology

- Tumor forms soft well-circumscribed encapsulated brown mass usually located superficially within the parotid gland.
- Cut surface shows irregular multiple cysts of variable diameter containing variably viscous fluid.
- The cyst fluid has a characteristic motor oil quality.
- The lymphoid component makes up the solid areas of the tumor (Figs 19.12 and 19.13).

Light Microscopy

Tumor is composed of mixture of epithelial and lymphoid elements.

- **Epithelial element:** Clefts and cysts are lined by pink staining double layer epithelium. Inner layer consists of tall columnar cells with granular cytoplasm (oncocytes) towards the luminal aspect lining the cystic spaces. Outer layer is composed of cuboidal cells along the basement membrane. Electron microscopy reveals presence of large number of mitochondria accounting for the granular cytoplasm, suggesting common feature for oncocytes in all epithelial tissues.
- **Stromal lymphoid tissue:** The epithelial cells are forming papillary projections into cystic glandular spaces embedded in dense stromal lymphoid tissue. The stroma contains florid lymphoid infiltrate in which some normal lymphoid follicles with germinal centers are present. Malignancy may develop either in the epithelial or lymphoid component.
- **Other findings:** Occasional goblet cells may be present within the epithelium mimicking oncocystic mucoepidermoid carcinoma. Squamous metaplasia with atypia may mimic squamous cell carcinoma if biopsy taken after fine needle aspiration.

Differential Diagnosis

It is worth mentioning that oncocytes are also demonstrated in oncocytic tumors. Lymphoid aggregates are demonstrated in lymphoepithelial cyst, chronic sialadenitis and Sjögren's syndrome. Differences between pleomorphic adenoma and Warthin's tumor of salivary glands are given in Table 19.9.

Therapeutic Correlation

Warthin's tumor is treated by surgical resection with preservation of facial nerve.

Fig. 19.12: Warthin's tumor (adenolymphoma) of the parotid gland. Cut surface of this benign tumor is multicystic. The cysts are filled with mucus. It is the second most frequent tumor of the parotid gland, after pleomorphic adenoma.

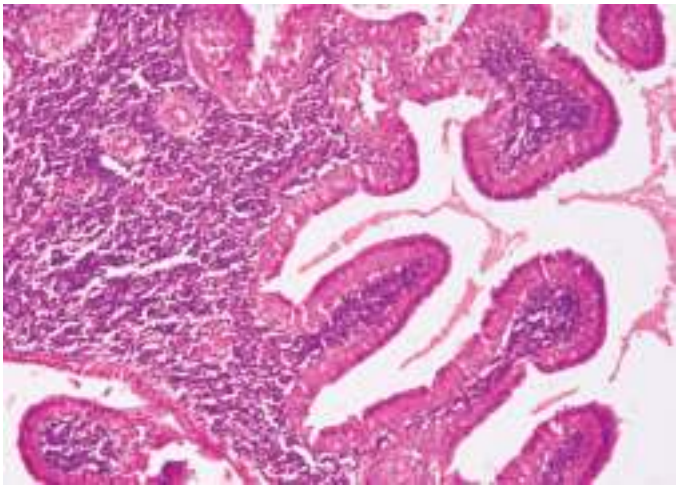

Fig. 19.13: Warthin's tumor. Tumor is composed of mixture of epithelial and lymphoid elements. Clefts and cysts are lined by pink staining double layer epithelium. These epithelial cells are forming papillary projections into cystic glandular spaces embedded in dense lymphoid tissue (400X).

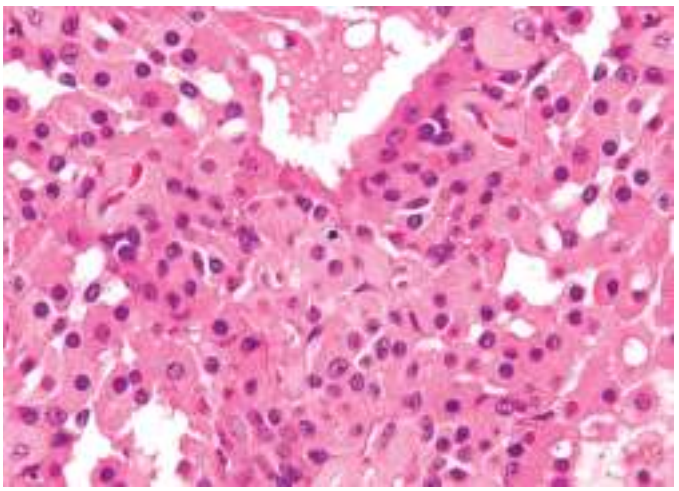

Fig. 19.14: Oncocytoma. Tumor is composed of cords of uniform polyhedral cells with distinct cell membrane, granular eosinophilic cytoplasm, central round vesicular nuclei, and thin fibrous stroma (400X).

ONCOCYTOMA

Oncocytoma is rare benign salivary gland tumor that affects elderly men and women. Recurrence rate is low after surgical excision (Fig. 19.14).

Site of Origin

Oncocytoma is mainly located in parotid gland in 80% of cases, submandibular gland in 10% of cases and rest in minor salivary glands (palate, buccal mucosa or tongue).

Clinical Features

Patient presents with slow-growing painless, firm, mobile, and nontender mass in superficial lobe of parotid gland.

Table 19.9 Differences between pleomorphic adenoma and Warthin's tumor of salivary glands

Parameters	Pleomorphic Adenoma	Warthin's Tumor
Origin	Intercalated ducts	Striated ducts
Glands involved	Parotid gland and minor salivary glands, e.g. palate, upper lip and mucosa (10%)	Parotid gland
Frequency	70–80%	10%
Sex predilection	Females preponderance	Males > females
Number	Solitary (90%)	Solitary (90%) and multiple (10%)
Laterality	Unilateral (most often)	Unilateral (most often)
Clinical features	Nodular firm inconsistency	Smooth soft and cystic lesion
Histology	Epithelial cells are embedded in chondromyxoid stroma	Double layer pink staining epithelium and lymphoid aggregates
Recurrence	Common after surgical excision	Uncommon after surgical excision

Surgical Pathology: Oncocytoma of Salivary Glands
Gross Morphology
Tumor is homogenous with a smooth surface. It may be divided into lobules by fibrous septae.
Light Microscopy
▪ Tumor is composed of uniform epithelial cells arranged in sheets or cords. ▪ Tumor cells contain abundant mitochondria constituting 60% of the cell volume, which impart a brightly eosinophilic look.
Electron Microscopy
Tumor cells contain hyperplasia of mitochondria constituting 60% of cell volume.

MYOEPITHELIOMA

Myoepithelioma is a rare benign tumor arising in parotid gland and minor salivary glands (hard or soft palate). It is occasionally seen in the submandibular glands. Local recurrence is more common than pleomorphic adenoma after surgical excision. It equally affects men and women over 50 years of age. Patient presents with slow-growing asymptomatic mass.

Surgical Pathology: Myoepithelioma	
Gross Morphology	
Tumor is well circumscribed similar to a pleomorphic adenoma but without the myxoid stroma.	
Light Microscopy	
Histologic variants of myoepithelioma include spindle cell type, hyaline type, plasmacytoid type or clear cell type. ▪ **Spindle cell variant of myoepithelioma:** It occurs in parotid gland. It is composed of spindle cells arranged in sheets and cords. ▪ **Plasmacytoid pattern of myoepithelioma:** It is less common but the most frequently encountered pattern in palate tumors. ▪ **Combined pattern of myoepithelioma:** It demonstrates a combination of the spindle and plasmacytoid cells. This variant is uncommon.	
Immunohistochemistry Technique	
Panel of immunomarkers is used to analyze expression in myoepithelioma on histopathologic sections.	
Markers	**Expression**
▪ S-100 protein ▪ Pancytokeratin ▪ Smooth muscle actin ▪ p63	▪ Positive ▪ Positive ▪ Positive ▪ Positive

MONOMORPHIC ADENOMA

Monomorphic adenoma is rare salivary gland tumor affecting 60–70 years of age group. Histologic variants of monomorphic adenoma include basal cell adenoma (most common in parotid gland), canalicular adenoma (minor salivary glands multifocal in origin), sebaceous adenoma, glycogen-rich adenoma and clear cell adenoma. Tumor is easily excised. Recurrence is rare after surgical excision.

Clinical Features

Patient presents with slow growing painless firm to fluctuant 1–2 cm nodule.

Surgical Pathology: Monomorphic Adenoma	
Gross Morphology	
Tumor is well circumscribed solid to cystic without capsule. Cut surface is tan to pink.	
Light Microscopy	
Monomorphic adenoma shows various histologic patterns. ▪ Monomorphic adenoma is composed of cords of cells forming duct-like structures in a background of fibrous stroma. ▪ Canalicular adenoma is composed of two rows of cells opposed to each other giving beaded appearance.	
Immunohistochemistry Technique	
Panel of immunomarkers is used to analyze expression in canalicular adenoma on histopathological sections.	
Markers	**Expression**
▪ S-100 protein ▪ Cytokeratin	▪ Positive ▪ Positive

MUCOEPIDERMOID CARCINOMA

Mucoepidermoid carcinoma is most common malignant tumor of the salivary glands. It most often occurs in the parotid glands. It may arise in minor salivary glands. Mucoepidermoid carcinoma is characterized by mucous, intermediate, epidermoid cells, columnar, clear cells and oncocytic features. All mucoepidermoid carcinomas are potentially malignant with metastatic potential regardless of their microscopic appearance.

Age Group

Mucoepidermoid carcinoma occurs more frequently in women than in men that affects of tumor young to elderly persons.

Molecular Genetic Alterations

Translocations of chromosomes 11q21 and 19p13 are demonstrated in mucoepidermoid carcinoma resulting in MECT-MAMAL2 fusion gene. The median survival of MECT-MAMAL2 fusion gene positive patients is >10 years. On the other hand, median survival of fusion gene negative patients is 1.6 years. Elevated HER2/neu gene expression and gene amplification have been demonstrated in mucoepidermoid carcinoma.

Clinical Features

Patient presents with slow-growing asymptomatic mass in salivary glands, very similar to that of benign tumor.

Surgical Pathology: Mucoepidermoid Carcinoma

Gross Morphology

Tumor is well circumscribed partially encapsulated with infiltrative edges. Cut surface is firm, smooth with cystic areas.

Light Microscopy

Mucoepidermoid carcinoma may be of low, intermediate or high grade. Histologic features and grading mucoepidermoid carcinoma are based on cystic appearance, necrosis, neural invasion, mitotic figures and anaplasia (Tables 19.10 and 19.11).

- **Low-grade mucoepidermoid carcinoma**: Tumor is composed of mixture of squamoid (epidermoid), mucus-secreting cells (eccentric nuclei). Squamoid cells are less than mucus cells. The proportion of different cell types and their architectural configuration (including cyst formation) varies. Tumor cells are arranged in sheets, nests and duct-like patterns. Keratin pearl formation may be seen in occasional case (Fig. 19.15).
- **Intermediate-grade mucoepidermoid carcinoma:** Tumor is composed of squamoid and mucus cells in equal proportion. Tumor cells show pleomorphism and are arranged in sheets, nests and duct-like patterns. Many mitotic figures may be demonstrated (Fig. 19.16).
- **High-grade mucoepidermoid carcinoma:** Tumor shows solid growth pattern with predominant epidermoid cells and increased cellularity with cellular atypia and frequent mitotic figures. It may be mistaken for squamous cell carcinoma (Fig. 19.17).

Differential Diagnosis

Differential diagnosis of mucoepidermoid carcinoma includes pleomorphic adenoma, acinic cell carcinoma and necrotizing sialometaplasia.

Histochemistry

Positive histochemical staining for mucin is seen in mucoepidermoid carcinoma rather than squamous cell carcinoma. Tumor with MUC4 positivity has better prognosis than MUC1 positivity.

Immunohistochemistry Technique

Low-grade mucoepidermoid carcinoma shows positivity for CK7 and CK14. Epidermoid cells and intermediate cells express p63 and p40.

Mode of Spread

Mucoepidermoid carcinoma may spread by direct invasion, lymphatic route and hematogenous route, i.e. lung, liver, bone and brain (Table 19.12).

Prognosis

Low-grade mucoepidermoid carcinoma has an excellent prognosis with 5-year survival in 90%, but high-grade tumors are associated with 5-year survival in 20–40% of cases.

Table 19.10 Histopathologic features and scores of mucoepidermoid carcinoma of salivary gland

Light Microscopic Findings	Scoring System
Cystic component >20%	2
Neural invasion	2
Necrosis	3
Mitotic figures 4 or greater than/high power field	3
Anaplasia	4

Table 19.11 Tumor grading and scoring of mucoepidermoid carcinoma

Tumor Grade	Scoring System
Low-grade neoplasm	0–4
Intermediate-grade neoplasm	5–6
High-grade neoplasm	7 or more

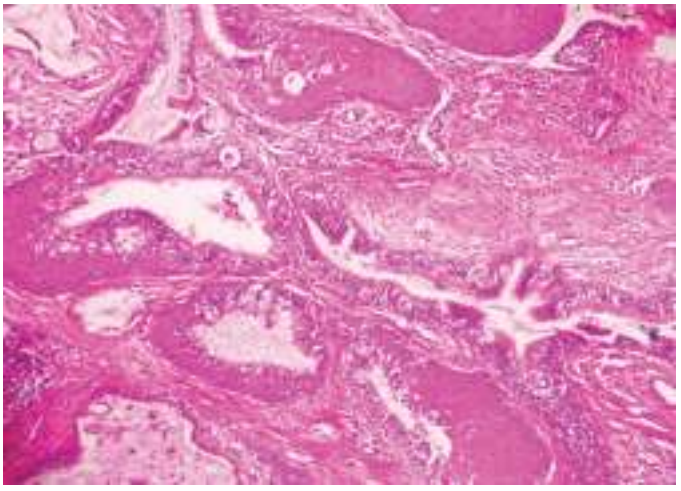

Fig. 19.15: Mucoepidermoid carcinoma (low-grade tumor). It is chiefly composed of mucus cells. Epidermal cells are less than mucus cells (400X).

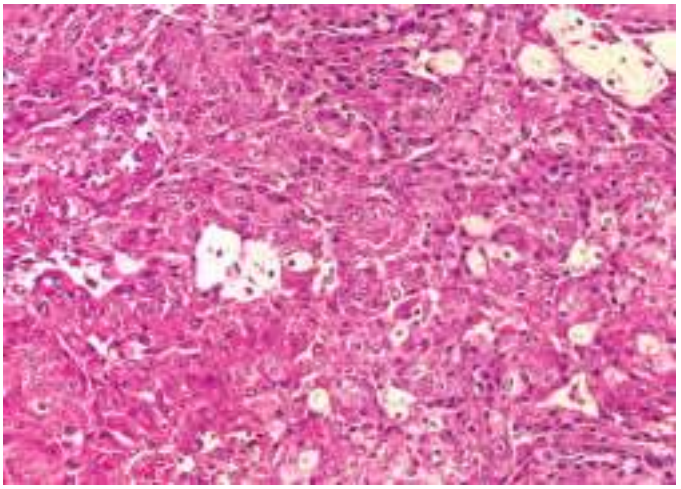

Fig. 19.16: Mucoepidermoid carcinoma (intermediate-grade tumor). It is composed of mucus and squamoid cells in equal proportion. Tumor cells are pleomorphic and showing mitotic figures (400X).

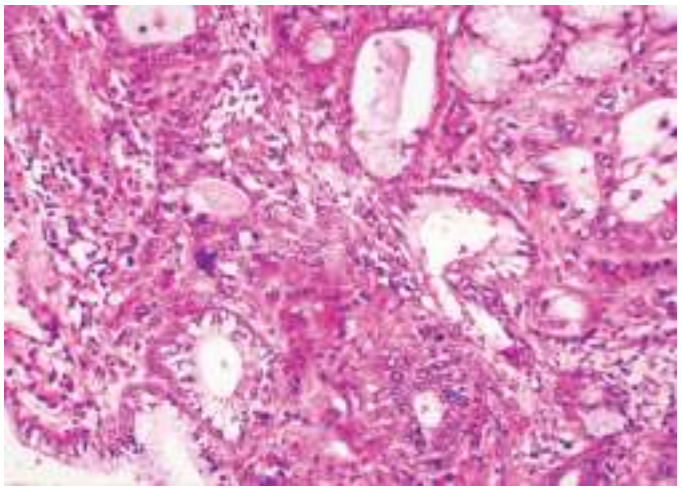

Fig. 19.17: Mucoepidermoid carcinoma (high-grade tumor). It is chiefly composed of squamoid cells and smaller population of mucus cells (400X).

ADENOID CYSTIC CARCINOMA

Adenoid cystic carcinoma is second most common malignant tumor of salivary gland. It most often invades perineural spaces (Figs 19.18 to 19.20).

- Tumor grows in cribriform and/or solid pattern. Solid pattern is associated with poor prognosis.

Fig. 19.18: Adenoid cystic carcinoma. It is well circumscribed solid tumor light tan with infiltrative margins.

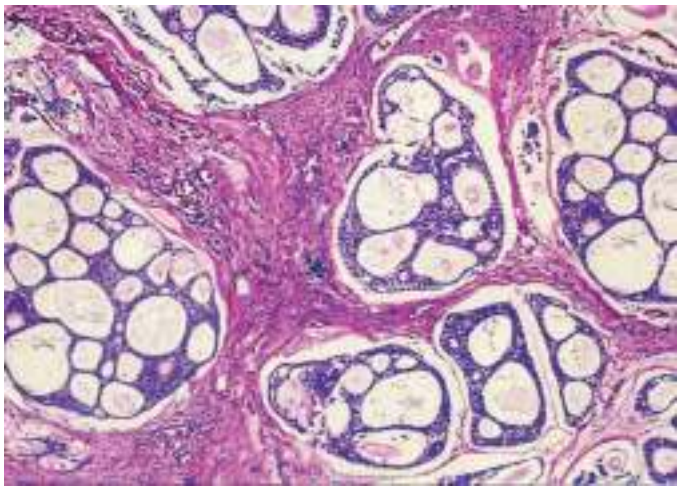

Fig. 19.19: Adenoid cystic carcinoma. It is composed of inner ductal cells and outer myoepithelial cells (400X).

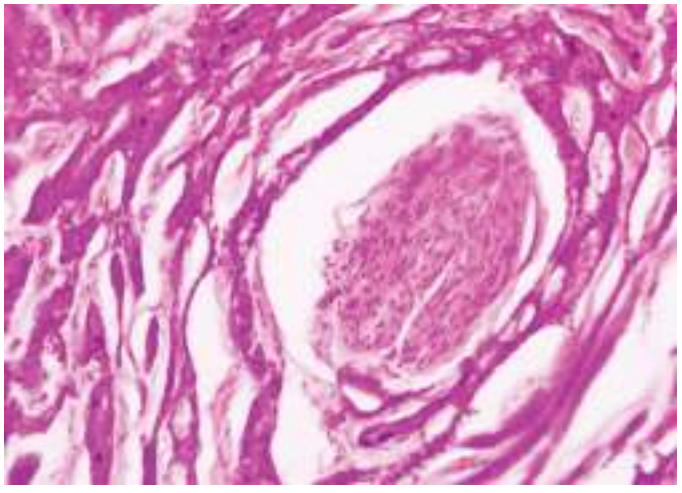

Fig. 19.20: Adenoid cystic carcinoma. It shows perineural invasion (400X).

Biphasic tumor shows ductal and myoepithelial differentiation.

- Tumor has a relentless clinical course with fatal outcome. Growth pattern is most commonly infiltrative and hence recurrence is common due to perineural invasion after surgical excision.

Table 19.12 Mode of spread and locations of mucoepidermoid carcinoma of salivary gland

Location of Tumor	Mode of Spread	Metastases
Parotid gland (most common site)	Lymphatic route	Pre-auricular and submandibular lymph nodes
Submandibular gland	Lymphatic route	Submandibular and upper jugular lymph nodes
Palate region	Direct invasion	Upper respiratory tract and base of skull
Lip region	Lymphatic route	Submental lymph nodes
Oral cavity	Lymphatic route	Submandibular, post-auricular and upper accessory nodes in neck level II then to levels III, IV and V

There may be widespread metastases to lung, liver, bone, and brain via hematogenous route.

Location

Adenoid cystic carcinoma occurs in submandibular gland (15% of cases), parotid gland (2% of cases), sublingual and minor salivary glands (15–20% of cases). It is a slow-growing tumor with extensive perineural invasion causing pain.

Age and Sex Predilection

Tumor affects equally men and women with peak in the 5th decade. It tends to recur after surgery.

Molecular Genetic Alterations

Frequent losses at 12q (33%), 6q23-q, 13q21-q22 and 19q have been reported in 40% of cases. About 60–90% of tumors carry MYB-NF1B and MYBL1-NF1B fusion.

Clinical Features

Patient with adenoid cystic carcinoma in major salivary gland especially in submandibular gland presents with asymptomatic slow-growing mass but highly malignant neoplasm followed by pain due to perineural invasion.

- Hypoglossal nerve involvement by tumor leads to impairment of tongue movements.
- Lingual nerve invasion by tumor causes tingling sensation of tongue. Facial nerve paralysis may also occur.
- Minor salivary gland adenoid cystic carcinoma is characterized by a submucosal mass with or without pain and ulceration.

Surgical Pathology: Adenoid Cystic Carcinoma

Gross Morphology

Tumor is well circumscribed but without capsule. It is invariably infiltrative tumor invading surrounding normal tissue. Despite its name, it is solid tumor that rarely displays obvious cystic spaces on cut surface.

Light Microscopy

Tumor is a basaloid tumor consisting of epithelial and myoepithelial cells in variable morphologic configurations. It shows two patterns: cribriform (most common), tubular or solid.

- **Cribriform pattern of tumor:** In adenoid cystic carcinoma, if the cystic spaces are large and numerous, it is termed cribriform pattern. It is often referred to as swiss cheese pattern. The tumor cells are small monomorphic with scant cytoplasm arranged in nests around cylindrical spaces that may contain mucinous or hyalinized material.
- **Solid pattern of tumor:** Adenoid cystic carcinoma is composed of sheets of tumor cells with no intervening spaces. The tumor is graded as 1, 2 and 3. Grade 1 tumor is composed of tubular and cribriform pattern. Grade 2 tumor contains 30–70% solid areas. Grade 2 tumor comprising >70% solid areas has poor prognosis.

Immunohistochemistry Technique

Panel of immunomarkers is used to analyze expression in adenoid cystic carcinoma on histopathological sections.

Markers	Expression
Ductal cells	
▪ CK-7	▪ Positive
▪ CAM 5.2	▪ Positive
Myoepithelial markers	
▪ Smooth muscle actin (SMA)	▪ Positive
▪ S-100 protein	▪ Positive
▪ Calponin	▪ Positive
▪ p40	▪ Positive
▪ p63	▪ Positive
▪ GFAP	▪ Positive
▪ Cytokeratins	▪ Positive

Differential Diagnosis

Differential diagnosis of adenoid cystic carcinoma includes basaloid squamous carcinoma, polymorphous low-grade adenocarcinoma, epithelial-myoepithelial carcinoma and membranous variant of basal cell adenoma.

Mode of Spread

- **Direct invasion:** Adenoid cystic carcinoma invades surrounding connective tissue involving perineural spaces. Tumor may permeate bones and penetrate through nose or antrum.
- **Hematogenous route:** Adenoid cystic carcinoma may metastasize to distant organs especially lungs.

Prognostic Factors

Prognostic factors that influence survival include histologic patterns, location of tumor, clinical stage, bone involvement and status of surgical margins.

- Tubular and cribriform patterns of adenoid cystic carcinoma have less aggressive course.
- Tumor with solid pattern of cells, tumor suppressor p53 gene mutation and foci of dedifferentiation has been associated with poor prognosis.

Therapeutic Correlation

Patient is treated by complete surgical excision of tumor and postoperative radiation therapy. Since tumor shows perineural invasion, hence facial nerve is also sacrificed along with tumor.

ACINIC CELL CARCINOMA

Acinic cell carcinoma is rare malignant tumor accounting for 2–3% of tumors in parotid glands, in which at least neoplastic cells demonstrate serous acinar cell differentiation with PAS-diastase positive zymogen

secretory granules. Salivary ductal cells are also present as a component of this neoplasm. Approximately 80–90% of these tumors occur within parotid glands.

Age Group

Acinic cell carcinoma is low-grade malignancy of salivary glands especially in children and young age group. Peak incidence is seen in the 5th decade especially women.

Clinical Features

Patient presents with slow-growing asymptomatic tumor in parotid glands. Acinic cell carcinoma may transform to high-grade adenocarcinoma or poorly differentiated carcinoma that presents with rapid growth, pain and facial nerve palsy. Clinical course of acinic cell carcinoma is characterized by metastases in 8–10% and local recurrence after surgical excision in 12–20% of patients. Treatment is surgical excision.

Surgical Pathology: Acinic Cell Carcinoma

Gross Morphology

- Tumor is well circumscribed without a capsule measuring 1–3 cm in largest dimension.
- Cut surface appears lobular with gray-white, friable, solid and cystic areas.

Light Microscopy

- Tumor is composed of acinic cells arranged in solid or papillary cystic or follicular pattern. The acinic cells show close resemblance to serous acini of salivary glands.
- Tumor cells show differentiation towards acinar cells and ductal cells; but lack myoepithelial differentiation. But there is loss of normal lobular architecture and lacking normal ducts in the tumor nodule.
- The surrounding stroma often shows presence of lymphoid infiltrate.
- Acinic cell carcinoma is graded based on nuclear and architectual features (Fig. 19.21).

Histochemistry

The acinic cells show PAS positive diastase resistant granules. These cells are negative for mucin stains.

Mode of Spread

Acinic cell carcinoma initially metastasizes to cervical lymph nodes and subsequently to more distant organs especially in the lungs.

Prognostic Factors

Histologic grading has been unsuccessful to predict prognosis. Poor prognostic factors include necrosis, extraglandular extension, increased pleomorphism, high mitotic rate, and prominent infiltration of nerves and blood vessels.

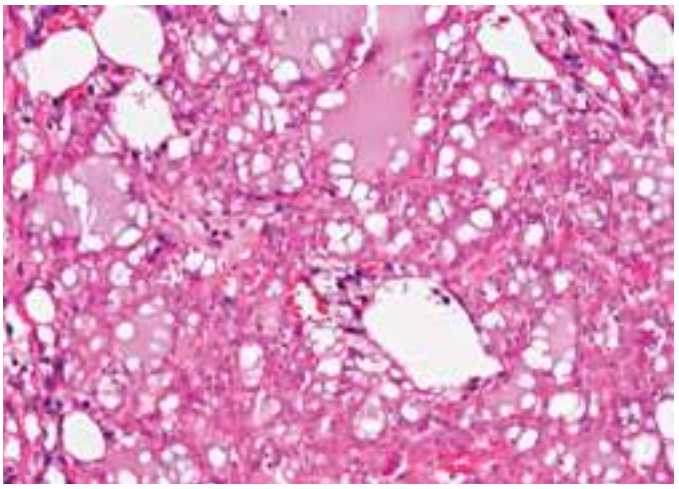

Fig. 19.21: Acinic cell carcinoma. It shows vacuolated cells similar in size to intercalated duct-type cells but have clear cytoplasmic vacuoles, which sometimes distend the cellular membranes (400X).

Prognosis

Circumscribed well-differentiated acinic cell carcinoma with abundant lymphoid aggregates has excellent prognosis.

POLYMORPHOUS LOW-GRADE ADENOCARCINOMA

Polymorphous low-grade adenocarcinoma is second common tumor of minor salivary glands. Most common sites include palate (60%), buccal mucosa, retromolar region, upper lip, and the base of the tongue. It affects over 40 years of age with equal frequency in men and women. It has infiltrative growth pattern with low metastatic potential (Fig. 19.22).

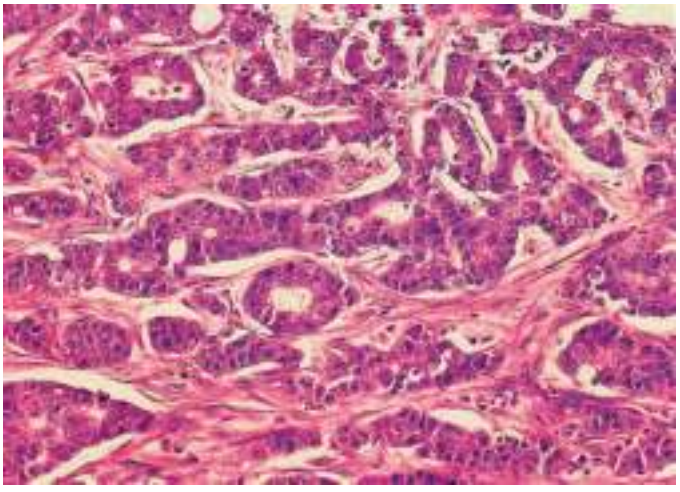

Fig. 19.22: Adenocarcinoma. It shows presence of glandular structures and absence of squamoid cells (400X).

Clinical Features

Painless mass in the palate is the most common clinical sign of polymorphous low-grade adenocarcinoma. Bleeding or ulceration of the overlying mucosa occurs occasionally.

Surgical Pathology: Polymorphous Low-grade Adenocarcinoma

Gross Morphology

- Tumor is solid firm circumscribed with irregular border invading into surrounding tissue.
- Cut surface is lobulated with yellow tan.

Light Microscopy

Tumor is composed of tumor cells forming glandular structures (*see* Fig. 19.22).

Immunohistochemistry Technique

Panel of immunomarkers is used to analyze expression in polymorphous low-grade adenocarcinoma on histopathologic sections.

Markers	Expression
CK-7	Positive (100%)
Vimentin	Positive (100%)
S-100 protein	Positive (97%)
CEA	Positive (54%)
GPAF	Positive (15%)
SMA	Positive (13%)
EMA	Positive (12%)
Galectin 3	Positive (many cases)
BCL-2	Positive (many cases)

Metastases

Tumor may metastasize to regional lymph nodes and distant organs (lung and bone) via hematogenous route.

CARCINOSARCOMA

Carcinosarcoma is a rare aggressive malignant salivary gland tumor composed of epithelial and mesenchymal components. It may occur in pleomorphic adenoma and malignant tumors (undifferentiated and adenocarcinoma) except acinic cell carcinoma.

- Most commonly, carcinosarcoma exists in the form of an undifferentiated carcinoma (30%) or adenocarcinoma (25%).
- Approximately, 25% of patients will have lymph node metastasis on clinical presentation. Currently recommended treatment includes radical surgery, neck dissection for palpable nodes and postoperative radiotherapy.

SQUAMOUS CELL CARCINOMA

Squamous cell carcinoma (SCC) is rare malignant tumor of salivary gland seen over 60 years of age. Men are more affected than women. High-grade mucoepidermoid carcinoma, metastatic SCC to the gland or intraglandular nodes and direct extension of a SCC must first be excluded to establish diagnosis.

- Gross and histologic appearance is similar to SCC seen in other sites. It varies from well-differentiated with keratinization to poorly differentiated without keratinization. It is an aggressive tumor, which may metastasize to regional lymph nodes.
- Treatment of SCC of salivary gland consists of surgical resection, neck dissection and postoperative radiation.

DISORDERS OF JAW

ANATOMY OF JAW

Jaw harbors odontogenic apparatus of deciduous and permanent dentitions.

- The teeth gums are composed of enamel, dermal papillae and tooth follicle.
- The enamel is composed of ectodermally derived epithelial cells, the ameloblasts.
- The dental papillae are derived from ectomesenchyme, forming dentine.
- The tooth follicle is also derived from ectomesenchyme that surrounds developing tooth and provides support to tooth and perichondrium.
- Odontogenic tissue may be source of cysts and tumors. Normal structure of tooth is shown in Fig. 19.23.

DENTAL AND PERIODONTAL DISORDERS OF JAW

DENTAL CARIES

Dental caries is the most prevalent chronic disease of the calcified tissues of the teeth. It begins with the disintegration of the enamel prisms, accumulation of debris and superadded *Streptococcus mutans* infections. These changes produce a small pit or fissure in the enamel (Fig. 19.24A to C).

Cavity Formation in Dentin

Reaching of infection at dentinoenamel junction leads to spread of infection laterally penetrating into the dentin along the dentinal tubules. It leads to formation of cavity in the dentin producing a flask-shaped lesion

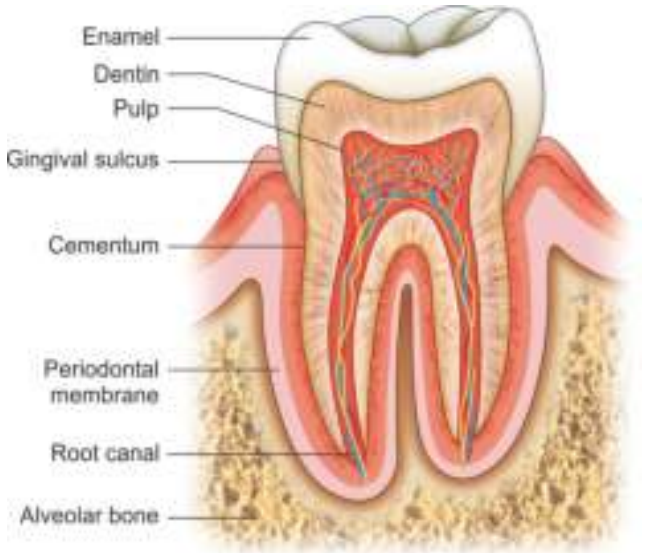

Fig. 19.23: Normal structure of tooth.

with a narrow orifice. Microorganisms may invade vascular pulp of the tooth.

Clinical Features

Patient may develop pulpitis that results in periapical granulation tissue and periodontitis of the marginal gingiva.

PERIODONTAL DISEASE

Periodontal disease refers to acute and chronic periodontal inflammatory disorders of the soft tissues surrounding the teeth. It leads to loss of supporting bone. Adults with poor oral hygiene develop chronic periodontal disease. There may be a strong family history of periodontal disease. Chronic periodontitis causes loss of more teeth in comparison to caries.

CYSTIC LESIONS OF JAW

Odontogenic and nonodontogenic cysts of jaw are given in Tables 19.13 and 19.14.

Table 19.13 Odontogenic cysts of jaw

Developmental Odontogenic Cysts
Dentigerous cysts (follicular cyst)
Keratocystic odontogenic tumor (odontogenic keratocyst)
Lateral periodontal cyst
Gingival cyst of adults
Calcifying cystic odontogenic tumor (calcifying odontogenic cyst, Gorlin cyst)
Glandular odontogenic cyst
Inflammatory Odontogenic Cysts
Periapical (radicular) cyst
Residual periapical (radicular) cyst

Table 19.14 Nonodontogenic cysts of jaw

Epithelial-lined Nonodontogenic Cysts (Fissural Cyst)
Nasopalatine duct cysts (fissural cysts)
Globulomaxillary cyst
Median palatal cysts
Nonepithelial-lined Nonodontogenic Cysts
Simple bone cysts
Aneurysmal bone cysts

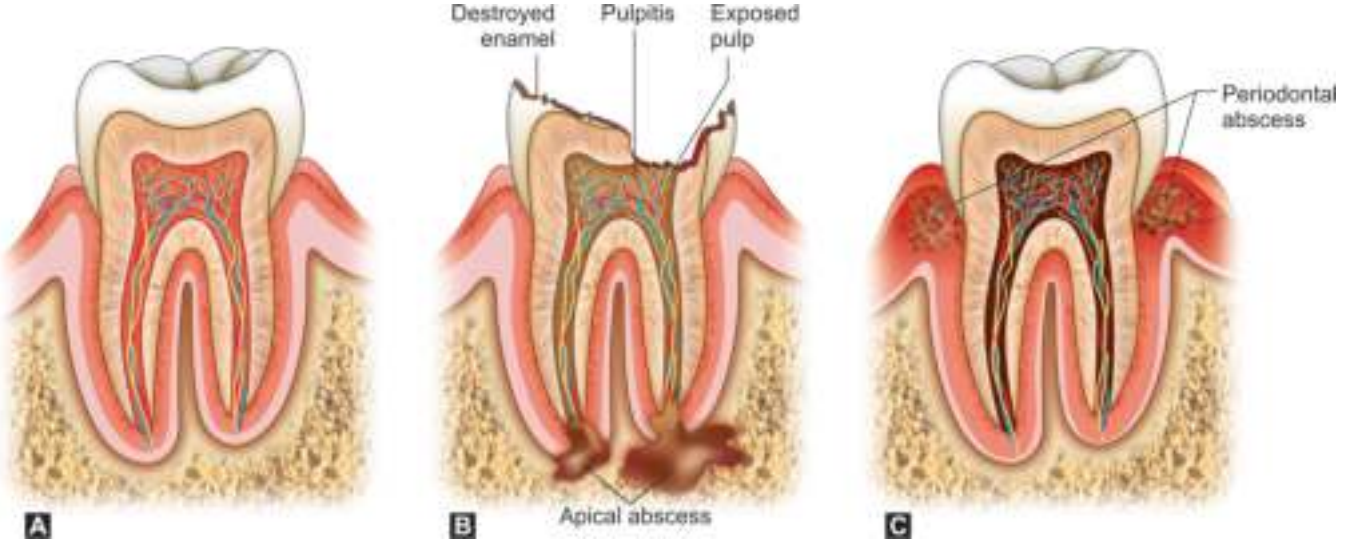

Fig. 19.24: Pathogenesis of dental caries. (A) Normal structure of tooth, (B) apical abscess, (C) periodontal abscess.

DENTIGEROUS CYST (FOLLICULAR CYST)

Dentigerous cyst is a unilocular cyst, which forms in association with the crown of an impacted molar or canine tooth. Enucleation and excision of the associated tooth are the treatment of choice.

- Patient presents with asymptomatic, well defined expansile radiolucent lesion.
- On histologic examination, dentigerous cyst is lined by cuboidal to flattened epithelial cells. There is presence of focal keratinization, mucous cells, inflammatory cells and dystrophic calcification.

KERATOCYSTIC ODONTOGENIC TUMOR (ODONTOGENIC KERATOCYST)

Odontogenic keratocyst is symptomatic unilocular cyst in the mandible or maxilla affecting 2nd to 4th decades of life that contains keratinous debris. On histologic examination, cyst shows palisading basal cells covered by a few layers of squamous cells under parakeratotic surface. Lack of rete ridges is diagnostic feature. Rarely carcinoma may arise from the cyst.

LATERAL PERIODONTAL CYST

Lateral periodontal cyst occurs in lateral surface of roots of mandibular premolar teeth during 5th to 7th decades. Periodontal cyst is well demarcated, radiolucent on radiograph. On light microscopy, cyst shows a thin layer of nonkeratinized epithelium with focal thickening. There is no inflammation surrounding the cyst.

GINGIVAL CYST

Gingival cyst occurs in the buccal gingiva of the mandible near the premolar and molar teeth during 5th to 6th decades. Gingival cyst may be single measuring <1 cm in diameter or multiple. On histologic examination, cyst is lined by a thin layer of epithelium. There is no inflammation in surrounding soft tissue.

CALCIFYING ODONTOGENIC CYST

Calcifying odontogenic cyst occurs as a radiolucent asymptomatic lesion in maxilla or mandible during 2nd and 3rd decades of life. On light microscopy, cyst shows a proliferating layer of columnar palisaded basal cells similar to ameloblasts. Superficial layer has large cells with eosinophilic cytoplasm lacking nuclei termed as ghost cells. Calcification may be seen. Recurrence is uncommon after enucleation of cyst.

GLANDULAR ODONTOGENIC CYST

Glandular odontogenic cyst is referred to sialo-odontogenic cyst. It occurs as a radiolucent lesion in anterior region of mandible or maxilla. Patient most often presents with painful swelling.

On histologic examination, cyst contains nonkeratinized epithelium, mucus secreting cells and focal solid areas. There may be presence of ghost cells and hyaline bodies. Surgical excision is the treatment of choice.

RADICULAR (PERIAPICAL CYST)

Radicular cyst (periapical cyst) is associated with nonviable carious teeth. It occurs in the apical third of tooth root during 3rd to 7th decades of life.

- Patient presents with painful swelling. On histologic examination, cyst shows inflammation surrounding the nonkeratinizing epithelium.
- There is presence of cholesterol clefts, foamy macrophages, dystrophic calcification, and intraepithelial hyaline bodies (Rushton bodies). Residual cyst is a variant of radicular cyst occurring at the site of extracted tooth.

NASOPALATINE DUCT CYST

Nasopalatine duct cyst is the most common lesion affecting 4th to 6th decades of life. It arises from moderate-sized nerves and small muscular arteries within incisive canal.

- Patient presents with swelling of the anterior palate with pain. It is well circumscribed radiolucent lesion demonstrated on radiograph.
- On histologic examination, cyst may be lined by stratified squamous, pseudostratified columnar cells within the incisive canal. Surgical enucleation is the treatment of choice.

GLOBULOMAXILLARY CYST

Globulomaxillary cyst originates from epithelium entrapped during fusion of the globular portion of the medial nasal process within maxillary process especially between the lateral incisors.

- Cyst is well circumscribed radiolucent demonstrated on radiograph.
- On histologic examination, cyst is lined by stratified squamous epithelium. Occasionally, it is lined by pseudostratified columnar ciliated epithelium. Enucleation is the treatment of choice.

MEDIAN PALATAL CYST

Median palatal cyst is believed to originate from epithelium entrapped along the embryonic line of fusion of the lateral palatal shelves of the maxilla affecting young adults.

- Patient presents with firm or fluctuant swelling in the midline of the hard palate posterior to the incisive

papilla. It is well-circumscribed radiolucent lesion in the midline of the hard palate demonstrated on radiograph.

- On histologic examination, cyst is lined by stratified squamous epithelium. Surgical enucleation is the treatment of choice.

SIMPLE BONE CYST

Simple bone cyst is known with multiple names such as unicameral bone cyst or solitary bone cyst, progressive bone cyst, traumatic bone cyst or hemorrhagic bone cyst, which is well circumscribed osteolytic lesion in the posterior mandible in young <20 years of age. Maxilla may be affected in some cases.

On histologic examination, cyst is lined by fibrovascular tissue with hemosiderin laden macrophages. There is presence of reactive bone and osteoclasts.

ANEURYSMAL BONE CYST

Aneurysmal bone cyst is rapidly enlarging blood-filled cystic lesion affecting first three decades of life. It occurs in mandible in 60% or maxilla in 40% of cases.

- The cystic lesion may be isolated or associated with chondroblastoma or osteoblastoma.
- On histologic examination, aneurysmal bone cyst shows fibrotic stroma with multinucleated giant cells, macrophages and hemosiderin granules. There may be presence of ossification (Fig. 19.25).

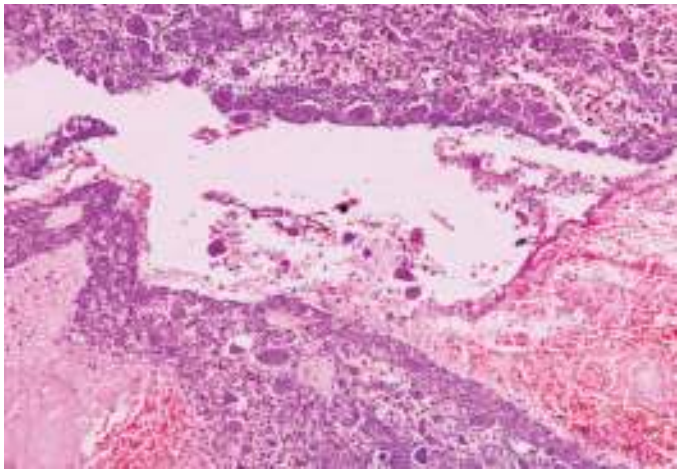

Fig. 19.25: Aneurysmal bone cyst shows fibrotic stroma with multinucleated giant cells, macrophages and hemosiderin granules (100X).

ODONTOGENIC TUMORS

Odontogenic tumors are derived from epithelial, ectomesenchymal and/or mesenchymal elements of the tooth forming apparatuses. It is worth mentioning that peripheral (extraosseous) equivalents of most central odontogenic tumors located in the mandibular or maxillary gingiva arise either from surface mucosa or dental lamina nests in the submucosa or sinonasal tract. WHO classification of tumors of odontogenic and maxillofacial bone tumors is given in Table 19.15.

Table 19.15 WHO classification of tumors of odontogenic and maxillofacial bone tumors

Odontogenic Carcinomas
- Ameloblastic carcinoma
- Primary intraosseous carcinoma, not otherwise specified
- Sclerosing odontogenic carcinoma
- Clear cell odontogenic carcinoma
- Ghost cell odontogenic carcinoma

Odontogenic Carcinosarcoma

Odontogenic Sarcoma

Benign Odontogenic Tumors
- Benign epithelial odontogenic tumors
  - Ameloblastoma
  - Ameloblastoma, unicystic type
  - Ameloblastoma, extraosseous/peripheral type
  - Metastasizing ameloblastoma
  - Squamous odontogenic tumor
  - Calcifying epithelial odontogenic tumor
  - Adenomatoid odontogenic tumor
- Benign mixed epithelial and mesenchymal odontogenic tumors
  - Ameloblastic fibroma
  - Primordial odontogenic tumor
  - Odontoma
  - Odontoma, compound type
  - Odontoma, complex type
  - Dentinogenic ghost cell tumor
- Benign mesenchymal odontogenic tumors
  - Odontogenic fibroma
  - Odontogenic myxoma/myxofibroma
  - Cementoblastoma
  - Cemento-ossifying fibroma

Odontogenic Cysts of Inflammatory Origin
- Radicular cyst
- Inflammatory collateral cysts

Odontogenic and Non-odontogenic Developmental Cysts
- Dentigerous cyst
- Odontogenic keratocyst
- Lateral periodontal cyst and botryoid odontogenic cyst
- Gingival cyst
- Glandular odontogenic cyst
- Calcifying odontogenic cyst
- Orthokeratinized odontogenic cyst
- Nasopalatine duct cyst

Contd...

Table 19.15 WHO classification of tumors of odontogenic and maxillofacial bone tumors (*Contd...*)

Malignant Maxillofacial Bone and Cartilage Tumors
▪ Chondrosarcoma
▪ Chondrosarcoma grade 1
▪ Chondrosarcoma grade 2/3
▪ Mesenchymal chondrosarcoma
▪ Osteosarcoma, not otherwise specified
▪ Low grade central osteosarcoma
▪ Chondroblastic osteosarcoma
▪ Parosteal osteosarcoma
▪ Periosteal osteosarcoma
Benign Maxillofacial Bone and Cartilage Tumors
▪ Chondroma
▪ Osteoma
▪ Melanotic neuroectodermal tumor of infancy
▪ Chondroblastoma
▪ Chondromyxoid fibroma
▪ Osteoid osteoma
▪ Osteoblastoma
▪ Desmoplastic fibroma
Fibro-osseous and Osteochondromatous Lesions
▪ Ossifying fibroma
▪ Familial gigantiform cementoma
▪ Fibrous dysplasia
▪ Cemento-osseous dysplasia
▪ Osteochondroma
Giant Cell Lesions and Bone Cysts
▪ Central giant cell granuloma
▪ Peripheral giant cell granuloma
▪ Cherubism
▪ Aneurysmal bone cyst
▪ Simple bone cyst
Hematolymphoid Tumors
Solitary plasmacytoma of bone

Contd...

ADENOMATOID ODONTOGENIC TUMOR

Adenomatoid odontogenic tumor most often occurs in anterior maxilla. It affects especially females during second decade of life. It is slow-growing tumor with progressive growth.

Surgical Pathology: Adenomatoid Odontogenic Tumor
Gross Morphology
Tumor is predominantly cystic simulating an odontogenic cyst.
Light Microscopy
▪ Tumor is composed of odontogenic epithelium embedded in a mature connective tissue. ▪ Tumor shows numerous duct-like structures lined by cuboidal or columnar cells. ▪ Hyaline and calcified deposits may be scattered throughout epithelial lining duct-like structures.

CALCIFYING EPITHELIAL ODONTOGENIC TUMOR (PINDBORG TUMOR)

Calcifying epithelial odontogenic tumor most often occurs in mandibular premolar–molar area in association with an embedded tooth. Tumor may occur in gingiva. It occurs during 4th and 5th decades with no sex predilection. Tumor may be invasive. It may recur after surgical excision. It is less aggressive tumor than ameloblastoma.

Surgical Pathology: Calcifying Epithelial Odontogenic Tumor
Gross Morphology
Tumor is solid. Cystic variety has been reported.
Light Microscopy
▪ Tumor is composed of closely packed polyhedral epithelial cells and scanty stroma. ▪ Tumor cells show mild pleomorphism. ▪ There is presence of eosinophilic homogenous amyloid-like material that becomes calcified.

SQUAMOUS ODONTOGENIC TUMOR

Squamous odontogenic tumor is a benign locally infiltrative tumor that occurs in anterior maxilla and posterior mandible. Tumor in the maxillary region tends to be more aggressive. On radiograph, tumor appears as a well-circumscribed semicircular radiolucency surrounded by sclerotic border.

Surgical Pathology: Squamous Odontogenic Tumor
Light Microscopy
Tumor is composed of nests and islands of well differentiated squamous epithelium lacking atypia located within a collagenous stroma of low to moderate cellularity.

AMELOBLASTIC FIBROMA

Ameloblastic fibroma most often affects younger age group. It has benign clinical course.

Surgical Pathology: Ameloblastic Fibroma
Gross Morphology
Tumor is solid. But cystic variant has been reported.

Light Microscopy

- Tumor is composed of neoplastic fibrous stroma enclosing thin strip of ameloblastic epithelium. The presence of mesenchymal component is diagnostic feature of this tumor.
- Epithelial component has two layers of cells.
- There may be presence of hard tooth structures such as dentin.
- Occasionally stellate reticulum is present.

ODONTOMA

Odontoma features production of calcified parts of teeth. It occurs in the alveolar ridge of the mandible or maxilla. There are three variants: complex, compound and ameloblastic odontomas.

Complex Odontoma

Complex odontoma most often occurs in molar areas of the mandible especially of females. It is a benign poorly differentiated tumor forming enamel, dentin or cementum in uncoordinated fashion. It is incidentally detected on routine radiographic examination.

Compound Odontoma

Compound odontoma most often occurs in the anterior region of maxilla. It is a benign well-differentiated tumor composed of masses of small denticles.

Ameloblastic Odontoma

Ameloblastic odontoma is aggressive tumor. It is currently regarded as immature complex odontoma. Tumor is solid and cystic. Tumor is composed of prominent epithelial component resembling ameloblastoma. It recurs after surgical excision.

CEMENTOMA

Cementoma is relatively common non-neoplastic disorder. It most often occurs in mandibular incisor region especially affecting females. It is restricted to small region surrounding apices of teeth. Lesion is asymptomatic and does not require treatment.

Surgical Pathology: Cementoma

Light Microscopy

- Cementoma is composed of curvilinear trabeculae resembling ginger root or irregularly shaped cementum-like masses.
- It should be differentiated from cemento-ossifying fibroma, which shows thin isolated trabeculae with prominent osteoblastic rimming.

ODONTOGENIC MYXOMA, MYXOFIBROMA AND FIBROMA

Odontogenic myxoma is derived from dental papilla (tooth germ origin), hence qualifies for odontogenic origin. It is related to malformed or missing teeth. It occurs during 2nd and 3rd decades in mandible and maxilla. It is cystic lesion demonstrated on radiograph. Recurrence is common after surgical removal. Odontogenic fibroma most often occurs in maxilla anterior to the molar teeth especially affecting females.

Surgical Pathology: Odontogenic Myxoma

Gross Morphology

Tumor is cystic in consistency.

Light Microscopy

- Tumor is composed of loose stellate cells with long branching odontogenic epithelium.
- Odontogenic fibroma differs from myxoma by the presence of fibrous tissue and odontogenic epithelial rests.
- Myxofibroma is composed of myxomatous and fibrous components in equal proportion.

Immunohistochemistry Technique

Tumor cells of odontogenic myxoma are immunoreactive for vimentin but negative for S-100 protein.

AMELOBLASTOMA (ADAMANTINOMA)

Ameloblastoma is the most common of the epithelial odontogenic tumors. It constitutes 1% of tumors and cysts of jaw during 3rd to 5th decades. Tumor arises from epithelial lining of dentigerous cyst, remnants of the dental lamina and enamel organ or basal layer of oral mucosa. Ameloblastoma occurs in the mandibular region in >08% and in molar ramus region in 70% of cases.

Surgical Pathology: Ameloblastoma

Gross Morphology

Traditionally, ameloblastoma has been divided into solid and multicystic, but this distinction is arbitrary.

Light Microscopy

Histologic variants of ameloblastoma are follicular, plexiform, acanthomatous, papilliferous-keratotic, granular cell, desmoplastic, vascular and dentinoameloblastoma. Two or more histologic patterns may coexist within the same tumor. Out of these follicular and plexiform histologic variants are more common.

- **Follicular variant of ameloblastoma:** Tumor is composed of outermost tall columnar cells with polarization of the nuclei away from basement membrane resembling inner dental epithelium of the developing tooth follicle (ameloblastic layer). The inner (central) portion of the epithelial island is composed of loose network of cells resembling stellate reticulum. Squamous metaplasia within the stellate reticulum gives rise to the acanthomatous variant.
- **Plexiform variant of ameloblastoma:** Tumor is composed of irregular nests and interdigitating cords of epithelial cells with a minimum of stroma (Figs 19.26 and 19.27).

Immunohistochemistry Technique	
Panel of immunomarkers is used to analyze expression in ameloblastoma on histologic sections. Granular cell ameloblastoma is positive for cytokeratin and CD68 but negative for S-100 protein. Tumor cells exhibit strong reactivity for cytokeratins.	
Markers	**Expression**
▪ CK5, CK14, CK8, CK18, CK19	▪ Positive
▪ Calretinin	▪ Positive (stellate reticulum areas)
▪ S-100 protein	▪ Negative
Electron Microscopy	
On electron microscopy study, tumor cells exhibit clear cut evidence of epithelial differentiation in the form of tonofilaments and complex desmosomes.	

Mode of Spread

Ameloblastoma has invasive property and tendency to recur after surgical excision. It is due to invasion and recurrence properties, this is placed under borderline (low-grade malignant) tumor category by oral pathologists and WHO classification of tumors of odontogenic and maxillofacial bone tumors. Distant metastases have been documented and in instances.

Fig. 19.26: Ameloblastoma of maxilla. Tumor is multilocular and located in maxilla arising from the enamel organ.

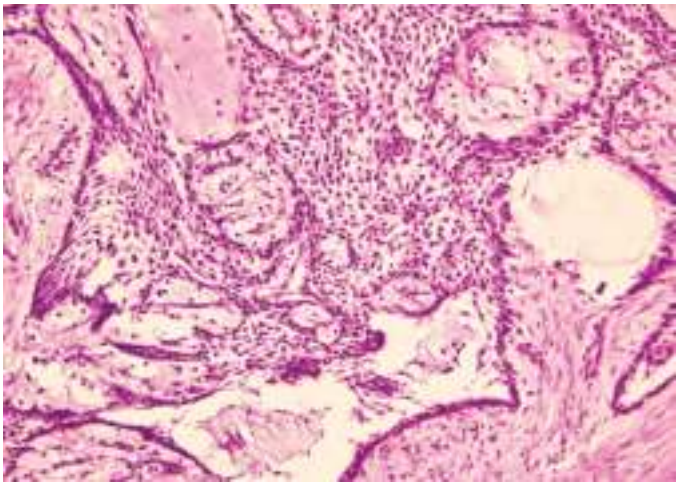

Fig. 19.27: Ameloblastoma. Tumor is composed of outermost tall columnar cells with polarization of the nuclei from basement membrane. The inner (central) portion of the epithelial island is composed of loose network of cells resembling stellate reticulum (100X).

Differential Diagnosis

Ameloblastoma has to be differentiated from focal reactive hyperplasia in a dentigerous cyst, unicystic ameloblastoma. Minimal diagnostic criteria for ameloblastoma are presence of a palisaded basal layer with stellate reticulum-like epithelium above immunoreactivity for calretinin supports the diagnosis.

Management

Enucleation of the ameloblastoma is most often curative. Local recurrence may occur after surgical excision if ameloblastic islands remain embedded in the cyst wall.

AMELOBLASTIC CARCINOMA

Ameloblastic carcinoma has microscopic architectural features of ameloblastoma with additional malignant component. Tumor shows lack of differentiation, increased cellularity, marked atypia, numerous mitoses, vascular and neural invasion.

ODONTOGENIC CARCINOMA

Odontogenic carcinoma is restricted to primary intraosseous carcinoma lacking ameloblastic-like pattern. It is considered to be of odontogenic origin either *de novo* or arising in a odontogenic cyst.

Clear Cell Odontogenic Carcinoma

Clear cell odontogenic carcinoma most often occurs in jaw. It simulates metastatic clear cell carcinoma of salivary gland. Tumor is composed of clear cells arranged in nests surrounded by mature collagenous stroma. Tumor cells lack glycogen and mucin.

Sclerosing Odontogenic Carcinoma

Sclerosing odontogenic carcinoma is composed of polygonal monomorphic epithelial cells arranged in small nests and thin cords embedded in abundant sclerosing hyaline stroma. Tumor cells exhibit skeletal muscle and neural infiltration.

AMELOBLASTIC FIBROSARCOMA

Ameloblastic fibrosarcoma morphology is similar to ameloblastic fibroma except it shows increased cellularity, cytologic atypia and aggressive clinical course. It has diminished or absent epithelial component. Some tumors containing combined features of ameloblastic carcinoma and fibrosarcoma are termed **ameloblastic carcinosarcoma**.

Table 19.16 Nonodontogenic tumors

Benign Fibro-osseous Lesions
▪ Fibrous dysplasia ▪ Juvenile ossifying fibroma: Trabecular and psammomatoid variants ▪ Cementosseous fibroma: Periapical or florid variants
Giant Cell Lesions
▪ Central (intraosseous) giant cell granuloma ▪ Brown tumor of hyperparathyroidism ▪ Cherubism ▪ Aneurysmal bone cyst

NONODONTOGENIC TUMORS

Nonodontogenic tumors are classified in Table 19.16.

FIBROUS DYSPLASIA

Fibrous dysplasia may be polyostotic or monostotic associated with somatic mutation of GNAS1 gene. Polyostotic form is associated with Albright syndrome. Mean age at the time of diagnosis is 25–35 years.

Clinical Features

Patient presents with painless unilateral swelling of maxilla or mandible.

Imaging Technique

On radiograph, lesion varies from cystic or translucent to sclerotic or radiopaque with ill-defined margins.

Surgical Pathology: Fibrous Dysplasia
Light Microscopy
▪ Fibrous dysplasia is composed of C-shaped or Chinese figure-like trabeculae of woven or immature bone within proliferating fibroblastic stroma. ▪ These trabeculae lack rimming by osteoblasts.
Immunohistochemistry Technique
Fibrous dysplasia shows stronger immunoreactivity for osteocalcin.

FIBROMA GROUP LESIONS

Fibroma group lesions are derived from periodontal ligament. These have predilection for molar–premolar region of mandible. These lesions are more amenable to surgical enucleation or curettage. These lesions are differentiated from fibrous dysplasia.

Ossifying Fibroma

Ossifying fibroma is composed of lamellar bone with osteoblastic rimming.

Cemento-ossifying Fibroma

Cemento-ossifying fibroma is composed of rounded psammoma-like masses resembling cement.

Juvenile (Aggressive) Ossifying Fibroma

Juvenile ossifying fibroma is actively growing affecting young persons and composed of cellular fibrous stroma.

CENTRAL GIANT CELL GRANULOMA

Central giant cell granuloma is most common cystic lesion affecting children and younger age group. It occurs in mandible or maxilla. Tumor occurs as a result of trauma resulting in organization of slow minute recurrent hemorrhages. These lesions are treated by surgical removal or curettage.

Peripheral giant cell granuloma is characterized by development of cystic mass on the gingiva or the alveolar process as a result of unusual proliferative reaction to local injury. It is seen as a mass covered by mucous membrane, which can be ulcerated.

Surgical Pathology: Central Giant Cell Granuloma
Light Microscopy
▪ This cellular lesion is composed of numerous multinucleated giant cells embedded in a fibrous stroma that also contains ovoid or spindle-shaped mesenchymal cells. ▪ Osteoclast-like giant cells have patchy distribution usually associated with areas of hemorrhage.

CHERUBISM

Cherubism is hereditary autosomal dominant disorder characterized by intraosseous fibrous swellings of the jaw. The gene responsible for cherubism has been mapped on chromosome 4p16.3. On histologic examination, it is indistinguishable from central giant cell granuloma. Young patient may present with bilateral involvement of mandible and maxilla.

BROWN TUMOR OF HYPERPARATHYROIDISM

Osteoclastic bone resorption results to osteitis fibrosa cystica (also known as brown tumor) in jaw and long bones. The lesion is expansile and multilocular with solid and cystic areas. Cystic areas have a brown color due to presence of abundant hemosiderin.

Recent Advances: Salivary Gland Tumor Specimen Handling in Surgical Pathology

- Although fine needle aspiration cytology (FNAC) is a diagnostic tool for preoperative evaluation of salivary gland tumors. Histopathology remains the gold standard for final diagnosis of tumors of major salivary glands (parotid, submandibular and sublingual glands), and minor salivary glands (mucous-secreting glands in the lining membrane of the aerodigestive tract). Pleomorphic adenoma and Warthin tumor arise in major salivary glands especially in parotid gland. Malignant tumors usually occur in the minor salivary glands especially in palate region. Proper diagnosis of malignant tumors with accurate staging is very important in the management of these cases.
- Ultrasound-guided fine needle aspiration cytology (FNAC) is recommended for salivary gland tumors to determine, where the tumor is benign or malignant. Computed tomography (CT) and magnetic resonance imaging (MRI) can confirm salivary gland malignant tumor infiltration in the adjacent skeletal muscle and to see if the tumor has spread to regional lymph nodes in the neck. CT scan has utility in proven malignancy to exclude distant metastases in lung, bone, brain, and liver associated with poor prognosis.
- Diagnosis of salivary gland tumors can be challenging due to varied and overlapping histologic features and immunohistochemical staining patterns of various histologic tumor types including technical limitations such as sampling errors, crush artifact and limited size tumor.
- Pathologist should take into considerations of clinical history, radiologic findings information, macroscopic tumor site, unifocal/multifocal tumor, tumor laterality, tumor size, tumor extent (extra-parenchymal extension, extraglandular soft tissue, facial nerve, ear canal, mandible, skull base, carotid artery encasement), histologic patterns (i.e. tubular and cribriform architecture of polymorphous adenocarcinoma, squamous differentiation in mucoepidermoid carcinoma, solid architecture of adenoid cystic carcinoma, mucin secreting tumor, Warthin tumor with oncocytic epithelial cells lining papillary and cystic structures in a lymphoid stroma, high-grade cytology, epithelial and lymphoid elements), and ancillary studies.
  - Recognition of specific histologic patterns can help narrow the differential diagnosis. Several important clinical features provide an important initial framework for the assessment of biopsy and resected surgical specimens.
  - Pathologist should follow reporting protocol including histologic grade, lymphovascular invasion, perineural invasion, tumor margin status, regional lymph nodes status with tumor, and number of lymph nodes examined, and distant sites in lung, bone, brain, and liver, if applicable.
- Molecular genetic alterations in salivary gland tumors can be identified by routine karyotype analysis or through fluorescence *in situ* hybridization (FISH) technique, which are helping to identify potential targets that may improve treatment for some of these salivary gland tumors.
  - Pleomorphic adenoma and carcinoma ex pleomorphic adenoma demonstrate PLAG1 rearrangements (8q12) or HMGA2 rearrangements (12q14.15). Adenoid cystic carcinoma is a highly malignant tumor, which arises in minor salivary glands and demonstrates chromosomal translocation t(6;9) → MYB-NFIB. Mucoepidermoid carcinoma is a highly malignant tumor, which involves mostly the parotid gland followed by the minor salivary glands and submandibular gland and demonstrates chromosomal translocation t(11;19 → CRTC1-MAML2).
  - Secretory carcinoma of salivary gland shows chromosomal translocation t(12;15) → ETC-NTRK3 fusion. Polymorphous adenocarcinoma demonstrates PRKD1 E710D hotspot activating mutations. Cribriform adenocarcinoma of the minor salivary gland shows PRKD1 rearrangements. Clear cell carcinoma demonstrates chromosomal translocation t(12;22) → EWSR1-ATF1.
- Surgical excision of benign tumors in parotid gland completely cures the patients. Malignant tumors in the submandibular gland are treated by adjuvant chemotherapy following surgery except in cases of small, low-grade tumors that have been completely excised. In the event of intraoperative tumor spillage, most cases need long-term follow-up for clinical observation. During parotidectomy, it is most important to preserve facial nerve function. Neck dissection is recommended in all cases of malignant tumors in parotid gland except low-grade small tumors.

GASTROINTESTINAL TRACT DISORDERS: DIAGNOSTIC APPROACH

GASTROINTESTINAL TRACT: OVERVIEW

EMBRYOLOGY

Most gastrointestinal tract organs are derived from endoderm, the innermost layer of developing embryo. During embryologic development, most visceral organs develop between 3 and 8 weeks. Blood flows through ductus venosus in the fetus via umbilical vein into inferior vena cava. Umbilical vein gives rise to the adult structure 'falciform ligament'.

- Diaphragm is derived from septum transversum, dorsal mesentery of the esophagus, pleuroperitoneal folds and body wall.

- Ventral pancreatic bud gives rise to main pancreatic duct, uncinate process, and head of the pancreas. Dorsal pancreatic bud ultimately gives rise to accessory pancreatic duct, pancreatic duct, the body, isthmus and tail of the pancreas.
- Primitive gut is divided into foregut (pharynx to duodenum), midgut (duodenum to transverse colon) and hindgut (distal transverse colon to rectum).
- Foregut is supplied by celiac trunk, midgut by superior mesenteric artery and hindgut by inferior mesenteric artery.

Developmental Anomalies of GIT

Developmental anomalies of GIT are cleft lip, cleft palate, atresia and stenosis of GIT, and tracheoesophageal fistula mentioned as under:

- **Cleft lip:** It occurs due to failure of fusion of the maxillary and medial nasal processes during embryonic development resulting in a gap in the upper lip while palate remains intact.
- **Cleft palate:** It occurs due to failure of fusion of the lateral palatine processes, the nasal septum, and/or the median palatine processes. The resulting gap leaves the nasal cavity in communication with the oral cavity.
- **Atresia and stenosis of GIT:** The normal GIT is a tube that develops from the cords of embryonic cells. The cells forming the central part of these cords of embryonic cells undergo apoptosis. If these centrally located cords of embryonic cells do not undergo apoptosis, it results in the absence of GIT lumen. The affected part of GIT becomes atretic. Duodenal atresia is the most common disorder usually associated with Down syndrome. Duodenal atresia is characterized by bile stained vomiting at birth. Abdominal radiograph demonstrates '**double bubble**' appearance of the duodenum.
- **Tracheoesophageal fistula (TEF):** It is the most common congenital anomaly. Most frequent type of tracheoesophageal fistula is distal tracheoesophageal fistula with proximal esophageal atresia.

HISTOLOGY

Entire GIT has a relatively uniform structure. It consists of four layers, i.e. innermost mucosa, submucosa, muscular coat and outermost serosa (adventitia). Adventitia in esophagus is linked with other thoracic organs.

GIT Divisions and Referred Pain in Related Disorders

Depending on the innervation of GIT, pain is referred in different regions.

- **Foregut:** It extends from esophagus to second part of duodenum, where common bile duct enters in this region. It comprises esophagus, stomach and duodenum. Visceral pain arising from foregut is referred to epigastrium.
- **Midgut:** It starts from the duodenum just distal to entry of common bile duct and extends to middle and distal thirds transverse colon known as **Cannon's point**. Midgut includes terminal ileum, tip of the appendix, and adjacent colon. Visceral pain arising from midgut radiates to periumbilical region. Pain in acute appendicitis is felt around periumbilical region. Pain in acute appendicitis is localized to right iliac fossa due to inflammation of the peritoneum.
- **Hindgut:** It starts from Cannon's point to distal structures of GIT. It includes small portion of transverse colon, descending colon and rectum.Visceral pain arising from hindgut radiates to suprapubic region.

GASTROINTESTINAL TRACT DISORDERS

Main disorders of the gastrointestinal tract include developmental disorders (e.g. atresia, stenosis, diverticulosis and fistula), inflammatory (e.g. esophagitis, inflammatory bowel disease), functional disorders, circulatory disorders and tumors. Obstructive disorders of gastrointestinal tract are given in Table 20.1.

Table 20.1 Obstructive disorders of gastrointestinal tract

Disorder	Features
Duodenal atresia	Duodenal atresia, most commonly associated with Down's syndrome, is characterized by vomiting of bile stained material at birth and an abdominal radiograph with the **double bubble sign**
Hirschsprung's disease (congenital megacolon)	▪ Disorder is characterized by congenital absence of ganglion cells due to gene mutation (endothelin 3) usually in the submucosal and muscular coat of large bowel ▪ Aganglionic segment of colon is permanently contracted causing intestinal obstruction. This obstruction leads to dilatation of proximal normal (ganglionic) segment ▪ Rectum is always involved, and this is the preferred site for biopsy. Sigmoid colon and proximal are involved, but entire colonic involvement is very rare

Contd...

Table 20.1 Obstructive disorders of gastrointestinal tract (*Contd...*)

Disorder	Features
Acquired megacolon	Disorder may be associated with Down's syndrome and Chagas' disease
Adhesions	The adhesions are commonly acquired from previous abdominal surgery
Direct inguinal hernia	Direct inguinal hernia occurs through the posterior wall of the inguinal canal in the center of Hesselbach's triangle
Indirect inguinal hernia	Indirect inguinal hernia is most common cause of intestinal obstruction, in which small bowel extends into the scrotal sac, lateral to the triangle of Hesselbach
Umbilical hernia	Umbilical hernia occurs in children and adults. Ascites and pregnancy precipitate hernias in adults
Incisional hernia	Incisional hernia occurs in previously surgical incision sites
Intussusception	▪ Intussusception is an invagination of one segment of proximal bowel (usually the terminal ileum) into the distal bowel (usually the cecum), causing intestinal obstruction and ischemia of inner loop; ileocecal (most common), jejunojejunal, ileoileal and colocolic ▪ Intussusception primarily affects children due to active peristalsis and lymphoid hyperplasia. In adults, pedunculated polyps are common cause of intussusception
Volvulus	▪ Volvulus is twisting of a mobile loop of the intestine (usually the sigmoid colon) around its own mesenteric root with subsequent obstruction and infarction. It is also found in the small intestine. It occurs in small intestine and sigmoid colon ▪ Complications of volvulus include strangulation, gangrene and obstruction
Malrotation of intestine	During fetal life, defective rotation of intestine occurs. As a result, large bowel does not descend into right iliac fossa. These patients are prone to develop volvulus and internal hernia
Paralytic ileus	▪ Paralytic ileus is a lack of intestinal peristalsis associated with stagnation of intestinal contents ▪ The most common causes include abdominal surgery persisting for 2–3 days, peritonitis, shock and vascular collapse
Gallstone ileus	Gallstone ileus occurs when a chronically inflamed gallbladder forms a fistula with the small intestine at ileocecal valve
Meconium ileus	Meconium ileus is a potential complication of a newborn with cystic fibrosis

Most important symptoms and signs pertaining to the GIT include dysphagia, vomiting, hematemesis, hematochezia, melena, colics, diarrhea and constipation. Causes of dysphagia are given in Table 20.2. Causes of gastrointestinal tract bleeding are given in Table 20.3.

AMYLOIDOSIS OF GIT

Amyloidosis occurs in tongue, stomach, and rectal mucosa. Biopsy must be taken from rectum (80% sensitivity), tongue and stomach. Fine needle aspiration of abdominal fat is ideal to establish diagnosis in 90%

Table 20.2 Causes of dysphagia

Mechanical Obstruction ▪ Esophageal webs ▪ Esophageal rings ▪ Esophageal stricture ▪ Esophageal scar ▪ Esophageal achalasia
Inflammatory Disorders
Eosinophilic Esophagitis
Neurological Disorders ▪ Injury to vagus nerve ▪ Diabetes mellitus involving autonomic nervous system ▪ Chagas disease (*Trypanosoma cruzi*) causing enlarged esophagus ▪ Dorsal motor neuron lesions
Infiltrative Disorders ▪ Amyloidosis ▪ Malignant tumors ▪ Sarcoidosis

Table 20.3 Causes of gastrointestinal tract bleeding

Upper Gastrointestinal Tract Bleeding
Esophageal varices
Esophageal neoplasms
Mallory-Weiss lacerations
Gastritis
Peptic ulcer disease
Lower Gastrointestinal Tract Bleeding
Rapid upper gastrointestinal bleeding
Diverticulosis
Infectious colitis
Angiodysplasia
Inflammatory bowel disease
Neoplasms
Anal fissure
Hemorrhoids

of cases. Sections obtained from biopsy should be stained by Congo red stain. Amyloid may be demonstrated by electron microscopy and immunofluorescence microscopy. Mass spectrometry distinguishes AL from AA.

EXTRANODAL LYMPHOMAS OF GASTROINTESTINAL TRACT

Gastrointestinal tract is the most common primary site of extranodal lymphomas, which account for 20–40% of all lymphomas. Gastric region is most often involved followed by the ileocecal region and the colon. Multiple lymphomas of the gastrointestinal tract occur in small proportion of cases. Predisposing factors of gastrointestinal tract lymphomas include *Helicobacter pylori* infection, celiac disease, ulcerative colitis and Crohn's disease. The development of different histologic types of lymphoma appears to be related to chronic antigenic stimulation, inadequate immune regulation, or a combination of these factors. Lymphomas of the gastrointestinal tract are given in Table 20.4. Clinical features and most common extranodal lymphomas of gastrointestinal tract are given in Table 20.5.

Table 20.4 Lymphomas of the gastrointestinal tract

Gastrointestinal Tract Region	Histologic Variant of Lymphoma
Gastric region	▪ B cell lymphoma ▪ Diffuse large B cell lymphoma (DLBCL) ▪ Extranodal marginal zone lymphoma (MZL) also known as MALT lymphoma ▪ Burkitt lymphoma ▪ Mantle cell lymphoma (MCL) ▪ Follicular lymphoma ▪ Peripheral T cell lymphoma (PTCL)
Small intestine	▪ B cell lymphoma ▪ Diffuse large B cell lymphoma (DLBCL) ▪ Extranodal marginal zone lymphoma (MZL) also known as MALT lymphoma ▪ Burkitt lymphoma ▪ Mantle cell lymphoma ▪ Follicular cell lymphoma ▪ T cell/NK cell lymphoma ▪ Peripheral T cell lymphoma, not otherwise specified ▪ NK/T cell lymphoma, nasal type
Colon region	▪ B cell lymphoma ▪ Diffuse large B cell lymphoma (DLBCL) ▪ Extranodal marginal zone lymphoma (MZL) also known as MALT lymphoma ▪ Burkitt lymphoma ▪ Mantle cell lymphoma ▪ Follicular cell lymphoma ▪ T cell/NK cell lymphoma ▪ Enteropathy-associated T cell lymphoma ▪ Peripheral T cell lymphoma, not otherwise specified
Anal region	▪ B cell lymphoma ▪ Diffuse large B cell lymphoma (DLBCL)

Table 20.5 Clinical features and most common extranodal lymphomas of gastrointestinal tract

Symptoms are distinctive for various types of lymphomas. The most common clinical presentation associated with GIT lymphoma includes abdominal pain, palpable mass, diarrhea, nausea, vomiting, fever, perforation and bleeding. Bulky lymphomas in the ileocecal region may cause intussusception

Gastric Region

- Gastric region is most common site of lymphoma in 55–75% of cases
- Most common histologic types of lymphomas in the gastric region include diffuse large B cell lymphoma (DLBCL) and extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue, also known as MALT lymphoma

Small Intestine

- Small intestine is next most common site of GIT lymphoma in 15–35% of cases
- Diffuse large B cell lymphoma (DLBCL) and extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue, also known as MALT lymphoma are most common lymphomas in small intestine especially in the ileocecal region
- Majority of B cell lymphomas arise in the small intestine in elderly persons. Mesenteric lymph node involvement is common
- Extra-abdominal spread is unusual. Patient presents with melena or obstruction

Large Intestine

- Large intestine is the primary site of GIT lymphomas in 3–20% of cases
- Most common lymphomas in large intestine include diffuse large B cell lymphoma (DLBCL) and extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue, also known as MALT lymphoma

Anal Region

Anal region is less common site of lymphoma. Most common histologic variant is diffuse large B cell lymphoma (DLBCL)

DISORDERS OF ESOPHAGUS

ESOPHAGUS: OVERVIEW

ANATOMY

Esophagus is a long hollow muscular tube. It consists of four layers. With the exception of infradiaphragmatic portion, esophagus is lined by nonkeratinized stratified squamous epithelium. The basal layer of lining epithelium constitutes 15% of total thickness of epithelium. The lower two-thirds of the esophagus has thick muscularis mucosa. Gastroesophageal reflux leads to increased thickness of lining epithelial layer.

PHYSIOLOGY

Esophagus participates in propulsion of food from the mouth to the stomach. It also prevents reflux of gastric contents from the stomach back into esophagus.

DEVELOPMENTAL ANOMALIES

Common congenital anomalies of the esophagus include tracheoesophageal fistula, esophageal atresia and esophageal cysts.

Tracheoesophageal Fistula

Tracheoesophageal fistula is a congenital disorder characterized by direct communication between trachea and esophagus. Food passing through fistula enters the trachea, resulting in choking, coughing and cyanosis on attempts at food intake soon after birth.

- Newborn may develop pneumonia as a result of milk reflux into the lungs resulting in distension of the stomach by air. This disorder requires immediate surgical correction. It occurs in three distinct variants.
- Upper esophagus ends in a blind pouch (esophageal atresia). The lower portion of esophagus communicates with the trachea near the tracheal bifurcation. It is the most common variant of tracheoesophageal fistula (90%). Maternal polyhydramnios (increased amniotic fluid) is frequently associated abnormality.
- In second most common variant of tracheoesophageal fistula, the upper portion of esophagus communicates with the trachea. The lower esophageal segment is not connected to the upper esophagus.
- In a third variant, there is a fistulous connection between the trachea and a completely patent esophagus.

Clinical Pearls: Symptoms Related to Esophageal Disorders

- **Dysphagia:** It refers to difficulty in swallowing of solid food (sign of obstruction) or solids as well as liquids (motor dysfunction). Obstruction of esophagus occurs due to strictures, webs, rings, tumor or functional disorders (achalasia or paralysis).
- **Odynophagia:** It refers to pain on swallowing. Most common causes include gastroesophageal reflux disease (GERD) and infectious esophagitis (e.g. virus and fungi).
- **Heartburn:** It refers to burning sensation in retrosternal region as a result of regurgitation of acid in mouth most often associated with gastroesophageal reflux disease.

Pathology Pearls: Gross Examination and Tissue Handling

- Various esophageal diseases are studied by tissue sections obtained by standard endoscopic biopsy, endoscopic mucosal resection (EMR) and esophagectomy (Table 20.6).
- Esophageal biopsy is considered more usful to establish gastroesophageal disease (GERD) in children than adults.

INFLAMMATORY LESIONS

ESOPHAGITIS

The esophagus, covered by squamous epithelium, is relatively resistant to infection. Esophagitis occurs due to gastroesophageal reflux disease, chemicals, cytotoxic drugs, uremia and irradiation.

- In immunocompromised host in AIDS, various opportunistic infectious agents cause esophagitis

Table 20.6 Gross examination and tissue handling of esophagus

Procedure	Characteristics
Standard endoscopic biopsy	Several small tissue fragments measuring 1–5 mm consist of mucosa and muscularis mucosae
Endoscopic biopsy with jumbo forceps	Several tissue fragments measuring 4–8 mm consist of mucosa and submucosa
Endoscopic mucosal resection (EMR)	En bloc resection of superficial malignant and premalignant lesions measuring 1–2 mm
Esophagectomy	Tissue specimens consist of esophagus, proximal stomach and attached soft tissue with lymph nodes

such as herpes simplex type 1, and cytomegalovirus. *Candida albicans* causes white mucosal painful patches in esophagus debilitated persons.

- Gastrointestinal tract disorders that can cause extensive eosinophilic infiltration in the esophageal mucosa include eosinophilic esophagitis, reflux esophagitis, parasitic infection, eosinophilic gastritis and allergic reaction to medication or food. Eosinophilic esophagitis involves middle-third of esophagus in children. Differences between reflux and eosinophilic esophagitis are given in Table 20.7.
- Diagnostic criteria of eosinophilic esophagitis include dysphagia, endoscopic evidence of concentric mucosal rings, presence of ≥15 eosinophils per high power field on histologic examination of esophageal biopsy.

GASTROESOPHAGEAL REFLUX DISEASE

Under physiologic state, lower esophageal sphincter (LES) prevents the entry of the gastric contents in the esophagus. Gastroesophageal reflux disease is popularly known as heartburn.

Gastroesophageal reflux disease refers to chronic backflow of digestive juices (hydrochloric acid and bile) into the esophagus due to transient relaxation of lower esophageal sphincter resulting in damage to epithelial lining of esophagus. Gastroesophageal reflux disease (GERD) is shown in Fig. 20.1A and B.

Predisposing Factors

Predisposing factors for GERD include hiatus hernia (most common), reflux esophagitis, incompetent lower esophageal sphincter, increased intra-abdominal pressure (pregnancy), scleroderma, decreased lower esophageal sphincter tone as a result of alcohol, smoking and caffeine.

Pathogenesis

Gastroesophageal reflux disease causes breach in mucosal barrier, which may allow invasion of infectious agents (e.g. *Candida albicans*, herpes simplex virus or cytomegalovirus and bacteria) resulting in acute inflammation of the lower-third of esophagus as well as metaplastic change in lining epithelium.

Table 20.7 Differences between reflux and eosinophilic esophagitis

Parameters	Reflux Esophagitis	Eosinophilic Esophagitis
Age group	Adults	Children
Sex predilection	Male and female equally affected	Males > females
Symptom	Heartburn	Dysphagia
Endoscopic findings	Variable	Stricture, ring
Histopathological examination	<5 eosinophils per high power field	>20 eosinophils per high power field, eosinophilic microabscesses
Treatment	Gastroesophageal reflux disease	Topical steroids
Complications	Barrett esophagus, stricture	Stricture

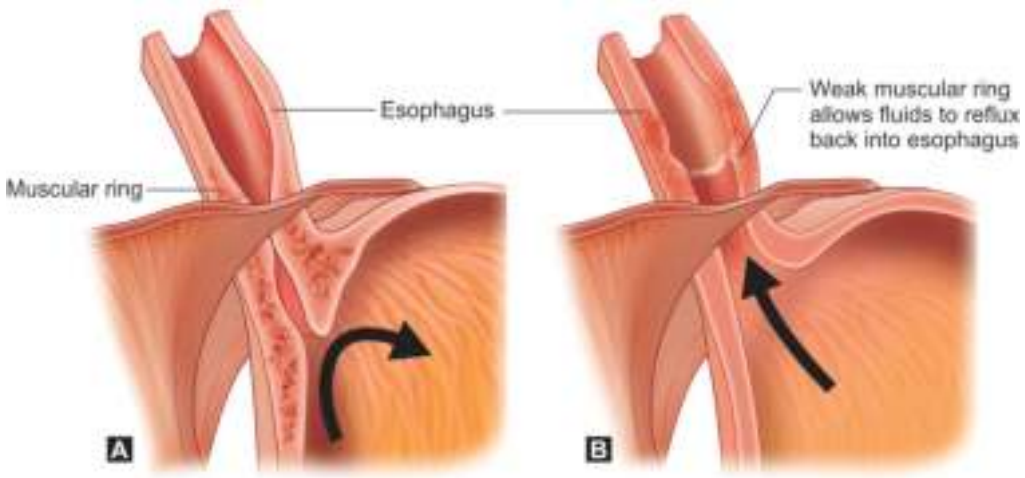

Fig. 20.1: Gastroesophageal reflux disease. (A) Normal esophagus, (B) esophagus is involved as a result of gastroesophageal reflux.

Clinical Features

Patient presents with acute epigastric pain at night (when reflux is worse), nocturnal cough, nocturnal asthma and hematemesis. Symptoms are relieved by antacids.

Complications

Chronic irritation of the esophageal epithelium due to gastroesophageal reflux disease (GERD) may cause several complications: Barrett esophagus, esophageal ulcers, stricture formation and respiratory injury are described as under.

- **Barrett esophagus:** It refers to replacement of the esophageal squamous epithelium by glandular columnar epithelium resembling gastric or colonic epithelium.
- **Esophageal ulcers:** These lesions may bleed or undergo superadded infection.
- **Stricture formation:** Chronic irritation to esophageal lining results in fibrosis forming esophageal stricture.
- **Respiratory injury:** Aspiration of gastric contents in the airways cause injury to larynx and lungs.

BARRETT ESOPHAGUS

Barrett esophagus is a pathologic change characterized by replacement of the esophageal squamous epithelium by glandular columnar epithelium resembling gastric or colonic epithelium. There is increased risk for adenocarcinoma of esophagus in 5–10% of cases.

Pathogenesis

Chronic gastroesophageal reflux disease induces esophagitis and glandular metaplasia in distal third of esophagus due to injury induced by gastric contents (acid, bile). Healing occurs by ingrowth of immature pluripotent stem cells resulting in replacement of esophageal squamous epithelium by columnar epithelium (similar to gastric or intestine) in distal third of esophagus. It is known as Barrett esophagus.

Surgical Pathology: Barrett Esophagus

Light Microscopy

- Definitive diagnosis of Barrett esophagus is established by demonstration of goblet cells with acidic mucin.
- Histologic examination reveals replacement of the esophageal squamous epithelium by glandular columnar epithelium (similar to gastric or intestinal columnar epithelium) in a patchy or circumferential manner, known as Barrett esophagus.
- Underlying connective tissue usually shows signs of chronic inflammation. Barrett esophagus shows glandular metaplasia (Fig. 20.2).

Histochemistry

Histochemical stain with Alcian blue/periodic acid–Schiff (AB/PAS/pH 2.5) is used to highlight goblet cells in a case of Barrett esophagus.

Immunohistochemistry Technique

Panel of immunohistochemical markers applied at site of Barrett's esophageal intestinal metaplasia at the gastroduodenal junction includes CK7, CK20, DAS1, MUC1 and MUC2.

Markers	Expression
▪ CK7	▪ Positive (surface and deep region)
▪ CK20	▪ Positive (surface region only)
▪ DAS1	▪ Positive
▪ MUC1	▪ Positive
▪ MUC2	▪ Positive

Clinical Features

Patient presents with painful swallowing (odynophagia), ulceration, hematemesis, and esophageal stricture.

Diagnostic Approach and Management

Diagnostic criteria for Barrett esophagus are endoscopic evidence of replacement of gray squamous mucosa by pink glandular mucosa, i.e. 'salmon red patches'.

- In the presence of low-grade dysplasia, endoscopy should be repeated in 6–12 months. Low-grade dysplasia is treated to resolve gastroesophageal reflux disease (GERD) and inflammation. Then rebiopsy should be performed in 3–6 months.
- High-grade dysplasia in Barrett esophgus is treated by endoscopic resection of the lesion. Keeping in view that lesion may undergo malignant transformation.

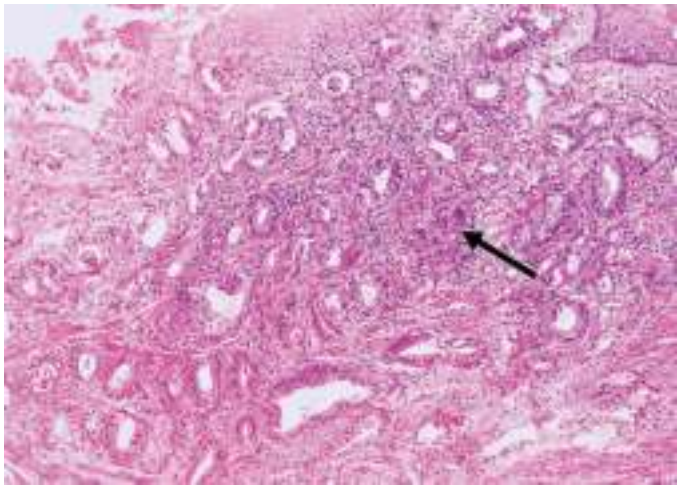

Fig. 20.2: Barrett esophagus. It shows dysplasia of gastric type of mucosa as a result of metaplasia. Goblet cells in columnar mucosa are seen (arrow).

High-grade dysplasia in Barrett esophagus is treated by photodynamic therapy, endoscopic mucosectomy and laser ablation.

Complications

Barrett esophagus is a definite risk factor for development of adenocarcinoma in 5–10% of cases.

- Severe dysplasia must be followed up clinically in every case, and partial resection of the esophagus is recommended in some cases.
- Other complications of Barrett esophagus besides malignancy are reflux esophagitis, aspiration pneumonia, esophageal stricture, esophageal ulcer, perforation and bleeding.

NON-NEOPLASTIC DISORDERS

ESOPHAGEAL DIVERTICULUM

Esophageal diverticulum refers to herniation (outpouching) of one or more layers of the esophageal wall. True diverticulum consists of mucosal, muscular, and serosal layers.

False (pulsion) diverticulum is created by increased intraesophageal pressure that results in herniation of mucosa, submucosa and muscularis propria through weak wall. Esophageal diverticula occur in three characteristic locations.

- **Zenker's diverticulum:** It is most common esophageal diverticulum; present above the upper esophageal sphincter due to defect in the cricopharyngeus muscle. It affects older than 60 years.
- **Traction diverticulum:** It is present near the midpoint of the esophagus due to motor abnormalities.
- **Epiphrenic diverticulum:** It is located above the lower esophageal sphincter due to motor abnormalities associated with achalasia (persistent constriction of the lower esophageal sphincter).

ESOPHAGEAL ACHALASIA

During swallowing, vasoactive peptides synthesized by ganglion cells in myenteric plexus result in relaxation of lower esophageal sphincter. Achalasia refers to loss of esophageal peristalsis and relaxation of lower esophageal sphincter resulting in dysphagia.

Pathogenesis

- **Congenital causes of esophageal achalasia:** Absence of ganglion cells in myenteric plexus in lower esophageal sphincter causes loss of esophageal peristalsis and relaxation of lower esophageal sphincter, it is known as '**achalasia**'. Proximal esophagus above LES (lower esophageal sphincter) is dilated.
- **Acquired causes of esophageal achalasia:** *Trypanosoma cruzi* infection (Chagas' disease) is the most important cause of achalasia in South America. Food is retained within the esophagus, and esophagus undergoes hypertrophy and dilatation.

Clinical Features

Patient presents with dysphagia for solids and liquids. Achalasia may lead to esophageal squamous cell carcinoma in about 5% of cases.

Surgical Pathology: Esophageal Achalasia
Light Microscopy
Histologic examination reveals absence of ganglion cells in the myenteric plexus of the lower esophageal sphincter, analogous to Hirschsprung's disease.

HIATUS HERNIA

Hiatus hernia is a protrusion of the stomach through an enlarged esophageal hiatus in the diaphragm. Patient presents with heartburn and regurgitation. Large herniation carries a risk of gastric volvulus or intrathoracic gastric dilation. There are two types of hiatal hernia—sliding and paraesophageal.

- **Sliding hiatal hernia:** It refers to protrusion of the proximal stomach upward above the diaphragm through a widened diaphragmatic hiatus (most common in 90% of cases). Patient presents with nocturnal epigastric distress, hematemesis, and dysphagia (stricture formation). Patient may develop Barrett's esophagus (glandular metaplasia) resulting in risk for adenocarcinoma in 5–10% of cases.
- **Paraesophageal hernia:** The gastroesophageal junction is in the normal location, but only small portion of the stomach rolls up (less common in 10% of cases) and may be strangulated by the diaphragm (Fig. 20.3).

SCLERODERMA

Scleroderma is an autoimmune disease associated with systemic increased synthesis of collagen in blood vessels, skin and internal organs. Anti-Scl-70 antibodies to nuclear topoisomerase are virtually specific for this autoimmune disease.

Lower esophageal sphincter is relaxed and dilated. There is absence of peristalsis in the proximal esophagus that causes dysphagia.

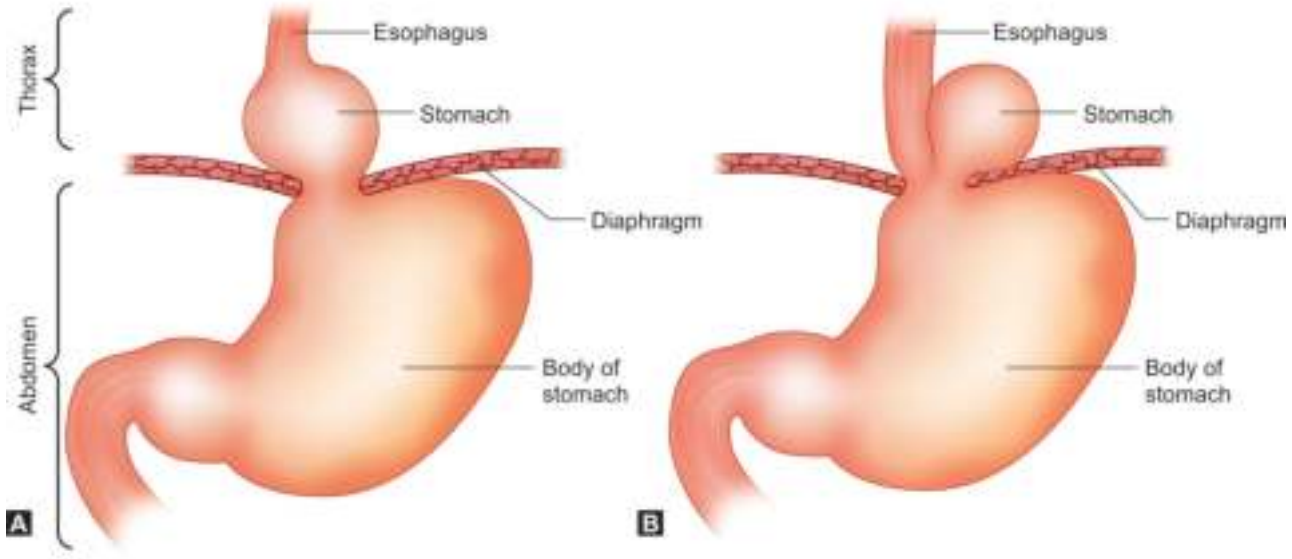

Fig. 20.3: Hiatal hernia. (A) Sliding hiatal hernia, (B) paraesophageal hiatal hernia.

Clinical Pearls: CREST Syndrome

- CREST syndrome, a variant of progressive systemic sclerosis, is also associated with esophageal motility problems.
- Patient presents with dysphagia, intermittent episodes of ischemia of the fingers, marked by pallor, paresthesia and pain known as Raynaud phenomenon.

ESOPHAGEAL STRICTURE

Esophageal stricture most often results from prolonged esophageal gastric acid reflux. It may also be caused by accidental ingestion of corrosive alkali or acid.

Strong acid produces esophageal coagulative necrosis, and strong alkali results in liquefactive necrosis, which heals with stricture formation in esophagus, and marked by progressive dysphagia.

POSTCRICOID WEBS (RINGS)

Postcricoid webs are thin mucosal membranes that projecting into the lumen of the esophagus most often seen in '**Plummer-Vinson syndrome**' also known as '**Paterson-Kelly syndrome**'.

Clinical Features

Patient presents with iron deficiency anemia, postcricoid webs in the esophagus resulting in dysphagia, glossitis, leukoplakia, koilonychia (spoon nails) and achlorhydria. There is increased risk for development of carcinoma of oropharynx and upper esophagus in Plummer-Vinson syndrome.

ESOPHAGEAL VARICES

Left gastric vein drains blood from distal esophagus and proximal stomach into the portal vein. Portal hypertension causes esophageal varices due to dilatation of left gastric vein.

- Esophageal veins are dilated veins immediately beneath the mucosa in the lower-third of esophagus in cirrhosis. These veins are linked to the portal system through gastroesophageal anastomoses. Left gastric vein is also dilated in these patients.
- Esophageal varices >5 mm in diameter are prone to rupture and life-threatening hemorrhage. Endoscopy is the primary diagnostic tool for confirming esophageal varices and treated by sclerotherapy.
- Esophageal varices cause hematemesis in liver cirrhosis, lacerations in Mallory-Weiss syndrome, esophagitis due to chemical agents or infection; and esophageal perforation in Boerhaave's syndrome.

SCHATZKI RING

Due to Schatzki ring, patient develops subepithelial semicircular fibrous strand in the wall of the esophagus resulting in narrowing of lumen at gastroesophageal junction. Patient presents with dysphagia. The lesion may be demonstrated by endoscopy. It is treated by balloon dilatation catheter technique.

VATER'S SYNDROME

Vater's syndrome is characterized by vertebral abnormalities, esophageal atresia, tracheoesophageal fistula, renal disease and absent radius bone.

BOERHAAVE'S SYNDROME

Boerhaave's syndrome is characterized by rupture of distal esophagus due to vomiting or retching regurgitating (forceful vomiting).

MALLORY-WEISS SYNDROME

Mallory-Weiss syndrome is characterized by mucosal tear of distal esophagus and upper stomach due to violent retching leading to bleeding. It is typically encountered in chronic alcoholics.

ESOPHAGUS: TUMORS

Leiomyoma, squamous cell carcinoma and adenocarcinoma are common tumors of esophagus. Histologic examination of esophageal malignancy reveals squamous cell carcinoma in 60% and adenocarcinoma in 40% of cases. Squamous cell carcinoma occurs worldwide. Primary melanoma of esophagus is extremely rare, but melanoma from other site may metastasize to esophagus. Revised 2019 WHO classification of esophageal tumors is given in Table 20.8. Benign and malignant tumors of esophagus are discussed below.

Table 20.8 Revised 2019 WHO classification of esophageal tumors

Benign Epithelial Tumors and Precursor Lesions
▪ Squamous cell papilloma, NOS
▪ Squamous papillomatosis
▪ Esophageal squamous dysplasia (intraepithelial neoplasia), low-grade
▪ Esophageal squamous dysplasia (intraepithelial neoplasia), moderate grade
▪ Esophageal glandular dysplasia (intraepithelial neoplasia), low-grade
▪ Esophageal glandular dysplasia (intraepithelial neoplasia), high-grade
Malignant Epithelial Tumors
▪ Squamous cell carcinoma, NOS
• Verrucous squamous cell carcinoma
• Squamous cell carcinoma, spindle cell variant
• Basaloid squamous cell carcinoma
▪ Adenocarcinoma, NOS
▪ Adenoid cystic carcinoma
▪ Mucoepidermoid carcinoma
▪ Adenosquamous carcinoma
▪ Carcinoma, undifferentiated, NOS
▪ Neuroendocrine tumors
• Neuroendocrine tumor grade 1
• Neuroendocrine tumor grade 2
• Neuroendocrine tumor grade 3
▪ Neuroendocrine carcinoma, NOS
• Large cell neuroendocrine carcinoma
• Small cell neuroendocrine carcinoma
▪ Mixed neuroendocrine and non-neuroendocrine neoplasm (MiNEN)
• Combined small cell—adenocarcinoma
• Combined small cell—squamous cell carcinoma

Adapted from 2019 WHO classification of tumors of digestive system.
Term NOS, not otherwise specified.
Other less common tumors derived from soft tissue are leiomyoma, lipoma, gastrointestinal stromal tumors (benign, ulcerated, potentially malignant and malignant), leiomyosarcoma and rhabdomyosarcoma. Metastatic esophageal tumors are breast carcinoma and lung carcinoma.

BENIGN POLYPOID LESIONS

Fibrovascular Polyps

Fibrovascular polyps are pedunculated intraluminal growth filling esophageal lumen. On histologic examination, polyps are composed of fibrovascular core covered by benign squamous mucosa.

Inflammatory Polyps

Inflammatory polyps are often related to gastroesophageal reflux disease (GERD) and present near the squamocolumnar junction of esophagus. On endoscopy, inflammatory polyp resembles adenocarcinoma. On histopathological examination, polyp is composed of inflamed squamous and/or foveolar mucosa.

Squamous Papilloma

Squamous papilloma is most often related to GERD. On histopathologic examination, tumor is composed of fibrovascular core covered by benign reactive squamous epithelium with varying degrees of inflammation.

SQUAMOUS CELL CARCINOMA

Squamous cell carcinoma is most common malignant tumor of the esophagus. It frequently affects 50–60 years old age group and is more common in men than women. It most often occurs in esophageal lower portion (30%) followed by middle portion (50%) and upper portion (20%). Distribution of esophageal carcinoma is shown in Fig. 20.4.

Predisposing Factors

Risk factors, clinical/endoscopic features, histologic features, immunohistochemistry, molecular genetic alterations and prognosis of esophageal squamous cell carcinoma are given in Table 20.9.

- Cigarette smoking and alcohol are well-known risk factors for esophageal squamous cell carcinoma.

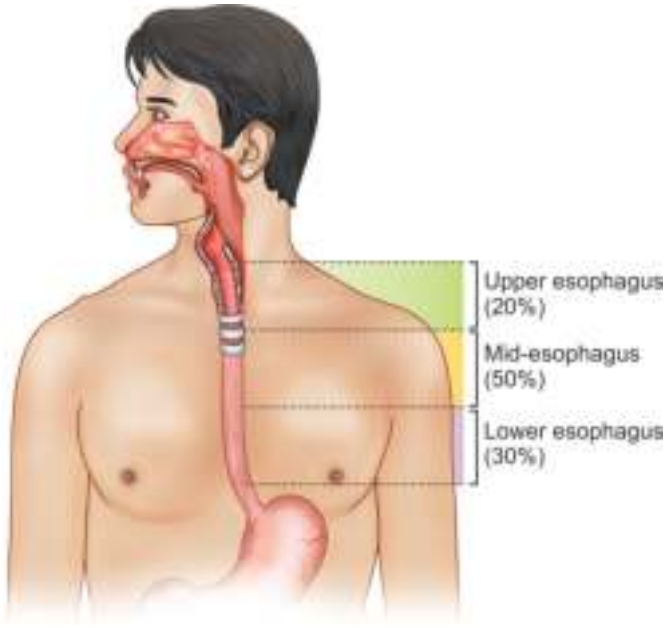

Fig. 20.4: Distribution of esophageal carcinoma.

- Other predisposing factors include Plummer-Vinson syndrome, achalasia, tylosis and Barrett esophagus. Human papillomavirus plays an etiologic role in esophageal carcinogenesis.
- Polycyclic hydrocarbons are aromatic hydrocarbons derived from animal fat by process of broiling of meats (e.g. smoked meat and fish). Ingestion of smoked meat containing polycyclic hydrocarbons undergoes hydroxylation in liver forming epoxides, results in forming covalent adducts, which bind to cellular DNA, RNA and proteins and alter the genome. Exposure to polycyclic hydrocarbons may produce cancers of oral cavity, esophagus (upper- and middle-third) and pancreas (Table 20.10).
- In immunocompromised state, patients may develop esophageal carcinoma, colorectal carcinoma, Burkitt lymphoma, diffuse large B cell lymphoma and Kaposi sarcoma in gastrointestinal tract.

Table 20.9 Risk factors, clinical/endoscopic features, histologic features, immunohistochemistry, molecular genetic alterations and prognosis of esophageal squamous cell carcinoma

Parameters	Features
Risk factors	
Socioeconomic status	Low socioeconomic status
Tobacco chewing/smoking	Most important risk factor, tobacco specific nitrosamines and polycyclic aromatic hydrocarbons main carcinogenic substances
Alcohol consumption	▪ Excessive alcohol consumption increases risk, acetaldehyde metabolite causes DNA abnormalities and structural and functional alterations of proteins ▪ Persons with ALDH2 and ALDH1 gene mutations lead to excessive accumulation of acetaldehyde
Drinking hot beverages	Consumption of hot beverages increase risk in Southern Brazil, Islamic Republic Iran
Dietary habits	Pickled vegetables associated with esophageal carcinoma
Increased body mass index	Associated with increased risk
Genetic factors	Tylosis autosomal dominant disorder due to RHBDF2 gene mutation on 17q25.3 increases risk in 90% of cases
Associated medical disorders	Plummer-Vinson syndrome related to iron deficiency, achalasia, radiotherapy to the chest area and caustic ingestion injury
Clinical and endoscopic features	
Age group	60–70 years
Esophagus involved	Middle third > distal third > proximal third
Morphology of growth	Fungating growth (most common), ulcerative growth, or infiltrative growth
Prognosis and survival	Aggressive tumor with poor prognosis and five-year survival
Histologic features	
Differentiation	▪ *Well-differentiated SCC:* Tumor cells are arranged in sheets, ample keratinization, formation of squamous pearls, intercellular bridges, few basaloid cells ▪ *Moderately differentiated SCC (most common):* Variable keratinization and significant proportion of basaloid cells are present ▪ *Poorly differentiated SCC:* Tumor cells are arranged in small or large nests, predominantly basaloid cells, or marked pleomorphism

Contd...

Table 20.9 Risk factors, clinical/endoscopic features, histologic features, immunohistochemistry, molecular genetic alterations and prognosis of esophageal squamous cell carcinoma (*Contd...*)

Parameters	Features
Histologic subtypes	Basaloid squamous cell carcinoma, spindle cell SCC (carcinosarcoma), verrucous squamous cell carcinoma
Immunohistochemistry technique	
TP63	Positive
CK5/CK6	Positive
CK7	Positive
CK14	Positive
CENP-H (centromere protein H)	Positive (associated with poor prognosis)
Molecular genetic alterations	
Genes that regulate cell cycle	TP53 gene mutation (60–90%), cell regulatory gene mutations such as CDKN2A(p16), RB1, CHEK1, CHEK2, NFEL2, CCND1, CDK4, CDK6, MDM2
Genes that control cell differentiation	NOTCH1 and NOTCH3 gene mutations (30%)
EGFR (HER1) signaling pathway	EGFR overexpression (60–75%), mutations and/or amplification in *ras* and AKT family oncogenes (75%)
Epigenetic factors	▪ DNA methylation, chromatin modification, RNA editing and loss of genomic printing ▪ Promotor hypermethylation-related silencing of CDKN2A results in overexpression of p53
Inherited factors	Tylosis (missense gene RHBDF2) results in overactivation of EGFR signaling pathway
Copy-number alterations and structural rearrangements	Gains of chromosomes 3, 10, 12 and 20 result from mutations and amplifications of genes
Other genetic abnormalities	Gene mutations of SNPs and TP53 due to acetaldehyde
Prognostic factors	
Tumor stage	Tumor, node, metastasis—metastatic classification
Tumor differentiation	Prognosis better in well differentiated squamous cell carcinoma, and poor in poorly differentiated carcinoma

Table 20.10 Chemical carcinogens associated with esophageal carcinoma

Chemical Carcinogen	Mechanisms of Entry in Body	Associated Cancers
Polycyclic hydrocarbons	Tobacco smoke, ingestion of smoked meat and fish	▪ Esophagus carcinoma (middle and distal) ▪ Oral carcinoma ▪ Pancreas carcinoma ▪ Lung carcinoma ▪ Renal pelvis transitional cell carcinoma ▪ Urinary bladder transitional cell carcinoma

Molecular Pathogenesis: Esophageal Squamous Cell Carcinoma

- Squamous cell carcinoma of esophagus develops by stepwise progression with genetic alterations driving progression from histologically normal squamous epithelium to intraepithelial neoplasia (dysplasia) to high-grade neoplasia (dysplasia) to invasive squamous cell carcinoma.
- TP53 tumor suppressor gene mutation is a key early driver mutation. Genetic abnormalities demonstrated at the intra-epithelial neoplasia stage include aneuploidy, copy-number genetic alterations, changes related to the amplification of genes such as EGFR and silencing of the CDKN2A (p16) by hypermethylation. Normally, cyclin-dependent kinases act as cell cycle regulatory proteins, that control the expression of various genes.
- Other gene mutations related to cell cycle regulators include NFE2L2, CHEK1, CHEK2, and amplifications of cell-cycle regulatory genes (CCND1, CDK4, CDK6 and MDM2). NOTCH1 and NOTCH3 gene mutations have demonstrated in 25% of cases.
- Oncogene activation and tumor suppressor gene mutation associated with esophageal carcinoma are given in Tables 20.11 and 20.12.

Table 20.11 Oncogenes, their mode of activation and associated with esophageal carcinoma

Category	Proto-oncogene	Mode of Activation	Associated Malignancies
Cyclins and cyclin-dependent kinases (cell cycle regulators)			
Cyclins	CCND1 (cyclin D1)	▪ Amplification ▪ Amplification ▪ Translocation	▪ Esophageal carcinoma ▪ Multiple myeloma ▪ Breast carcinoma ▪ Mantle cell lymphoma

Table 20.12 Tumor suppressor gene mutation associated with esophageal carcinoma

Gene	Protein	Function	Familial Tumors	Sporadic Cancers
Cell cycle progression inhibitors				
CDKN2A	$p16^{INK4a}$ and p14 ARF	▪ p16 inhibits CDK ▪ p14 indirectly activates p53 tumor suppressor	Familial melanoma	▪ Esophageal carcinoma ▪ Pancreas carcinoma ▪ Breast carcinoma

Locations

- Squamous cell carcinoma may occur in any portion of esophagus. But it most commonly develops in the middle region (most common site) and lower-thirds in areas of normal anatomic constrictions. Distally located tumor often invades the stomach. It is an aggressive cancer associated with rapid progression and short survival.
- Growth protrudes into the esophageal lumen and spreads by local extension into adjacent structures, i.e. trachea, bronchi, or aorta, or diffuse infiltration into the esophageal wall.

Clinical Features

Patient presents with dysphagia, weight loss, and anorexia. Occasionally, pain or hematemesis may occur.

Surgical Pathology: Esophageal Squamous Cell Carcinoma

Gross Morphology

- The tumor is usually circumferential and often ulcerated (most common) with sharply demarcated margins. It may be a fungating growth obstructing esophageal lumen.
- Cut surface of tumor is gray white, which invades muscular wall, extends out and involves trachea (Fig. 20.5).

Fig. 20.5: Squamous cell carcinoma of esophagus: It shows fungating growth invading wall (arrow).

Light Microscopy

Squamous cell carcinoma of esophagus has both vertical and horizontal growth of neoplastic squamous epithelium beyond the basement membrane. Grading of the tumor is based on the degree of cytological atypia, mitotic activity and presence of keratinization (Fig. 20.6).

- **Well-differentiated (grade 1) SCC:** Tumor is composed of large cells with abundant eosinophilic cytoplasm, ample keratinization, formation of squamous pearls, intercellular bridges, few basaloid cells; arranged in sheets. Cytologic atypia is minimal with low mitotic activity. The invasive margin of the tumor is pushing.
- **Moderately differentiated (grade 2 most common) SCC:** Tumor demonstrates cytological atypia, mitoses, surface parakeratosis and infrequent keratinization, significant proportion of basaloid cells.
- **Poorly differentiated (grade 3) SCC:** Tumor is composed of predominantly basaloid cells with marked pleomorphism arranged in small or large nests.

Immunohistochemistry Technique

Expression of cytokeratin (CK5/CK6, CK7, CK14) in squamous cell carcinoma is related to the degree of differentiation of tumor. Tumor shows positivity for TP63. Centromere protein H (CENP-H) is one of the fundamental components of the human active kinetophore. High expression of CENP-H is related to poor prognosis in squamous cell carcinoma.

Markers	Expression
▪ TP63	▪ Positive
▪ CK5/CK6	▪ Positive
▪ CK7	▪ Positive
▪ CK14	▪ Positive
▪ CENP-H	▪ Positive (associated with poor prognosis)

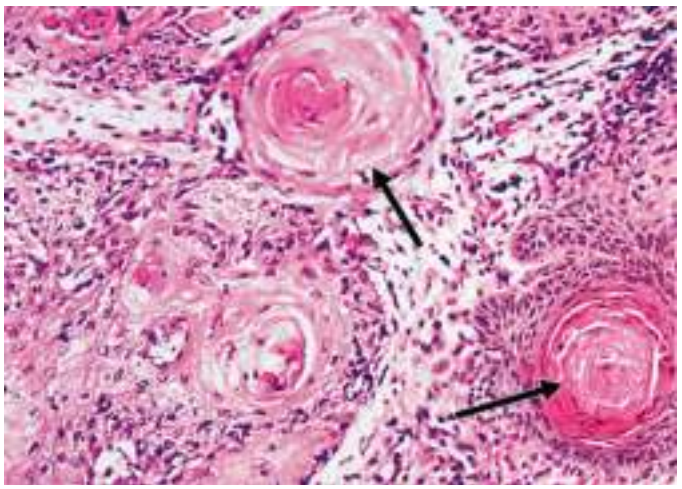

Fig. 20.6: Squamous cell carcinoma of esophagus: Tumor is composed of large cells with abundant eosinophilic cytoplasm, keratinization, keratin pearls (arrows) and intercellular bridges arranged in sheets (400X).

Mode of Spread

- **Local spread:** Esophageal squamous cell carcinoma invades in longitudinal and transverse directions. Longitudinal spread may involve gastric region. There may be formation of tracheoesophageal fistula.
- **Lymphatic spread:** Esophagus has abundant lymphatic drainage.
  - Tumor first spreads beneath the mucosa, then locally by lymphatic channels that drains into periesophageal area below the diaphragm and upward into the cervical lymph nodes.
  - The tumor may also metastasize to submucosa of stomach, probably through the submucosal lymphatic channels. Lymph node metastases occur early in the course of the disease. This is the main reason for treatment failure.
- **Hematogenous spread:** Tumor metastasizes via hematogenous route to the liver, lungs and adrenal glands.

ADENOCARCINOMA

Adenocarcinoma most often occurs in the lower-third of the esophagus especially in the setting of Barrett esophagus. Gastroesophageal reflux disease plays key role in the pathogenesis of Barrett disease.

Barrett esophagus is a pathologic change characterized by replacement of the esophageal squamous epithelium by glandular columnar epithelium resembling gastric or colonic epithelium. There is increased risk for adenocarcinoma of esophagus in 5–10% of cases. Risk factors for esophageal adenocarcinoma are given in Table 20.13.

Surgical Pathology: Esophageal Adenocarcinoma

Gross Morphology

Tumor is a small polypoidal, elevated, flat, occult or even depressed lesion. It is located close to gastroesophageal junction.

Light Microscopy

- Tumor is composed of infiltrative tubular or papillary structures. Signet ring cells with mucin production may be demonstrated. Presence of signet cell must be differentiated from signet ring cell gastric carcinoma composed of >50% signet cells.
- Esophageal adenocarcinoma may be well-differentiated with >95% of tumor composed of glands, moderately differentiated in 50–90% of cases and poorly differentiated in <50% of cases. Well-differentiated esophageal adenocarcinoma poses diagnostic challenge (Fig. 20.7).

Immunohistochemistry Technique

More than 90% of esophageal adenocarcinoma express CK7. Approximately 40% of these tumors also express CD20.

Markers	Expression
▪ CK7	▪ Positive (90%)
▪ CD20	▪ Positive (40%)

NEUROENDOCRINE TUMOR

Neuroendocrine tumor is an epithelial neoplasm with prominent neuroendocrine differentiation. Tumor can occur in middle or distal esophagus in elderly persons. Pathologic spectrum of neuroendocrine tumor can be low-grade, high-grade or large cell variant.

Table 20.13 Risk factors for esophageal adenocarcinoma

Risk Factors	Comments
Gastroesophageal reflux disease (GERD)	Most important risk factor for esophageal adenocarcinoma, Barrett disease
Abdominal obesity	Abdominal obesity related to adipokines increase GERD, Barrett disease
Male sex	Higher androgen levels increase risk
Tobacco smoking	Tobacco smoking increases Barrett esophagus and esophageal adenocarcinoma
Helicobacter pylori infection	*Helicobacter pylori* associated with atrophic gastritis and esophageal adenocarcinoma
Anti-reflux therapies	Long-term use of proton-pump inhibitors increases risk
Medications	Large doses of nonsteroidal anti-inflammatory drugs increase risk

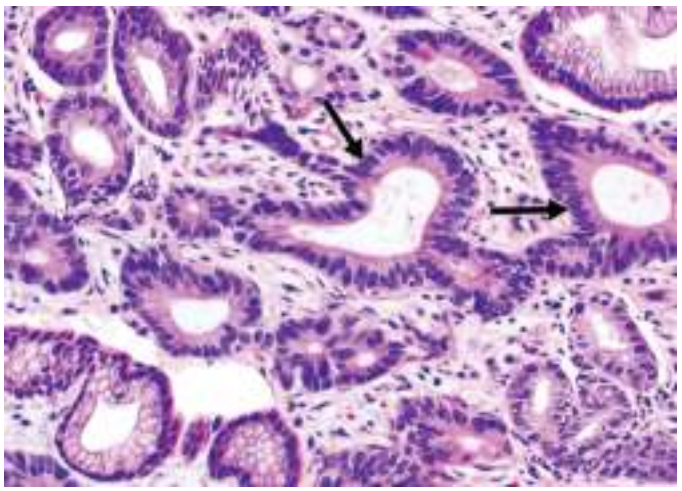

Fig. 20.7: Adenocarcinoma of esophagus (arrows) (400X).

Clinical Features

Neuroendocrine tumor of esophagus is usually an incidental finding on radiological studies or upper gastrointestinal tract endoscopy.

- High-grade neuroendocrine tumor of esophagus causes dysphagia, weight loss and chest pain.
- Tumor is diagnosed on biopsy or surgical resection.

Surgical Pathology: Neuroendocrine Tumor

Gross Morphology

Neuroendocrine tumor of esophagus is a small polypoidal or fungating or deeply invasive.

Light Microscopy

- **Well differentiated (low-grade) tumor:** Tumor is composed of uniform, small, bland tumor cells arranged in solid trabecular, gyriform or glandular patterns. It may have paneth cell differentiation. Patient has favorable prognosis.
- **Poorly differentiated (high-grade) tumor:** Tumor can be large cell or small cell tumors.
  - Large cell tumor is composed of nests of pleomorphic, large cells with prominent nucleoli and a moderate amount of cytoplasm, prominent crush artifact and Azzopardi phenomenon, necrosis, high mitotic activity and lymphovascular invasion. Tumor cells are arranged in solid or cribriform patterns. Patient has poor prognosis.

Histologic Grading of Tumor

- **Grade 1 tumor:** It shows <2 mitoses/10 HPF or <2% Ki-67 index.
- **Grade 2 tumor:** It shows 2–20 mitoses/10 HPF or 3–20% Ki-67 index.
- **Grade 3 tumor:** It shows >20 mitoses/10 HPF or >20% Ki-67 index.

Immunohistochemistry Technique

Neuroendocrine tumors show positivity for synaptophysin, chromogranin A, neuron-specific enolase (NSE) and CD56 (neural cell adhesion molecule—NCAM).

Markers	Expression
▪ Synaptophysin	▪ Positive
▪ Chromogranin A	▪ Positive
▪ NSE (neuron-specific enolase)	▪ Positive
▪ CD56 (NCAM)	▪ Positive

MESENCHYMAL TUMORS

Leiomyoma

Leiomyoma is the most common mesenchymal tumor of esophagus. It is demonstrated as an intramural, well circumscribed growth in the middle or distal esophagus. Cut surface is gray white. Histologic examination reveals benign smooth muscle bundles arranged in whirling pattern.

Gastrointestinal Stromal Tumor

Gastrointestinal stromal tumor (GIST) occurs as intraluminal mass in distal portion of esophagus. The tumor is CD117+.

Granular Cell Tumor

Granular cell tumor is demonstrated as incidental submucosal lesion. On histologic examination, tumor is composed of bland cells with granular cytosplasm arranged in sheets and nests. Cytoplasm shows positivity with S-100 and PAS stain.

Vascular Tumors

Capillary or cavernous hemangiomas appear as polypoidal intramural masses. Lymphangiomas are small sessile to pedunculated growth in the middle- to lower-third of esophagus.

OTHER TUMORS

Melanoma

Primary melanoma most often occurs as pigmented, polypoidal mass in the middle or distal portion of esophagus.

Lymphoma

Primary lymphoma rarely occurs in esophagus. On histologic examination, diffuse large B cell lymphoma, mucosa-associated lymphoid tissue lymphoma and T cell lymphoma have been described.

Metastases

Esophagus is uncommonly involved due to metastases. Breast carcinoma, lung carcinoma and melanoma may metastasize to the esophagus.

DISORDERS OF STOMACH

STOMACH: OVERVIEW (ANATOMY AND PHYSIOLOGY)

Stomach is divided into five regions: cardia, fundus, body (corpus), antrum and pylorus. The pylorus ends in a strong muscular sphincter at the gastroduodenal junction. The pylorus is a muscular zone of stomach controlling passage of food into duodenum. Cardiac region is poorly defined extending up to 5 cm distal to gastroesophageal junction. Stomach also has lesser and greater curvatures.

HISTOLOGY

Stomach has five layers: mucosa, submucosa, smooth muscle, subserosa and serosa. Mucosa of the stomach is composed of tubular glands. The cardiac region consists of mucus secreting glands. Fundus and body regions of stomach consist of glands that synthesize acid pepsin juices. Pylorus region consists of endocrine cells, which synthesize gastrin hormone.

Pathology Pearls: Gastric Glands in Body of Stomach

Gastric gland consisting of surface mucosal cells form gastric pits of foveola. It consists of three portions: isthmus, neck and base. Parietal cells are located in isthmus. Neck of stomach contains parietal cells, mucosal cells and stem cells.

- **Chief cells (zymogenic cells):** Chief cells synthesize pepsinogen. Hydrochloric acid synthesized by parietal cells converts pepsinogen into pepsin. Pepsin breaks certain peptide bonds in proteins. Chief cells secrete gastric lipase, which splits short chain triglycerides into fatty acids and monoglycerides.
- **Parietal cells (oxyntic cells):** Parietal cells secrete intrinsic factor, which is needed for absorption of vitamin B_{12}, required for erythropoiesis. Deficiency of vitamin B_{12} causes macrocytic anemia. Parietal cells also secrete hydrochloric acid, which kills microorganisms in food, denatures proteins and converts pepsinogen into pepsin.
- **Mucus surface and neck cells:** Mucus cells secrete mucus, which forms a protective barrier that prevents digestion of stomach wall.
- **Enteroendocrine G cells:** Enteroendocrine G cells stimulate chief cells to secrete pepsinogen and parietal cells to secrete HCl. It provides acidic pH (pH 1.8). It converts proenzyme pepsinogen into active pepsin. Pepsin converts proteins into peptides. Rennin is a proteolytic enzyme found in stomach of infants which helps in the digestion of milk proteins.
- **Brunner's glands:** Brunner's glands present in the duodenum synthesize alkaline fluid to buffer gastric acid and mucus for protection and lubrication.

VESSELS AND NERVES

Blood Supply

Most of the blood supply to stomach is derived from the celiac artery. Left and right gastric arteries are present along the lesser curvature. Left and right gastroepiploic arteries are present along great curvature. Proximal stomach also receives blood supply from inferior phrenic and short gastric arteries.

Venous Drainage

Venous drainage parallels the arterial supply of stomach. Left and right gastric vein drains into the portal vein. Right gastroepiploic veins drain into superior mesenteric vein, while left gastroepiploic vein drains into the splenic vein.

Lymphatic Drainage

Lymphatic drainage from superior gastric, suprapyloric, pancreaticoduodenal and inferior gastric/subpyloric regions of stomach drain into celiac group of lymph nodes and thoracic duct.

Innervation

Stomach is supplied by vagus nerve (parasympathetic system) and sympathetic system *via* the celiac plexus.

HELICOBACTER PYLORI-INDUCED GASTROINTESTINAL TRACT DISORDERS

Helicobacter pylori is transmitted by fecal–oral route. The bacterium resides within the mucosal layer lining pits beneath the bicarbonate-rich mucous barrier, where the pH approaches neutrality. *Helicobacter pylori* does not survive in metaplastic glands. Mucus and bicarbonate secretion are defense mechanisms against acid and pepsin (Fig. 20.8A and B). Role of *Helicobacter pylori* in gastrointestinal tract disorders is given in Table 20.14.

HELICOBACTER PYLORI-INDUCED MUCOSAL INJURY

Helicobacter pylori induces mucosal injury by following mechanisms. Role of *Helicobacter pylori* in gastrointestinal disorders is shown in Fig. 20.9A to D.

Attachment of Helicobacter Pylori to Mucosal Cells

The pathogen attaches to mucosa with the help of cell adhesion molecules.

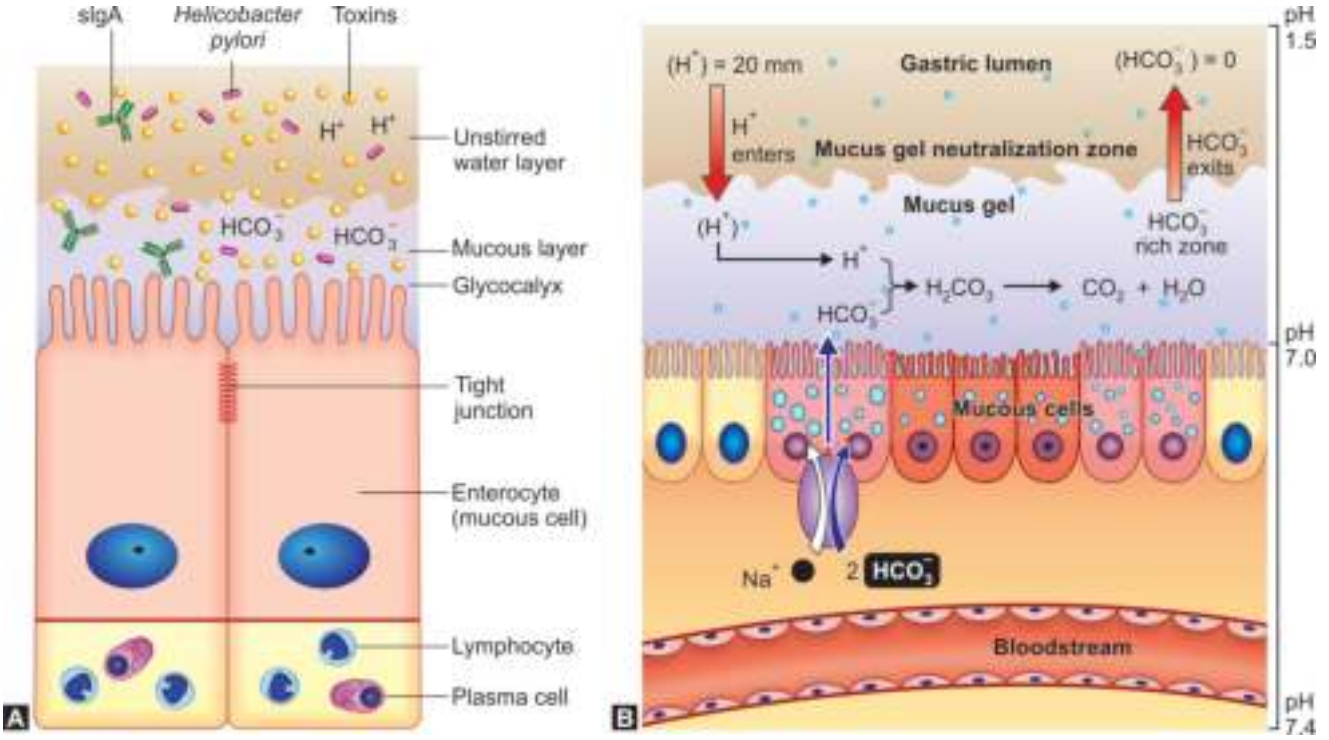

Fig. 20.8A and B: Gastroduodenal mucus and bicarbonate secretion into the adherent layer of mucus gel creates a pH gradient with a neural pH at the epithelial surfaces in stomach and duodenum. the mucus gel (rich in mucus and bicarbonate) acts as a barrier and provides the first line of mucosal protection against luminal acid and pepsin.

Table 20.14 Role of *Helicobacter pylori* in gastrointestinal disorders

Acute Erosive Gastritis
Chronic Gastritis
▪ Chronic gastritis type A (autoimmune gastritis autoantibodies against parietal cells and intrinsic factor in 10%) ▪ Chronic gastritis type B (non-autoimmune gastritis due to *Helicobacter pylori* in 90%) ▪ Chronic gastritis type AB
Granulomatous Gastritis
Chronic atrophic gastritis with extensive inflammation and glandular atrophy (glands widely spaced)
Lymphocytic Gastritis (Associated with Celiac Disease)
▪ Giant fold gastritis ▪ Some forms of autoimmune gastritis

Contd...

Hyperplasia and Metaplasia	
▪ G cell hyperplasia	▪ Intestinal metaplasia
Large Gastric Folds	
Ménétrier disease (hypertrophic gastropathy, i.e. idiopathic enlargement of mucosal folds)	
Peptic Ulcer Disease (10%)	
▪ Gastric ulcer	▪ Duodenal ulcer
Gastric Polyps	
Hyperplastic polyps	
Malignant Tumors (1–2%)	
▪ Gastric adenocarcinoma ▪ Gastric MALT (MALT, mucosa-associated lymphoid tissue) lymphoma	

Gastritis occurs in all cases.

Role of VacA Exotoxin

VacA exotoxin released by *Helicobacter pylori* enhances the ability of bacteria to colonize in the gastric epithelium and contributes to the pathogenesis of peptic ulcer disease and gastric carcinoma. VacA exotoxin disrupts gastric epithelial function due to vacuoles formation in the epithelium, '**cytochrome c**' released induced apoptosis of epithelium and blockade T cell response.

Role of DNA Segment (CagA) Effector Molecules

CagA effector molecules of *Helicobacter pylori* alter signaling pathway and tight junctions. These also induce IL-8 synthesis.

Role of Immunologic T and B Cells

The T and B cells synthesize thrombotic platelet activating factor (PAF), which acts on bacterial gene

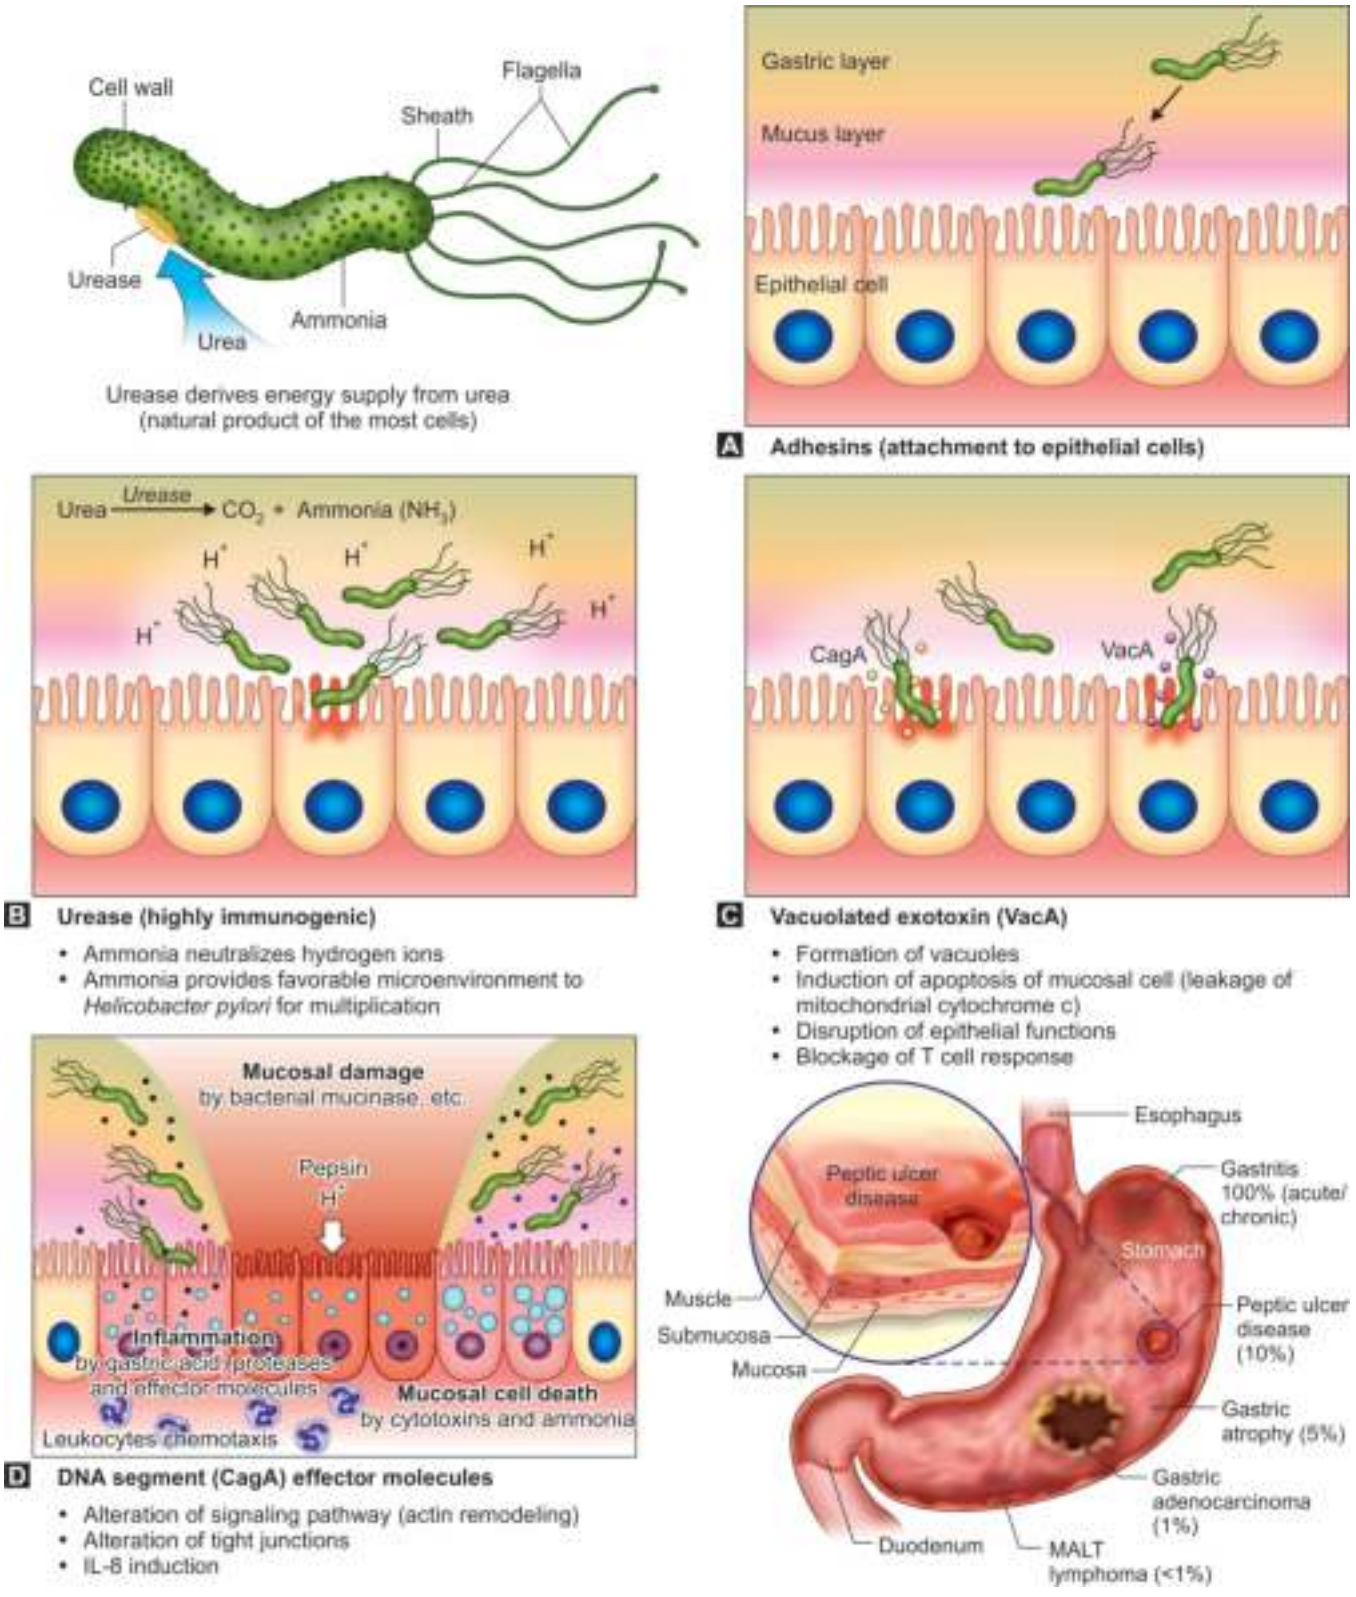

Fig. 20.9A to D: Role of *Helicobacter pylori* in gastrointestinal tract disorders.

products of *Helicobacter pylori* resulting in synthesis of proteases, phospholipases, and urease responsible for mucosal injury.

Role of Urease

Urease of *Helicobacter pylori* derives energy from urea. Urease converts urea into ammonia and CO_2.

Ammonia neutralizes hydrogen ions present in mucus layer of gastric mucosa and provides favorable microenvironment for growth of *Helicobacter pylori*.

- Ammonia stimulates gastrin, which enhances hydrochloric acid production resulting in mucosal injury due to impaired duodenal bicarbonate levels.
- Myeloperoxidase converts ammonia into monochloramine, which causes mucosal injury.

Role of Protease Enzyme

Protease breaks down mucus glycoproteins and destroys mucosal barrier of gastrointestinal tract.

Role of Phospholipase

Phospholipase damages surface epithelial cells of gastrointestinal tract. It also enhances release of leukotrienes, which attract polymorphonuclear cells resulting in release of myeloperoxidase.

Pathology Pearls: Diagnostic Tests for *Helicobacter pylori*

Tests for diagnosis of *Helicobacter pylori* infection fall into two categories: (i) Noninvasive and (ii) invasive.

- **Urea breath test:** Radiolabeled urea is administered to the patient. Urease produced by *Helicobacter pylori* combines with CO_2, which can be detected on breath.
- **Serology:** Antibody to *Helicobacter pylori* can be demonstrated in serum of patient.
- **Stool examination:** *Helicobacter pylori* can be demonstrated in stool of patient.
- **Culture:** *Helicobacter pylori* can be cultured from the biopsy specimen.
- **Rapid urease test:** It is also known as Campylobacter like organism (CLO) test. The basis of the test is the ability to synthesize urease enzyme, which catalyzes the conversion of urea to ammonia.
- **Histology:** *Helicobacter pylori* can be demonstrated by Giemsa, Warthin-Starry and Steiner stain in biopsy specimen.
- **Molecular study:** *Helicobacter pylori* (bacterial antigen) can be demonstrated by immunohistochemistry technique and polymerase chain reaction technique in biopsy specimen.

HELICOBACTER PYLORI-INDUCED GIT MALIGNANCIES

World Health Organization has designated *Helicobacter pylori*—a potential human carcinogen. It is strongly associated with gastric adenocarcinoma (lower portion) and gastric B cell lymphoma of the mucosa-associated lymphoid tissue (MALT).

- *Helicobacter pylori* causes gastric adenocarcinoma (lower portion) through its role in the development of chronic gastritis, gastric atrophy and intestinal metaplasia, hypochlorhydria, intragastric bacterial growth converting dietary amines into nitrosamines (potent carcinogenic agent), sustained epithelial proliferation, genomic mutation, dysplasia, early gastric carcinoma and advanced gastric carcinoma.
- Consumption of smoked fish and meat is rich in nitrosamines. Nitrosamines are also derived from nitrates and nitrites being used as preservative for salted pickled vegetables.
- In the advanced gastric carcinoma; urea breath test or antibody test for *Helicobacter pylori* must be performed.

INFLAMMATORY DISORDERS

Gastritis is inflammation of the mucosa of the stomach. It may be acute or chronic gastritis.

ACUTE EROSIVE GASTRITIS

Acute erosive gastritis occurs due to nonsteroidal anti-inflammatory drugs, cigarette smoking, heavy alcohol intake, biliary regurgitation, severe burns (Curling's ulcer), AIDS (cytomegalovirus) and brain injury. Nonsteroidal anti-inflammatory drugs cause hemorrhagic gastritis by disrupting bicarbonate-rich mucous barrier.

Surgical Pathology: Acute Erosive Gastritis

Light Microscopy

Gastric mucosa shows multiple erosions not extending beyond the muscularis mucosa and acute inflammation, necrosis, and hemorrhage.

CHRONIC GASTRITIS

Chronic gastritis refers to atrophy of gastric glands secondary to chronic inflammation. *Helicobacter pylori*-induce chronic gastritis, eosinophilic gastritis, lymphocytic gastritis and granulomatous gastritis.

- On gross examination, gastric mucosa is inflamed (Fig. 20.10). On histologic examination, chronic gastritis reveals atrophy of the gastric glands as well as lamina propria, intestinal metaplasia and lymphocytic infiltrate in the atrophic mucosa (Fig. 20.11).
- As *Helicobacter pylori* does not survive in the metaplastic intestinal glands, hence not demonstrated in biopsies. Histologic types of chronic gastritis include type A, type B and type AB.

Atrophic Gastritis

Atrophic gastritis is reserved for chronic gastritis with intestinal metaplasia. The crypts of the gastric

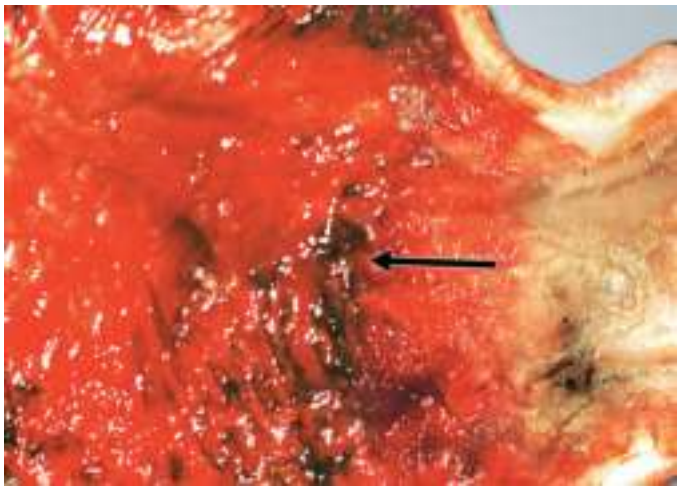

Fig. 20.10: Chronic gastritis. It shows inflamed gastric mucosa (arrow).

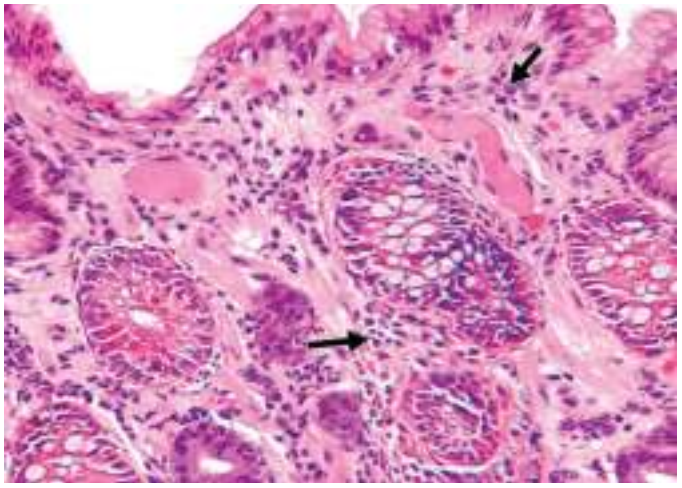

Fig. 20.11: Chronic gastritis light microscopy shows chronic inflammatory infiltrate in gastric region with intestinal metaplasia (arrows) (400X).

corpus are replaced by intestinal glands with goblet cells. There is elongation of glandular necks with extended epithelial regeneration and dysplasia. Risk for gastric carcinoma is increased in patients with chronic atrophic gastritis.

Chronic Atrophic Gastritis

Chronic Gastritis Type A/Autoimmune Gastritis

Chronic gastritis type A is an autoimmune-mediated chronic gastritis involving gastric fundus and body. Autoimmune diseases associated with autoimmune gastritis are given in Table 20.15.

Autoantibodies are formed against parietal cells and intrinsic factor. These autoantibodies are detected in serum and gastric secretions. Patient develops megaloblastic anemia due to vitamin B_{12} deficiency and achlorhydria. Bone marrow shows megaloblastic erythropoiesis. Peripheral blood smear shows macrocytes, leukopenia and thrombocytopenia. Polymorphonuclear cells show hypersegmented nuclei. Patient may develop gastric adenocarcinoma, in 10% of cases, carcinoid tumor and chronic thyroiditis.

Table 20.15 Autoimmune diseases associated with autoimmune gastritis

Hashimoto's thyroiditis
Thyrotoxicosis
Celiac disease
Insulin-dependent diabetes mellitus
Juvenile autoimmune thyroid disease
Dermatitis herpetiformis
Vitiligo
Idiopathic hypoadrenalism
Idiopathic hypoparathyroidism

Surgical Pathology: Chronic Atrophic Gastritis Type A

Light Microscopy

Histologic examination of gastric biopsy shows following features:

- There is diffuse mucosal damage and atrophy of the oxyntic acid producing mucosa within the gastric fundus and body.
- Antral mucosa lacks inflammation.
- Deep gastric glands are infiltrated by lymphocytes, macrophages and plasma cells.
- Intestinal metaplasia and antral G cell hyperplasia are seen.

Chronic Gastritis Type B/Non-autoimmune Gastritis

Helicobacter pylori resides in the gastric antrum and pylorus. It is associated with chronic gastritis type B.

These patients are also associated with gastroduodenal ulcers, gastric adenocarcinoma and MALT (mucosa-associated lymphoid tissue) lymphoma. Differences between chronic gastritis type A and type B are given in Table 20.16.

Chronic Gastritis Type AB

Chronic gastritis type AB is associated with combination of *Helicobacter pylori* and dietary factors, which predisposes to gastric adenocarcinoma.

Granulomatous Gastritis

Granulomatous gastritis occurs in patient suffering from Crohn's disease, sarcoidosis and infectious agent, e.g. Mycobacterium tubercle bacilli, fungi, cytomegalovirus and *Helicobacter pylori*.

Table 20.16 Differences between chronic atrophic gastritis type A and type B

Parameters	Chronic Atrophic Gastritis Type A (Autoimmune)	Chronic Atrophic Gastritis Type B (Non-autoimmune)
Patient population	Older age group (White women)	Adults (worldwide)
Pathogenesis	▪ Autoimmune mechanism ▪ Autoantibodies against parietal cells and intrinsic factor	▪ Nonimmune mechanism ▪ *Helicobacter pylori*
Clinical manifestations	▪ Pernicious anemia (megaloblastic erythropoiesis) ▪ Decreased gastric acid secretion	▪ Abdominal pain and dyspepsia ▪ Upper gastrointestinal bleeding
Light microscopy	▪ Chronic gastritis ▪ Progressive destruction of glands in fundus region ▪ Intestinal metaplasia (pyloric region) and entero-chromaffin cells hyperplasia	▪ Chronic gastritis ▪ Destruction of glands absent ▪ Intestinal metaplasia (pyloric region, if body involved)
Serum gastrin level	Elevated	Normal or low
Complications	▪ Gastric adenocarcinoma (10%) ▪ Carcinoid tumors ▪ Chronic thyroiditis	▪ Gastric adenocarcinoma (lower gastric region) ▪ Gastric MALT lymphoma (mucosa-associated lymphoid tissue lymphoma) ▪ Gastroduodenal ulcers (peptic ulcer disease)
Clinical course	Chronic aggressive course	Chronic less aggressive course

Chronic atrophic gastritis type AB caused by Helicobacter pylori and dietary factors predisposes to gastric adenocarcinoma.
Eosinophilic gastritis is related to allergens and characterized by transmural infiltration by eosinophils and muscular hypertrophy.

PEPTIC ULCER DISEASE

Peptic ulcer disease occurs in duodenum, stomach, and lower end of the esophagus including Meckel's diverticulum. *Helicobacter pylori* is most often associated with duodenal ulcers in 90% and gastric ulcers in 65% of cases. Eradication of *Helicobacter pylori* contributes to the healing of peptic ulcers.

Peptic ulcer disease is most often solitary, but may be multiple in 20% of cases. Vagotomy is performed only in the treatment of complicated persistent duodenal ulcers resistant to other treatment modalities. Pathogenesis and clinical course of peptic ulcer disease is shown in Fig. 20.12.

LOCATIONS

Duodenal peptic ulcer most often occurs in first portion of the duodenum just close to the pylorus, lesser curvature of stomach and gastric antrum. It is associated with hypersecretion of gastric acid and pepsin and *Helicobacter pylori* infection. Most common cause of duodenal ulcer is *Helicobacter pylori* infection.

- *Helicobacter pylori* increases gastric acid secretion and impairs mucosal defenses. Gastric peptic ulcer most often occurs at lesser curvature just at the junction of the body and pyloric antrum. Differences between duodenal and gastric peptic ulcers are given in Table 20.17.

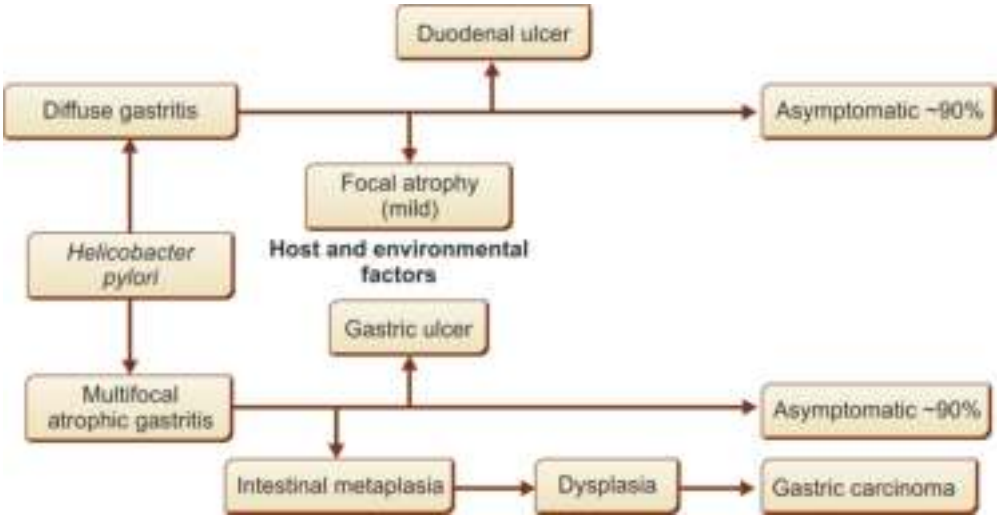

Fig. 20.12: Pathogenesis and clinical course of peptic ulcer disease.

Table 20.17 Differences between duodenal and gastric peptic ulcers

Parameters	Duodenal Ulcer	Gastric Ulcer
Age group	25–50 years of age	More than 50 years
Sex predilection	Men > women	Men and women equally affected
Risk factors	MEN 1, cirrhosis, chronic obstructive pulmonary disease, chronic renal failure, hyperparathyroidism	Smoking delays healing of ulcer
Frequency	More often (75% cases)	Less often (25%)
Increased incidence	Blood group O	Blood group A
Etiology	*Helicobacter pylori* is responsible for defective mucosal barrier in 80–90% of cases	Due to disruption of mucosal barrier due to mucosal ischemia (reduced PGE), bile reflux, delayed gastric emptying
Basal acid output (BAO) and maximal acid output (MAO)	Acid levels high	Normal to low. May be increased due to enhanced gastrin secretion
Number of peptic ulcer	Solitary	Solitary
Location	Anterior portion of first part of duodenum in 90% cases and posterior portion	Lesser curvature of antrum (same location for cancer)
Perforation	Ulcer present in posterior portion of duodenum may perforate into pancreas results in pancreatitis	Perforation is less common
Clinical manifestations	Burning epigastric pain 1–3 hours after eating. Epigastric pain relieved by eating	Epigastric pain exacerbated by eating
Malignant transformation	Duodenal ulcers never undergo malignant transformation	Malignant transformation is more common
Complications	▪ Bleeding from gastroduodenal artery, perforation (air under diaphragm, pain radiates to left or right shoulder) ▪ Gastric outlet obstruction and pancreatitis	▪ Bleeding from left gastric artery ▪ Perforation of gastric ulcer
Endoscopy accuracy	90–95%	90–95%
Upper GIT barium study	Diagnostic in 70–80% of cases	Diagnostic in 70–80% of cases
Histopathological examination	Not essential as not undergoing malignant transformation	Essential to rule out malignant transformation in 1–4% of cases
Treatment	▪ Avoid NSAIDs, alcohol, smoking ▪ Eradication of *Helicobacter pylori* ▪ Highly selective vagotomy in resistant cases	▪ Avoid NSAIDs, alcohol, smoking ▪ Eradication of *Helicobacter pylori* ▪ Hemigastrectomy without vagotomy in resistant cases

- Other sites of peptic ulcer disease are gastroesophageal junction in the settings of Barrett esophagus/GERD, Meckel diverticulum containing ectopic gastric mucosa, and mucosa adjacent to the anastomoses line in patient underwent gastrointestinal tract surgery.

ETIOPATHOGENESIS

Since the gastric ulcer patients do not contain unusually high quantities of hydrochloric acid or pepsin, it is postulated that glands are damaged by back diffusion of hydrogen ions (most important). *Helicobacter pylori*, spicy food, alcohol and drug aspirin disrupt mucosal barrier resulting in mucosal injury due to back diffusion of hydrogen ions. *Campylobacter pylori*, a common cause of gastritis has been associated with peptic ulcer disease and gastric carcinoma.

Helicobacter Pylori

- *Helicobacter pylori* increases gastric acid secretion and apparently impair both gastric and duodenal mucosal defenses resulting in duodenal ulcer (90%) and gastric ulcer (65%).
- *Helicobacter pylori* synthesizes urease, phospholipase and protease which cause breakdown of glycoproteins resulting in defective mucosal barrier.
- Increased permeability of the gastric mucosa to hydrogen ion leads to back diffusion of hydrogen ions resulting in injury to the gastric mucosa (mucosal ischemia due to reduced PGE).
- Eradication of *Helicobacter pylori* infection is curative of peptic ulcer disease in most patients.

Bile Reflux and Delayed Gastric Emptying

These conditions may also cause peptic ulcer disease.

Dietary Factors and Acid Secretion

Alcohol, spicy food, and substances that stimulate acid secretion may play a pathogenetic role in peptic ulcer disease. Duodenal ulcer is always associated with hypersecretion of gastric acid and pepsin.

- Due to increased parietal cell mass, basal acid output and maximal acid output are increased in duodenal ulcer.
- On the other hand, basal acid output (BAO) and maximal acid output (MAO) are normal to low in gastric ulcer.

Nonsteroidal Anti-inflammatory Drugs (NSAIDs)

Nonsteroidal anti-inflammatory drugs such as aspirin inhibit prostaglandin synthesis resulting in damage to mucosal barrier resulting in peptic ulcer disease.

Tobacco Smoking

The incidence of peptic ulcer disease is two-fold greater in tobacco smokers.

Zollinger-Ellison Syndrome

Recurrent intractable peptic ulcer disease or peptic ulcer in aberrant sites, i.e. the jejunum is characteristic of the Zollinger-Ellison syndrome with excess gastrin production from a gastrinoma (islet cell tumor of the pancreas).

Genetic Factors

Increased frequency of occurrence of peptic ulcer disease in persons with blood group O suggests that genetic factors may play a pathogenetic role in peptic ulcer disease.

Hyperparathyroidism

Peptic ulcer disease is sometimes associated with primary hyperparathyroidism.

Multiple Endocrine Neoplasia 1 (MEN 1)

Peptic ulcer disease may occur in MEN 1, an autosomal dominant disorder characterized by adenomas or hyperplasia of pituitary, thyroid, parathyroid, adrenal and pancreatic islet cells.

Hypercalcemia increases serum gastrin, thereby stimulating gastric acid secretion. Defensive and aggressive factors in relation to peptic ulcer disease are shown in Fig. 20.13.

CLINICAL FEATURES

Patient with gastric ulcer presents with immediate epigastric pain just after food intake. While pain occurs within 1–3 hours after food intake in duodenal ulcer.

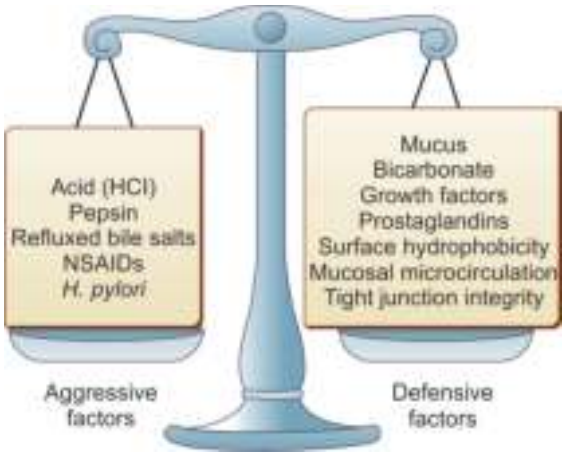

Fig. 20.13: Defensive and aggressive factors in relation to peptic ulcer disease.

Surgical Pathology: Peptic Ulcer Disease

Gross Morphology

Morphologic features of peptic ulcer disease are described in Fig. 20.14.

- **Size and shape:** Most peptic ulcers are small round or oval defect of the mucosa measuring 1–2 cm in diameter, and rarely exceeding 4 cm in size.
- **Base of the ulcer:** Base of the ulcer is smooth and clean due to action of hydrochloric acid and pepsin, but it may be covered with fibrin.
- **Margin of ulcer:** Gastric ulcer shows radiating folds of gastric mucosa starting at the ulcer with punched out margins appearing as radiating fold in a spoke-like fashion, in contrast to gastric carcinoma, which often has an irregular necrotic base and firm and raised margins.
  - The distinction between gastric peptic ulcer and ulcerated gastric carcinoma must be established by biopsy.
  - In contrast to malignant gastric ulcer, peptic ulcer disease usually heals with conservative management.

Light Microscopy

On histologic examination, peptic ulcer shows following four zones from superficial layer to deep base. The mucosal defect may extend all the way to the muscle layer (Figs 20.15 and 20.16).

- **Floor/base:** It is superficial zone of peptic ulcer and composed of necrotic fibrinous amorphous debris.
- **Zone of acute inflammatory exudates:** This zone is infiltrated by numerous neutrophils. Inflammation is present beneath floor/base of ulcer, and merges with granulation tissue.
- **Granulation tissue:** Granulation tissue is composed of blood vessels, fibroblasts, macrophages, lymphocytes and plasma cells. Granulation tissue gradually transforms into a zone of fibrous scarring.
- **Zone of fibrous scarring:** Granulation tissue rests on a solid fibrous or collagenous scar. If the ulcer extends into the muscle layer, it may erode blood vessels and cause bleeding.

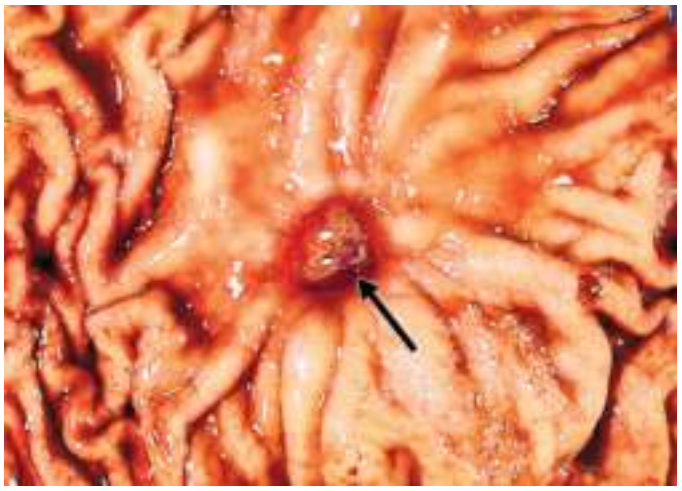

Fig. 20.14: Peptic ulcer disease. A partial gastrectomy was performed because of hematemesis. There was a bleeding artery in the base of the ulcer (arrow).

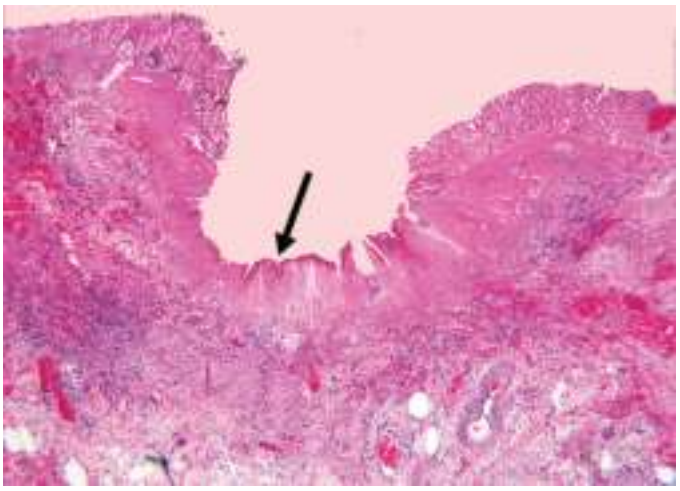

Fig. 20.15: Chronic peptic ulcer. It shows base composed of necrotic fibrinous amorphous debris, overlying inflammatory infiltrate, granulation tissue and fibrous tissue (arrow) (100X).

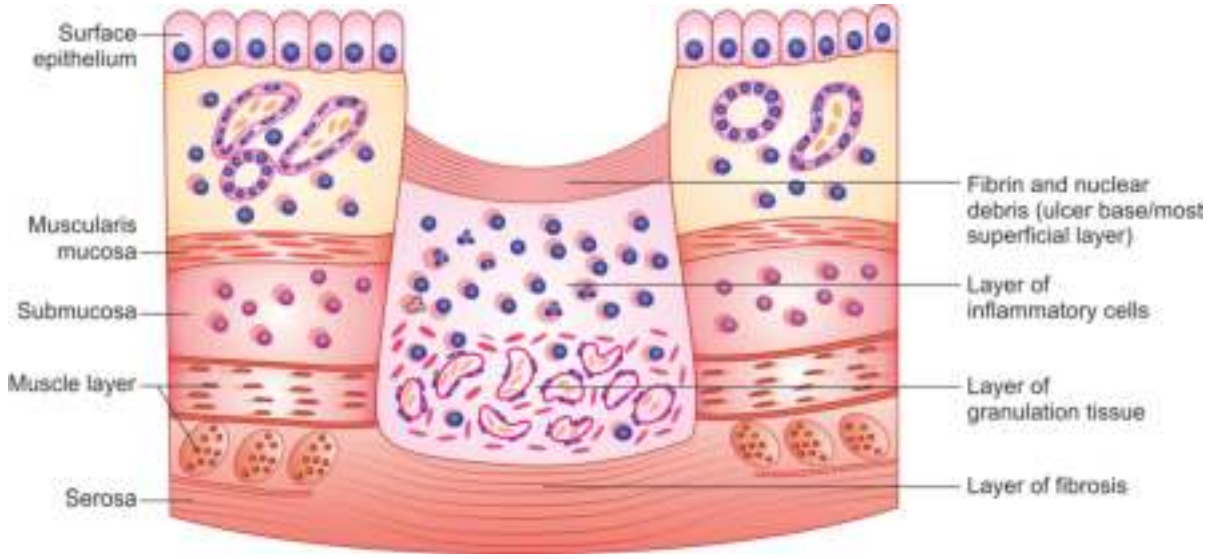

Fig. 20.16: Peptic ulcer disease shows four zones from superficial layer to deep base: superficial floor/base, zone of inflammatory exudate, zone of granulation and zone of fibrous scarring.

Clinical Pearls: Complications of Peptic Ulcer Disease

Complications of peptic ulcer disease include hemorrhage, perforation, stenosis, pancreatitis and malignant transformation. Reasons for surgery in patient with peptic ulcer disease are hemorrhage, perforation, obstruction and exclusion of malignant transformation of peptic ulcer disease.

- **Hemorrhage:** Hemorrhage is the most common complication of peptic ulcer disease. Patient presents with hematemesis with melena (black stools containing blood). Ulcer erodes the wall of arteries supplying to the region. Gastroduodenal artery bleeds in duodenal ulcer, whereas bleeding occurs from left gastric artery in gastric ulcer. Severe bleeding is life-threatening in 10–20% of patients. Melena is commonly seen in patients who suffer from chronic peptic ulcer disease.
- **Perforation:** Duodenal ulcer most often perforates than gastric ulcer disease in 10% of cases. Patient develops peritonitis and paralytic ileus. Air is demonstrated under the diaphragm (pneumoperitoneum) by imaging techniques. Perforation with severe hemorrhage is responsible for hypotensive shock with fatal outcome patients. Fibrosis around healed gastric ulcer causes narrowing in center of the stomach giving hourglass deformity. Patient with healed ulcer in duodenum develops pyloric stenosis.
- **Pancreatitis:** Perforation of posterior wall of duodenal ulcer may cause peritonitis or involvement of liver. Pancreatitis is accompanied by dull pain and elevated serum amylase and lipase.
- **Malignant transformation:** Most gastric ulcers are benign, but small percentage of cases may undergo malignant transformation. Duodenal ulcers never undergo malignant transformation. Peptic ulcer disease shows distribution of benign ulcers in stomach and duodenum and malignant gastric ulcers (Fig. 20.17 and B). Differences between benign and malignant ulcers are given in Table 20.18.

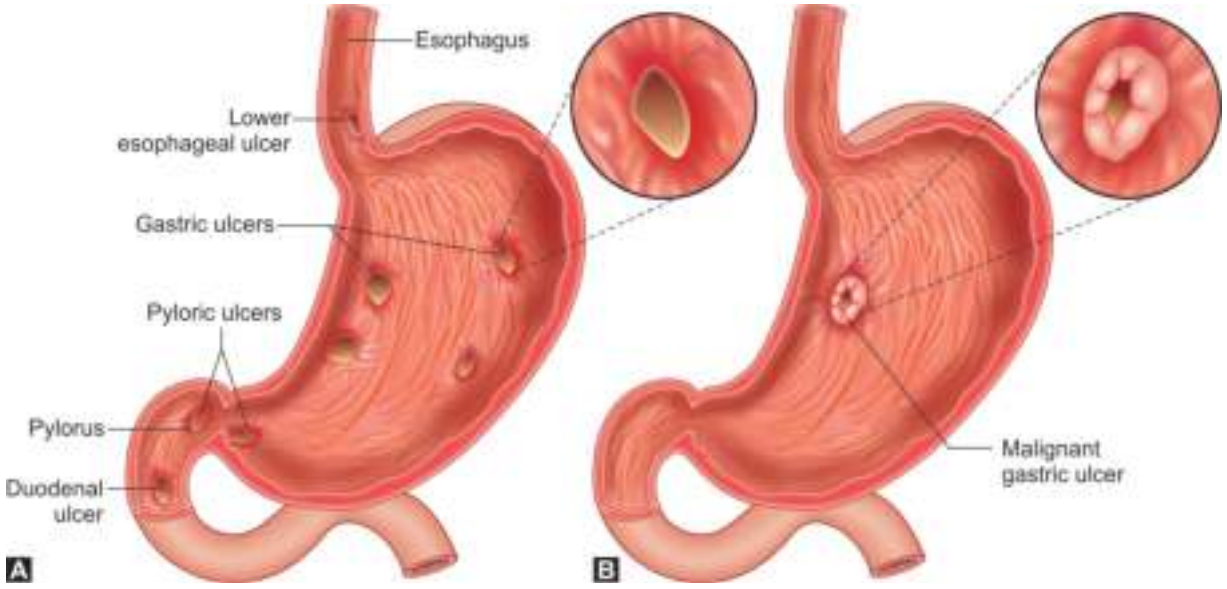

Fig. 20.17: (A) Peptic ulcer disease shows distribution of ulcers in stomach and duodenum, (B) malignant gastric ulcer.

Table 20.18 Differences between benign and malignant gastric ulcers

Parameters	Benign Gastric Ulcer	Malignant Gastric Ulcer
Age group	Younger age group	Older age group
History	Longer history	Shorter history
Pain abdomen	Common	Less common
Gender	Male predominance	Male and female equally affected or male predominance
Site of ulcer	Antrum, lesser curvature of stomach	Along greater curvature of stomach
Base of ulcer	Clear and hemorrhagic	Necrotic debris
Gastric mucosal folds	Radiating mucosal folds	Interrupted mucosal folds
Margins of ulcer	Sharply punched-out	Irregular heaped up
Barium meal study	Sharp punched-out lesion	Irregular lesion
Light microscopy	Composed of necrotic floor base, numerous neutrophils, granulation tissue and fibrosis	Showing features of malignancy, that may disseminate to distant organs

GASTRIC POLYPS

The term gastric polyp usually refers to any lesion which projects above the mucosal plane into the lumen of the stomach. Gastric polyps can be divided into neoplastic and non-neoplastic categories.

- **Gastric hyperplastic polyps:** These are composed of elongated, dilated, branching foveola and inflammed lamina propria. These may occur in Osler-Weber-Rendu syndrome. Size of the polyp is >2 cm seen in >50 years of age.
- **Fundal gland polyps:** These are composed of cystically dilated spaces partially lined by parietal cells. These may occur in familial adenomatous polyposis (FAP) coli syndrome or sporadic cases.
- **Inflammatory fibroid polyps:** Inflammatory fibroid polyp most commonly occurs in the gastric antrum. On histologic examination, it is composed of a submucosal collection of bland spindle cells in a background of dilated vascular channels and inflammatory cells especially eosinophils. Spindle cells are CD34+.
- **Gastric adenomatous polyps:** These can develop anywhere in the stomach. These growths can often be precursor of gastric carcinoma.
- **Gastric hamartomatous polyps:** These are demonstrated in patients with Peutz-Jeghers syndrome, Cowden's disease and juvenile polyposis.

NEOPLASTIC DISORDERS OF STOMACH

Most common benign gastric neoplasms include hyperplastic polyps, fundic gland polyps and adenomas. Malignant tumors are gastric adenocarcinoma (90–95%), gastrointestinal tract lymphoma (3%), gastrointestinal tract stomal tumors, e.g. leiomyoma (1%), carcinoid

tumors (1%) and diffuse gastric carcinoma [known as '**linitis plastica**' (**leather bottle stomach**) results in a thickened rigid stomach caused by the extensive infiltration of neoplastic cells in the gastric wall].

- According to Bormann classification of advanced gastric adenocarcinoma includes: type 1 (polypoid fungating growth), type 2 (ulcerative with elevated distinct borders), type 3 (ulcerative with elevated indistinct borders); and type 4 (diffuse with indistinct borders).
- Risk factors for developing gastric adenocarcinoma include chronic gastritis; dietary nitrates/smoked food/pickled vegetables, *Helicobacter pylori* infection, history of adenomatous polyps and decreased intake of fresh fruits/vegetables. Patient presents with weight loss, abdominal pain, dysphagia, anorexia, nausea and vomiting.
- Primary gastric adenocarcinoma involves mucosa, whereas secondary tumors (e.g. breast carcinoma, malignant melanoma and leukemic infiltration) involve submucosa and muscularis. Revised 2019 WHO classification of tumors of the stomach is given in Table 20.19. Risk factors for development of gastric carcinoma is given in Table 20.20.
- **Krukenberg tumor** is metastasis from breast lobular carcinoma and diffuse gastric carcinoma known as 'linitis plastica' to the ovaries. Histologically, tumor shows signet-ring cell features.
- **Virchow node** is firm palpable left supraclavicular lymph nodes that represents metastatic carcinoma, typically from a primary carcinoma in the thorax and abdomen.

Pathology Pearls: Gastric Dysplasia Types

Gastric dysplasia is of three types described as under.

- **Adenomatous gastric dysplasia:** It is intestinal/type 1 dysplasia. It may be tubular or villus resembling colonic adenoma.
- **Hyperplastic gastric dysplasia:** It is gastric foveolar/type 2 dysplasia. It most often occurs in a case of chronic atrophic gastritis with immature intestinal metaplasia.
- **Tubule neck gastric dysplasia:** It is also known as globoid dysplasia. Its histopathologic features are similar to the invasive diffuse type of gastric adenocarcinoma. In tubule neck dysplasia, there is presence of aggregates of enlarged clear cells with vacuolated cytoplasia and dysplastic nuclei.

GASTRIC CARCINOMA

Gastric carcinoma is the most common tumor, which constitutes 90–95% of all gastric cancers. It is often

Table 20.19 Revised 2019 WHO classification of tumors of the stomach

Benign Epithelial Tumors and Precursor Lesions
■ Glandular intraepithelial neoplasia, low-grade
■ Glandular intraepithelial neoplasia, high-grade • Serrated dysplasia, low-grade • Serrated dysplasia, high-grade • Intestinal-type dysplasia • Foveolar type (gastric-type) dysplasia • Gastric pit/crypt dysplasia
■ Intestinal-type adenoma, low-grade
■ Intestinal-type adenoma, high-grade • Sporadic intestinal-type gastric adenoma • Syndromic intestinal-type gastric adenoma
■ Adenomatous polyp, low-grade dysplasia
■ Adenomatous polyp, high-grade dysplasia
Malignant Epithelial Tumors
■ Adenocarcinoma, NOS • Tubular adenocarcinoma • Parietal adenocarcinoma • Adenocarcinoma with mixed subtypes • Papillary adenocarcinoma, NOS • Micropapillary carcinoma, NOS • Mucoepidermoid carcinoma • Mucinous adenocarcinoma • Signet ring cell carcinoma • Poorly cohesive carcinoma • Medullary carcinoma with lymphoid stroma • Hepatoid adenocarcinoma • Paneth cell carcinoma
■ Squamous cell carcinoma, NOS
■ Carcinoma, undifferentiated, NOS • Large cell carcinoma with rhabdoid phenotype • Pleomorphic carcinoma • Sarcomatoid carcinoma • Carcinoma with osteoclast-like giant cells
■ Gastroblastoma
■ Neuroendocrine tumors, NOS • Neuroendocrine tumor, grade 1 • Neuroendocrine tumor, grade 2 • Neuroendocrine tumor, grade 3 • Gastrinoma, NOS • Somatostatinoma, NOS • Enterochromaffin cell carcinoid • Enterochromaffin like (ECL) cell malignant
■ Neuroendocrine carcinoma, NOS • Large cell neuroendocrine carcinoma • Small cell neuroendocrine carcinoma
■ Mixed neuroendocrine–non-neuroendocrine neoplasm (MiNEN)

Adapted from 2019 WHO classification of tumors of digestive system. Other less common tumors derived from soft tissue are leiomyoma, gastrointestinal stromal tumors, glomus tumor, granular cell tumor, Kaposi sarcoma, synovial sarcoma. Primary lymphoma may occur. Stomach may be involved due to metastases from breast carcinoma, melanoma and leukemia.

Contd...

Table 20.20 Risk factors for development of gastric carcinoma

Risk Factors	Comments
Host factors/predisposing conditions	
Gender	More common in men than women
Age group	>50 years especially in blood group A
Geographical region	Japan, Finland, Iceland, Russia, China and Southern and Eastern USA
Tobacco chewing or smoking	Higher risk for carcinoma at esophageal gastric region increased
Ménétrier disease (hypertrophic gastropathy)	Higher risk for gastric carcinoma due to unknown reason
Common variable immunodeficiency (CVID)	Higher risk for gastric carcinoma and MALT lymphoma
Gastric adenoma	Size >2 cm increased risk for gastric carcinoma
Previous partial gastrectomy for peptic ulcer	Higher risk for gastric carcinoma in gastric cancer after many years
Environmental factors	
Helicobacter pylori	▪ Single most important factor in the development of gastric cancer ▪ *Helicobacter pylori* gastritis affects 40–75% of persons are at high risk ▪ Cag positive *Helicobacter pylori* has ability tumor suppressor genes such as TP53 and RUNX3 ▪ Increases the risk for gastric carcinoma by five to six folds ▪ Intestinal type adenocarcinoma of stomach ▪ Gastric MALT lymphoma
Chronic gastritis	▪ Hypochlorhydria favors colonization of *Helicobacter pylori* ▪ Intestinal metaplasia in chronic gastritis is a precursor lesion
Pernicious anemia	Hypochlorhydria due to decreased synthesis of hydrochloric acid by parietal cells favors colonization of *Helicobacter pylori*
Dietary factors/nutritional factors	▪ Diet rich in nitrosamines in preserved food (nitrates are converted to nitrites) ▪ Consumption of smoked fish rich in nitrosamines
Occupational exposure to coal, asbestos, rubber products	Higher risk for gastric carcinoma
Epstein-Barr virus	Higher risk for gastric carcinoma (intestinal type and linitis plastica)
Radiation	▪ Dose-dependent increase in gastric carcinoma occurs in Japanese atomic bomb survivors suggesting ionization radiation may play role in the gastric carcinoma ▪ Radiotherapy of the abdomen for lymphoma and testicular tumors in young patient increase the risk for development of gastric carcinoma
Inherited cancer syndrome	
Familial gastric carcinoma (E-cadherin gene mutation)	Higher risk for gastric carcinoma (linitis plastica variant)
β-Catenin gene mutation	Higher risk for gastric carcinoma (linitis plastica variant)
Familial adenomatous polyposis (FAP) due to APC gene mutation	Higher risk for gastric carcinoma at younger age
Li-Fraumeni syndrome (p53 gene mutation)	Higher risk for gastric carcinoma at younger age
Peutz-Jeghers syndrome (STK1 gene mutation)	Higher risk for gastric carcinoma
p16 gene mutation	Higher risk for gastric carcinoma
Hereditary nonpolyposis colorectal cancer syndrome (Lynch syndrome): MLH1, MSH2, MSH6, PMS1, PMS2, TGF	Higher risk for gastric carcinoma
Family history of gastric carcinoma in first degree relatives	Higher risk for gastric carcinoma
BRCA1 and BRCA2	Higher risk for gastric carcinoma

discovered at advanced stage. Practically all gastric adenocarcinomas arise from generative or basal cells of foveolae. Intestinal metaplasia is precursor lesion of gastric adenocarcinoma. Locations and frequency of gastric carcinoma are given in Table 20.21. Distribution of gastric carcinoma is shown in Fig. 20.18A and B.

Table 20.21 Location and frequency of gastric carcinoma

Location	Frequency
Pyloantrum region (anterior and posterior walls and lesser curvature of stomach)	50–60%
Cardiac region of stomach	25%
Body and fundus region	25%
Greater curvature of stomach	12%

Predisposing Factors

- **Gender:** Gastric carcinoma is more common in men than women.
- **Age group:** There is a sharp increase in frequency of gastric carcinoma in people over the age of 50 years especially in men. Most people with gastric carcinoma are diagnosed in their late 60s and 80s.
- **Geographical incidence:** Incidence of gastric carcinoma is higher in Japan, Finland, and Iceland, Chile, Russia, China and Southern and Eastern Europe, but low incidence in USA. Its incidence is higher in South India than rest of the country.
- ***Helicobacter pylori:*** Incidence of gastric carcinoma in the lower (distal) part of the stomach parallels the presence of chronic gastritis secondary to *Helicobacter pylori*. Persistent infection by *Helicobacter pylori* is associated with chronic atrophic gastritis, sustained epithelial proliferation, genomic mutation, dysplasia, early gastric carcinoma and advanced gastric adenocarcinoma, MALT (mucosa-associated lymphoid tissue) lymphoma and carcinoid tumors. *Helicobacter pylori* induces mucosal injury and converts dietary amines into nitrosamines (carcinogenic agent).
- **Occupational exposure:** Workers in the coal, asbestos, and rubber industries seem to have a higher risk for gastric carcinoma.
- **Dietary factors:** Diet rich in nitrosamines increases the risk for gastric carcinoma. Consumption of smoked fish and meat is rich in nitrosamines. Nitrosamines are also derived from nitrates and nitrites being used as preservative for salted pickled vegetables. Dietary nitrates and nitrites are converted to nitrosamines by *Helicobacter pylori*. On the other hand, eating lots of fresh fruits and vegetables appear to lower the risk for gastric carcinoma. Green leafy vegetables and citrus fruits act as antioxidants and thus are protective against gastric carcinoma. A high intake of animal fat has also been considered a protective factor against gastric carcinoma.
- **Tobacco chewing or smoking:** Tobacco chewing or smoking increases gastric carcinoma risk in the upper portion of the stomach near the esophagus. The rate of gastric carcinoma is about double in tobacoo smokers.
- **Blood group A:** For unknown reasons, people with blood group A have a higher risk of developing gastric carcinoma in 4% of cases.
- **Previous gastric surgery:** Partial gastrectomy performed in peptic ulcer disease increases risk for gastric carcinoma after many years of surgery. It is due to decreased secretion of gastric acid, which allows more nitrite-producing bacteria to be present. Reflux of bile from the small intestine into the stomach after surgery may also increase the risk for gastric carcinoma.

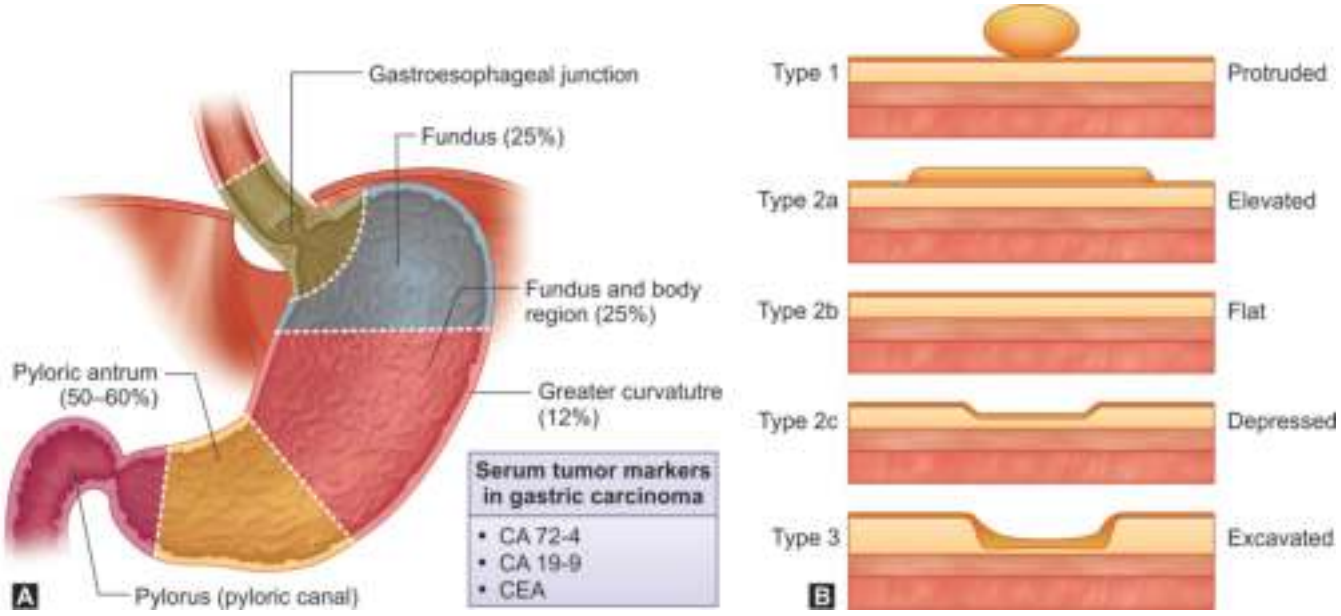

Fig. 20.18: (A) Distribution of gastric carcinoma including serum tumor markers. (B) Endoscopic classification of early gastric cancer (ECG) is defined as involvement of mucosa and submucosa, irrespective of lymph node status. Advanced gastric carcinoma involves muscular coat and beyond.

- **Pernicious anemia:** Intrinsic factor synthesized by parietal cells is required for absorption of vitamin B_{12}. Autoantibodies formed against intrinsic factor cause megaloblastic anemia. Risk for gastric carcinoma increases in patients suffering from pernicious anemia.
- **Ménétrier disease (hypertrophic gastropathy):** This disorder is characterized by excessive growth of gastric lining resulting in large mucosal folds. There is low level of gastric acid in this disorder. Due to unknown reason, there is increased risk for gastric carcinoma.
- **Inherited cancer syndromes:** Some inherited conditions may raise a person's risk for gastric carcinoma. Gene mutations such as E-cadherin, β-catenin, APC tumor suppressor gene, fibroblast growth factor, DNA repair genes and FGF3 participate in the pathogenesis of gastric carcinoma. Oncogenes, tumor suppressor gene mutations and chemical carcinogens associated with gastric carcinoma are given in Tables 20.22 to 20.24.
  - **Germline mutation of E-cadherin (CDH1):** Under physiologic state, E-cadherin (CDH1) participates in adhesion of intercellular junctions of gastric mucosal cells. A minority of gastric carcinoma cases is related to germline defects of E-cadherin (CDH1). Mutation of E-cadherin causes impairment of intercellular junctions of gastric mucosal cells. It seems a key step in development of gastric signet ring adenocarcinoma with diffuse infiltration resulting in a linitis plastica (leather bottle) gross appearance.
  - **Mutation of β-catenin:** Under physiologic state, β-catenin, a protein binds to E-cadherin. Mutation of β-catenin is associated with gastric signet ring

Table 20.22 Oncogenes, their mode of activation associated with gastric carcinoma

Category	Proto-oncogene	Mode of Activation	Associated Malignancies
Growth factors			
Fibroblast growth factors (FGFs)	FGF3	Amplification	▪ Osteosarcoma ▪ *Gastric carcinoma* ▪ Bladder cancer ▪ Breast cancer ▪ Melanoma
Growth factor receptors			
Receptor for KIT ligand	KIT	Point mutation	▪ *Gastrointestinal tumors* ▪ Seminoma ▪ Leukemia

Table 20.23 Tumor suppressor gene mutations associated with gastric carcinoma

Gene	Protein	Function	Familial Tumors	Sporadic Cancers
Mitogenic signaling pathway inhibitors				
APC	Adenomatous polyposis coli (locus 5p21), mutation by deletion or nonsense	APC protein inhibits Wnt signaling activator pathway, thus prevents nuclear transcription. It degrades β-catenin	Familial polyposis coli with malignant transformation	▪ *Gastric carcinoma* ▪ Colon carcinoma ▪ Pancreas carcinoma ▪ Thyroid carcinoma ▪ Melanoma
Inhibitors of invasiveness and metastases				
CDH1	E-cadherin	Participates in cell adhesion and inhibits cell motility	*Familial gastric carcinoma*	▪ *Gastric carcinoma* ▪ Breast lobular carcinoma

Table 20.24 Chemical carcinogens associated with gastric carcinoma

Chemical Carcinogen	Examples	Associated Cancers
Nitrosamines	Nitrates and nitrites widely used as fertilizers and as food additives converted to nitrosamines by gut bacteria in hypochlorhydria	*Gastric carcinoma*
Occupational asbestosis	Asbestos in building material	▪ *Gastric carcinoma* ▪ Lung carcinoma ▪ Mesothelioma

carcinoma (**linitis plastica variant**). There is increased risk of development of lobular carcinoma breast.

- **Hereditary nonpolyposis colorectal cancer (HNPCC):** This inherited genetic disorder is also known as Lynch syndrome which increases risk for gastric carcinoma (linitis plastica). In most cases, HNPCC is caused by a defect in either MLH1 or MSH2 gene, but other genes can cause HNPCC, including MLH3, MSH6, TGFBR2, PMS1, and PMS2.
- **Familial adenomatous polyposis (FAP):** It is caused by mutations in the APC gene. People with this disorder are at higher risk for colorectal carcinoma and gastric carcinoma.
- **BRCA1 and BRCA2 mutations:** Women who carry mutations of the inherited breast cancer genes BRCA1 or BRCA2 may also have a higher rate of gastric carcinoma.
- **Li-Fraumeni syndrome:** Li-Fraumeni syndrome is caused by a mutation in the TP53 gene. There is increased risk for gastric carcinoma at young age in patient suffering from this syndrome.
- **Peutz-Jeghers syndrome:** It is caused by mutations in the gene STK1. This disorder is characterized by hamartomatous polyps in the stomach, intestines, nose, airways and lungs and dark freckle-like spots on the lips and inner cheeks. The patient with Peutz-Jeghers syndrome is at increased risk for development of cancers of the breast, colon, pancreas, stomach, and several other organs.
- **A family history of gastric carcinoma:** People with first-degree relatives (parents, siblings, or children) who have had gastric carcinoma are more likely to develop this disease.
- **Common variable immunodeficiency (CVID):** People with CVID have an increased risk for gastric carcinoma. The immune system in these patients fails to synthesize antibodies against pathogens. There is increased risk for atrophic gastritis, pernicious anemia, gastric carcinoma and gastric MALT lymphoma.

Gastric Carcinoma: Classification

Gastric carcinoma is classified on the basis of depth of invasion (e.g. early and advanced gastric adenocarcinoma), macroscopic growth pattern (e.g. flat mucosal lesions, exophytic, ulcerative and diffuse infiltrating types) and histologic types (e.g. intestinal adenocarcinoma and diffuse infiltrative type, e.g. linitis plastica).

Classification of gastric carcinoma based on macroscopic growth patterns, endoscopic, histologic features and involvement of gastric wall is given in Table 20.25.

Table 20.25 Classification of gastric carcinoma based on macroscopic growth patterns, endoscopic, histologic features and involvement of gastric wall

Characteristics	Comments
Classification of gastric adenocarcinoma based on macroscopic growth patterns	
Flat/depressed lesion	Lesion without obvious tumor confined to mucosa (lesion slightly elevated, flat or depressed)
Exophytic/polypoidal/fungating lesion	Solid tumor projecting into the gastric lumen
Excavated/ulcerative lesion	Shallow or deep erosive crater in the wall of stomach mimicking gastric ulcer
Borrmann classification based on macroscopic appearance of advanced gastric adenocarcinoma	
Type 1 advanced gastric adenocarcinoma	Polypoid fungating growth
Type 2 advanced gastric adenocarcinoma	Ulcerative with elevated distinct borders
Type 3 advanced gastric adenocarcinoma	Ulcerative with elevated indistinct borders
Type 4 advanced gastric adenocarcinoma	Diffuse with indistinct borders
Endoscopic classification of early gastric carcinoma	
Type 1 (exophytic/polypoidal/fungating mass)	Solid tumor growth protruding into the gastric lumen as a polypoidal or nodular mass
Type 2a (slightly elevated lesion)	Superficial growth slightly elevated above mucosal surface
Type 2b (flat)	Growth pattern flat
Type 2c (growth depressed)	Growth pattern depressed below mucosal surface
Type 3 (excavated lesion)	Shallow or deep erosive crater in the wall of stomach may closely resemble chronic peptic ulcer disease

Contd...

Table 20.25 Classification of gastric carcinoma based on macroscopic growth patterns, endoscopic, histologic features and involvement of gastric wall (*Contd...*)

Characteristics	Comments
Lauren classification of gastric adenocarcinoma depending on histologic type	
Intestinal type of gastric adenocarcinoma	▪ Polypoid fungating or ulcerated mass (Borrmann type 1 and type 2) ▪ Cohesive tumor cells forming recognizable glands regardless of their degree of cytologic differentiation
Diffuse infiltrative gastric adenocarcinoma (linitis plastica)	▪ Linitis plastica type mass (diffuse involvement of gastric wall) (Borrmann type 3 and type 4) ▪ Discohesive tumor cells (signet ring cells) resembling histiocytes with little differentiation penetrate through the gastric wall, most abundant in superficial portions of the gastric mucosa. Submucosal fibrosis with or without mucosal ulceration
Classification of gastric adenocarcinoma based on involvement of gastric wall	
Early gastric adenocarcinoma	▪ Mucosa and submucosa without penetration of muscular coat regardless of lymph node status ▪ Risk factors for recurrence of early gastric carcinoma include poor differentiation, vascular invasion and occult metastasis ▪ Excellent prognosis ▪ Five-year survival (93–95%)
Advanced gastric adenocarcinoma	▪ Mucosa, submucosa and penetration into muscular coat and beyond ▪ Early gastric carcinoma takes eight years to become advanced invasive disease ▪ Poor prognosis ▪ Five-year survival (5–15%)

According to Depth of Invasion of Tumor

According to depth of invasion, gastric adenocarcinoma has been divided into early and advanced gastric adenocarcinoma. Approximately, 5-year survival rate after surgical resection in early gastric adenocarcinoma has been found to be 93–99%, in comparison with 5–15% in advanced gastric adenocarcinoma.

- **Early gastric adenocarcinoma:** Early gastric adenocarcinoma is confined to the mucosa or submucosa without penetration of the muscularis coat regardless of the lymph node status of the patient. It has an excellent prognosis. It takes 8 years to become more invasive. It is diagnosed by barium study or endoscopy and biopsy. Risk factors for recurrence in early gastric adenocarcinoma include vascular invasion, poor differentiation and presence of occult metastases.
- **Advanced gastric adenocarcinoma:** When gastric adenocarcinoma infiltrates the muscular coat or beyond, it is termed advanced gastric adenocarcinoma with poor prognosis.

According to Growth Patterns of Tumor

Based on gross appearance, gastric carcinoma has been classified into following types:

- **Flat gastric mucosal lesions:** Early intramucosal carcinomas may present in the form of mucosal patches or loss of rugae. Flat mucosal lesions are not visible on endoscopy. High-risk people are screened yearly with endoscopy and cytologic examination of gastric brushings for early detection of gastric carcinoma especially in Japan.
- **Exophytic gastric carcinoma:** Intestinal type of gastric adenocarcinoma is polypoidal or fungating growth (cauliflower) protruding into the lumen of the stomach.
- **Ulcerated gastric carcinoma:** It is most often >2 cm in diameter along the lesser curvature, pylorus and antrum in majority of cases. Ulcerated gastric carcinoma also known as malignant ulcer has rolled elevated edges (crate-like) and not clearly demarcated from the normal mucosa. Benign peptic ulcers have sharp regular margins. Biopsy is essential to differentiate benign gastric ulcer from malignant ulcer.
- **Diffuse infiltrative gastric carcinoma:** It is also known as linitis plastica. It is diffuse infiltrative type of gastric carcinoma converting the gastric wall into rigid thick structure known as leather bottle appearance.

Histologic Variants of Gastric Carcinoma

According to Lauren's classification, two major categories of gastric carcinoma exists, which have been designated intestinal type of gastric adenocarcinoma (53%), diffuse infiltrative type/linitis plastica (33%) and the remainders are heterogeneous in composition.

Table 20.26 Comparison of intestinal type of gastric adenocarcinoma and diffuse type of gastric carcinoma based on Lauren classification

Features	Intestinal Type of Gastric Adenocarcinoma	Diffuse Type of Gastric Carcinoma
Epidemiology	Epidemic seen in high risk population	Endemic seen in high risk population
Age group	>55 years	Younger persons
Sex predilection	Males > females	Males and females equally affected
Frequency	53%	33%
Precursor lesion (chronic gastritis)	Present	Absent
Role of *Helicobacter pylori*	Present	Absent
Role of dietary nitrosamines and consumption of smoked fish	Present	Absent
Location of tumor	▪ Gastric lesser curvature, pylorus and antrum (50–60%) ▪ Cardiac region (25%) ▪ Fundus and body of stomach (uncommon sites)	Diffuse involvement of gastric wall by tumor cells (signet ring cells) especially in superficial mucosal region
Gastric peristalsis	Present	Absent
Molecular genetic alterations	▪ APC gene mutation ▪ p53 gene mutation ▪ p16 gene mutation	E-cadherin gene mutation
Gross morphology	Polypoid fungating or ulcerated mass (Borrmann type 1 and type 2)	Linitis plastica type mass (diffuse involvement of gastric wall) (Borrmann type 3 and type 4)
Endoscopy	Polypoid fungating mass (Borrmann type 1 and type 2)	Depressed or excavated (Paris system type 2c, type 3)
Light microscopy	Cohesive tumor cells forming recognizable glands regardless of their degree of cytologic differentiation	▪ Dyscohesive tumor cells (signet ring cells) resembling histiocytes with little differentiation penetrate through the gastric wall, most abundant in superficial portions of the gastric mucosa ▪ Submucosal fibrosis with or without mucosal ulceration
Immunohistochemistry	▪ HER2/neu positive (well differentiated tumor and hepatoid variant) ▪ Cytokeratins positive ▪ EMA (epithelial membrane antigen) positive	Hep Par 1 positive
Metastasis	▪ Regional lymph nodes ▪ Discrete hepatic metastases	Diffuse, transperitoneal metastases involving ovaries (Krukenberg tumor)
Prognosis	Better survival	Poor survival

According to Borrmann classification of advanced gastric carcinoma include: Type 1 (polypoid fungating growth), type 2 (ulcerative with elevated distinct borders), type 3 (ulcerative with elevated indistinct borders), and type 4 (diffuse with indistinct borders).

- Extracellular mucin release in either types of gastric carcinoma can result in formation of large mucin lakes that dissect tissue planes. Intestinal gastric adenocarcinoma and diffuse infiltrative (linitis plastica) gastric carcinoma are described as under.
- Comparison of intestinal type of gastric adenocarcinoma and diffuse type of gastric carcinoma based on Lauren classification is given in Table 20.26.

Intestinal Type of Gastric Adenocarcinoma

Intestinal type of gastric adenocarcinoma arises from precursor lesions in stomach. It is associated with autoimmune-mediated chronic gastritis (type A), *Helicobacter pylori* associated chronic gastritis (type B), dietary nitrosamines and ingestion of smoked food.

Surgical Pathology: Intestinal Type of Gastric Adenocarcinoma

Gross Morphology

Tumor is solid polypoidal (fungating) mass projecting into the lumen of the stomach. It may undergo ulceration (Figs 20.19 and 20.20).

Light Microscopy

- On histologic examination, gastric adenocarcinoma may exhibit papillary, tubular, mucinous, poorly cohesive or mixed patterns.
- Tumor is composed of tumor cells with hyperchromatic nuclei and arranged in well-defined glandular and papillary structures.
- These glandular structures are lined by tall columnar cells containing mucin resembling colonic adenocarcinoma (Fig. 20.21).

Immunohistochemistry Technique

Panel of immunomarkers is used to analyze expression in intestinal type of gastric adenocarcinoma on tissue sections are cytokeratins (CKs), epithelial membrane antigen (EMA), carcinoembryonic antigen (CEA) and CDX2.

Markers	Expression
▪ Cytokeratins (CKs)	▪ Positive
▪ EMA	▪ Positive
▪ CEA	▪ Positive
▪ CDX2	▪ Positive (specific marker)

Diffuse Infiltrative Type of Gastric Carcinoma

Diffuse infiltrative type of gastric carcinoma (linitis plastica) does not develop from precursor lesions in stomach. It is not associated with *Helicobacter pylori*. It constitutes 10% of all gastric carcinomas. No true tumor mass is seen macroscopically.

In a family with CDH1 gene mutation in case of hereditary diffuse gastric carcinoma, prophylactic total gastrectomy is recommended after attaining age of 20 years. BRCA2 gene mutation is also demonstrated in diffuse infiltrative type of gastric carcinoma (linitis plastica). Linitis plastica spreads to the muscular coat of the stomach wall and makes it thicker and more rigid.

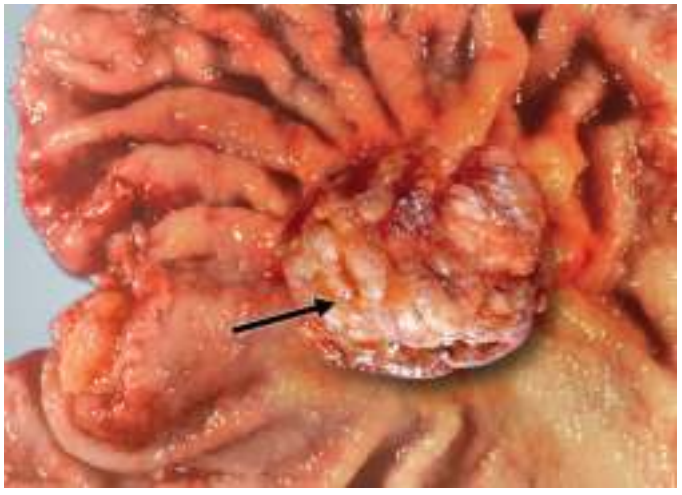

Fig. 20.19: Polypoid adenocarcinoma of the stomach. The patient was treated by partial gastrectomy (arrow).

Fig. 20.20: Gastric carcinoma: It shows ulceroproliferative growth (arrows). (*Courtesy*: Dr. Sujata Kanetkar, Professor and Head, Department of Pathology, Krishna Institute of Medical Sciences, Karad, Maharashtra.)

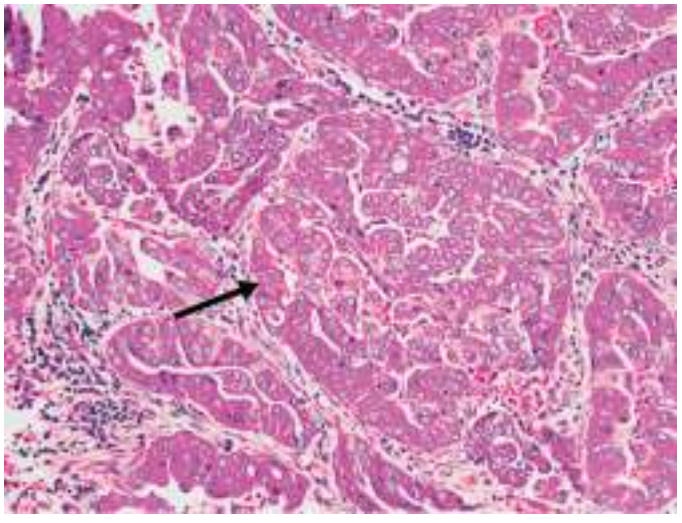

Fig. 20.21: Gastric adenocarcinoma (arrow). Tumor is composed of neoplastic cells with hyperchromatic nuclei cells are arranged in well-differentiated glandular and papillary structures lined by tall columnar cells (400X).

Surgical Pathology: Diffuse Infiltrative Type of Gastric Carcinoma (Linitis Plastica)

Gross Morphology

- The stomach becomes stiff rigid walls due to infiltration of tumor cells in all gastric layers and extensive fibrosis (desmoplastic reaction) giving radiologic leather bottle appearance of stomach. It has been referred to as a linitis plastica.
- Peristalsis is absent in linitis plastica variant of gastric carcinoma (Fig. 20.22).

Light Microscopy

- Tumor is composed of small cells, containing abundant mucin pushing the nuclei to the periphery called **signet ring cells**. Glandular differentiation is not seen.

- Tumor cells permeate mucosa as well as gastric wall individually or in small clusters. These are often confused with macrophages. Submucosal fibrosis is present with or without mucosa ulceration (Fig. 20.23).

Pathology Pearls: Mode of Spread with Gastric Carcinoma

Gastric carcinoma especially diffuse infiltrative type (linitis plastica variant) spreads by local/direct extension, lymphatic, hematogenous and transcoelomic routes.

- **Local/direct route:** Gastric carcinoma invades gastric wall (full thickness), duodenum, pancreas, liver and retroperitoneum.
- **Lymphatic route:** Gastric carcinoma invades submucosal and subserosal lymphatics and draining lymph nodes depending on location of gastric carcinoma.
  - Supraclavicular metastasis is known as 'Virchow sign'. Virchow lymph node is supraclavicular lymph node, which filters the lymph from the thoracic duct prior to its entry into the systemic veins.
  - Tumor located in proximal stomach and gastroesophageal junction metastasizes to mediastinal and pericardial lymph nodes.
  - Tumor located in body of stomach metastasizes to lymph nodes present in lesser and greater curvature.
  - Tumor located in distal part of stomach metastasizes to lymph nodes present in periduodenal, peripancreatic and porta hepatic lymph nodes.
- **Hematogenous route:** Intestinal type of gastric adenocarcinoma via hematogenous route metastasizes to liver, lung and bone.
- **Transcoelomic route:** Diffuse infiltrative type of gastric carcinoma (linitis plastica variant) metastasizing to the ovaries is known as **Krukenberg tumor**. The tumor cells contain abundant mucin, displacing nucleus to one side giving signet ring-like cells.

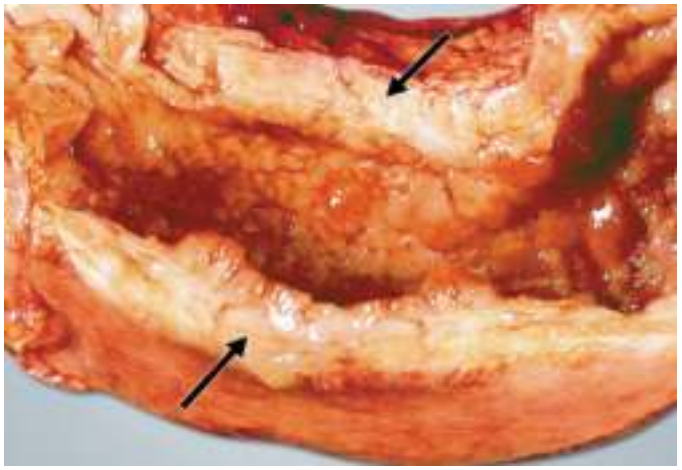

Fig. 20.22: Diffuse infiltrative type of gastric carcinoma (linitis plastica). In linitis plasica, the tumor cells infiltrate beneath the mucosa and produce marked fibrosis and thickening of the stomach wall (arrows).

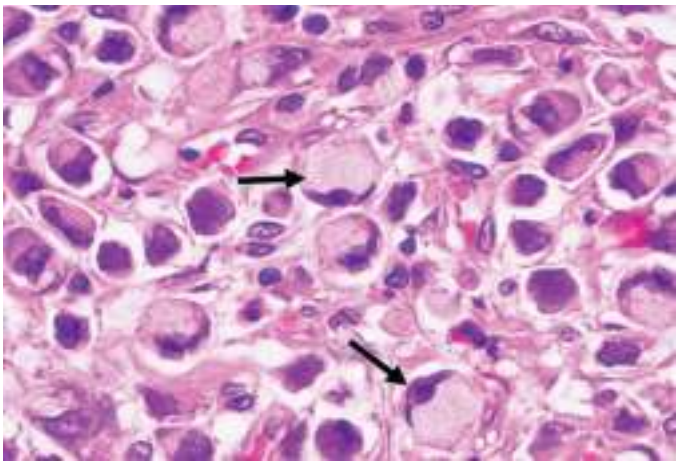

Fig. 20.23: Linitis plastica (diffuse infiltrative type) gastric carcinoma showing tumor cells containing abundant mucin pushing the nuclei to the periphery called signet ring cells (arrows) (400X).

Clinical Pearls: Mary Joseph Nodule in Periumbilical Region

- Mary Joseph nodule is formed due to metastases from gastric carcinoma (50%), colon carcinoma, pancreatic carcinoma in the subcutaneous region of periumbilical region. It is named after nurse Mary Joseph, who noticed nodule in periumbilical region.
- Other primary sites include ovarian and endometrial carcinoma. Proposed mechanism of spread is via direct transperitoneal, lymphatics, hematogenous, falciparum ligament, median umbilical ligament and remnant of vitelline duct routes.

Clinical Features

Weight loss and epigastric pain are the most common symptoms of gastric carcinoma. Other symptoms include vomiting, hematemesis or melena, anorexia, abdominal mass, dysphagia, diarrhea and iron deficiency anemia. Patient develops symptoms depending on involvement of organs due to metastases.

Clinical signs include cachexia, anemia, epigastric mass, hepatomegaly, palpable supraclavicular lymph node. Virchow node is supraclavicular lymph node, which filters the lymph from the thoracic duct prior to its entry into the systemic veins.

Pathology Pearls: Laboratory Diagnosis of Gastric Carcinoma

Gastric carcinomas are diagnosed by following diagnostic tools described as under.

- **Serum tumor markers:** CA 72-4 and carcinoembryonic antigen (CEA) are used to detect gastric adenocarcinoma. Serum CA 72-4 is also increased in colon carcinoma. Serum CEA is also increased nonseminomatous germ cell testicular tumor, colon carcinoma, gastric carcinoma, pancreatic carcinoma, lung carcinoma and breast carcinoma.
- **Serum pepsinogen level:** It is a specific marker for intestinal metaplasia precursor of gastric carcinoma.

- **Gastric function tests:** Gastric hydrochloric acid is decreased in gastric adenocarcinoma resulting in achlorhydria or hypochlorhydria.
- **Exfoliative cytology:** Examination of tumor cells obtained by gastric lavage is a diagnostic tool. Gastric lavage with chymotrypsin softens mucus over gastric carcinoma.
- **Endoscopy:** It is performed to know the extent of growth and obtain biopsies from representative areas.
- **Imaging techniques:** Barium meal study is useful in diagnosis of diffuse infiltrative type of gastric carcinoma (linitis plastica). It shows persistent, irregular, filling defect. USG, CT scan and MRI are done to rule out secondary deposits in celiac lymph nodes and distant organs, i.e. liver and ovaries. Double contrast barium swallow has 90% accuracy, but it is difficult to differentiate between malignant and benign peptic ulcers. CT scan is useful for evaluation of distant disease.
- **Histologic examination:** Biopsies are processed and sections are examined. Histochemical stain mucicarmine demonstrates mucin.
- **Immunohistochemistry and FISH techniques:** Gastric carcinomas that are HER2/neu positive can be treated with drugs that target the HER2/neu protein, such as trastuzumab (Herceptin®). The biopsy sample may be tested in two different ways:
  - Immunohistochemistry (IHC) technique: In this test, special antibodies that stick to the HER2/neu protein are applied to the sample, which cause cells to change color if many copies are present. This color change can be seen under a microscope. The test results are reported as 0, 1+, 2+, or 3+.
  - Fluorescent *in situ* hybridization (FISH) technique: This test uses fluorescent pieces of DNA that specifically stick to copies of the HER2/neu gene in cells, which can then be counted under a special microscope.

GASTRIC MALT LYMPHOMA

Gastric mucosa-associated lymphoid tissue (MALT) lymphoma is the most common form of extranodal lymphoma of B cell origin (mucosa-associated lymphoid tissue). It is low-grade lymphoma associated with *Helicobacter pylori* infection.

Demonstration of light chain restriction is helpful in differentiating MALT lymphoma from reactive lymphoid lesions.

Predisposing Factors

Predisposing factors for gastric MALT lymphoma include AIDS, celiac disease and Mediterranean α-heavy chain disease. During immunocompromised state, patients may develop diffuse large B cell lymphoma, Burkitt lymphoma, esophageal carcinoma, colorectal carcinoma and Kaposi sarcoma.

Pathogens Linked Gastrointestinal Cancers

- World Health Organization has designated *Helicobacter pylori*—a potential human carcinogen. *Helicobacter pylori* is strongly associated with gastric adenocarcinoma in lower half of gastric region and low-grade B cell lymphoma of the MALT. Some of MALT lymphomas regress after eradication of *Helicobacter pylori* infection with antibiotics.
- *Borrelia burgdorferi*, a spirochete and *Campylobacter jejuni* have been associated with gastrointestinal tract lymphoma.

Molecular Genetic Alterations

Gastric mucosa-associated lymphoid tissue (MALT) lymphoma shows three types of chromosomal translocation: (a) t(11;18) (p21;q21) is most common type of translocation. It predicts resistance to remission after eradication of *Helicobacter pylori* with antibiotic therapy, and (b) t(1;14) (p22;q22), and (c) t(14;18) (q32;p21).

NF-κB transcription factor promotes B cell growth and their survival. Monoclonality is demonstrated by restricted expression of κ or λ immunoglobulin light chain, which differentiates from reactive lymph node lesions.

Clinical Features

Patient presents with nonspecific symptoms such as weight loss, dyspepsia, and abdominal pain.

Surgical Pathology: Gastric MALT Lymphoma

Gross Morphology

Gastric MALT lymphoma replaces normal mucosa (Fig. 20.24).

Light Microscopy

- Gastric mucosa and submucosa are infiltrated by small cleaved lymphocytes forming follicles, lymphoepithelial lesion and Dutcher bodies.
- Lymphoepithelial lesion consists of >3 lymphocytes, that displacing adjacent epithelial cells and destroying the gastric gland.
- Gastric mucosa may show erosion, intestinal metaplasia, atrophy and *Helicobacter pylori* (Fig. 20.25).

Immunophenotyping

Panel of immunomarkers used to analyze expression in gastrointestinal tract MALT lymphoma includes CD20, CD79a, CD21, CD35,CD43, IgM, IgA, IgG and BCL-2. Comparison of gastric mucosa-associated lymphoid tissue (MALT) lymphoma and chronic lymphocytic gastritis is given in Table 20.27.

Markers	Expression
CD20	Positive
CD79a	Positive
CD35	Positive
CD43	Positive
IgM>IgA>IgG	Positive (25%)
BCL-2	Positive

▪ IgD	▪ Negative
▪ CD5	▪ Negative
▪ CD10	▪ Negative
▪ BCL-16	▪ Negative
▪ Cyclin D1	▪ Negative

There is no definite immunohistochemical marker for gastric MALT lymphoma. Panel of immunohistochemical markers is apple to assess architecture of infiltration lymphoid cells, immunophenotype and chain restriction.

Prognosis

Gastric MALT lymphoma has a considerably better prognosis than gastric carcinoma (5-year survival rate is 45%).

GASTROINTESTINAL STROMAL TUMORS

Gastrointestinal stromal tumors (GISTs) are defined as cellular, spindle cells, epithelioid or occasionally pleomorphic mesenchymal tumors, which express c-KIT (CD117) protein and demonstrated by immunohistochemistry a few exceptions occur due to fixation defects, sampling errors, following STI-571B therapy and some tumors lacking c-KIT (CD117) expression.

- Gastrointestinal stromal tumors originate from stromal stem cells that are precursors of smooth muscle cells (GI fibroblasts or pacemaker cells of Cajal controlling peristalsis). These tumors may be associated with neurofibromatosis and Carney's triad (GIST, paraganglioma and pulmonary chondroma).
- A gain-of-function mutation in KIT or *PDGFRA* gene may exist. Gastrointestinal stromal tumors with a KIT mutation respond to Gleevec (imatinib) therapy.

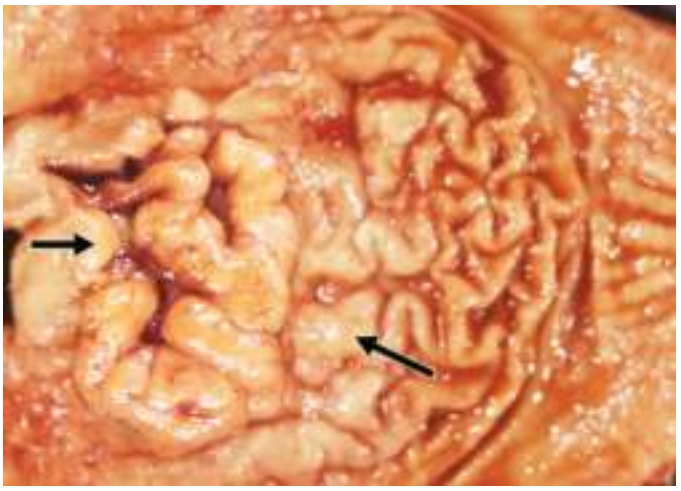

Fig. 20.24: Gastric lymphoma. Tumor is replacing most of normal gastric mucosa (arrows).

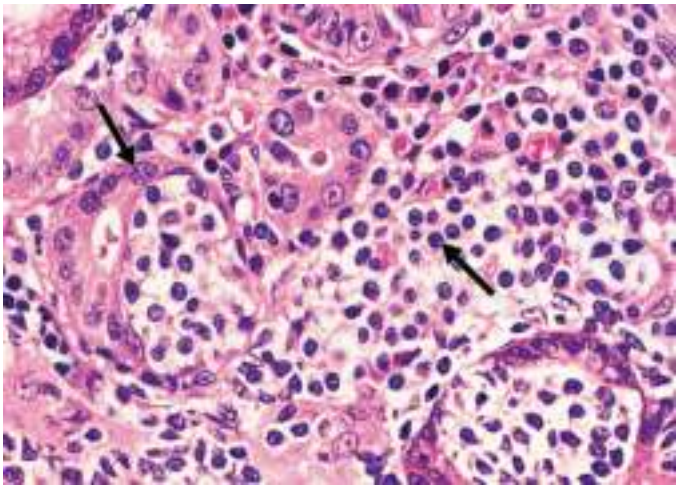

Fig. 20.25: Gastric lymphoma. Tumor shows small lymphocytes forming follicles (arrows) (400X).

Table 20.27 Comparison of mucosa-associated lymphoid tissue (MALT) lymphoma and chronic lymphocytic gastritis

Feature	Gastric MALT Lymphoma	Chronic Lymphocytic Gastritis
Light microscopy		
Lymphocyte number	Significantly increased	Significantly increased
Lymphocyte distribution	About three or four lymphocytes arranged in clusters (forming lymphoid follicles)	Single lymphocyte arranged in linear fashion in the gastric epithelium
Interfollicular lymphocytes	Malignant B cells with irregular nuclear contour	Mature T cells
Cytologic atypia of lymphocytes	Present	Absent
Perilymphocytic halo	Common	Uncommon
Significant gastric epithelial destruction	Present	Absent
Diffuse lamina propria infiltration and destruction by atypical lymphocytes	Present	Absent
Plasma cells	Present in variable number beneath surface lining epithelium shows light chain restriction	Present diffusely in lamina propria and lacking light chain restriction

Immunomarkers	▪ CD19 (pan B cell marker) ▪ CD20 (pan B cell marker) ▪ CD22 ▪ CD79a ▪ κ Light chain ▪ λ Light chain ▪ BCL-2	▪ CD2 ▪ CD3 (pan T cell marker) ▪ CD4 (T helper cell marker) ▪ CD5 ▪ CD7 ▪ CD8 (cytotoxic T cell marker)

Tumor size and mitotic rate features determine the risk of aggressive behavior.

Locations

Gastrointestinal stromal tumors (GISTs) occur in entire gastrointestinal tract such as stomach (50%), small intestine (25%), large intestine (10%), and extra-gastrointestinal sites. Gastric stromal tumors are usually submucosal and covered by intact mucosa.

Molecular Genetic Alterations

Approximately 75–80% of GISTs have KIT gene mutations. Mutations in platelet-derived growth factor receptor-α (*PDGFRA*) have been demonstrated in 10% of cases.

Surgical Pathology: Gastrointestinal Stromal Tumors

Gross Morphology

GISTs range from a few mm to >40 cm with mean size of 6 cm. Tumor is well circumscribed. Cut surface is smooth, lobulated with whorled-silk appearance. Prominent fibrohyaline areas undergoing calcification may be demonstrated.

Light Microscopy

Gastrointestinal stromal tumors are classified into three categories based on histopathological examination: (a) spindle cell, (b) epithelioid, and (c) mixed cell variants.

- Tumor may be composed of fascicles and bundles of spindle cells or epithelioid cells with vacuolated cytoplasm or mixture of spindle and epithelioid cells with focal pleomorphism.
- Benign gastrointestinal stromal tumors are small and measuring 2–5 cm and may show a few mitoses.
- Malignant stromal tumors measure >6 cm and show areas of hemorrhage, necrosis, high mitoses and features of anaplasia. Proposed guidelines for assessing malignant potential of gastric GISTs are given in Table 20.28.

Immunohistochemistry Technique

Panel of markers is used to analyze expression in gastrointestinal stromal tumors on histopathologic sections.

Markers	Expression
▪ c-KIT oncogene (CD117) encoding tyrosine kinase*	▪ Positive (95% of cases)
▪ DOG1 (protein of unknown function)	▪ Positive (most specific marker)
▪ CD171 (cell adhesive molecule)	▪ Positive
▪ Protein kinase C theta	▪ Positive
▪ Vimentin	▪ Positive
▪ Smooth muscle actin encoded by ACTA2 gene located on 10q–24q	▪ Positive
▪ CD34	▪ Positive
▪ Desmin	▪ Positive (5% of cases)

**CD117 positivity is seen in GIST cells, melanocytes, mast cells and germ cells.*

Phenotype Categories

A gastrointestinal stromal tumor shows histologic sign of smooth muscle differentiation is called leiomyoma or leiomyosarcoma.

Table 20.28 Proposed guidelines for assessing malignant potential of gastric GISTs

Tumor Size	Mitoses	Predictable Behavior
≤2 cm	≤5 mitoses/50 HPFs	Benign, metastasis rate or tumor-related mortality: 0%
>2–10 cm	5 mitoses/50 HPFs	Very low malignant potential, metastasis rate or tumor-related mortality: <3%
>10 cm	≤5 mitoses/50 HPFs, or ≤5 cm >5 mitoses/50 HPFs	Low to moderate malignant potential, metastasis rate or tumor-related mortality: 12–15%
>5 cm	>5 mitoses/50 HPFs	High malignant potential, metastasis rate or tumor-related mortality: 49–86%

GIST shows neural differentiation in autonomic nervous system is known as GANT. GISTs may show dual smooth muscle and neural differentiation.

Behavior

Mitotic count, size, and location help in predicting the behavior of gastrointestinal stromal tumors. GISTs in small intestine most often behave like leiomyosarcoma as opposite to the stomach. GISTs are considered to be of low malignant potential and removed surgically.

Management

Surgical resection of gastrointestinal stromal tumor and treatment with imatinib cure the patients. Therapeutic agent imatinib inhibits the tyrosine kinase activity of c-KIT and *PDGFRA*.

GASTRIC NEUROENDOCRINE TUMORS

Gastric neuroendocrine tumors are present in stomach (body and fundus) and proximal duodenum. These tumors synthesize histamine, somatostatin and serotonin.

- There are three types of gastric neuroendocrine tumor. Type 1 neuroendocrine tumor is associated with autoimmune chronic atrophic gastritis. Type 2 neuroendocrine tumor is associated with multiple endocrine neoplasia type 1 (MEN 1) and Zollinger-Ellison syndrome. Type 3 neuroendocrine tumor occurs in sporadic cases.
- Duodenal neuroendocrine tumors are associated with Zollinger-Ellison syndrome or neurofibromatosis type 1 or sporadic. Carcinoid (neuroendocrine) tumors are discussed in details under small intestinal tumors.

GASTRIC NON-NEOPLASTIC DISORDERS

CONGENITAL PYLORIC STENOSIS

Congenital pyloric stenosis is a male-dominant disorder and more common in identical twins. It is characterized by hypertrophy of the circular smooth muscle in the pyloric region of the stomach resulting in obstruction of the outlet of stomach. The only consistent microscopic abnormality is hypertrophy of the circular muscle coat.

Clinical Features

Patient presents with projectile vomiting of non-bile stained fluid 2–4 weeks after birth. On clinical examination, palpable mass is observed through the abdominal wall in the epigastric region. Surgical resection within first 6 months of life gives excellent results.

MÉNÉTRIER DISEASE

Ménétrier disease (giant hypertrophic gastritis) is characterized by extreme enlargement of gastric rugae (greater curvature in the fundus and body of the stomach) and sometimes by severe loss of plasma proteins from the altered mucosa. The disease occurs due to cytomegalovirus in children and adults. Overexpression of TGF-α is seen in adulthood form. Affected patients have an increased risk of gastric carcinoma.

PANCREATIC HETEROTROPIC RESTS

Pancreatic heterotropic rests most commonly occur in the wall of the stomach.

HYPERPLASTIC (REGENERATIVE) POLYPS

Hyperplastic (regenerative) polyps are non-neoplastic polyps that may be associated with chronic blood loss.

TRICHOBEZOAR

Trichobezoar is usually seen in long-haired girls or young women who eat their own hair as a nervous habit. Trichobezoar may grow by accretion to form a complete cast of the stomach. Strands of hair may extend into the bowel as far as the transverse colon known as Rapunzel syndrome (Fig. 20.26).

Fig. 20.26: Trichobezoar shows hair forming cast in stomach. (*Courtesy*: Dr. Sujata Kanetkar, Professor and Head, Department of Pathology, Krishna Institute of Medical Sciences, Karad, Maharashtra.)

DISORDERS OF SMALL INTESTINE

ANATOMY AND HISTOLOGY

Small intestine is 6–7 meters long. It comprises duodenum, jejunum and ileum. It begins at the distal gastric pylorus and ends at ileocecal region. It consists of mucosa, submucosa, muscular coat and serous coat.

- Small intestine is lined by villus mucosa. The individual villus consists of finger-like projections, which is lined by tall columnar absorptive cells, goblet cells, crypt cells, neuroendocrine cells and Paneth cells. The lamina propria contains plasma cells. Peyer's patches composed of aggregates of lymphocytes are distributed throughout the mucosa of small intestine.
- Duodenum contains Brunner's glands in the submucosa. The entire mucosa rests on muscularis mucosae. The smooth muscle layer delineates the lamina propria from the submucosa.

CONGENITAL ANOMALIES

MECKEL'S DIVERTICULUM

Meckel's diverticulum is a remnant of the omphalomesenteric duct. It causes outpouching of four layers of small intestine (true diverticulum) in the antimesenteric aspect of ileum, within 60–100 cm from ileocecal valve. Intermittent painless rectal bleeding is the classic presentation due to acid-related bleeding of aberrant mucosa (remnant of embryonic yolk sac) in children under age of two years. The Tc-99m pertechnetate scan also known as Meckel's scan is diagnostic. Meckel's diverticulum follows the rule of 2s:

- 2% of population affected
- 2% feet from the ileocecal valve
- 2 inches in length
- 2:1 male to female ratio
- 2 types of tissue (gastric and pancreatic tissue)
- Occurs in the first 2 years of age.

Surgical Pathology: Meckel's Diverticulum
Gross Morphology
Meckel's diverticulum shows outpouching of small intestine (Fig. 20.27).
Light Microscopy
Meckel's diverticulum may contain heterotropic rests such as pancreatic tissue, gastric, duodenal, or colonic mucosa (Fig. 20.28).

Clinical Features

Most patients are generally asymptomatic. Patient may develop bleeding in Meckel's diverticulum owing to the presence of heterotropic rests of gastric or pancreatic mucosa.

Complications

Approximately 2% of patients may develop ectopic peptic ulcers, ileoumbilical fistula, intussusception, volvulus, intestinal obstruction, perforation, diverticulitis and mucocele.

HETEROTROPIC GASTRIC MUCOSA

Presence of heterotropic gastric full thickness fundic type oxyntic mucosa produces small nodule or sessile

Fig. 20.27: Meckel's diverticulum. It shows outpouching of small intestine (arrow).

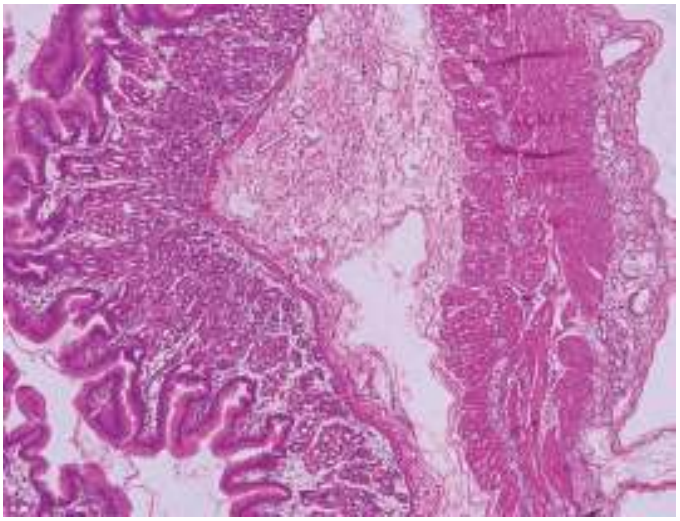

Fig. 20.28: Meckel's diverticulum. It shows heterotropic rests of gastric mucosa (100X).

polyp in the duodenal bulb. This entity differs from foveolar surface metaplasia of duodenal mucosa seen in secondary to inflammation of duodenum by *Helicobacter pylori*.

HETEROTROPIC PANCREAS

Patient with heterotropic pancreas presents with mass in duodenum. On histologic examination of duodenal mass, the lesion is composed of pancreatic ducts and acini with or without islets of Langerhans.

MALROTATION OF SMALL INTESTINE

During fetal life, defective rotation of small intestine occurs. As a result, large bowel does not descend into right iliac fossa. These patients are prone to develop volvulus and internal hernia.

DUPLICATION OF SMALL INTESTINE

Duplication of the small intestine may be tubular or cystic. Approximately 75% are not contagious with the lumen of the associated segment of small intestine. Duplications comprise all the layers of the segment.

MALABSORPTION SYNDROME

Malabsorption syndrome is defined as increased fecal excretion of fat with concurrent deficiencies of vitamins, minerals, carbohydrates, and proteins. Bile salts and fatty acids are required to micellarize monoglycerides and fatty acids. Small intestinal villi are required to reabsorb micelles. Deficiency of pancreatic lipase leads to malassimilation of the fats in the small bowel. Mechanisms of malabsorption are given in Table 20.29.

Etiopathogenesis

Malabsorption syndrome is caused by pancreatic insufficiency, chronic pancreatitis, bile salts/bile acid deficiency due to cirrhosis, cholestasis and small bowel disease (e.g. celiac disease).

Table 20.29 Mechanisms of malabsorption syndrome

Mechanisms	Causes
Impaired intraluminal digestion	▪ Pancreatic insufficiency ▪ Defective bile secretion
Primary mucosal cell abnormality	▪ Lactose intolerance ▪ Bacterial overgrowth
Reduced surface area	▪ Celiac disease ▪ Tropical sprue ▪ Inflammatory bowel disease
Obstruction of lymphatics	▪ Lymphoma ▪ Tuberculosis
Infections	▪ Enterocolitis ▪ Parasitic infection

- Other causes of malabsorption syndrome include Whipple disease, Crohn's disease and diseases obstructing the intestinal lymphatics.
- Small bowel disorders linked to malabsorption syndrome include celiac disease, refractory sprue, collagenous sprue, autoimmune enteropathy, common variable immunodeficiency, microvillus inclusion disease, lymphangiectasia, disaccharidases deficiency and abetalipoproteinemia.
- Causes of malabsorption syndrome are given in Table 20.30. Causes of clinical manifestations of malabsorption syndrome are given in Table 20.31.

Clinical Features

Patient presents with steatorrhea, weight loss, diarrhea, and malnutrition. Steatorrhea denotes passage of excessive sticky stools that float as a result of mal-digestion of fats by small bowel as a result of pancreatic insufficiency.

Complications

Patient develops complications as a result of deficiencies of vitamins (e.g. fat-soluble and water-soluble), pitting edema (e.g. hypoproteinemia), and recurrent infections, and dimorphic anemia (e.g. iron and folate deficiency).

Table 20.30 Causes of malabsorption syndrome

Primary Causes	Secondary Causes
Celiac disease	Mucosal damage (Crohn's disease, tubercular intestine, NHL intestine, radiation)
Whipple disease	Chronic pancreatitis causing pancreatic insufficiency
Refractory sprue	Liver disorders (cirrhosis, cholestasis causing bile salts/bile acid deficiency)
Collagenous sprue	Surgical resection of small intestine
Autoimmune enteropathy	Parasitic infestations (hookworm, roundworm, Giardia)
Common variable immunodeficiency	Drugs administration (methotrexate, neomycin)
Microvillus inclusion disease and disaccharidases deficiency	Impaired transport (lymphangiectasia and abetalipoproteinemia)

Table 20.31 Clinical manifestations of malabsorption syndrome

Dietary Constituents	Site of Absorption	Essential Requirement	Clinical Manifestations
Carbohydrates			
Starch	Small intestine	▪ Amylase ▪ Maltase ▪ Isomaltase-α-dextrin	▪ Diarrhea ▪ Flatulence ▪ Abdominal discomfort
Sucrose	Small intestine	Sucrase	▪ Dehydration ▪ Abdominal discomfort
Lactose	Small intestine	Lactase	▪ Dehydration ▪ Abdominal discomfort
Fats, proteins, water and electrolytes			
Fat	Upper jejunum	▪ Pancreatic lipase ▪ Bile salts ▪ Functioning lymphatic channels	▪ Weight loss ▪ Steatorrhea ▪ Fat-soluble vitamins deficiency
Proteins	Small intestine	Pancreatic enzymes (e.g. trypsin, chymotrypsin, elastin)	Edema, loss of muscle mass, weakness
Water and electrolytes	Mainly small intestine	Osmotic gradient	Diarrhea, dehydration, muscle cramps
Vitamins			
Vitamin B_{12}	Ileum	Intrinsic factor	Megaloblastic anemia, glossitis, peripheral neuropathy
Folic acid	Upper jejunum	Absorption may be impaired by anticonvulsant drugs	Glossitis, cheilosis
Vitamin A	Upper jejunum	Bile salts	Night blindness, exophthalmia, corneal irritation
Vitamin D	Upper jejunum	Bile salts	Bone pain, fractures, tetany
Vitamin K	Upper jejunum	Bile salts	Easy bruising and bleeding
Vitamin E	Upper jejunum	Bile salts	Uncertain
Minerals			
Calcium	Duodenum	Vitamin D and parathormone	Bone pain, fractures, tetany
Iron	Duodenum and jejunum	Normal pH (hydrochloric acid)	Iron deficiency anemia, glossitis

Laboratory Diagnosis

General screening tests for malabsorption syndrome disorders include 24 hours fecal fat and serum β-carotene. The gold standard test to document fat malabsorption is the quantitative 72 hours fecal stool test. Decreased absorption of D-xylose indicates small bowel disease. It is useful in identifying assimilation of proteins in the small bowel (decreased uptake of the pentose sugar).

CELIAC DISEASE

Celiac disease is an autoimmune disease caused by sensitivity to gluten in cereal products. Autoantibodies to gluten result in flattening or destruction of intestinal villi. It is also known as celiac sprue, nontropical sprue or gluten-induced enteropathy. Genetic and immune-mediated mechanisms may be involved in the pathogenesis of celiac disease. Patient presents with chronic diarrhea, abdominal distension and malabsorption syndrome.

Pathology Pearls: Diagnostic Criteria of Celiac Disease

Diagnostic criteria of celiac disease are described as under:

- **Clinical features:** Patient presents with clinical manifestations of malabsorption syndrome and/or iron deficiency anemia.
- **Serum autoantibodies assay:** There is presence of serum IgA antibodies to gliadin (AGA-IgA), tissue transglutaminase (tTg-IgA), endomysium (EMA-IgA-1) and IgG to gliadin (AGA-IgG).
- **Histologic examination:** Intestinal biopsy shows villus atrophy and elongation of crypts due to hyperplasia. Lamina propria shows infiltration by macrophages, lymphocytes and plasma cells.
- **Response to treatment with gluten-free diet:** Patient is advised to take gluten-free diet.

Genetic Predisposition

Incidence of celiac disease increases in association with human leukocyte antigens (HLAs), HLA-B8 and HLA-DW3, type 1 diabetes mellitus and dermatitis herpetiformis, an autoimmune IgA-mediated vesicular disease of skin associated with celiac disease. Genetic factors in celiac disease are given in Table 20.32.

Diseases associated with celiac disease include intestinal adenocarcinoma, enteropathy associated T cell lymphoma, dermatitis herpetiformis, lymphocytic colitis and lymphocytic gastritis.

Etiopathogenesis

Gluten is a name for group of proteins present in grains such as wheat, oat, rye, barley and spelt.

- **Physiologic state:** Normally, digestive enzymes split gluten into small chains of amino acids resulting in absorption of gluten by intestinal villi.
- **Pathologic state:** In celiac disease, digestive enzymes split gluten into long chain amino acid known as gliadin. Disease producing gliadin is absorbed into intestinal villi. Autoantibodies to gliadin result in triggering inflammatory response. Intestinal biopsy (e.g. proximal jejunum and distal ileum exhibiting villus atrophy) is essential for diagnosis. Pathogenesis of celiac disease is shown in Fig. 20.29.

Surgical Pathology: Celiac Disease

Light Microscopy

- Normal intestinal villi are slender and much longer than crypts.
- In celiac disease, intestinal biopsy shows villus atrophy (complete loss of villi), elongation of crypts due to hyperplasia.
- Overall thickness of the mucosa may not be reduced significantly as a result of crypt hyperplasia. Enterocyte damage may be evidenced by flattening and/or cytoplasmic vacuolization.
- Lamina propria shows infiltration by macrophages, lymphocytes and plasma cells. These changes can revert to normal in response to a gluten-free diet.
- Disorders that may mimic gluten-sensitive enteropathy are given in Table 20.33. Light microscopy of celiac disease is shown in Fig. 20.30A and B.

Clinical Features

Children suffering with celiac disease present with diarrhea, i.e. pale, bulky, frothy, foul-smelling stools, failure to thrive, growth retardation, weight loss, weakness and abdominal distension with nonspecific symptoms or anemia.

Table 20.32 Genetic factors in celiac disease

Categories	Examples
Human leukocyte antigens (HLAs)	▪ HLA DQ2 (class II) ▪ HLA DQ8 (class II) ▪ HLA-DW3
Polymorphism of immune regulatory genes determining mucosal epithelial cell polarity	▪ IL-2 ▪ IL-21 ▪ CCR3 ▪ SH2B3
Associated disorders	▪ Diabetes mellitus type 1 ▪ Sjögren's syndrome ▪ Ataxia-telangiectasia ▪ Autism ▪ IgA nephropathy ▪ Down's syndrome ▪ Turner's syndrome ▪ Dermatitis herpetiformis

Complications

Celiac disease is complicated by splenic atrophy and less commonly, large T cell lymphoma of the small bowel and small intestinal obstruction.

Laboratory Diagnosis

Diagnostic modalities of celiac disease include 24 hours fecal fat excretion, D-xylose test, anti-tissue transglutaminase circulating autoantibodies and intestinal biopsy. Demonstration of autoantibodies in serum may also be used for screening prior to definitive diagnosis by intestinal biopsy.

Treatment

A gluten-free diet cures celiac disease. Gluten is not present in corn, quinoa, potatoes, nuts, rice or soy. Flour made from these foods, vegetables and meat deficient in gluten are advised in celiac disease.

REFRACTORY SPRUE

Refractory sprue refers to unresponsiveness to a gluten-free diet. Relapse of symptoms occurs despite gluten restriction. It is not distinguishable from classic celiac disease. Some gastroenterologists consider refractory sprue as a type of T cell lymphoma. There may be presence of numerous neutrophils on histopathological examination.

COLLAGENOUS SPRUE

Collagenous sprue is characterized by flattening of mucosal villi and deposition of collagen fibers in subepithelial region of small intestine.

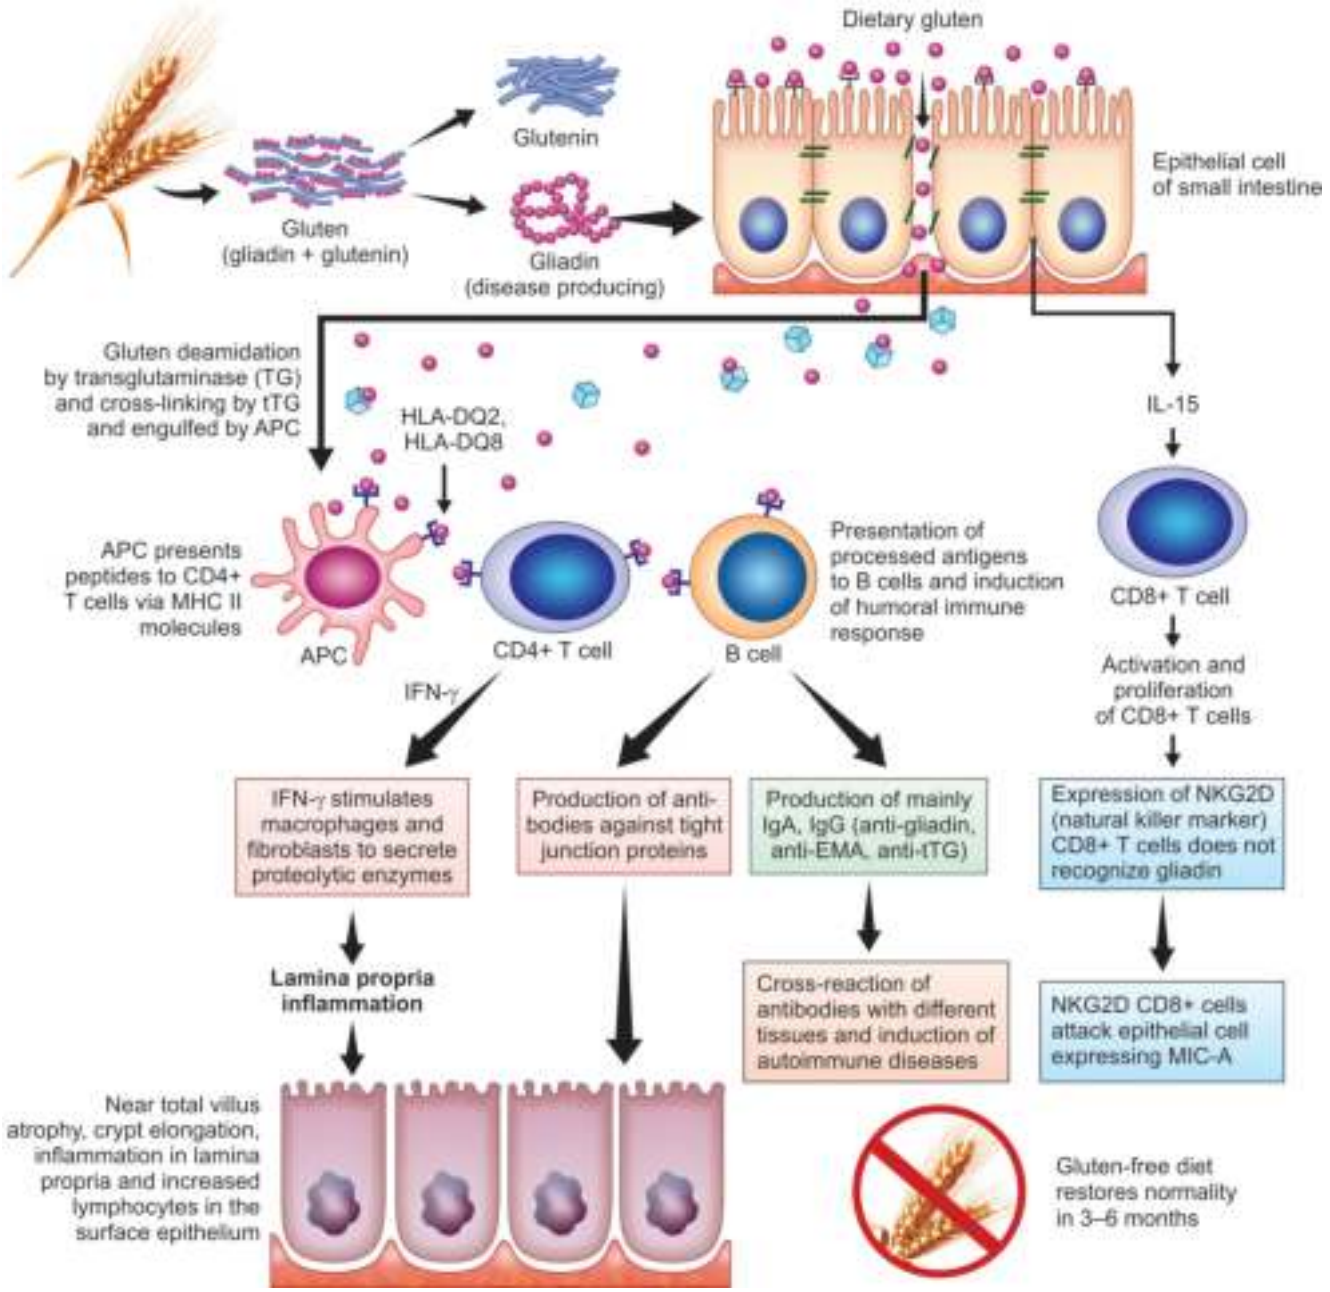

Fig. 20.29: Pathogenesis of celiac disease. Sensitivity to gliadin (disease producing) causes villus atrophy due to epithelial cell destruction, crypt hyperplasia due to expansion of epithelial cells in the proliferative compartment at the bases of the crypts inflammation of lamina propria and increased number of natural killer cells and CD8+ cytotoxic T cells in the epithelium.

Table 20.33 Disorders that may mimic gluten-sensitive enteropathy

Celiac disease/gluten-sensitive enteropathy	HIV enteropathy
Tropical sprue	Food allergies
Helicobacter pylori infection	Giardiasis
Bacterial overgrowth	Crohn's disease
Autoimmune enteropathy	Zollinger-Ellison disease
Nonsteroidal anti-inflammatory drug administration	Systemic autoimmune diseases
Dermatitis herpetiformis	Viral enteritis

Contd...

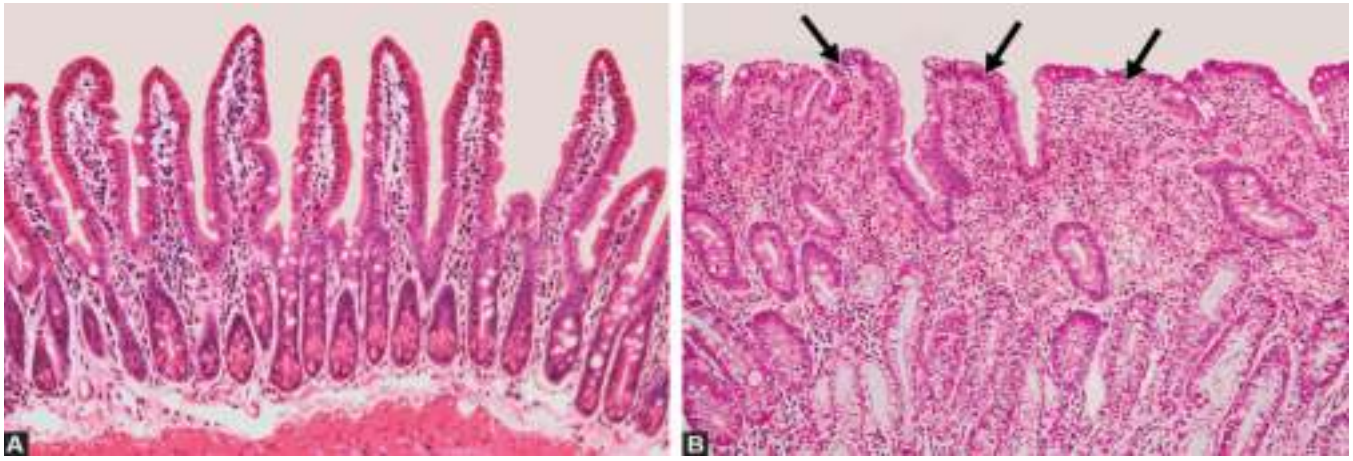

Fig. 20.30: Celiac disease. (A) Shows normal villi of small intestine, (B) shows villus atrophy and chronic inflammatory cells in lamina propria in celiac disease (arrows) (100X).

AUTOIMMUNE ENTEROPATHY

Autoimmune enteropathy shares clinical and histopathologic features with celiac disease. It involves both small intestine and large intestine. Clinical response to corticosteroids may help to establish diagnosis.

Surgical Pathology: Autoimmune Enteropathy

Light Microscopy

- Intestinal biopsy study shows increased intraepithelial CD8+ cytotoxic T cells and plasma cells.
- There is presence of villus atrophy exhibiting blunted or flattened appearance.
- Crypt hyperplasia is demonstrated.
- Apoptotic bodies are apparent.

EOSINOPHILIC GASTROENTERITIS

Eosinophilic gastroenteritis involves mucosa of stomach and intestine. On histologic examination, the mucosa shows infiltration by eosinophils. There is presence of cryptitis and crypt abscess formation. Parasitic infestations, food allergy to cow's milk protein, drug reaction, connective tissue disorders and tumors must be excluded.

COMMON VARIABLE IMMUNODEFICIENCY

Common variable immunodeficiency is characterized by loss of plasma cells in lamina propria. Histologic examination shows variable degree of blunting of villi, lymphocytic infiltration in epithelium and lymphoid aggregates. Giardia should be searched in the biopsies.

MICROVILLUS INCLUSION DISEASE

Microvillus inclusion disease is an autosomal recessive disorder causing diarrhea in infancy. Basic defect is loss of normal brush border on the luminal surface of the enterocytes as a result of incorporation of brush border into the cytoplasm appearing as apical microvillus inclusions. Microvillus inclusion disease is diagnosed by histologic, immunohistochemical, periodic acid–Schiff (PAS) stain, electron microscopy and immunohistochemistry (carcinoembryonic antigen, CD10 or villin). Histologic examination shows diffuse villus atrophy lacking inflammatory response.

INTESTINAL LYMPHANGIECTASIA

Intestinal lymphangiectasia is characterized by abnormal dilated lymphatic channels of small intestine, which may be congenital or secondary. It is an additional cause of malabsorption syndrome. It leads to marked protein loss with resultant hypoproteinemia and generalized edema.

DISACCHARIDASE DEFICIENCY

Lactose is one of the most common disaccharides in dairy products. The intestinal brush border contains disaccharidases that are important for cleavage of lactose to free glucose and galactose for absorption.

Acquired Disaccharidase Deficiency

Acquired disaccharidase deficiency is a widespread disorder of carbohydrate absorption. It leads to milk intolerance. The symptoms of this disease typically begin in adolescence, when patients complain of flatulence and diarrhea after the ingestion of dairy products. Histologic changes in the intestine are not significant.

Congenital Lactase Deficiency

Congenital lactase deficiency may be lethal if not recognized. Infants are unable to break down lactose in breast milk.

Table 20.34 Infectious causes of watery diarrhea

Pathogen	Clinical Presentation	Comments
Salmonella typhi	▪ Vomiting ▪ Fever ▪ Pain abdomen	Associated with ingestion of undercooked beef or chickens
Vibrio cholerae	▪ Vomiting ▪ Dehydration within 12–48 hours ▪ 'Rice water' stool	Cholera toxin in water
Clostridium difficile	Pseudomembranous colitis	Associated with infection by *Clostridium difficile* in patient receiving broad-spectrum antibiotics suppressing normal bacterial flora of intestine
Escherichia coli	▪ Osmotic diarrhea (3–6 days) ▪ Fever	▪ Infant diarrhea ▪ Traveler's diarrhea ▪ Tropical sprue
Rotavirus	▪ Severe dehydration ▪ Nausea ▪ Vomiting	Infant diarrhea during winter
Norwalk virus	▪ Mild diarrhea ▪ Nausea ▪ Vomiting	▪ Fecal–oral transmission ▪ Usually seen in cruise ships
Adenovirus	Moderate vomiting	Second most common cause of infant diarrhea
Giardia lamblia	▪ Steatorrhea (small intestine) ▪ Foul smelling stool	History of camping/hiking
Cryptosporidium	Severe dehydration due to large volume fluid loss	Seen in immunocompromised persons especially HIV infection

ABETALIPOPROTEINEMIA

Abetalipoproteinemia is an inherited disorder, which impairs the normal absorption of fats and certain vitamins from the diet. Patient develops symptoms due to deficiency of vitamins in the body. Peripheral blood examination shows acanthocytes.

DIARRHEA

Diarrhea is passage of >250 gm of stool per day (normal 100 g/day). Diarrhea may be acute (<3 weeks duration) and chronic (>4 weeks duration). Infectious causes of watery diarrhea are given in Table 20.34. Causes and mechanisms of diarrhea are given in Table 20.35. Signs and symptoms associated with chronic diarrhea are given in Table 20.36.

Table 20.35 Causes and mechanisms of diarrhea

Mechanism	Causes
Secretory diarrhea	▪ Rotavirus ▪ *Vibrio cholerae* ▪ *Giardia lamblia*
Osmotic diarrhea	▪ Disaccharidase deficiency ▪ Lactulose therapy
Exudative diarrhea	▪ Shigella (diagnosed by stool culture) ▪ *Salmonella typhi* ▪ Inflammatory bowel disease
Malabsorption	▪ Celiac disease ▪ Tropical sprue ▪ Inflammatory bowel disease

Table 20.36 Signs and symptoms associated with chronic diarrhea

Signs and Symptoms	Chronic Diarrhea	
Arthritis	▪ Ulcerative colitis ▪ Crohn's disease	▪ Whipple's disease
Liver disease	▪ Ulcerative colitis ▪ Crohn's disease	▪ Colon carcinoma with metastases
Fever	▪ Ulcerative colitis ▪ Crohn's disease ▪ Amoebic colitis	▪ Tubercular intestinal disease ▪ Whipple disease
Neuropathy	▪ Amyloidosis	▪ Diabetic diarrhea
Severe weight loss	▪ Malabsorption syndrome	▪ Inflammatory bowel disease
Lymphadenopathy	▪ GIT lymphoma ▪ AIDS ▪ Ulcerative colitis	▪ Crohn's disease ▪ Whipple's disease
Erythema nodosum	▪ Ulcerative colitis	▪ Crohn's disease
Dermatitis herpetiformis	Celiac disease	
Flushing	Carcinoid tumors	
Pyoderma gangrenosum	Ulcerative colitis	

PATHOGENS ASSOCIATED WITH DIARRHEA

- **Rotavirus:** It is the most common childhood cause of watery diarrhea without blood in children <2 years of age. It is transmitted by the fecal–oral route. Rotavirus is demonstrated in duodenal biopsy specimens in 50% of cases.
- **Norwalk virus:** It is most common cause of diarrhea in childhood and adults.
- **Food poisoning:** Patient presents with gastroenteritis from ingestion of contaminated food. Microbial pathogens include *Staphylococcus aureus*, *Clostridium botulinum* (in canned foods; toxins block cholinergic nerves in infants), *Bacillus cereus* (contaminated fried rice), *Clostridium perfringens* and Salmonella.
- ***Clostridium difficile*:** Patient develops pseudomembranous colitis caused by *Clostridium difficile* due to antibiotic-induced (most commonly ampicillin and clindamycin). It is best diagnosed by toxin assay of stool. It is treated with metronidazole.
- ***Shigella sonnei:*** It is transmitted by the fecal–oral route. Patient presents with bloody diarrhea as a result of pseudomembranous inflammation in the ileum and colon.
- ***Salmonella typhimurium:*** It is transmitted by fecal–oral route from animal reservoirs (poultry turtles). Patient develops enterocolitis.
- ***Salmonella typhi:*** It is transmitted by fecal–oral route. Pathogen invades Peyer's patches and produces septicemia during the first week. Blood is the best culture medium for pathogen isolation. Second week of the infection is marked by diarrhea. In addition, patient has classic triad of bradycardia, absolute neutropenia, and hepatosplenomegaly. It may produce chronic carrier state. The organism persists in gallbladder for one year after infection.
- ***Campylobacter jejuni:*** It is contracted by eating contaminated poultry or drinking contaminated milk. It is the most common invasive bacterial enterocolitis in the United States. Patient presents with bloody diarrhea with crypt abscesses in intestine, and the ulcers resembling ulcerative colitis.
- ***Vibrio cholerae:*** It produces a powerful enterotoxin that stimulates adenyl cyclase in the small bowel, leading to severe secretory diarrhea (rice water stool). It is best treated with a glucose/electrolyte solution.
- ***Escherichia coli (E. coli):*** *E. coli* pathogen produces toxin-induced and invasive diarrheas. Heat labile strain stimulates cyclic AMP producing secretory diarrhea. Enteroinvasive strain is associated with an invasive enterocolitis. Enterohemorrhagic strain associated with the O157:H7 serotype contaminating raw ground beef, may produce hemolytic uremic syndrome and hemorrhagic or pseudomembranous colitis. Enteropathogenetic strain produces mild diarrhea in infants and children.

Clinical Pearls: Types of Diarrhea

Osmotic Diarrhea

Nonabsorbable osmotic substances (e.g. mannitol, sorbitol, sugar-free gum or magnesium sulfate from Epsom salt) stimulate osmotic influx of water and electrolytes into the intestinal lumen producing osmotic diarrhea. Intake of milk products by children due to genetic deficiency of lactase enzyme causes withdrawing of water into the lumen, resulting in a hypotonic diarrhea without mucosal inflammation.

Secretory Diarrhea

- In secretory diarrhea, the intestinal cells secrete more water than they can absorb. *Vibrio cholerae* without causing intestinal mucosal inflammation secretes toxin that activates the adenyl cyclic AMP-dependent water pump in the cell membrane.
- The intestinal cells secrete chloride accompanied by water into the lumen producing secretory diarrhea. *E. coli* toxin that is heat stable toxin stimulates water influx through mechanisms that are not cyclic AMP dependent.
- Other causes of secretory diarrhea include Rotavirus, Norwalk virus. Neuroendocrine tumors (e.g. carcinoids and pancreatic islet cell tumors) synthesize vasoactive amines (e.g. serotonin and other polypeptides) responsible for secretory diarrhea.

Exudative (Invasive) Diarrhea

- Exudative diarrhea is caused by pathogens (e.g. *E. coli, Clostridium difficile* and Shigella).
- The organisms cause inflammation of intestinal mucosa with production of inflammatory exudates.
- Fecal smears show leukocytes. Other causes include ulcerative colitis, Crohn's disease, lymphomas and carcinomas.

INFECTIOUS DISORDERS

TROPICAL SPRUE AND BACTERIAL OVERGROWTH

Tropical sprue and bacterial overgrowth simulate celiac disease. It may involve the entire small intestine with more severe disease in distal segment. Clinical history and travel history are important in establishing diagnosis.

WHIPPLE DISEASE (TROPICAL SPRUE)

Tropical sprue is also known as Whipple disease, which occurs due to *Tropheryma whipplei*, in that often responds well to tetracycline. It may involve the entire small intestine with more severe disease in distal segment. It may resemble celiac disease, but megaloblastic anemia dominates the clinical picture. Intestinal biopsy shows only partial villus atrophy.

Etiopathogenesis

Whipple disease is caused by *Tropheryma whipplei* bacteria, which usually affects 30–60 years of age group, involving multiple organs such as small intestine (jejunum and ileum), joints (arthralgia) and cardiac and neurologic manifestations. The organism blocks lymphatic channels of small intestine and interferes with uptake of fat (malabsorption). Draining mesenteric lymph nodes, liver, lung, heart, brain, bone and synovial membrane are also infiltrated by macrophages carrying organisms.

Clinical Features

Patient presents with fever, chronic diarrhea, joint pain, gray-brown skin pigmentation, and generalized lymphadenopathy; antibiotics are curative.

Surgical Pathology: Whipple Disease (Tropical Sprue)

Gross Morphology

- Small intestinal wall is thickened and edematous with dull-colored serosa.
- Mesentery is thickened and indurated with mesenteric lymphadenopathy.

Light Microscopy

- Histologic examination shows blunting and widening of the villi of jejunum and ileum.
- Lamina propria is infiltrated by large number of foamy macrophages widening of the villi. Histologic changes in Whipple disease are shown in Fig. 20.31A and B.

Histochemistry

- The *Tropheryma whipplei* organisms are present in macrophages of intestinal mucosa, which are visualized by diastase resistant PAS stain and Gomori's methenamine silver as rod-shaped in liver, lung, heart, brain, bone and synovial membrane are also infiltrated with organisms carrying macrophages.
- These organisms may demonstrated by polymerase chain reaction and electron microscopy.

Treatment

These patients are treated by antibiotics therapy.

GIARDIASIS

Giardiasis is caused by *Giardia lamblia*. It does not induce significant villus architectural changes. The parasite is demonstrated on the luminal surface of normal appearing mucosa on histopathologic examination. The parasite is mistaken as cytoplasmic debris. Giemsa stain and trichrome stain highlight the parasite. Histologic findings demonstrating *Giardia lamblia* are shown in Fig. 20.32.

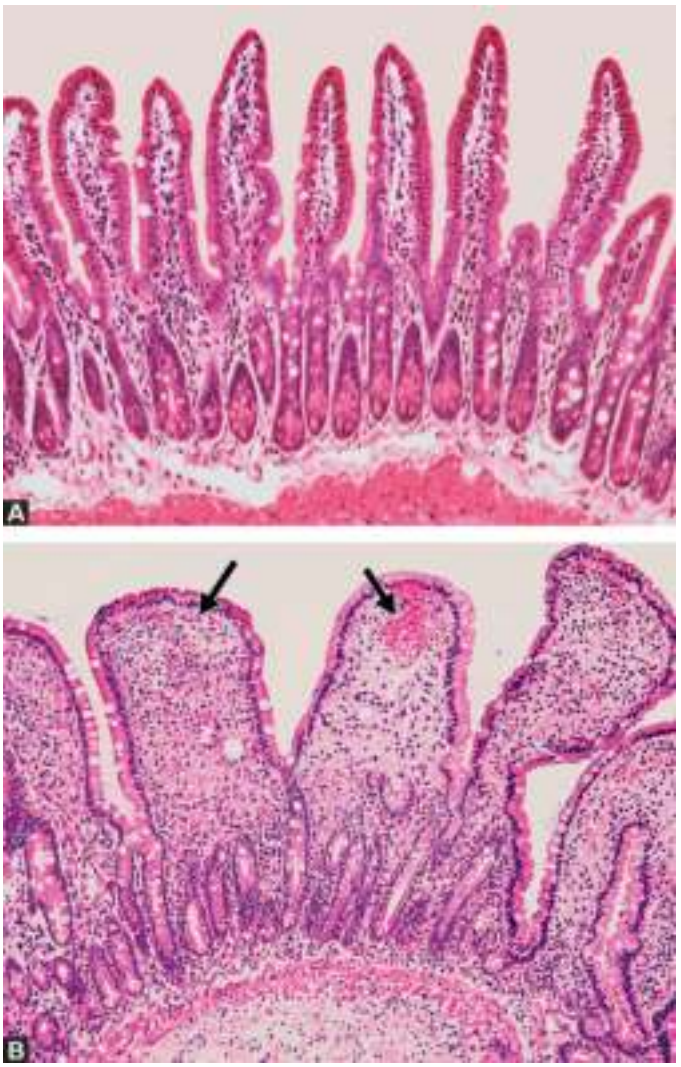

Fig. 20.31: Histologic changes in Whipple disease. (A) It shows normal villi of small intestine, (B) it shows blunting and widening of the villi of jejunum and lamina propria is infiltrated by large number of foamy macrophages (arrows) (100X).

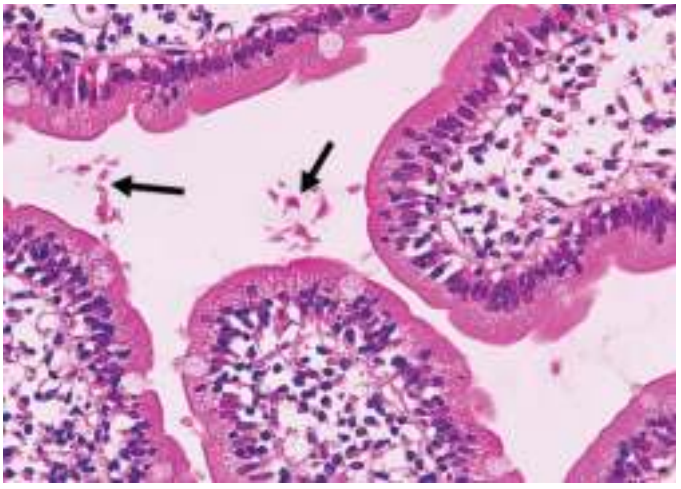

Fig. 20.32: Giardiasis. *Giardia lamblia* parasites are seen on the mucosal side of intestine (arrows).

Fig. 20.33: *Ascaris strongyloides. Strongyloides stercoralis* (roundworm nematode) causing gangrene of small intestine (arrows). (*Courtesy:* Dr. Sujata Kanetkar, Professor and Head, Department of Pathology, Krishna Institute of Medical Sciences, Karad, Maharashtra.)

ASCARIS STRONGYLOIDIASIS

Strongyloidiasis is a human disease caused by nematode roundworm called *Strongyloides stercoralis*. It most often infects small intestine and rarely colon. The parasite is diagnosed by demonstration of larvae, eggs and adult worms embedded in the crypts. Eosinophils, sometimes with Charcot-Leyden crystals may be present. Gastric strongyloidiasis may occur in association with human T-lymphotropic virus causing adult T cell lymphoma. Multiple roundworms of *Strongyloides stercoralis* are shown in Fig. 20.33.

TUBERCULAR INTESTINAL ULCER

Tuberculosis is worldwide health problem caused by tubercle bacilli (homis strain). It is transmitted by inhalation of droplets (most common), ingestion of infected milk and skin inoculation (handling infected specimens).

Mycobacterium tubercle bacilli reach the intestine by either ingestion of infected sputum or ingestion of unpasteurized milk. Tuberculosis affects terminal ileum and most often ileocecal region.

Primary Intestinal Tuberculosis

Mycobacterium tubercle bacilli (bovis strain) reach the intestine due to ingestion of unpasteurized milk. Draining lymph nodes of small intestine are enlarged and matted with caseous necrosis known as 'tabes mesenterica'. It most often heals by fibrosis and dystrophic calcification.

Secondary Intestinal Tuberculosis

- Mycobacterium tubercle bacilli reach the intestine by swallowing of infected sputum in a case of pulmonary tuberculosis. Intestinal lesions are more prominent than draining lymph nodes.
- The tubercular lesions begin in the Peyer's patches (lymphoid follicles) and spread through lymphatic channels resulting in tubercular ulcer in terminal ileum especially in ileocecal region. It produces circumferential ulcers perpendicular to long axis of small intestine. Fibrosis in ileocecal region is responsible for stricture formation. Tubercular stricture formation of intestine is shown in Fig. 20.34.
- Hyperplastic ileocecal tuberculosis is a variant of intestinal tuberculosis characterized by thickening of terminal ileum, cecum and ascending colon with mucosal ulceration. On clinical examination, hyperplastic ileocecal tuberculosis is palpable and mistaken for cecal carcinoma.

Surgical Pathology: Intestinal Tuberculosis

Light Microscopy

- Histologic examination of intestine reveals epithelioid cell granulomas, caseous necrosis and Langhans' giant cells.
- Crohn's disease also produces stricture formation, in which segmental involvement of intestine occurs with skip areas thickened wall resembles pipe-like and shows irregular linear ulcers in the mucosa.

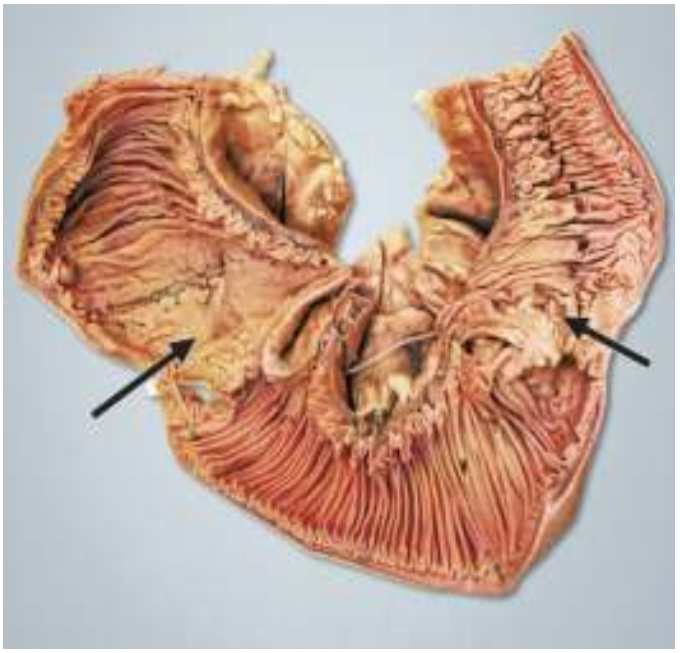

Fig. 20.34: Tubercular stricture of intestine (arrows). (*Courtesy:* Dr. Sujata Kanetkar, Professor and Head, Department of Pathology, Krishna Institute of Medical Sciences, Karad, Maharashtra.)

INTESTINAL ULCERS IN TYPHOID FEVER

Typhoid fever is a systemic disease caused by *Salmonella typhi* bacilli. Patient presents with continuous fever with relative bradycardia, abdominal symptoms and psychosis. There is involvement of mononuclear phagocytic system with nodule formation in the Peyer's patches of lower ileum.

Mode of Transmission

Salmonella typhi has three antigenic structures: O antigens, H antigens and Vi antigens. The organism is transmitted by fecal–oral route.

Clinical Features

Patient may present with step-ladder rise of fever during first week and continued during second and third weeks, headache, nausea, vomiting, abdominal tenderness, rose spots (2–4 mm on trunk) and hepatosplenomegaly.

Clinical manifestations and laboratory findings in typhoid fever are given in Table 20.37. Differences between tubercular and typhoid ulcers are given in Table 20.38.

Pathogenesis

Ingested *Salmonella typhi* pathogen invades the mucosa, engulfed by macrophages and transported to regional lymph nodes. Multiplication of pathogen occurs in the lymphoid tissue resulting in bacteremia. *Salmonella typhi* reinfects lymphoid tissue and liberates endotoxin leading to delayed hypersensitivity reaction. Erythrophagocytosis is demonstrated in histopathologic examination of tissue sections.

Extraintestinal Lesions

Proliferation of reticuloendothelial cells occurs in spleen (sinus histiocytes), liver (Kupffer's cells), lymph nodes and bone marrow. Patient develops splenomegaly, hepatomegaly and lymphadenopathy.

Intestinal Pathology

Terminal ileum and cecum are involved due to *Salmonella typhi* infection. There are four stages lasting for 4 weeks.

- **Hyperplasia of Peyer's patches during first week:** In the first week of infection, hyperplasia of Peyer's

Table 20.37 Clinical manifestations and laboratory findings in typhoid fever

Clinical Features	First Stage (1st Week)	Second Stage (2nd Week)	Third Stage (3rd Week)	Fourth Stage (4th Week)
Rose spots	Present on 5th day	Persists till 10th day	Absent	Absent
Splenomegaly	Slightly palpable on 6th day	Moderate enlarged	Moderate enlarged	Moderate enlarged
Psychosis and confusion	Absent	Present on 10th day	Present	Absent
Leukopenia	Present on 5th day	Present	Present	Absent
Blood culture	+++	+++	+/–	–
Stool culture	–	+	+++	–
Widal reaction	–	++	+++	–

Table 20.38 Differences between tubercular and typhoid ulcers

Characteristics	Tubercular Ulcer	Typhoid Ulcer
Causative organism	Mycobacterium tubercle bacilli	*Salmonella typhi*
Site of gut involvement	Ileocecal region	Terminal ileum (most common), may occur in jejunum or colon
Lymphoid involvement	Peyer's patches	Peyer's patches and also lymphoid follicles
Arrangement of ulcers	Transverse axis of intestine	Longitudinal axis of intestine
Size of ulcer	Large	Small
Margin	Irregular ulcer may encircle gut	Regular well circumscribed
Base of ulcer	Caseous material (creamy white)	Black due to sloughing of mucosa
Perforation of ulcer	Absent	Common
Bleeding from ulcer	Absent	Common
Stricture formation	Present as a result of fibrosis	Absent
Light microscopy	Caseous necrosis, epithelioid granulomas, Langhans' giant cells and demonstration of acid-fast bacilli	Erythrophagocytosis and presence of organisms in macrophages

patches (lymphoid tissue) of terminal ileum occurs in the mucosa and extending to submucosa in the terminal ileum. Mucosa is projecting on the surface. Blood culture is positive for *Salmonella typhi* but stool culture is negative.

- **Necrosis of Peyer's patches during second week:** Necrosis of Peyer's patches occurs from center to periphery exhibiting yellow or greenish-brown discoloration. Blood culture and stool culture are positive.
- **Mucosal ulceration of intestine during third week:** In the third week of infection, mucosal surface of ileum shows round to oval deep ulcers along the long with axis of intestine on gross examination. Stool culture and Widal reaction are positive. These ulcers may perforate leading to hemorrhage.
- **Healing of intestinal ulcer during fourth week:** Healing of intestinal ulcers occurs in the 4th week of infection. Widal reaction is positive. Typhoid ulcers in small intestine are shown in Figs 20.35 and 20.36.

OBSTRUCTIVE DISORDERS

Partial or complete obstruction of lumen of small intestine is a serious clinical disorder. Small bowel obstruction can be simple, strangulated (interrupting blood supply) and closed loop type (isolating from rest of small intestine).

Small bowel obstruction occurs due to adhesions from previous surgery and congenital bowel deformities, which can be due to intraluminal (e.g. tumor, foreign bodies), intramural and extra-intestinal etiology.

DUODENAL ATRESIA

Duodenal atresia occurs either due to failure of the gut to canalize or failure of segment to develop during fetal growth. The normal gastrointestinal system is a tube that develops from cords of embryonic cells. The embryonic cells forming the central part of these cords undergo apoptosis resulting in formation of lumen. If the centrally located cells do not undergo apoptosis, the lumen never forms and the affected segment of the GIT system will be atretic (i.e. unpassable).

Duodenal atresia is most commonly associated with Down syndrome and characterized by vomiting of bile stained material at birth. Abdominal radiograph demonstrates double bubble sign.

MECONIUM ILEUS

Meconium ileus is a bowel obstruction that occurs when the meconium in child's intestine is thicker and sticker than normal meconium, creating a blockade in the ileum. Meconium ileus in babies with cystic fibrosis may be complicated by volvulus and intestinal atresia.

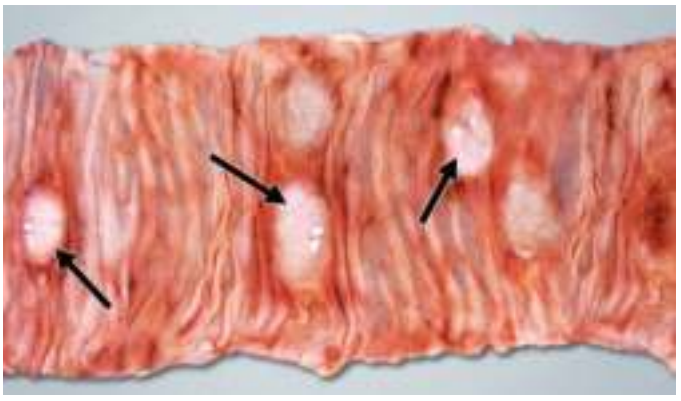

Fig. 20.35: Typhoid ulcers in small intestine. The Peyer's patches are prominent. Round to oval ulcers with hemorrhage are present along the long axis of intestine (arrows).

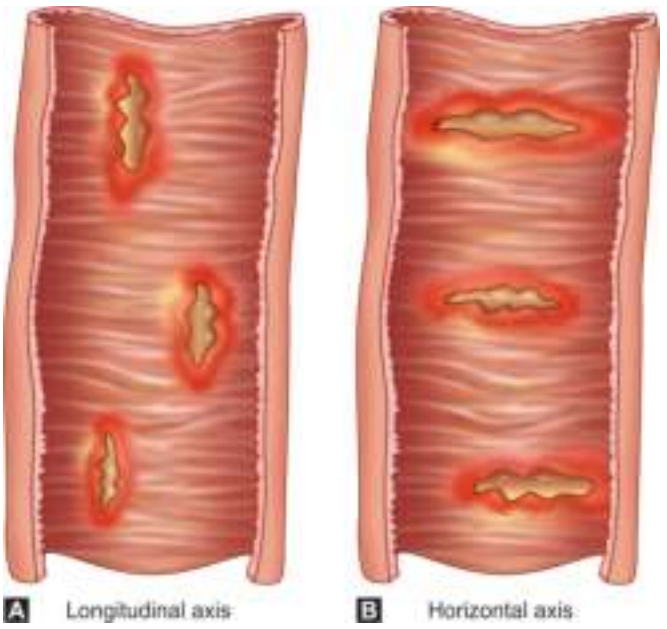

Fig. 20.36: Ulcers in small intestine. (A) Typhoid ulcers, (B) tubercular ulcers.

INTESTINAL INTUSSUSCEPTION

Intestinal intussusception is an invagination of one segment of proximal bowel (usually the terminal ileum) into the distal bowel (usually the cecum), causing intestinal obstruction.

- Intestinal intussusception is a common cause of intestinal obstruction in children due to active peristalsis between 3 months and 6 years of age.
- In adults, intestinal intussusception occurs due to pedunculated polyps or malignant growth. Small pedunculated tumors carried by peristalsis may pull forward the loop to which such a tumor is attached.
- Based on the location, intestinal intussusception may be ileocecal (most common), jejunojejunal, ileoileal and colocolic. The inner loop of the gut may become necrotic unless the invagination is everted surgically.

Pathology

Intestinal intussusception progresses to tissue necrosis of segment of intestine as a result of decreased blood flow, swelling and inflammation. It can lead to intestinal perforation and infection. Septic shock and dehydration can occur very rapidly. Gross morphology of intussusception is shown in Fig. 20.37.

Clinical Features

Child presents with signs of obstruction (paroxysmal abdominal colicky pain) and rectal bleeding (currant jelly stools) from bowel infarction. On clinical examination, abdominal distension and decreased bowel sounds are observed. Features of dehydration include rapid pulse, pallor and marked sweating.

Diagnostic Evaluation

Abdominal radiograph may show absence of gas in right upper quadrant. Ultrasonography may be done to locate area of telescoped bowel.

PARALYTIC ILEUS

Paralytic ileus refers to lack of intestinal peristalsis associated with stagnation of intestinal contents. The most common causes of paralytic ileus include abdominal surgery persisting for 2–3 days, peritonitis, shock and vascular collapse.

GALLBLADDER STONE ILEUS

In some cases of gallbladder stone disease, gallstone erodes through the gallbladder into the adjacent small bowel forming cholecystoenteric fistula. Gallbladder stone enters ileum through the fistulous tract and blocks the intestine known as gallstone ileus. It can be very serious disorder which requires immediate surgery. It primarily occurs in patients over age 65, and can sometimes be fatal.

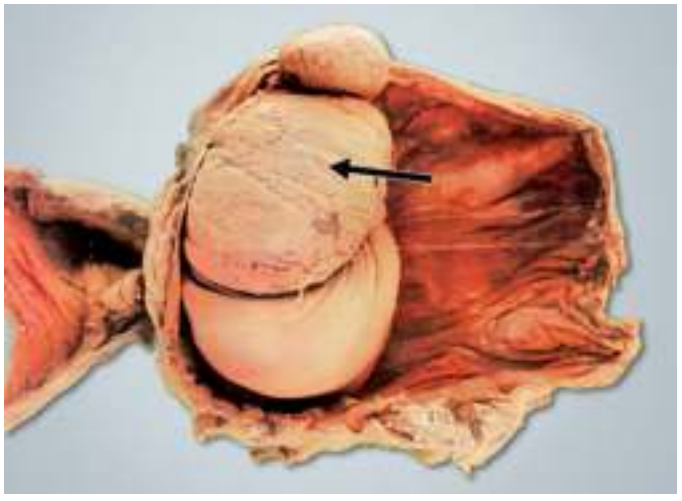

Fig. 20.37: Intussusception. It shows invagination of one segment of proximal bowel (usually the terminal ileum) into the distal bowel (arrow). (*Courtesy:* Dr. Sujata Kanetkar, Professor and Head, Department of Pathology, Krishna Institute of Medical Sciences, Karad, Maharashtra.)

INGUINAL HERNIA

In inguinal hernia, the hernial contents are intestine, omentum, or other abdominal contents that pass through the inguinal canal opening into the hernial sac.

- Direct inguinal hernia occurs through the posterior wall of the inguinal canal in the center of Hesselbach's triangle.
- Indirect inguinal hernia is most common cause of intestinal obstruction, in which small bowel extends into the scrotal sac, lateral to the triangle of Hesselbach.

ADHESIONS

Adhesions are most common cause of gastrointestinal obstruction. These are most commonly acquired from previous abdominal surgery.

UMBILICAL HERNIA

Umbilical hernias occur in children and adults. Ascites and pregnancy precipitate hernias in adults. Umbilical hernia can cause segment of bowel out of abdomen and produce symptoms.

VENTRAL INCISIONAL HERNIA

Ventral incisional hernia occurs in previous surgical incision sites. In a strangulated ventral hernia, bowel gets tightly caught within an opening in abdominal wall.

VASCULAR DISORDERS

SMALL BOWEL INFARCTION

Occlusion of superior mesenteric artery is most common cause of small bowel infarction. Small intestine is supplied by superior mesenteric artery. Colon receives blood from inferior mesenteric artery. Atheromatous plaques are common in superior mesenteric artery due to its oblique origin from the abdominal aorta.

Etiopathogenesis

Decreased blood supply to small intestine occurs due to thrombus over an atheromatous plaque of supplying blood vessel, emboli from left heart, hypovolemic shock, vasospasm (digitalis), venous thrombus (polycythemia) and mechanical obstruction (volvulus). Systemic arterial thrombi may embolize to mesenteric arteries resulting in small bowel infarction.

Clinical Features

Patient presents with diffuse abdominal pain, nausea, vomiting and bloody diarrhea.

Complications

In transmural gut infarction; there is danger of gut perforation with mucosal ulcerations and formation of pseudomembrane.

POLYPS AND TUMORS

Polyps and tumors of the small intestine make up a small percentage of gastrointestinal tract neoplasms. The most common malignant tumors are neuroendocrine (carcinoid) tumors, lymphoma, adenocarcinoma, and GISTs.

Non-neoplastic lesions are more common in small intestine. Revised 2019 WHO classification of tumors of small intestine and ampulla of Vater is given in Table 20.39.

ADENOCARCINOMA

Adenocarcinoma of small intestine is much less common than adenocarcinoma of colon. Approximately 40–50% of cases have tumor in the duodenum in the region of ampulla of Vater. It may also occur in jejunum or ileum. Disorders associated with an increased risk for small intestinal carcinoma are given in Table 20.40.

Surgical Pathology: Adenocarcinoma of Small Intestine

Gross Morphology

- Duodenal adenocarcinoma is relatively circumscribed with polypoidal appearance and central ulceration.
- Adenocarcinoma in jejunum or ileum shows circumferential involvement with extensive ulceration and annular appearance.

Light Microscopy

- Tumor is well differentiated adenocarcinoma producing mucin.
- Scattered neuroendocrine cells may be present.

NEUROENDOCRINE (CARCINOID) TUMORS

Carcinoid tumors are neuroendocrine tumors of low-grade malignancy. These are most commonly located in the submucosa of the intestinal tract, e.g. appendix (40% cases), terminal ileum (25% cases), colon, rectum (10–20% cases), duodenum (2–5% cases), esophagus and stomach.

- Carcinoid tumors are multicentric in stomach and ileum. Peak incidence is in the sixth decade. The tumors are well differentiated and composed of cells similar to those of normal counterparts.

Table 20.39 Revised 2019 WHO classification of tumors of small intestine and ampulla of Vater

Benign Epithelial Tumors and Precursor Lesions
▪ Adenomatous polyp, low-grade dysplasia
▪ Adenomatous polyp, high-grade dysplasia • Intestinal-type adenoma, low-grade • Intestinal-type adenoma, high-grade • Serrated dysplasia, low-grade • Serrated dysplasia, high-grade • Noninvasive pancreatobiliary papillary neoplasm with low-grade dysplasia • Noninvasive pancreatobiliary papillary neoplasm with high-grade dysplasia • Intra-ampullary papillary-tubular neoplasm
Malignant Epithelial Tumors
▪ Adenocarcinoma, NOS
▪ Mucinous adenocarcinoma
▪ Signet ring cell carcinoma
▪ Medullary carcinoma, NOS
▪ Adenocarcinoma, intestinal type
▪ Pancreatobiliary-type carcinoma
▪ Tubular adenocarcinoma
▪ Neuroendocrine tumor, NOS • Neuroendocrine tumor, grade 1 • Neuroendocrine tumor, grade 2 • Neuroendocrine tumor, grade 3 • Gastrinoma, NOS • Enterochromaffin-like cell carcinoid • Extra-adrenal paraganglioma, NOS
▪ Neuroendocrine carcinoma, NOS • Large cell neuroendocrine carcinoma • Small cell neuroendocrine carcinoma
▪ Mixed neuroendocrine-non-neuroendocrine neoplasm (MiNEN)

Adapted from 2019 WHO classification of tumor of digestive system.
Term NOS (not otherwise specified).
Other less common tumors derived from soft tissue are leiomyoma, gastrointestinal stromal tumors, lipoma, angiosarcoma, Kaposi sarcoma. Hematolymphoid neoplasms are Burkitt lymphoma, follicular lymphoma, diffuse large B cell lymphoma and T cell lymphoma.

Table 20.40 Disorders associated with an increased risk for small intestinal carcinoma

Sporadic adenomatous polyps
Familial adenomatous polyposis (FAP)
Hereditary nonpolyposis colon cancer syndrome (Lynch syndrome)
Juvenile polyposis syndrome
Crohn's disease
Celiac disease
Gardener's syndrome
Peutz-Jeghers syndrome
α-Chain disease

Table 20.41 Features of neuroendocrine (carcinoid) tumors in gastrointestinal tract

Parameters	Foregut Carcinoids (Proximal to Ligament of Treitz)	Midgut Carcinoids	Hindgut Carcinoids
Structures	▪ Stomach (body and fundus) ▪ Proximal duodenum but rare in esophagus	▪ Terminal ileum ▪ Jejunum	▪ Tip of appendix ▪ Colorectal region
Size	1–2 cm or more	<3.5 cm	Appendix (up to 1 cm) and colon up to 5 cm
Frequency	2–5%	60–80%	10–20%
Substances synthesized	Histamine, somatostatin and serotonin	Serotonin, substance P and polypeptide YY	Serotonin, substance P
Clinical course	Asymptomatic course	Aggressive course due to greater depth of local invasion, necrosis and mitosis with poor outcome	Rectal carcinoids producing polypeptide hormones, colonic carcinoid may metastasize
Tumor cells	Argyrophilic cells	Argentaphilic cells	Argyrophilic cells
Carcinoid syndrome	Rare	Most common	Rare

- Goblet cell carcinoid tumor consisting of mucin secreting and goblet-like cells is known as adenocarcinoid tumor with aggressive behavior than classic carcinoid tumor. Features of neuroendocrine (carcinoid) tumors in gastrointestinal tract are given in Table 20.41.

Neuroendocrine Cells

Neuroendocrine cells of the gut utilize amino acids, or derivatives of amino acids, as chemical messengers mediating paracrine and neuroendocrine effects. They are known as APUD cells (amine precursor uptake and decarboxylation).

- **Enterochromaffin cells:** Enterochromaffin cells are named after their staining characteristics after chromate fixation. These are found in groups at the bases of the intestinal crypts small intestine. These cells synthesize 5-HT (5-hydroxytryptamine) and kallikrein.
- **Nonchromaffin enteroendocrine cells:** These cells are dispersed as single cells in the crypt and villus epithelium, and bowel wall.

Neuroendocrine Tumors: Categories

Neuroendocrine tumors are categorized into three grades (G1, G2 and G3) according to mitotic count and Ki-67 proliferative index. The term neuroendocrine carcinoma is reserved for poorly differentiated neuroendocrine tumor with marked nuclear atypia and high mitotic rate (>20 high power field). Classification and grading of neuroendocrine tumors (carcinoids) of the GI tract are given in Table 20.42.

Surgical Pathology: Neuroendocrine Tumors of Intestine

Gross Morphology

Following formalin fixation, tumor acquires yellow color. Infiltration of the submucosa by tumor is the rule.

Light Microscopy

- Neuroendocrine tumors of small intestine are composed of neuroendocrine cells.
- Tumor cells are round with uniform nuclei, scanty cytoplasm and indistinct cell borders. Tumor cells are arranged in solid nests, cords separated by thin fibrous septa.
- Tumor cells may form rosettes around blood vessels, which secrete hormones into the systemic circulation (Fig. 20.38).

Histochemical Staining

Silver staining demonstrates black granules in the cytoplasm of tumor cells. Argentaffin cells containing granules have the property of reducing silver salts without the help of reducing agent, while argyrophil cells reduce silver salts to metallic silver (black color) only after addition of a reducing agent.

Electron Microscopy

Tumor cells show cytoplasmic granules, which are stained red with eosin, yellowish brown with chrome salts, black with iron-hematoxylin and metallic black with silver salts.

Immunohistochemistry Technique

Panel of immunohistochemical markers used in gastrointestinal tract carcinoid (neuroendocrine) tumors includes synaptophysin, chromogranin A, neuron-specific enolase (NSE), CD56 (neuronal cell adhesion molecule—NCAM), cytokeratins (AE1/AE3 and CAM 5.2 epithelial marker) and CDX2 (polyclonal marker).

Markers	Expression
▪ Synaptophysin	▪ Positive
▪ Chromogranin A	▪ Positive
▪ NSE (neuron-specific enolase)	▪ Positive
▪ CD56 (NCAM)	▪ Positive
▪ AE1/AE3 and CAM 5.2	▪ Positive
▪ CDX2	▪ Positive (50%)

Table 20.42 Classification and grading of neuroendocrine tumors (carcinoids) of the GI tract

Classification	Grade	Cytological Features	Mitotic Count
Neuroendocrine tumor	1 2	▪ Cytological bland ▪ Cytological bland	▪ <2 per HPF and/or 2% Ki-67 index ▪ 2–20 per HPF and/or 3–20% Ki-67 index ▪ >20 per 10 HPF and/or >20% Ki-67 index
Neuroendocrine carcinoma (NEC)	3	Tumor displaying at least 30% component of adenocarcinoma	
Hyperplastic or preneoplastic lesions	–	–	–

Grading requires mitotic count in at least 50 HPFs and Ki-67 percentage in at least 500–2000 cells within the area of strongest nuclear labeling.

Metastases

Carcinoid tumor of appendix and rectum is seldom malignant. Most carcinoid tumors invade submucosa and muscularis and sometimes penetrate bowel wall. Metastases may be seen in 5% of cases having tumor <1 cm size. However, large carcinoid tumor >2 cm size in ileum and appendix has tendency to spread to regional lymph nodes and distant organs such as liver, lungs and bones in 66% of cases.

Carcinoid Syndrome

Neuroendocrine tumors metastasizing to the liver can lead to carcinoid syndrome as a result of synthesis of 5-HT (5-hydroxytryptamine), serotonin, and bradykinin. 5-HT increases gut motility resulting in diarrhea, excessive bowel sounds (borborygmi) and abdominal pain.

- Kallikrein produces flushing of skin, bronchospasm and diarrhea. 5-HT is inactivated in the liver by monoamine oxidase to form 5-hydroxyindoleacetic acid (5-HIAA), and this is excreted in the urine.
- Urinary 5-hydroxyindoleacetic acid (5-HIAA) may be elevated in these patients.
- Patient presents with cutaneous flushing, watery diarrhea, abdominal cramps, bronchospasm and valvular lesions of the right side of the heart. Clinical manifestations of neuroendocrine (carcinoid) tumors of small intestine are given in Table 20.43.

Carcinoid Heart Disease

The products synthesized by carcinoid tumor such as 5-HT, serotonin, and bradykinin enter into hepatic veins and affect the right side of the heart. The patient develops tricuspid valve incompetence and pulmonary valve stenosis as a result of formation of fibrous plaques. Smooth muscle cells within endocardium may undergo proliferation as a result of stimulation by kallikrein.

GASTROINTESTINAL STROMAL TUMORS

Gastrointestinal stomal tumors (GISTs) are most common mesenchymal neoplasms that originate primarily in the wall of gastrointestinal tract.

- Clinical behavior ranges from benign/low-grade to malignant tumors. Malignant gastrointestinal stromal tumors can disseminate to liver and intra-abdominal structures associated with fatal outcome.
- Instead of dividing GISTs into benign/low-grade to malignant; risk of progression to malignant phenotype is based on anatomic location, size and mitotic activity of gastrointestinal stromal tumors.

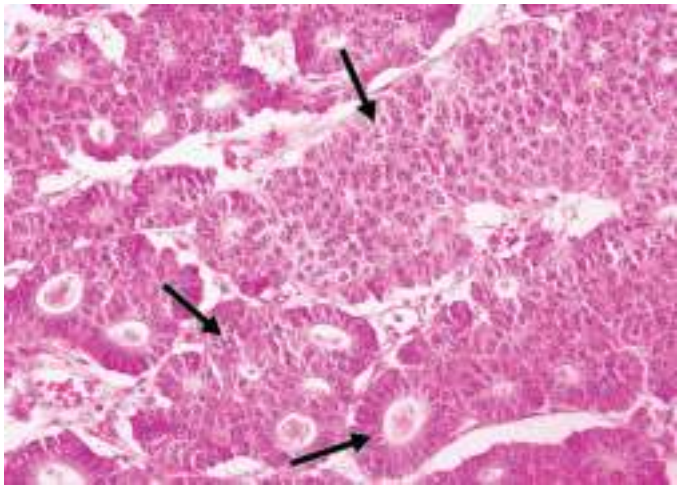

Fig. 20.38: Neuroendocrine tumor of ileum is composed of uniform cells with stippled chromatin (arrows) (400X).

Table 20.43 Clinical manifestations of neuroendocrine (carcinoid) tumors of small intestine

Organs Involved	Clinical Manifestations
Liver	Metastases
Vascular phenomenon	Flushing, cyanosis and telangiectasia
Respiratory system	Bronchoconstriction
Heart	Pulmonary and tricuspid valvular disease
Blood and tissue cells	5-Hydroxytryptamine (5-HT) and serotonin
Urine analysis	↑ 5-Hydroxyindoleacetic acid (5-HIAA) excretion
Skin	Hyperpigmentation
Legs	Edema

Table 20.44 Classification of gastrointestinal stromal tumors

Benign Tumors
Benign gastrointestinal stromal tumor
Intermediate (Locally Aggressive) Tumors
Gastrointestinal stromal tumor of uncertain malignant potential
Malignant Tumors
Malignant gastrointestinal stromal tumor

Classification of gastrointestinal stromal tumors is given in Table 20.44.

Origin, Location and Age Distribution

Gastrointestinal stromal tumors (GISTs) originate from stromal stem cells, that are precursors of smooth muscle cells (i.e. gastrointestinal fibroblasts or pacemaker cells of Cajal controlling peristalsis).

- Most common sites of gastrointestinal stromal tumor are stomach (60%), small intestine (30%), colon, appendix (10%), rectum and gallbladder.
- Rare sites of extra-gastrointestinal stromal tumors are omentum, mesentery, retroperitoneum and pelvis. It usually affects adult males with median age of 58 years.
- GISTs may be associated with neurofibromatosis and Carney triad (GIST, paraganglioma and pulmonary chondroma). It can affect children and young adults in the setting of Carney syndrome.

Molecular Genetic Alterations

Approximately 90% of GISTs demonstrate c-KIT (CD117) mutation. Mutation in *PDGFRA* is demonstrated in 10% of cases. A gain of function in c-KIT (CD117) or *PDGFRA* gene may coexist. GISTs with c-KIT (CD117) mutation respond to Gleevec (imatinib) therapy.

Clinical Features

Patient presents with anemia due to ulceration and bleeding of GIST, fatigue, pain abdomen and distension abdomen. GIST is detected as an incidental finding in surgical specimens such as gastrectomy for gastric carcinoma. Carney's syndrome is characterized by Carney's triad (gastric GIST, extra-adrenal paraganglioma and pulmonary chondroma) in children.

Radiologic Findings

CT and MRI scans are performed to diagnose gastrointestinal stromal tumor. Endoscopy and ultrasonography are useful diagnostic techniques to detect gastrointestinal stromal tumors.

Surgical Pathology: Gastrointestinal Stromal Tumors (GISTs) of Small Intestine

Gross Morphology

- Gastrointestinal stromal tumors are either unilobular or multilobular with smooth circumscribed borders. These may vary from small mural nodule to large pedunculated mass in serosa.
- Duodenal GISTs measure 5 cm in diameter; and 7 cm in diameter of GIST in jejunum and ileum. Ulceration is commonly demonstrated in large tumor.
- Cut surface of tumor is fleshy and cystic with areas of hemorrhage and necrosis (Fig. 20.39).

Light Microscopy

- Gastrointestinal stromal tumors are composed of either epithelioid or spindle-shaped cells. Majority of GISTs show combined cytomorphologic features of epithelioid and spindle-shaped cells. Cardinal diagnostic features of GISTs include lack of pleomorphism and low mitoses.
- Epithelioid GIST is composed of epithelioid tumor cells with round-elongated nuclei, fine chromatin, inconspicuous nucleoli and abundant fibrillary cytoplasm; and arranged in either in sheets or nests.
- Spindle cell GIST is composed of spindle-shaped neoplastic cells with round-elongated nuclei, fine chromatin, inconspicuous nucleoli and abundant fibrillary cytoplasm; and arranged in fascicular pattern. Spindle cell GISTs may demonstrate smooth muscle component, and neural differentiation shows nuclear palisading resembling schwannoma (Fig. 20.40).

Electron Microscopy

Analysis of GISTs shows lack of differentiation, i.e. incomplete differentiation of or neuroaxonal differentiation.

Histochemistry

A small set of GISTs has acellular collagen bundles known as 'skeinoid fibers', that are demonstrated by PAS stain.

Differential Diagnosis

Gastrointestinal stromal tumor should be differentiated from leiomyoma, leiomyosarcoma, schwannoma, desmoid fibromatosis, malignant melanoma and carcinoma.

Immunohistochemistry Technique

Gastrointestinal stromal tumors show positivity for c-KIT (CD117) encoding tyrosine kinase, DOG1 (most specific marker), CD34 (75%), and smooth muscle actin (40%), c-KIT (CD117) staining is most often diffuse and strong membranous, cytoplasmic or paranuclear globular staining pattern, protein kinase c-theta, smooth muscle actin encoded by ACTA2 gene, vimentin and desmin. About 5% of GISTs are negative for KIT (CD117). Majority of these tumors are of epithelioid GISTs show *PDGFRA* gene mutations.

Markers	Expression
c-KIT (CD117)	Positive (90%)
DOG1	Positive
PDGFRA	Positive
CD34	Positive (75%)
Smooth muscle actin	Positive (40%)
Protein kinase c-theta	Positive
Vimentin	Positive
Desmin	Positive (5%)
S-100 protein	Negative

Molecular Genetic Alterations

Loss of material from the short arm of chromosome 1 and monosomy for chromosome 14 and chromosome 22 are most common cytogenetic profile in GISTs. Loss of material from the short arm of chromosomes 9 and 11 is less common and associated with aggressive clinical course.

Prognosis, Clinical Behavior and Treatment

Mitotic count, size, and location help in predicting the behavior of GISTs. GISTs in small intestine most often behave like leiomyosarcoma as opposite to the stomach. GISTs are considered to be of low-malignant potential and are removed surgically. Proposed guidelines for predicting malignant behavior of GISTs are given in Table 20.45.

- Majority of GISTs exhibit benign clinical course. Recurrence and metastases are demonstrated in 50% of cases.
- GISTs have tendency for intra-abdominal spread and metastasize to liver. Lymph node metastasis is extremely rare. Lungs are the most common site of metastasis outside the abdomen.

DIFFUSE LARGE B CELL LYMPHOMA

Diffuse large B cell lymphoma (DLBCL) can arise from the abundant lymphoid tissue of the small intestine, which accounts for 50% of all lymphomas. Patient may present with malabsorption syndrome when there is diffuse involvement.

Surgical Pathology: Diffuse Large B Cell Lymphoma
Gross Morphology
Large polypoidal or ulcerated circumferential tumor mass of DLBCL is seen in small intestine (Fig. 20.41).
Light Microscopy
Tumor is composed of sheets of large lymphoid cells with vesicular nuclear chromatin, prominent nucleoli, irregular contours and scanty cytoplasm (Fig. 20.42).

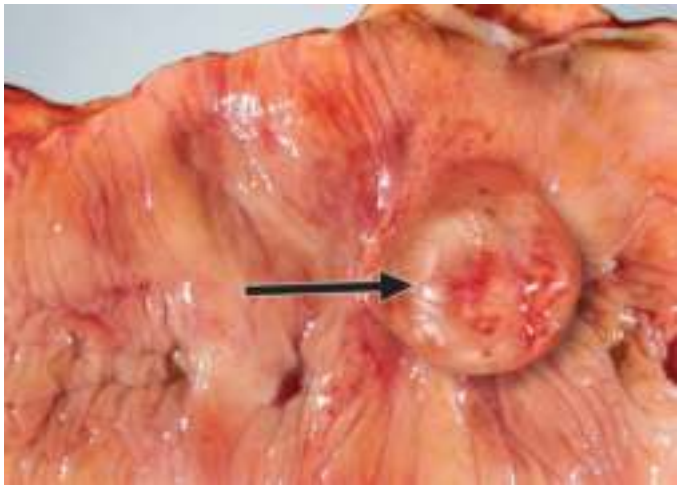

Fig. 20.39: Gastrointestinal stromal tumor. It shows well circumscribed tumor projecting towards lumen of intestine (arrow). Cut surface of tumor may show hemorrhage and necrosis.

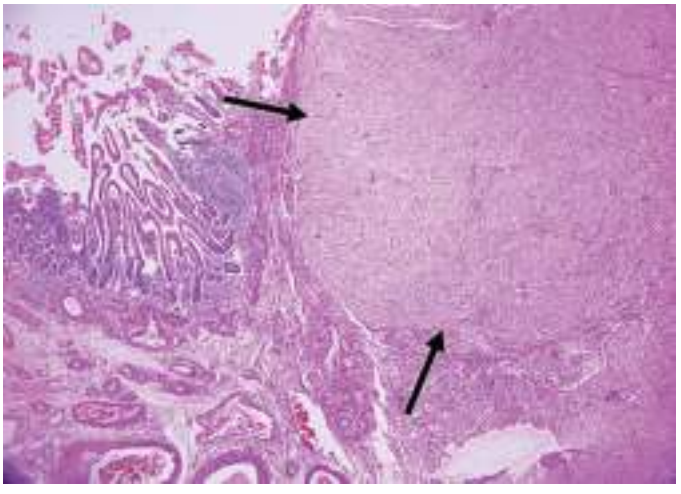

Fig. 20.40: Gastrointestinal stromal tumors. Tumor is composed of epithelioid and spindle cells arranged in sheets. Tumor lacks pleomorphism and mitosis (arrows) (100X).

Table 20.45 Proposed guidelines for predicting malignant behavior of gastrointestinal stromal tumors

Tumor Size	Light Microscopy	Clinical Behavior	Metastases and Mortality
≤2 cm	≤5 mitoses/50 HPF	Benign course	Prognosis excellent
≤2 cm and ≥5 cm	≤5 mitoses/50 HPF	Low malignant potential	Metastases and fatal outcome (4%)
≥5 cm and ≤10 cm	≤5 mitoses/50 HPF	Moderately malignant	Metastases and fatal outcome (25%)
>10 cm	≤5 mitoses/50 HPF	Highly malignant	Metastases and fatal outcome (50–90%)

Fig. 20.41: Large polypoidal and ulcerated circumferential tumor mass of diffuse large B cell lymphoma is seen in small intestine (arrows).

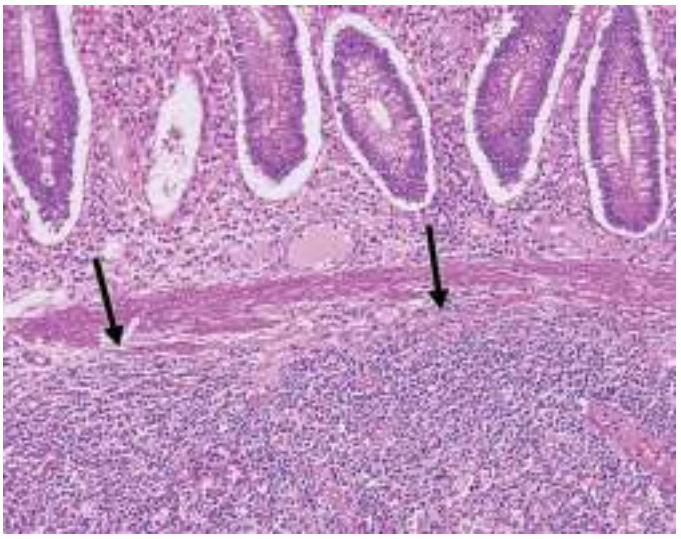

Fig. 20.42: Diffuse large B cell lymphoma. Tumor is infiltrating intestinal mucosa and composed of sheets of large atypical lymphoid cells (arrows) (400X).

DISORDERS OF LARGE INTESTINE

ANATOMY AND PHYSIOLOGY

Large intestine measures 1.5–1.8 meters in length extending from ileocecal valve to dentate line of the anal canal. It consists of right and left colon. Right colon is subdivided into cecum, ascending colon and proximal transverse colon.

- Left colon consists of distal transverse colon, descending colon, sigmoid colon and rectum. Rectum measures 10.5–12 cm in length.
- Transverse colon always has mesentery. Mesentery is seen in ascending colon in 12% and descending colon in 22% of cases.

BLOOD SUPPLY

Superior mesenteric artery supplies blood to the right colon as far as distal transverse colon. Inferior mesenteric artery supplies blood to left colon and rectum. Remainder of the rectum and anal canal are supplied by middle rectal arteries and branches of the pudendal arteries.

HISTOLOGY

Large intestine consists of mucosa, submucosa, muscular coat and serous coat. Mucosa of colon is lined by simple columnar epithelium with thin brush border and numerous goblet cells. The crypts of Lieberkühn are straight and branched lined by goblet cells. At the base of the crypts endocrine and undifferentiated cells are present.

- Mucosa absorbs some ions, soluble compounds and maintains water balance. It secretes mucus, which lubricates colon and protects mucosa. Mucosa breaks down undigested carbohydrates, proteins, and amino acids into products that can be expelled in feces or absorbed and detoxified by liver.
- Large intestine synthesizes certain vitamins of B complex and vitamin K. Muscular layer moves contents along length of colon into sigmoid colon and rectum by contraction of circular and longitudinal muscles.

NEUROMUSCULAR DISORDERS

HIRSCHSPRUNG'S DISEASE

Hirschsprung's disease, also referred as congenital megacolon, is characterized by congenital absence of ganglion cells usually in the submucosal and muscular coat of large bowel (distal sigmoid colon and rectum). It most often affects male infants in 80% of cases (Fig. 20.43).

Predisposing Factors

Hirschsprung's disease is associated with Down syndrome and Waardenburg syndrome. Waardenburg syndrome is characterized by congenital deafness, gut malrotation, gastric diverticulum, intestinal atresia, urogenital abnormalities and cardiovascular abnormalities. Acquired megacolon may be associated with Chagas' disease.

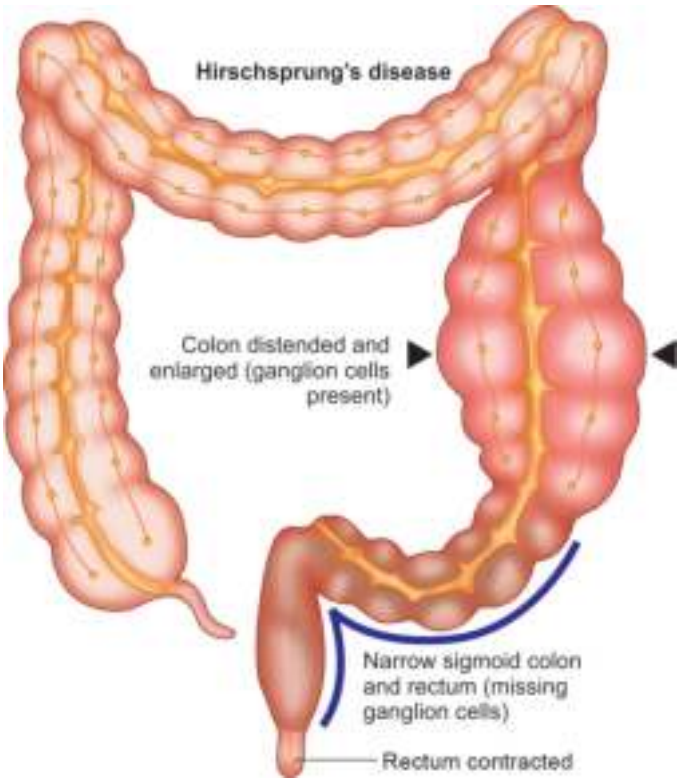

Fig. 20.43: Hirschsprung's disease. It shows narrow sigmoid colon absence of ganglion cells and dilated normal colon with presence of ganglion cells proximal to constricted segment.

Molecular Genetic Alterations

RET gene located on 10q11.2 is the most common gene mutation demonstrated in Hirschsprung's disease. Other gene mutations in this disorder include EDNRB gene (located on 13q22), SOX10 (located on 22q13), SIP1 gene (located on 2q22), PHOX2B gene (located on 4q12) and neuregulin gene (located on 8).

EDNRB gene present on surface of cells encodes protein that connects the neural crest cells to digestive tract. Interaction of endothelin 3 with endothelin receptor type B protein is essential for development of enteric neurons. Gene mutations in Hirschsprung's disease are given in Table 20.46.

Table 20.46 Gene mutations in Hirschsprung's disease

Gene Mutation	Located on Chromosome
RET gene	10q11.2
EDNRB gene	13q22
SIP1 gene	2q22
PHOX2B	4q12
Neuregulin gene	8

Pathogenesis

Marked dilation of the colon (ganglionic segment) occurs proximal to the stenotic rectum (aganglionic segment), with clinical signs of intestinal obstruction.

- **Physiologic state:** During intrauterine life, the neural crest cells migrate into upper alimentary tract and then follow caudally via vagus nerve fibers by 12 weeks of gestation. These ganglion cells are present in submucosa (Auerbach's plexus) and between muscular coats (Meissner's plexus). Ganglion cells are responsible for the peristaltic moment of the intestine in postnatal life.
- **Pathologic state:** Failure of migration of ganglion cells in the submucosal (Auerbach's plexus) and muscular coat (Meissner's plexus) in the large intestine, especially rectum results in Hirschsprung's disease. Immune-mediated neuronal necrosis has been suggested in the pathogenesis of Hirschsprung's disease, that shows aberrant expression of MHC class II molecules in colon responsible for recurrence of disease after surgery.

Colon Sites Involved

Rectum is always involved and hence the preferred site for biopsy. Sigmoid colon and adjacent proximal colon are involved, but entire colonic involvement very rare. Aganglionic segment of colon is permanently contracted causing intestinal obstruction, which leads to dilatation of proximal normal (ganglionic) segment.

Classification

Based on length of large intestine in Hirschsprung's disease involved, infant has classic segment (<40 cm colon), long segment (colon involvement extending to small intestine), short segment (a few cm of colon involved), ultra-short (<2 cm colon involved) and zonal form (skip areas in colon).

Clinical Features

Newborn with Hirschsprung's disease develops delayed passage of meconium, severe constipation, vomiting and abdominal distension. There may be electrolyte imbalance, peritonitis, superimposed enterocolitis, toxic megacolon and perforation.

On clinical examination, anal canal and rectum are small devoid of stool with tight anal sphincter. Abdominal distension, radiograph and barium enema findings in Hirschsprung's disease are shown in Fig. 20.44A to C.

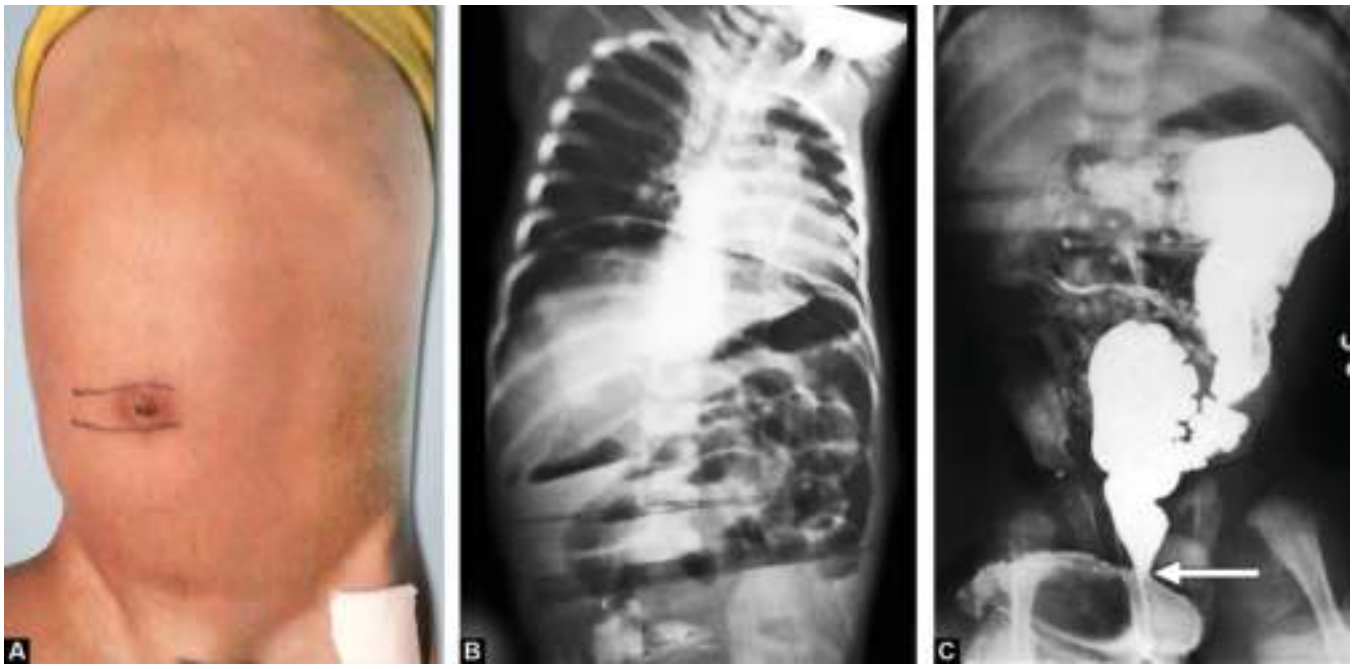

Fig. 20.44: Hirschsprung's disease. (A) Child shows abdominal distension, (B) abdominal radiograph shows dilated loops with multiple air fluid levels suggestive of intestinal obstruction, (C) barium enema shows cone-shaped transition zone at the rectosigmoid junction (arrow).

Surgical Pathology: Hirschsprung's Disease	
Gross Morphology	
▪ Sigmoid colon and rectum (aganglionic bowel) are narrowed due to absence of ganglion cells. ▪ Proximal segment of colon (ganglionic bowel) is dilated (Fig. 20.45).	
Light Microscopy	
Narrowed distal segment shows complete absence of ganglion cells in submucosa (Auerbach's plexus) and muscular coat (Meissner's plexus). It is accompanied by hypertrophy of nerves (Fig. 20.46).	
Immunohistochemistry Technique	
▪ Identification of ganglion cells may be difficult in neonates due to immaturity of the ganglion cells. ▪ Ganglion cells are positive for neuron-specific enolase (NSE). Hypertrophied nerve bundles are positive for S-100, and cathepsin D. ▪ Another promising marker is calretinin, a vitamin D-dependent calcium binding protein, absence of which has been seen in Hirschsprung's disease.	
Markers	**Expression**
▪ Neuron-specific enolase (for ganglion cells) ▪ S-100 protein (for nerve bundles) ▪ Cathepsin D (for nerve bundles) ▪ Calretinin (vitamin D-dependent calcium binding protein)	▪ Positive ▪ Positive ▪ Positive ▪ Positive

Laboratory Diagnosis

The diagnosis of Hirschsprung's disease is made clinically (chronic constipation in a young child) but must be confirmed by biopsy, which typically shows an absence of ganglion cells.

- **Rectal biopsy:** Rectum is always involved in Hirschsprung's disease and this is the preferred site for biopsy at least 2 cm above anal verge in infants and 3 cm above anal verge in children.

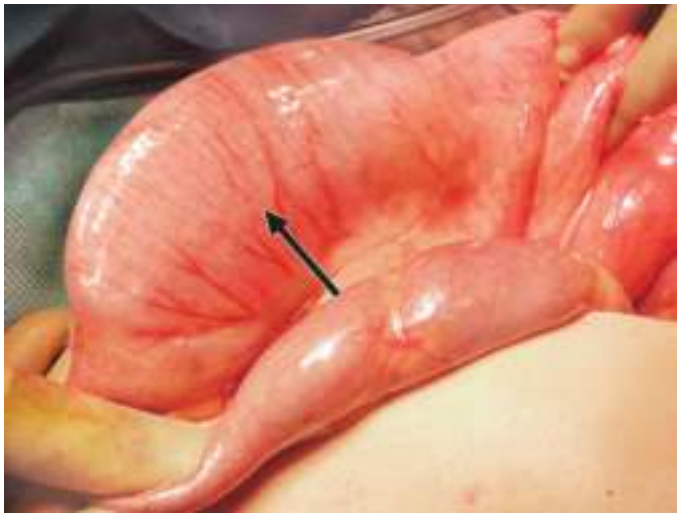

Fig. 20.45: Hirschsprung's disease. The baby of one week had been constipated since birth and exhibited signs of intestinal obstruction. Barium enema showed a narrowed lower rectal segment with dilated rectum above it. There were no ganglion cells in the narrowed segment (arrow). (*Courtesy:* Dr. Anusha S Bhatt.)

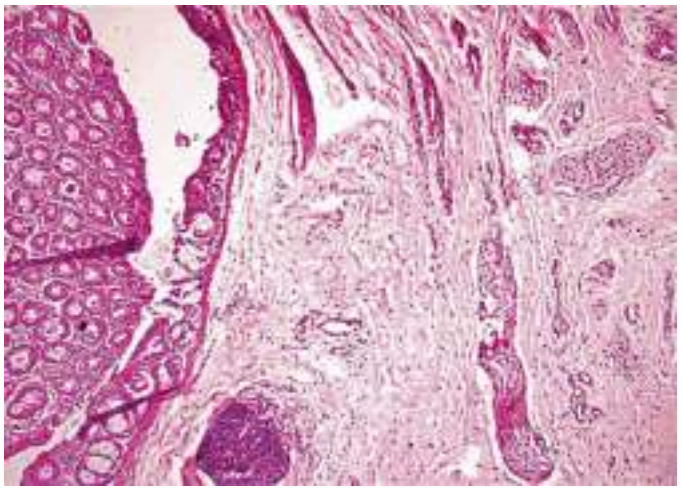

Fig. 20.46: Hirschsprung's disease. Punch biopsy from the rectosigmoid region shows increase in the number and size of nerve bundles in the submucosa with conspicuous absence of ganglion cells (100X).

- **Histologic examination:** Light microscopy shows absence of ganglion cells in the affected segment of intestine.
- **Imaging techniques:** Barium enema-contrast material flows into an unexpanded distal segment, then passes through a cone-shaped area and finally enters the dilated proximal bowel.
- **Electromanometry:** It is only useful to confirm the diagnosis in cases of ultra-short segment of Hirschsprung's disease.
- **Frozen section:** Acetylcholinesterase is used to demonstrate marked increase in thick nerve fibers in the wall of affected intestine. Ratio of acetylcholinesterase to butyryl cholinesterase is increased in Hirschsprung's disease.

Surgical Treatment

The part of the intestine that does not contain ganglion cells must be resected.

PSEUDO-OBSTRUCTION SYNDROME

Pseudo-obstruction syndrome is a heterogeneous group of neuromuscular disorders characterized by colonic inertia and constipation.

Diagnosis is really a challenge. Careful evaluation of nerves or muscle fibers of the muscularis propria on histopathologic examination, special stains and clinical correlation help in establishing diagnosis.

DIVERTICULAR DISORDERS

DIVERTICULOSIS

Diverticulum is pulsion (or false) herniation of pockets of mucosa and submucosa through the defects in weakened muscular propria throughout the colon along the antimesenteric taeniae coli, where arteries penetrate the muscular propria.

Locations

Diverticula are almost always multiple. Diverticulosis most often occurs in the sigmoid colon in 85% of cases. Sigmoid diverticular disease is the most common cause of hematochezia (bright red blood in stool) from lower intestinal tract and colovesical fistulas. Diverticulum disease of large intestine is shown in Fig. 20.47.

Pathogenesis

Diverticuli occur due to increased intraluminal pressure presumably due to low fiber content in diet especially in older persons. These diverticuli are pulsion diverticula that form two rows along the antimesenteric taeniae coli at the site, where arteries perforate the muscular propria. These are most common in men older than age 40 and in people who eat a low fiber diet.

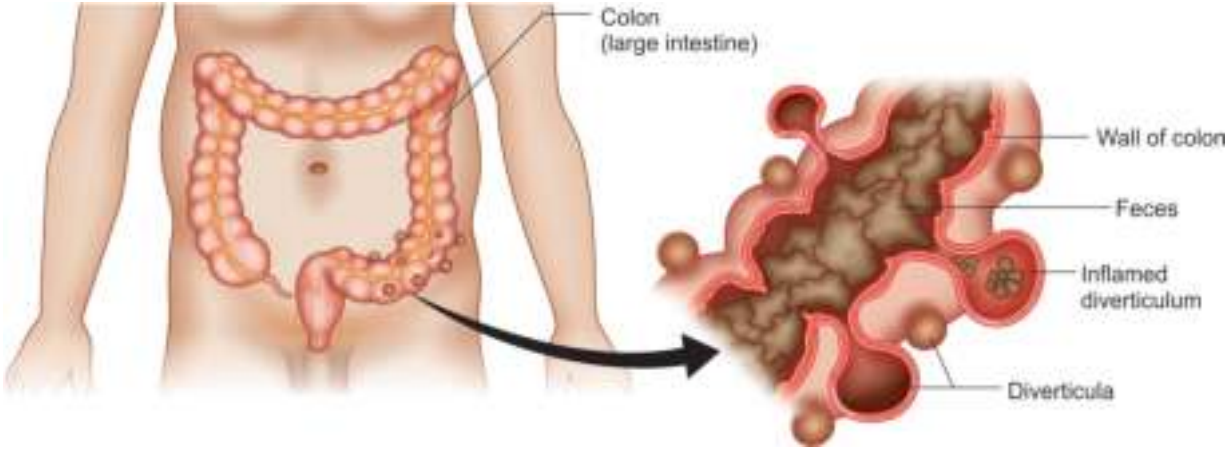

Fig. 20.47: Diverticulum disease of large intestine.

Clinical Features

Patient with diverticulosis most often becomes asymptomatic and will remain so unless diverticulitis develops.

- Diverticulitis results from the irritation caused by retained fecal material that obstructs the lumen of a diverticulum.
- Long-standing cases present with ribbon-like stools, intermittent diarrhea, abdominal distension, abdominal rigidity and pain, nausea, vomiting with diminishing or absent bowel sounds. Clinical features of diverticular disease of large intestine are given in Table 20.47.

Complications

Complications of diverticular disease include acute inflammation, perforation, fistula, stricture and bleeding. Complications of diverticular disease are given in Table 20.48.

Diagnosis

Diverticular disease is diagnosed by double contrast barium enema and colonoscopy. Fistulas are demonstrated by barium enema radiologic examination. Most diverticular abscesses are confirmed by ultrasonography.

Table 20.47 Clinical features of diverticular disease of large intestine

Disorder	Clinical Features
Diverticulosis	▪ Asymptomatic lesion ▪ Colicky abdominal pain ▪ Altered bowel habit
Acute diverticulitis	▪ Constant abdominal pain ▪ Fever ▪ Nausea and vomiting ▪ Bleeding ▪ Altered bowel habit ▪ Localized or generalized abdominal pain

Laparotomy is performed for generalized peritonitis to remove pus and feces.

Table 20.48 Complications of diverticular disease

Complications	Clinical Findings
Acute inflammation	▪ Abscess formation ▪ Peritonitis (local or generalized)
Perforation	▪ Local fecal peritonitis ▪ Generalized fecal peritonitis
Fistula	▪ Colovesical fistula ▪ Colovaginal fistula
Stricture	Stricture formation
Bleeding	Bleeding from diverticuli

Radionuclide imaging and arteriography are performed to localize the source of bleeding as well as angiodysplasia.

DIVERTICULITIS

Diverticulitis refers to inflammation of diverticula. It commonly affects elderly persons. In diverticulitis, retained undigested food and bacteria accumulate in the diverticular sac.

Pathogenesis

Colonic bacteria attack the thin walls of the diverticulum resulting in perforation, peritonitis (most serious complication), abscess formation, bowel obstruction, or hemorrhage. Occasionally, the inflamed colon segment may adhere to the bladder or other organs and cause a fistula.

Clinical Features

Patient presents with lower abdominal pain, tenderness, and bright red rectal bleeding (most frequent finding). Patient has other signs of acute inflammation such as fever and leukocytosis.

OBSTRUCTIVE DISORDERS

INTESTINAL OBSTRUCTION

Intestinal obstruction refers to partial or complete obstruction of the bowel lumen. Obstruction of small intestine is more serious. Most common cause of bowel obstruction is adhesions from previous surgery. It may also occur due to congenital bowel deformities. Bowel obstruction is of three kinds: intraluminal (e.g. tumor, foreign bodies), intramural and extraintestinal.

Pathology

In initial phase of bowel obstruction peristalsis temporarily increases in attempt to force contents past obstruction. Bowel distension impedes venous blood supply to bowel, halting normal absorptive processes.

- Bowel wall swells and becomes edematous as water, sodium, and potassium are secreted into intestine and not absorbed from it.
- Gas-forming bacteria collect above obstruction enhancing distension. Untreated patient develops severe hypovolemia and sepsis with fatal outcome.

Clinical Features

Patient suffering from bowel obstruction presents with colicky pain followed by a pain-free interval accompanied by constipation and inability to pass gas (flatus). Untreated complete obstruction of the large

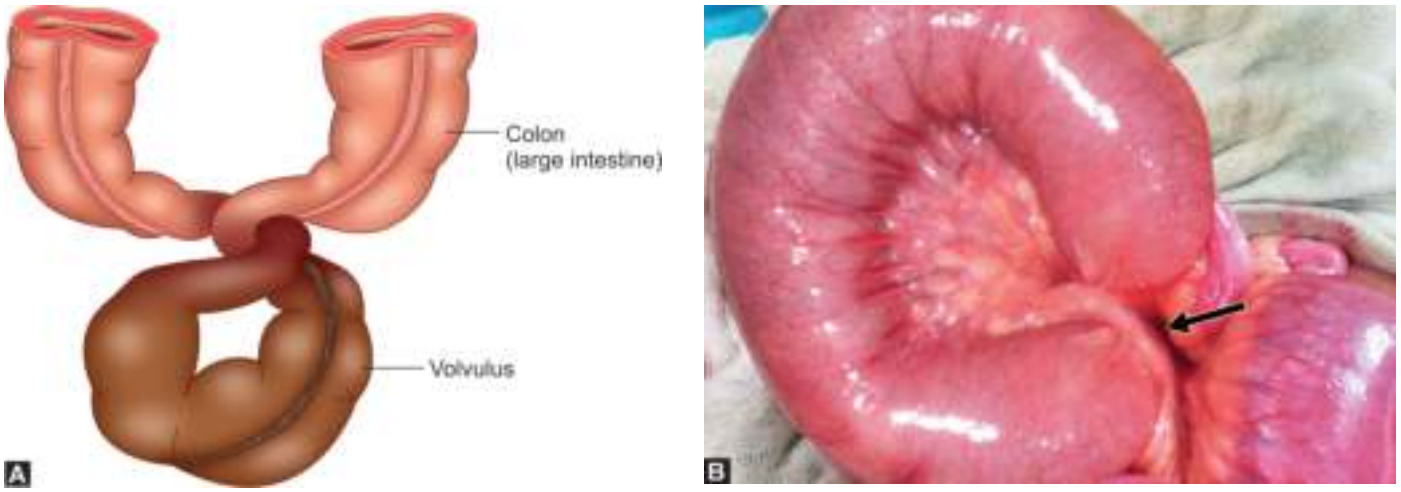

Fig. 20.48: (A) Volvulus shows twisting of a mobile segment of the intestine, (B) its mesenteric root (arrow).

bowel can cause death within hours due to shock and vascular collapse. Ultimately, bowel obstruction may lead to ischemia, necrosis, and death.

VOLVULUS

Volvulus is twisting of a mobile segment of the intestine on its mesenteric root. It occurs in sigmoid colon (most common site) and small intestine. The twist is counterclockwise in most cases. Volvulus is always a consequence of congenital anomaly.

Pathology

During intrauterine life, defective intestine rotation results in abnormal positions of the small intestine and colon, anomalous attachments, and bands. Kinking of bowel interrupts the blood supply resulting in bowel infarction, intestinal gangrene and obstruction. Volvulus shows twisting of a mobile segment of the intestine on its mesenteric root is shown in Fig. 20.48A and B.

INTUSSUSCEPTION

An intussusception is an invagination of one segment of proximal bowel (usually the terminal ileum) into the distal bowel (usually the cecum), causing intestinal obstruction. Colo-colic intussusception is relatively uncommon. The inner loop of the gut may become necrotic unless the invagination is everted surgically.

- Intussusception is most common cause of intestinal obstruction in children <2 years of age due to active peristalsis.
- In adults, intussusception occurs due to organic cause such as pedunculated polyps or malignant tumor growth. Small pedunculated tumors carried by peristalsis may pull forward the loop to which such a tumor is attached.

Clinical Features

Child presents with signs of obstruction (colicky pain) and rectal bleeding (currant jelly stools) from bowel infarction.

INFLAMMATORY BOWEL DISEASE

INFLAMMATORY BOWEL DISEASE: OVERVIEW

Inflammatory bowel disease (IBD) comprises two diseases: ulcerative colitis (most common) and Crohn's disease of unknown etiology, however psychological, infectious and autoimmune factors have been implicated.

- Ulcerative colitis and Crohn's disease share many features, but may differ from one another. The diagnosis is made by exclusion and correlating all the clinical, endoscopic, radiologic findings.
- Peak incidence of IBD is observed in the same age group (15–25 years). Females are more affected than males in 20–25 years of age group. There is family history of inflammatory bowel disease in 20% of cases. Features of inflammatory bowel disease are shown in Fig. 20.49A and B and pathogenesis of inflammatory bowel disease is shown in Fig. 20.50.
- Inflammatory bowel disease is associated with intestinal complications and extraintestinal manifestations.

Clinical Pearls: Inflammatory Bowel Disease (IBD)

- **Inflammatory bowel disease:** Ulcerative colitis and Crohn's disease can present with abdominal pain, bloody diarrhea, fever and weight loss. Involvement of colon can lead to colon cancer. Screening colonoscopy should be performed every 1–2 years after 8–10 years of colonic involvement.

- **Clinical features:** Patient suffering from ulcerative colitis most often presents with abdominal pain and bloody diarrhea. Crohn's disease presents with involvement of upper gastrointestinal tract, masses, skip lesions, fistulous tracts, obstruction, transmural granulomas, malabsorption of fats and vitamin B_{12}, perianal disease, cholesterol gallbladder stones. Extraintestinal manifestations of IBD are arthralgia, ocular lesions (iritis, uveitis), sclerosing cholangitis and skin lesions (pyoderma gangrenosum, erythema nodosum).
- **Laboratory findings:** Serum anti-*Saccharomyces cerevisiae* (ASCA) is positive in ulcerative colitis and negative in Crohn's disease. Serum antineutrophil cytoplasmic antibody (ANCA) is negative in ulcerative colitis and positive in Crohn's disease.
- **Treatment:** Steroids can be used to control acute exacerbations of inflammatory bowel disease. Ulcerative colitis is cured by colectomy. TNF inhibitors (e.g. adalimumab, certolizumab, etanercept, golimumab, infliximab) control Crohn's disease associated with fistula formation. TNF inhibitors reactivate tuberculosis. Patient should be screened for tuberculosis. Always screen the patients with a PPD prior to its use in fistulizing Crohn's disease. Azathioprine and 6-mercaptopurine are administered in severe disease with recurrent symptoms.

Locations

Ulcerative colitis begins in the rectum (friable red mucosa) and extends in continuity to involve part or

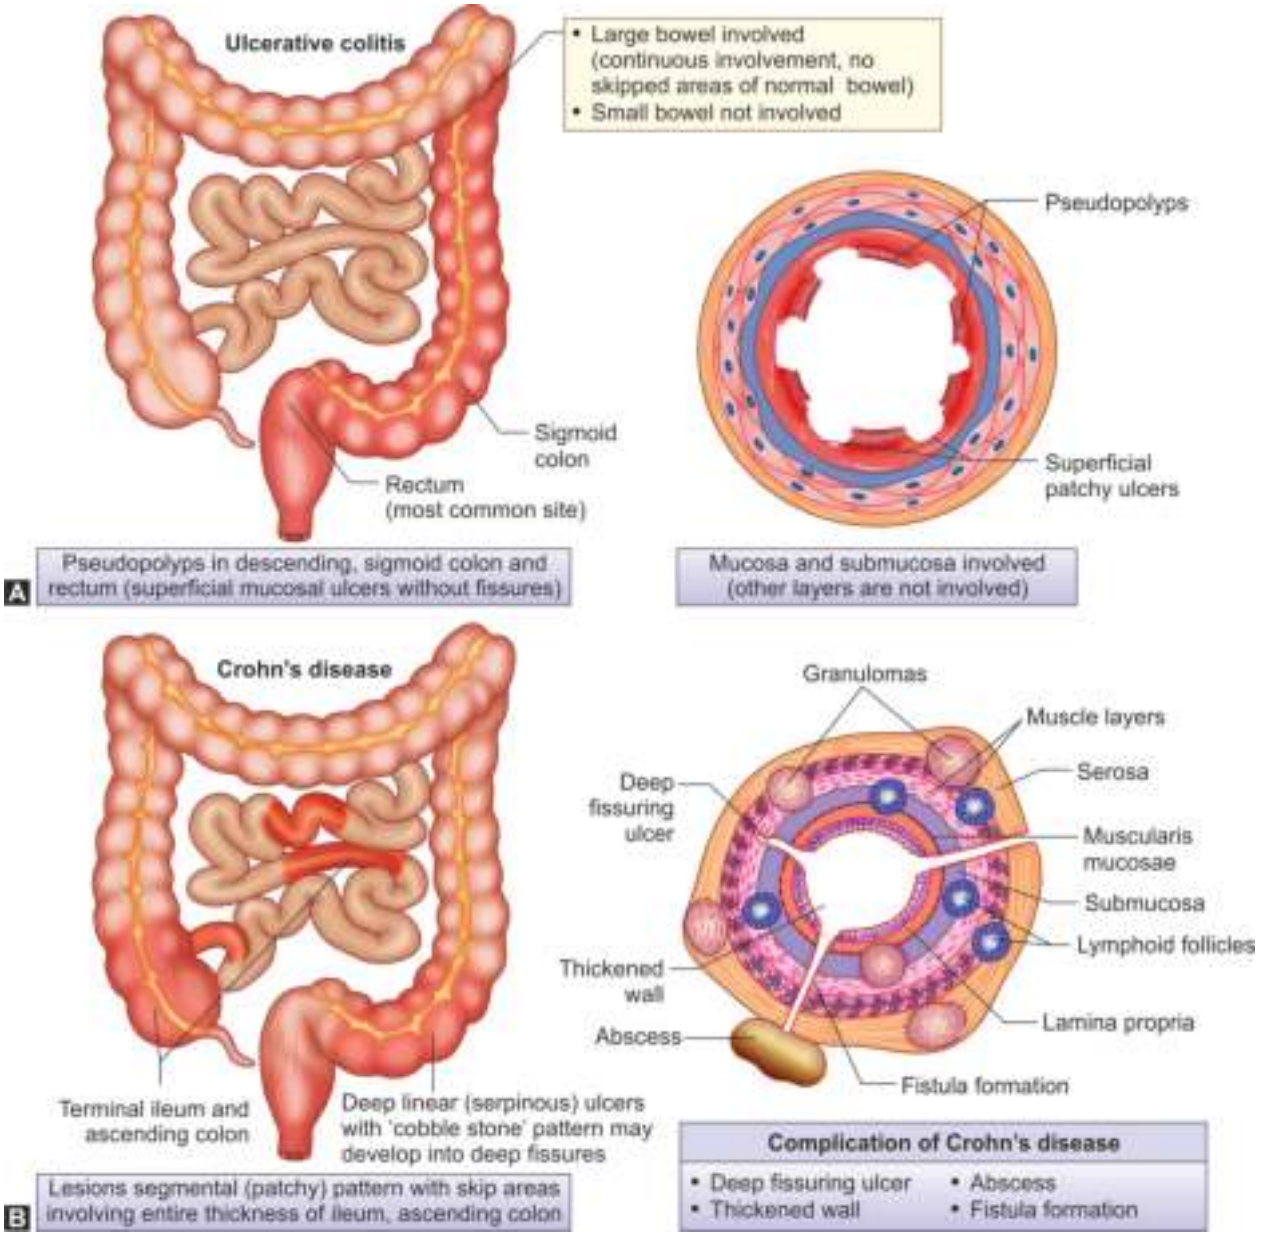

Fig. 20.49: Features of inflammatory bowel disease (IBD). (A) It shows ulcerative colitis, (B) it shows Crohn's disease.

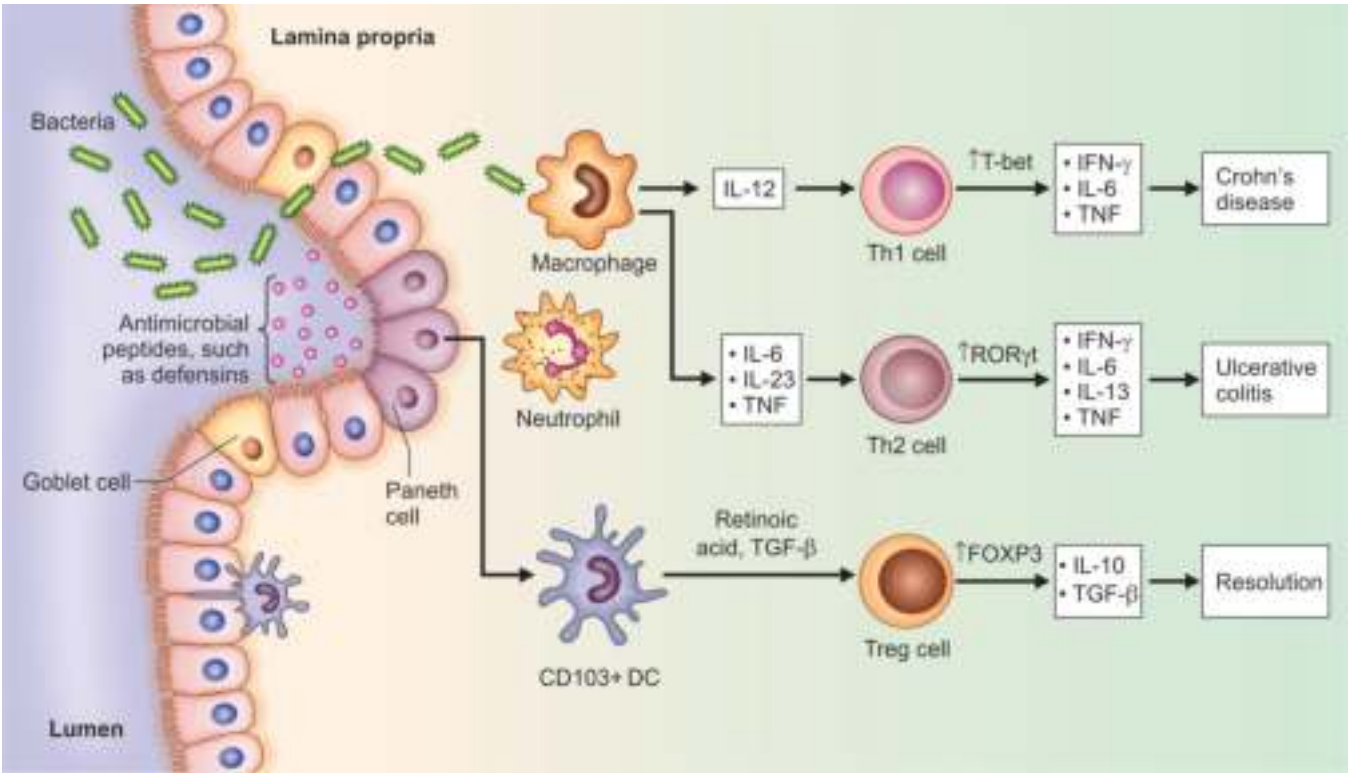

Fig. 20.50: Pathogenesis of inflammatory bowel disease.

the entire colon. On the other hand, Crohn's disease involves terminal ileum (30%), colon and small bowel (50%), colon alone (20%) having discontinuous/skipped involvement of the bowel.

Surgical Pathology: Inflammatory Bowel Disease

Gross Morphology

- In ulcerative colitis, mucosa and submucosa of the rectum, colon and appendix show ulcerations forming pseudopolyps. There is absence of fistulae formation. Anus is not commonly involved.
- Crohn's disease involves all layers of small or large intestine.

Light Microscopy

- Ulcerative colitis produces crypt abscesses due to accumulation of neutrophils resulting in rupture and crypt atrophy.
- Crohn's disease is associated with noncaseating granulomas in 50% of cases, lymphoid aggregates, and aphthoid mucosal ulcers. Involvement of the ileum also favors Crohn's disease.

Endoscopy

Ulcerative colitis produces ulceration of colon with pseudopolyp formation due to bulging of inflamed mucosa surrounded by areas of ulceration.

Crohn's disease produces linear ulcers, cobble stone appearance, luminal narrowing (string signs on barium studies), and fistula formation.

Complications

Ulcerative colitis most often results in colon adenocarcinoma in an inflammation-dysplasia-carcinoma sequence.

- On the other hand, conventional colorectal carcinoma develops in an adenoma-carcinoma sequence. HLA-B27 positive patient may develop ankylosing spondylitis, toxic megacolon and sclerosing cholangitis (increased risk with duration), HLA-B27 positive ankylosing spondylitis, toxic megacolon, and sclerosing pericholangitis.
- Crohn's disease may involve whole gastrointestinal tract from mouth to anus with formation of fissures and fistulae.

Extraintestinal Manifestations

Extraintestinal manifestations in patient with ulcerative colitis and Crohn's disease include uveitis, episcleritis, skin lesions, e.g. erythema nodosum, pyoderma gangrenosum and granulomatous inflammation; joint involvement, e.g. migratory polyarthritis, ankylosing spondylitis and sacroilitis; sclerosing cholangitis especially in ulcerative colitis; pulmonary lesion, e.g. bronchiectasis; and venous and arterial thromboembolism.

Clinical Features

Patient with ulcerative colitis presents with abdominal cramps, diarrhea with blood and mucus, rectal bleeding,

and tenesmus (ineffective and painful straining of stool).

On the other hand, patient with Crohn's disease presents with right lower quadrant colicky pain (obstruction) with diarrhea and anal bleeding. Differences between ulcerative colitis and Crohn's disease are given in Table 20.49.

ULCERATIVE COLITIS

Ulcerative colitis is chronic superficial inflammatory disease that affects the mucosa and submucosa of the colon and rectum resulting in mucosal ulcerations, pseudopolyps (mucosal remnants of previous severe ulceration) formation. Disease is of unknown etiology, which begins in the rectum and sigmoid colon, rarely

Table 20.49 Differences between ulcerative colitis and Crohn's disease

Character	Ulcerative Colitis	Crohn's Disease
Gross morphology		
Distribution	▪ Diffuse pattern (continuous without skip lesions) ▪ Sigmoid colon (common) ▪ Ileum involvement (<10%) ▪ Rectum always involved ▪ Upper GIT involvement (usually absent)	▪ Segmental (patchy) pattern with skip lesions ▪ Terminal ileum and ascending colon (common) ▪ Ileum involvement common ▪ Rectum always spared ▪ Upper GIT involvement (may be with lesions from mouth to anus)
Lumen of intestine	Dilated megacolon	Stenosis (string sign)
Depth of inflammation	Mucosal and submucosal layers (superficial lesions)	Transmural (entire thickness) involvement
Bowel wall thickness	Thin	Thickened or normal
Creeping mesenteric fat	Absent	Present (common finding)
Mucosal surface appearance	Friable, hemorrhagic, ulcerated and pseudopolyps (common finding)	Deep linear patchy ulceration; cobblestone-like appearance, but formation of pseudopolyps rare
Ulcers formation	Superficial mucosal ulcers without fissures	Deep linear ulcers with formation of deep fissures
Submucosa	Normal to reduction in width	Widened due to edema and lymphoid aggregates
Muscular layer	Usually spared except in cases of megacolon	Always involved showing presence of noncaseating granuloma in 60% cases
Serous layer	Normal (smooth)	Inflammation present
Complications		
Ulceration of mouth and stomach	Absent	May be present in 1–5% cases
Fibrous strictures	Never	Common due to fibrosis
Fistula formation and sinus tracts	Extremely rare	Internal and external fistulas in 10% cases
Toxic megacolon	Present (hypotonic and distended bowel)	Absent
Perianal abscess and fistula	Absent	Present in 50% of cases
Malignant change	May occur infrequently in disease of more than 10 years duration	Present in 1% cases
Type of malignancy	Carcinoma is more common than lymphoma	Lymphoma is more common than carcinoma
Light microscopy		
Crypt abscess	Present in mucosa	Absent in mucosa
Inflammatory cells	Nonspecific acute and chronic inflammatory cells (e.g. lymphocytes, plasma cells, neutrophils, eosinophils and mast cells) confined to mucosa and submucosa	Chronic inflammatory cells (e.g. lymphocytes, plasma cells and macrophages) forming lymphoid aggregates are seen involving all layers of intestine (transmural)
Well-formed granulomas	Absent	Most often present in 60% cases in muscular coat
Transmural lymphoid aggregates	Absent	Common

Contd...

Table 20.49 Differences between ulcerative colitis and Crohn's disease (*Contd...*)

Character	Ulcerative Colitis	Crohn's Disease
Immunologic features		
Lymphocytes	CD4+, Th2	CD4+, Th1
Cytokines	IL-4, IL-5, IL-13 and TGF-β	IL-12, TNF-α and IFN-γ
ANCA-P antibodies	Positive in most cases (70%)	Positive in a few cases
Clinical features		
Age group	Young adults	Young adults
Gender predilection	No gender predilection	Women > men
Clinical findings	Recurrent left-sided abdominal cramping with bloody diarrhea and mucus	Recurrent right lower quadrant colicky pain (obstruction with diarrhea)
Primary sclerosing cholangitis	More common	Less common
Antibodies to *Saccharomyces cerevisiae*	Negative	Positive

affects terminal ileum. The disease cycles between exacerbation and remission.

Age Group

Ulcerative colitis occurs primarily in young adults (15–30 years) and then 55–65 years of age.

Clinical Features

Patient presents with recurrent bloody diarrhea with mucus (hallmark), abdominal cramping, tenesmus (ineffective and painful straining of stool), weight loss, anorexia, nausea, vomiting, and weakness.

Surgical Pathology: Ulcerative Colitis

Gross Morphology

- Ulcerative colitis is characterized by superficial ulcerations limited to mucosa and submucosa of large intestine.
- It begins in the rectum (friable red mucosa) and extends in continuity to involve part or the entire colon.
- Ulcerative colitis does not involve the mucosa of the anal transitional zone or the anal canal.
- Ulceration in colon is continuous in its distribution, so skip lesions are not encountered (Fig. 20.51A and B).

Light Microscopy

Colon mucosal biopsy in a patient with ulcerative colitis is performed for assessment of disease activity, surveillance of dysplasia and exclusion of other superimposed disease processes.

Colonic changes are confined to mucosa and submucosa in ulcerative colitis. Histologic changes depend on progression of disease (Fig. 20.52A and B).

- **Abscesses formation:** Rectum and colon show extensive ulceration of mucosa and submucosa. Mucosa shows hyperemia resulting in mucosal friability. Exudative inflammation leads to crypt abscesses formation in colon. Polymorphonuclear cells are particularly evident as aggregates within distended crypts (crypt abscess) of Lieberkühn resulting in rupture and atrophy. Initially, the colon's mucosal surface becomes dark, red, and velvety.
- **Ulcers formation:** Abscesses form and coalesce into ulcers. The ulcers are irregular in outline involving mucosa and submucosa, but in severe cases there is extension into the main muscular coat and perforation is likely. The ulcers expand and coalesce involving large areas. Ulcerations are continuous unlike Crohn's disease. Sloughing of mucosa results into bloody mucus filled stools.
- **Healing stage:** The intestinal wall becomes thickened and fibrosed. As granulation tissue replaces the muscle layer, the colon narrows, shortens, and loses its characteristic pouches (haustral folds). Colon shows formation of pseudopolyps due to mucosal remnants of previous severe ulceration.

Complications

HLA-B27 positive persons develop ankylosing spondylitis, toxic megacolon, and sclerosing pericholangitis in ulcerative colitis cases. Presence of ulcerative colitis-associated dysplasia is usually indication for colectomy. Complications of ulcerative colitis are given in Table 20.50.

- **Acute complications of ulcerative colitis:** These include toxic megacolon (medical emergency-marked dilation of colon), perforation, hemorrhage, and dehydration due to electrolytes imbalance.
- **Chronic complications of ulcerative colitis:** Patient may develop anemia (bloody diarrhea) and colon adenocarcinoma (increased risk with duration 5–10% per decade of pancolitis). HLA-B27 positive persons develop ankylosing spondylitis, and sclerosing pericholangitis.

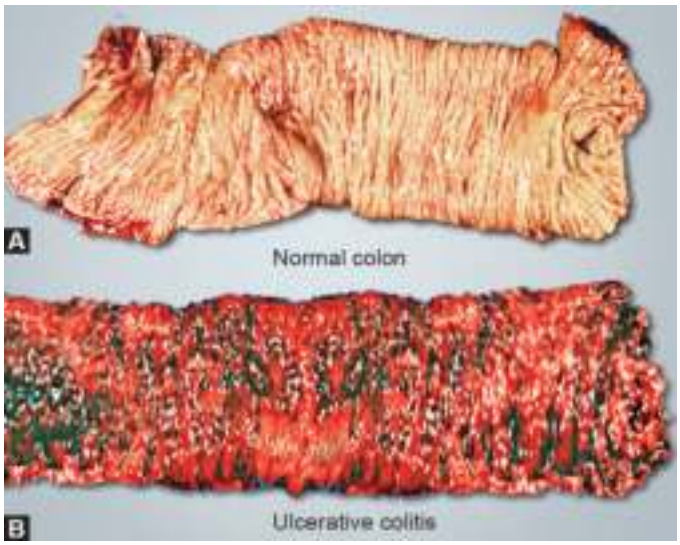

Fig. 20.51: Ulcerative colitis. (A) Normal colon, (B) ulcerative colitis with pseudopolyps formation as a result of intense inflammation of mucosa and submucosa. Inflammation begins in the rectum involving sigmoid colon and extends upward and around to the ascending colon.

Laboratory Diagnosis

The diagnosis of ulcerative colitis is made by exclusion and correlating all the clinical, endoscopic, radiologic, and pathologic findings.

Table 20.50 Complications of ulcerative colitis

Complications	Common Findings
Blood loss	▪ Acute hemorrhage ▪ Chronic hemorrhage leading to anemia
Electrolyte disturbances	Due to severe diarrhea in acute phase
Toxic megacolon	May develop insidiously
Colorectal carcinoma	Increased risk of colorectal carcinoma, if patient develops disease in childhood, with clinically severe attack, total involvement of the colon and continuous rather than intermittent symptoms
Skin	Erythema nodosum (subcutaneous inflammation)
Liver	▪ Pericholangitis (inflammation around bile ducts) ▪ Sclerosing cholangitis (fibrous constriction and obliteration of bile ducts) ▪ Cholangiocarcinoma ▪ Chronic active hepatitis
Eye	▪ Iritis ▪ Uveitis ▪ Episcleritis
Joints	Increased incidence of ankylosing spondylitis

CROHN'S DISEASE

Crohn's disease is one of the main entities in inflammatory bowel disease and is characterized by transmural chronic inflammation of terminal ileum (most common), ascending and sigmoid colon (20%). Disease may involve lymph nodes and supporting membranes. Presence of noncaseating granulomas in ileum favors Crohn's disease. It can affect different regions of the bowel, stomach, or intestines. There are five different types of Crohn's disease, each affecting different parts of the gastrointestinal tract: ileocolitis, ileitis, gastroduodenal, jejunoileitis and Crohn's colitis.

Age Group

Crohn's disease affects men and women equally in 20–40 years of age group, although no age group is exempted. It also tends to run in families up to 20% of patients. It occurs most frequently in people of Jewish

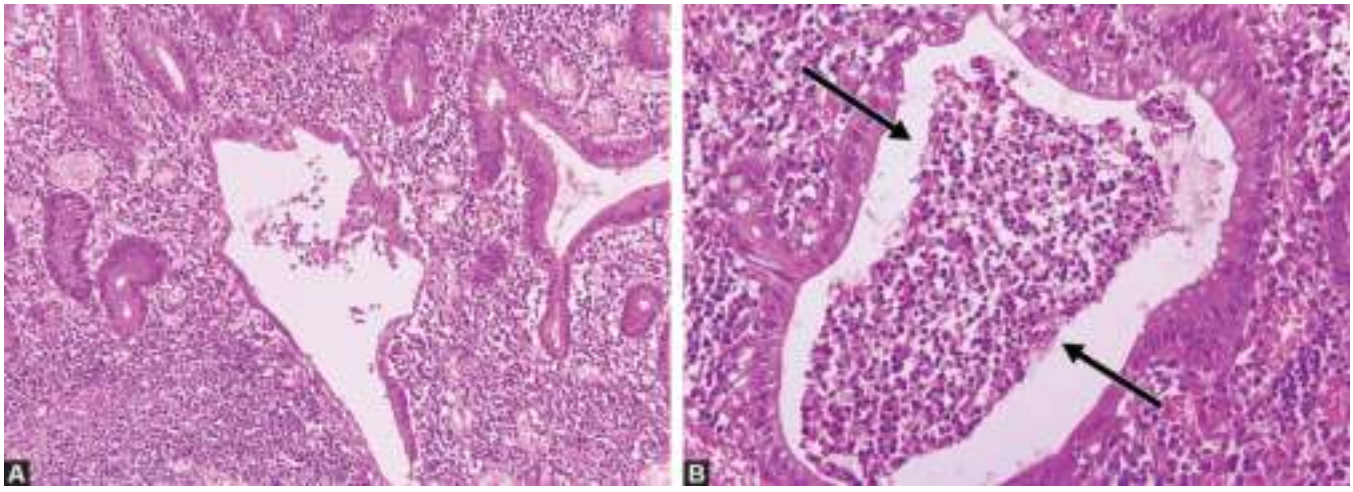

Fig. 20.52A and B: Ulcerative colitis. The intense inflammation of ulcerative colitis is confined primarily to the mucosa and submucosa. The colonic mucosal epithelium demonstrates loss of goblet cells. Crypt abscesses are a histologic finding more typical with ulcerative colitis (arrows) (400X).

descent. Neoplastic transformation is much less frequent in Crohn's disease than in ulcerative colitis.

Clinical Features

Patient presents with generalized abdominal pain especially in right lower quadrant, diarrhea, fever, malabsorption, weight loss, intestinal obstruction due to fibrous stricture, and pain or drainage near or around the anus due to inflammation and fistulas between loops of intestine and between the intestine, urinary bladder, vagina, and skin.

Pathology Pearls: Molecular Pathogenesis of Crohn's Disease

- Modern theory on the pathogenesis of Crohn's disease has proven that gut microbiota (ecological communities of commensal, symbiotic and pathogenetic microorganisms) and environmental factors lead to abnormal immune response in genetically predisposed patients.
- Genome-wide association analysis in patients with Crohn's disease worldwide demonstrated several genetic mutations that increase the risk for Crohn's disease.
- Gut microbiota is considered a compulsory and an essential part in the pathogenesis of Crohn's disease. Intestinal dysmicrobism with excessive amounts of different bacterial strains can be demonstrated in all patients of inflammatory bowel disease. The discovery of *Escherichia coli* entero-invasive on resection biopsies in patients with Crohn's disease now increases the likelihood of antimicrobial or vaccination-type treatments.
- Recent studies on Crohn's disease has been focused on intestinal immunology such as molecular activation pathways and targeted therapy.
- Leukocyte adhesion inhibitors block the leukocyte homing mechanism and prevent cellular immune response.
- Clinical trials are going on treatment of Crohn's disease with anti-integrin antibodies, chemokine receptor antagonists and SMAD4 antisense oligonucleotides. MicroRNAs are disease biomarkers of Crohn's disease.
- Chronic inflammation involves all layers of the intestinal wall (transmural involvement) in Crohn's disease described as under:
  - **Cobblestone appearance of mucosa:** Lymphatic channels of submucosa blocked by enlarged lymph nodes result in edema linear mucosal ulcers oriented along long axis of intestine. Elevation of surviving mucosa between the ulcers gives nodular cobblestone appearance. Submucosal edema, abscesses, later fibrosis and fissures are also seen.
  - **String sign:** Fibrosis of intestinal wall causes thickening and narrowing of the lumen. Intestinal lumen shows narrowing is demonstrated as 'string sign' on barium studies.
  - **Noncaseating epithelioid cell granulomas:** These are seen in 50% of cases.
  - **Skipping lesions:** Crohn's disease has skipping lesions (ulcerations) on the mucosa while ulcerative colitis has continuous lesions.
  - **Oval elevated patches in mucosa:** Peyer's patches of small intestine are also inflamed, exhibiting oval elevated patches.
  - **Inflammation of serous coat:** Serous coat of intestine is inflamed, that gets adhered to other intestinal loop.
  - **Strictures:** Strictures are formed in the involved bowel due to thickening, shortening and narrowing.
  - **Fistulous tract:** Narrow fissures formed may penetrate deep and forms fistulous tract with adjacent loop of gut.

Surgical Pathology: Crohn's Disease

Gross Morphology

- Wall of the gut shows thickening due to inflammation, fibrosis and hypertrophy of the muscular coat giving rubbery appearance and stricture formation.
- Crohn's disease produces skipped lesions. Linear mucosal ulcers are oriented along long axis. Mucosa between the ulcers gives nodular cobblestone appearance. Narrow fissures formed may penetrate deep and form fistulous tract with adjacent loop of gut (Fig. 20.53A and B).

Light Microscopy

- Histologic examination shows transmural inflammation composed of lymphocytes, plasma cells and histiocytes.
- Submucosa and subserosa of the gut show noncaseating granulomas, and lymphoid aggregates, which may also be seen in regional lymph nodes (Fig. 20.54).

Comparison of histologic features useful in differential diagnosis of Crohn's disease and intestinal tuberculosis is given in Table 20.51.

COLITIS: OTHER CAUSES

PSEUDOMEMBRANOUS COLITIS

Pseudomembranous colitis is potentially fatal acute mucosal reaction of colon to toxins produced by *Clostridium difficile*. Most cases are associated with prior administration of antibiotics resulting in loss of normal intestinal bacterial flora. There is formation of pseudomembrane composed of superficial plaque-like irregular grayish mucosal fibrinous exudates. Rectosigmoid colon is the most common site of pseudomembranous colitis.

Pathogenesis

Administration of broad-spectrum antibiotics suppresses the normal flora of intestine and causes overgrowth of *Clostridium difficile*.

- *Clostridium difficile* exotoxin causes acute inflammation of colonic mucosa. Increased vascular permeability leads to exudation of proteins especially fibrinogen, which gets polymerized to insoluble fibrin.

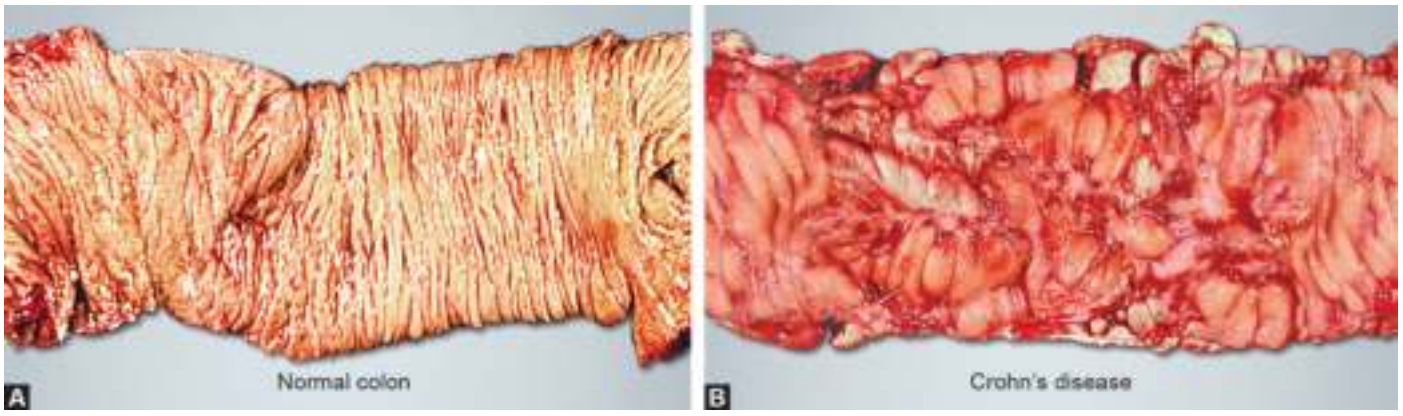

Fig. 20.53: Crohn's disease of the terminal ileum. It shows thickening of the wall and irregular nodular 'cobblestone' appearance of the mucosal surface. The patient presented with recurrent attacks of lower abdominal pain and vomiting for 6 weeks. A mass was palpable in the right iliac fossa.

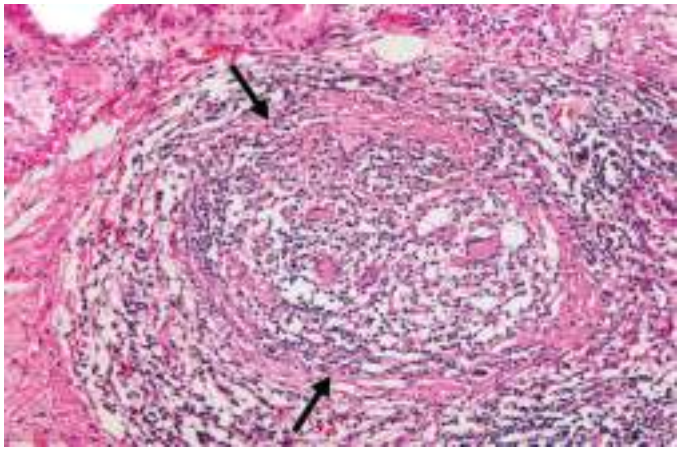

Fig. 20.54: Crohn's disease. It shows transmural inflammation with lymphocytes, epithelioid cell granulomas and giant cells (100X). Special stains for organisms were negative (arrows) (100X).

- Fibrin admixed with mucus from the colonic glands and necrotic tissue forms pseudomembrane attached loosely to the remnants of mucosa beneath it. Forceful removal of pseudomembrane leaves behind bleeding ulcerations.

Clinical Features

Patient presents with diarrhea, fever, and lower abdominal tenderness occurring in patients on broad-spectrum antibiotic therapy.

Therapeutic Correlation

Specific administration of antibiotics (vancomycin, metronidazole), hydration and discontinuation of antibiotics are effective measures to eradicate *Clostridium difficile*.

Diagnostic Approach

Lesions can be demonstrated by endoscopy. *Clostridium difficile* toxin is demonstrated in the stool.

AMOEBIC COLITIS

Amoebic colitis is caused by *Entamoeba histolytica* transmitted by fecal–oral route. The cyst of parasite

Table 20.51 Comparison of histologic features useful in differential diagnosis of Crohn's disease and intestinal tuberculosis

Histologic Features	Crohn's Disease	Intestinal Tuberculosis
Caseating epithelioid cell granulomas	Absent	Frequent
Confluent epithelioid cell granulomas	Absent	Frequent
Numerous granulomas	Rare	Common
Prominent lymphoid cuff	Uncommon	Frequent
Ulcers in intestine (both aphthous and deep)	Uncommon	Common
Architectural distortion	Common	Common
Changes of chronicity unassociated with sites of granulomatous inflammation	Common	Absent
Multiple sites of intestine involvement	Common	Common
Mucosal cobblestone appearance	Common	Uncommon
Fistula formation	Common	Uncommon
Anal/perianal disease	Common	Rare

invades colonic mucosa (intestinal amoebiasis) or by hematogenous route reaches the liver, lung and brain resulting in extraintestinal amoebiasis (amoebic abscess).

Pathogenesis

Cecum or ascending colon are most common sites of amoebic ulcers.

- Cysts of *Entamoeba histolytica* ingested become small trophozoites in the alkaline medium of intestine. Small trophozoites develop into adult trophozoites, move to cecum and become highly invasive pathogen. These trophozoites cause lysis the host tissue. These are converted to cysts.
- Direct extension of the liver abscess through the diaphragm into the right lobe of lung.
- Patient may present with ameobic dysentery and low-grade fever. Comparison of typhoid fever, bacillary dysentery and intestinal amoebiasis is shown in Table 20.52.

Surgical Pathology: Amoebic Colitis

Gross Morphology

- Amoebic ulcers are most often seen in cecum or ascending colon. Less common sites of involvement include ascending colon, sigmoid colon, rectum and appendix.
- Ulcers range from pinpoint-sized to flask-shaped in cecum, which give reddish brown hue resembling anchovy paste (Fig. 20.55).

Light Microscopy

- *Entamoeba histolytica* is demonstrated in the base and at the margins of ulcers, chiefly in the submucosa. Some red blood cells are phagocytosed by the trophozoites termed erythrophagocytes.
- Intestine biopsy shows large number of trophozoites of *Entamoeba histolytica* is shown in Fig. 20.56.

CHOLERA

Vibrio cholerae without causing mucosal inflammation (small bowel, colon) secretes toxin that activates the adenyl cyclic AMP dependent water pump in the cell membrane. The intestinal cells secrete chloride accompanied by water into the lumen producing secretory diarrhea.

RADIATION COLITIS

Radiation colitis occurs as a result of radiation therapy given in prostate and cervical cancers. Radiotherapy produces lesions ranging from reversible injury of the intestinal mucosa to chronic inflammation, ulceration, and fibrosis of the intestine.

Table 20.52 Comparison of typhoid fever, bacillary dysentery and intestinal amoebiasis

Causative Organisms	*Salmonella typhi*	*Clostridium difficile* Exotoxin	*Entamoeba histolytica*
Intestinal involvement	Lower ileum and cecum	Sigmoid and rectum	Cecum
Inflammation	Typhoid granuloma	Fibrinous pseudomembrane	Necrosis
Location of ulcers	Longitudinal axis of intestine	Map-like ulcer	Flask-shaped ulcers with reddish brown hue resembling anchovy paste
Clinical features	Continued fever, diarrhea, confusion and bradycardia	Bloody mucoid diarrhea and tenesmus	Diarrhea with bleeding

Fig. 20.55: Intestinal amoebiasis. Large bowel shows flask-shaped amoebic ulcers with reddish brown hue resembling anchovy paste (arrows).

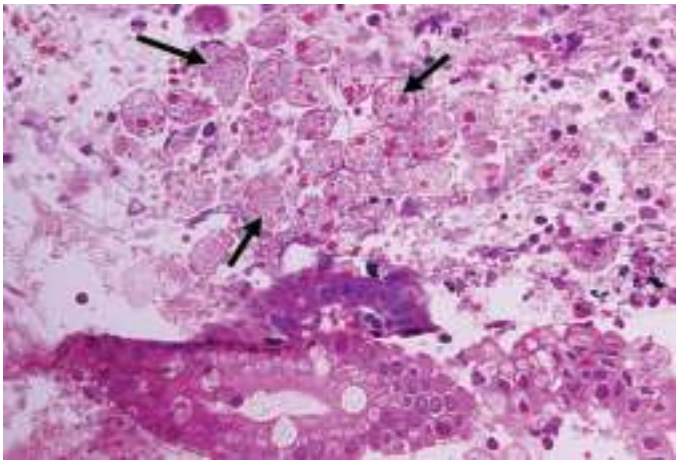

Fig. 20.56: Intestine biopsy shows large number of trophozoites of *Entamoeba histolytica* (arrows) (400X).

DIVERSION COLITIS

Diversion colitis refers to an inflammatory response in the blind segment, most often the rectum Hartmann pouch following ileostomy or colostomy formation. This process is caused by deficiency of short-chain fatty acids.

Pathologic findings include granular friable mucosa with marked lymphoid hyperplasia and cryptitis mimicking inflammatory bowel disease. Clinical history is most important to exclude other causes.

COLLAGENOUS COLITIS

Collagenous colitis refers to presence of thick collagen layer at the subepithelial region. Thickness of the collagen layer is variable. On endoscopy, colonic mucosa looks normal. Patient presents with chronic diarrhea more often in middle aged woman. There is presence of capillaries and inflammatory cells entrapped in collagenous fibers of colon. Evaluation requires well-oriented sections in difficult case. Masson's trichrome stain may be useful to demonstrate collagen fibers in the colon.

STERCORAL ULCER

Incomplete evacuation of the feces in debilitating disease or old persons may lead to fecal impaction. Fecal impaction causes pressure necrosis of the mucosa resulting in stercoral ulcer. Complications of stercoral ulcer include rectal bleeding and perforation.

VASCULAR DISORDERS OF COLON

LARGE BOWEL INFARCTION/ISCHEMIC BOWEL DISEASE

Large bowel has arterial blood supply from more than one artery. Splenic flexure and rectosigmoid junction are the most common sites of infarcts in colon. These are less vascularized areas known as **watershed regions**.

Locations

Ischemic bowel disease occurs in the watershed zones, i.e. splenic flexure between superior and inferior mesenteric arteries. Less commonly, ischemic bowel disease occurs in rectosigmoid junction (Sudeck's point) due to its presence distal to the last collateral arterial connection with proximal arteries.

Large bowel infarction with watershed zones is shown in Fig. 20.57. Causes of large bowel ischemia are given in Table 20.53.

Pathology

Arterial insufficiency of colon results in mucosal, mural, or transmural infarction involving the wall of the colon. In transmural infarctions, the bowel undergoes hemorrhagic infarction (danger of perforation) with mucosal ulcerations and pseudomembrane formation. Acute ischemic injury of the large bowel is given in Table 20.54.

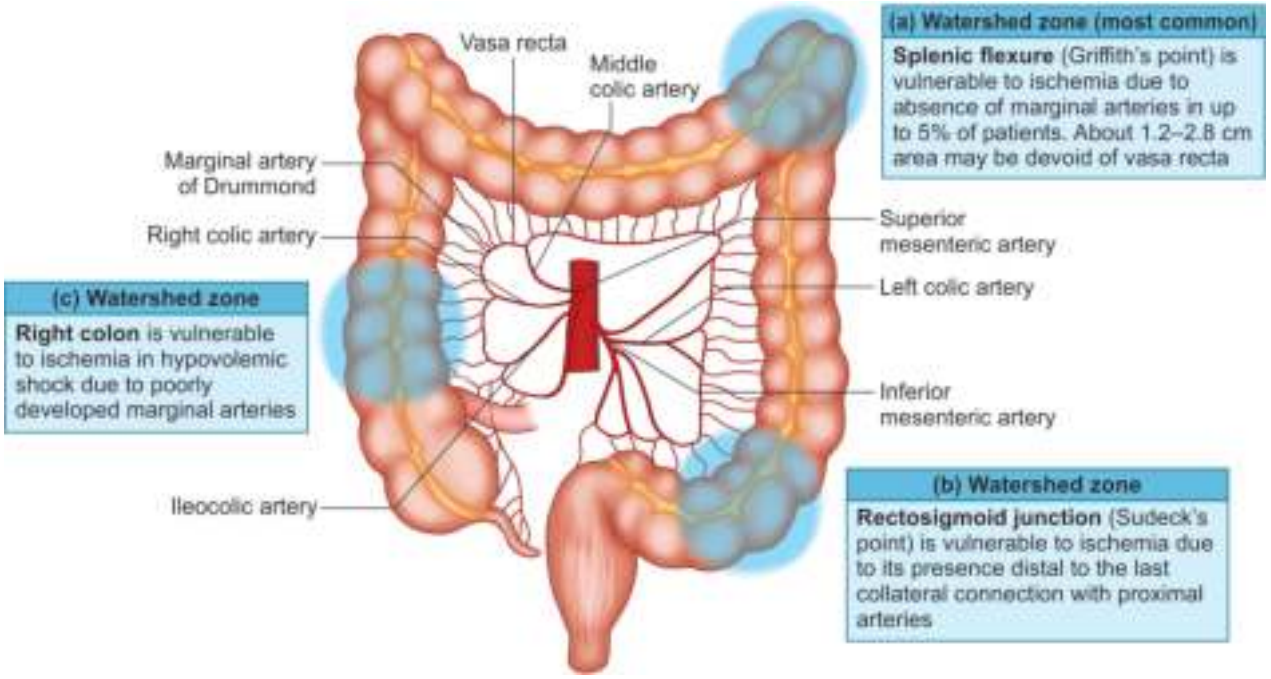

Fig. 20.57: Large bowel infarction with watershed zones.

Table 20.53 Causes of large bowel ischemia

Categories	Disorders
Acute vascular occlusion	Thrombosis or embolism
Nonocclusive mesenteric ischemia	Necrotizing enterocolitis
Blood vessel diseases	Vasculitides and vasculopathies
Vascular compression	▪ Volvulus ▪ Intussusception ▪ Celiac axis compression
Hypercoagulable states	▪ Pancreatic carcinoma ▪ Myeloproliferative syndromes ▪ Antiphospholipid antibodies (APAs) ▪ Hyperhomocysteinemia ▪ Heparin-induced thrombocytopenia
Drugs	Chemotherapeutic agents
Infections	▪ *Clostridium difficile* ▪ *Escherichia coli* ▪ Staphylococcal enterocolitis ▪ Cytomegalovirus ▪ *Aspergillus flavus* ▪ *Candida* species

Mucosal ischemic colitis is caused by Clostridium difficile, Escherichia coli, nonsteroidal anti-inflammatory drugs, Crohn's disease, radiation and collagen colitis.

Surgical Pathology: Ischemic Bowel Disease

Gross Morphology

Morphology of ischemic bowel disease is variable depending on duration and severity of vascular compromise. Ischemic bowel segment shows dusky appearance (Fig. 20.58).

Light Microscopy

- Histologic examination in acute ischemic colitis shows sloughing of surface epithelium. The blood vessels are congested.
- There is presence of acute inflammatory cells in the wall. Chronic bowel ischemia shows atrophic surface epithelium and fibrotic lamina propria (Fig. 20.59).

Clinical Features

Patient with ischemic bowel disease presents with pain in splenic flexure region and bloody diarrhea. Repair occurs by fibrosis that may eventuate in ischemic strictures.

ANGIODYSPLASIA OF COLORECTAL REGION

Angiodysplasia occurs due to dilation of mucosal and submucosal venules of cecum or ascending colon and rectum in elderly persons. Mesenteric angiography is a diagnostic tool.

Fig. 20.58: Ischemic bowel disease. It shows dusky blackish discoloration.

Table 20.54 Acute ischemic injury of the large bowel

Stage of Ischemic Injury	Gross Morphology	Histologic Features	Prognosis
Mucosal necrosis	Mucosa shows congestion, hemorrhage and small shallow ulcers	Intestine shows mucosal and crypts disruption, hemorrhage, edema and neutrophilic infiltration	Changes are usually reversible on restoration of vascular supply
Mural necrosis	Mucosa shows marked congestion, hemorrhage and ulcers; serosa shows congestion	Mucosa, submucosa and inner muscular layer shows necrosis and hemorrhage; neutrophilic infiltrate in the inner muscular layer	Mural necrosis progresses to transmural necrosis; healing leads to submucosal scar and stricture formation
Transmural necrosis	Intestine shows gangrenous, flaccid, dilated intestine with fibrinous exudate; perforation	Muscular layer shows congestion necrosis, edema and neutrophilic infiltrate; congestion of serosa	Transmural necrosis leads to intestinal perforation; surgical resection of massive gangrenous gut always indicated

Fig. 20.59: Ischemic bowel disease. It shows sloughing of epithelium, congested blood vessels and acute inflammatory cells (100X).

Clinical Features

Patient presents with unexplained lower bowel bleeding (bright red blood in stool known as hematochezia). It is associated with aortic stenosis and von Willebrand's disease due to unknown etiology. It is the second most common cause of hematochezia after diverticulosis. Causes of gastrointestinal hemorrhage are given in Table 20.55.

Table 20.55 Causes of gastrointestinal hemorrhage

Age Group	Disorders
Children	▪ Meckel's diverticulum ▪ Juvenile polyp ▪ Ulcerative colitis ▪ Crohn's disease
Adults	▪ Ulcerative colitis ▪ Crohn's disease ▪ Adenomatous polyp ▪ Gastric carcinoma ▪ Colorectal carcinoma ▪ Arteriovenous malformations ▪ Hereditary telangiectasia ▪ Nonsteroidal anti-inflammatory drugs ▪ Infective colitis ▪ Hemorrhoids ▪ Solitary rectal ulcer ▪ Anal fissure
Elderly persons	▪ Diverticular disease ▪ Angiodysplasia ▪ Adenomatous polyp ▪ Gastric carcinoma ▪ Colorectal carcinoma ▪ Ischemic colitis ▪ Ulcerative colitis ▪ Crohn's disease ▪ Radiation proctitis

NEOPLASTIC DISORDERS OF LARGE INTESTINE

Polyp is a gross description of any circumscribed mass of tissue that develops on the inside wall of a hollow organ and projects above surrounding mucosa. The polyp by itself has no clinical significance. Polyps may be neoplastic, inflammatory, or hamartomatous. Histologic examination of the excised polyp establishes the nature and its clinical significance. Hyperplastic polyp, pedunculated tubular adenoma and sessile villus adenoma in colorectal region are shown in Fig. 20.60.

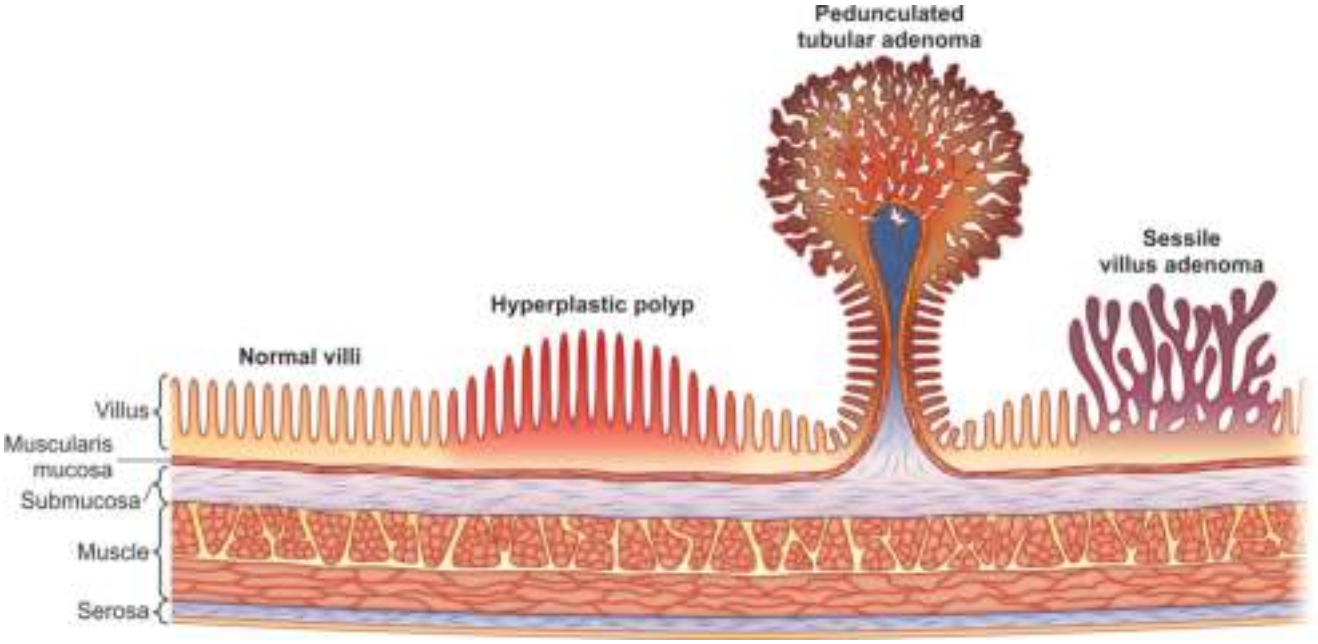

Fig. 20.60: Hyperplastic polyp, pedunculated tubular adenoma and sessile villus adenoma in colorectal region.

Table 20.56 Revised (2019) WHO classification of tumors of the colon and rectum

Benign Epithelial Tumors and Precursor Lesions	Malignant Epithelial Tumors
Serrated dysplasia, low-grade	**Adenocarcinoma, NOS (70–80%)** ▪ Serrated adenocarcinoma (10%) ▪ Mucinous (colloid) adenocarcinoma (8–10%) ▪ Signet ring cell carcinoma (2%) ▪ Medullary carcinoma (1%) ▪ Adenoma-like adenocarcinoma ▪ Micropapillary adenocarcinoma ▪ Poorly cohesive carcinoma ▪ Adenosquamous carcinoma ▪ Carcinoma, undifferentiated, NOS ▪ Carcinoma with sarcomatoid component
Serrated dysplasia, high-grade ▪ Hyperplastic polyp, microvesicular type ▪ Hyperplastic polyp, goblet cell ▪ Hyperplastic polyp, mucin type	
Adenomatous polyp, low-grade dysplasia	
Adenomatous polyp, high-grade ▪ Tubular adenoma, low-grade ▪ Tubular adenoma, high-grade ▪ Villus adenoma, low-grade ▪ Villus adenoma, high-grade ▪ Tubulovillus adenoma, low-grade ▪ Tubulovillus adenoma, high-grade ▪ Advanced adenoma	**Neuroendocrine tumor, NOS** ▪ Neuroendocrine tumor, grade 1 ▪ Neuroendocrine tumor, grade 2 ▪ Neuroendocrine tumor, grade 3 ▪ L cell tumor ▪ Glucagon-like peptide-producing tumor ▪ PP/PYY-producing tumor ▪ Enterochromaffin-like cell carcinoid ▪ Serotonin-producing tumor
Glandular intraepithelial neoplasia, low-grade	**Neuroendocrine carcinoma, NOS** ▪ Large cell neuroendocrine carcinoma ▪ Small cell neuroendocrine carcinoma
Glandular intraepithelial neoplasia, high-grade	Mixed neuroendocrine-non-neuroendocrine neoplasm (MiNEN)

Term NOS, not otherwise specified. Adapted from 2019 WHO classification of tumors of digestive system.

Large intestine harbors most malignant lesions. Colorectal carcinoma is currently the most common tumor, which affects both men and women with peak in 7th decade. Rectum is the most common site for adenocarcinoma followed by sigmoid colon. Moderately differentiated adenocarcinoma is the most common histologic variant of adenocarcinoma of colon. Patient with colorectal carcinoma has varied clinical presentation depending on the primary location in the large intestine. Revised (2019) WHO classification of tumors of large intestine is given in Table 20.56.

Table 20.57 Serrated polyps of the colon and rectum

Hyperplastic polyps (HPs) in distal colon (70–85%)
Microvesicular hyperplastic polyps (MVHPs)
Goblet cell hyperplastic polyps (GCHPs)
Mucin-poor hyperplastic polyps (MPHPs)
Traditional serrated adenomas (TSAs)
Sessile serrated adenomas/polyps (SSA/Ps)
Sessile serrated adenomas/polyps with cytologic dysplasia

SERRATED POLYPS

Serrated polyps are the most common polyps in distal colon and rectum. Hyperplasia of colonic epithelium leads to formation of elongated glands with saw-tooth appearance on cross section.

- Serrated polyps consist of hyperplastic polyps, sessile serrated adenoma polyp with or without cytologic dysplasia, traditional serrated adenomas and serrated polyposis syndrome (Table 20.57).
- Microvesicular hyperplastic polyps (MVHPs), traditional serrated adenomas and serrated polyposis syndrome are believed to be precursor lesions for colorectal carcinomas evolving through BRAF (V600E) mutation and subsequent DNA methylation.
- According to WHO definition, hyperplastic polyposis is characterized by criteria: (a) presence of at least five histologically diagnosed serrated polyps proximal to the sigmoid colon, out of which two are larger than 10 mm; or (b) presence of any number of serrated polyps proximal to the sigmoid colon in someone who has first-degree with serrated polyposis syndrome or (c) presence of more than serrated polyps of any size that are distributed throughout colorectal region.

Hyperplastic Polyps

Hyperplastic polyps have been subdivided into three types: microvesicular hyperplastic polyps (MVHPs), goblet cell hyperplastic polyps (GCHPs) and mucin-poor hyperplastic polyps (MPHPs). Vast majority of hyperplastic polyps are of microvesicular type. Incidence of K-RAS mutations, BRAF (V600E) mutations have been demonstrated in all three subtypes of hyperplastic polyps in colon and rectum.

Surgical Pathology: Hyperplastic Polyps in Colon and Rectum

Gross Morphology

On gross examination, hyperplastic polyps in colon and rectum tend to be small, dome-shaped (convex) structure. Color is paler than the surrounding mucosa. These polyps often sit on the crest of the mucosal folds. Occasionally, hyperplastic polyps may be pedunculated and grossly mimic adenomas.

Light Microscopy

Hyperplastic polyps have been subdivided into three types: microvesicular hyperplastic polyps, goblet cell hyperplastic polyps and mucin-poor hyperplastic polyps.

- **Microvesicular hyperplastic polyps (MVHPs):** In MVHP, the epithelial cells are an admixture of goblet cells and columnar cells with apical microvesicular mucin vacuoles. The goblet cells are decreased in numbers compared with normal mucosa. MVHP has a large proliferative zone that occupies basal half of the mucosa. Rarely, eosinophilic absorptive cells are demonstrated. The cells at the crypts base appear crowded, with somewhat hyperchromatic nuclei. These polyps should not be confused with an adenoma.
- **Goblet cell hyperplastic polyps (GCHPs):** Goblet cell hyperplastic polyps are observed in the distal colon and rectum. The mucosa is thickened. Subepithelial basement membrane and goblet cells are quite prominent.
- **Mucin-poor hyperplastic polyps (MPHPs):** Mucin-poor hyperplastic polyps are uncommon. Columnar cells and mucin are depleted. These histologic changes mimic those of epithelial regeneration and similar to seen in prolapse.

Traditional Serrated Polyps

Traditional serrated polyps tend to be pedunculated/polypoidal lesions. At low magnification, traditional serrated polyps have complex serrated architecture, hence often misdiagnosed as villus adenomas. These polyps composed of uniform population of penicillate cells with bright eosinophilic cytoplasm, elongated nuclei and small nucleoli. These lesions may undergo dysplastic change and progression to malignancy.

Sessile Serrated Adenoma/Polyp with Dysplasia

Sessile serrated adenomas/polyps with dysplasia have been characterized by combinations of classic adenoma, hyperplastic polyp, sessile serrated adenoma/polyp and traditional serrated adenoma.

PEUTZ-JEGHERS SYNDROME

Peutz-Jeghers syndrome is an autosomal dominant disorder due to LKB1/STK11 gene mutation in 75% of affecting young children of 10–15 years of age. It is characterized by multiple hamartomatous polyps in gastrointestinal tract, i.e. small intestine (most common), stomach and colon in decreasing frequency; melanotic pigmented macules (1–5 mm) of lips, perioral skin, hands and genitalia. There is increased risk of cancers of gastrointestinal tract, thyroid, breast, lung, pancreas, gonads, and urinary bladder in Peutz-Jeghers syndrome. On histologic examination, polyp is composed of branching network of smooth muscle fibers continuous with the muscularis mucosa that support irregularly arranged glands of the polyp.

Diagnostic Criteria

Diagnostic criteria for Peutz-Jeghers syndrome include (a) two or more histologically confirmed polyps in Peutz-Jeghers syndrome, (b) any number of polyps in Peutz-Jeghers syndrome, (c) characteristic, prominent mucocutaneous pigmentation with a family history of Peutz-Jeghers syndrome, and (d) any number of polyps in Peutz-Jeghers syndrome. Uncommon tumors associated with Peutz-Jeghers syndrome are ovarian sex cord tumors and uterine cervical adenoma/adenocarcinoma; and Sertoli cell tumor in males.

Molecular Genetic Alterations

Genetic basis for the Peutz-Jeghers syndrome is a germline mutation in the LKB1/STK11 gene located on chromosome 19. STK11 is a serine-threonine kinase, which participates in proliferation in the mammalian target of rapamycin (mTOR) signaling pathways. Clinical trials are going on mTOR rapamycin inhibitor.

Clinical Features

Most patients are diagnosed in their second decade. Clinical presenting symptoms of hamartomatous polyps depend on location and size of polyps. Small polyps can cause obstruction and abdominal pain, whereas polyps in rectosigmoid region present with bloody stools or prolapse protrusion or prolapse of the polyps.

Pathologic Features

Hamartomatous polyps in Peutz-Jeghers syndrome vary in size from <1 to >3.5 cm. These may be sessile or pedunculated. Basic architecture of polyp is that of glandular epithelium with 'Christmas tree'-like appearance resting on branching smooth muscle framework that originates from the muscularis

mucosa. The glandular epithelium of polyp resembles the normal epithelium of the intestine. Diagnostic difficulty occurs in polyps with ischemic changes often secondary to intussusception. Areas of adenomatous and carcinomatous transformation within these hamartomatous polyps have been demonstrated in 5–10% of cases.

COWDEN SYNDROME

Cowden syndrome is nonhereditary disorder, which affects >50 years of age. It is characterized by hamartomatous polyps in colon. There is presence of crypt dilatation and edema in nonpolypoidal mucosa. There is increased risk of benign and malignant tumors of thyroid and breast in Cowden syndrome.

JUVENILE RECTAL POLYP

Juvenile rectal polyp is a solitary hamartomatous pedunculated polyp also known as retention polyp, which affects children in first two decades of life, most often in <5 years of age. It is usually solitary and localized chiefly in the rectum. Approximately 40% of the cases are autosomal dominant, which have risk for development of cancers of stomach, small intestine and colon.

Diagnostic Criteria

Juvenile polyp may be associated with the juvenile polyposis syndrome. The diagnostic criteria for polyposis syndrome include: (a) presence of >5 juvenile polyps in the small intestine and rectum, (b) presence of juvenile polyps in throughout the gastrointestinal tract, and (c) presence of any number of polyps in a patient with a family history of juvenile polyposis. Juvenile polyps may be present throughout gastrointestinal tract in infants, which may present with diarrhea, anemia and hypoalbuminia.

Molecular Genetic Alterations

Gene mutations of BMPR1 (10q22) and SMAD4/DPC (18q21) have been demonstrated in juvenile rectal polyps. Associated intestinal and extraintestinal defects (e.g. malrotation of gut, mesenteric lymphangioma, Fallot tetralogy, coarctation of aorta, hydrocephalus) have been reported in these cases.

Surgical Pathology: Juvenile Rectal Polyp

Gross Morphology

- Juvenile rectal polyp is mainly pedunculated, rarely sessile, and usually <3 cm in diameter.
- Juvenile rectal polyp smooth glistening and gelatinous surface with reddish to tan discoloration.
- On cut section, juvenile rectal polyp is filled with cystic-filled spaces.

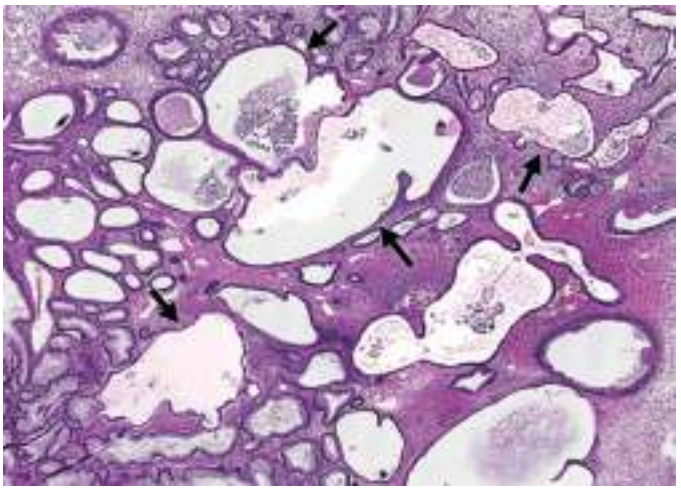

Fig. 20.61: Juvenile rectal polyp shows mucus-filled cystic glands and edematous, usually inflamed stroma (arrows) (100X).

Light Microscopy

- Juvenile polyp is composed of mucus-filled cystic, dilated and torturous glands and in edematous and inflamed stroma.
- The glands are composed of well-formed mucus-secreting cells that may become flattened and attenuated. The stroma usually contains acute and chronic inflammatory cells and granulation tissue.
- When dilated and tortuous glands rupture into the stroma leading to a foreign body giant cell reaction.
- Occasionally, osseous metaplasia may be demonstrated in juvenile polyp (Fig. 20.61).

FAMILIAL JUVENILE POLYPOSIS

Familial juvenile polyposis is an autosomal dominant disorder characterized by multiple juvenile polyps in the gastrointestinal tract. Familial juvenile polyps may undergo malignant transformation.

INFLAMMATORY POLYPS

Inflammatory polyps may be secondary to inflammatory disorders of the intestine. These are demonstrated in the setting of ulcerative colitis (10–20%), Crohn's disease, ischemic disease, amoebiasis, schistosomiasis and adjacent to ulcers and at surgical anastomosis sites.

- Inflammatory polyps may be rounded nodules comprising caps of granulation tissue and remnants of mucosa in the setting of chronic inflammatory bowel disease. Rectal mucosa is most common site.
- The entities of inflammatory polyps secondary to mucosal prolapse are inflammatory cap polyps, inflammatory myoglandular polyps and diverticular polyps.
- Inflammatory polyps are limited to the rectosigmoid region and distal colon. Inflammatory myoglandular polyps are mainly located in the distal colon and

Table 20.58 Differences between tubular and villus adenomas in colorectal regions

Parameters	Tubular Adenoma	Villus Adenoma
Definition	Consisting of >75% tubular appearance	Consisting of >50% villus appearance
Occurrence	90–95% of total adenomas	<1% of total adenomas
Location	▪ Colon (90%) ▪ Rectosigmoid region (50%)	▪ Rectum ▪ Rectosigmoid region
Age group	Earlier age group	Elderly persons
Gross morphology	Small, pedunculated	Large sessile velvet-like appearance projecting above normal mucosa
Light microscopy	Stalk composed of fibrovascular tissue covered by benign mucin secreting mucosal cells	Frond-like villus structures covered by dysplastic and disordered columnar epithelial cells
Risk of malignancy	Uncommon	Relatively common

rarely in ileum, that may cause intussusception. Diverticular polyps occur in the background of diverticular disease.

CRONKHITE-CANADA SYNDROME

Cronkhite-Canada syndrome is a nonhereditary disorder affecting >50 years of age. It is characterized by multiple hamartomatous polyps in stomach, small intestine and colorectal region associated with protein losing enteropathy alopecia, nail atrophy and cutaneous hypopigmentation.

- Patient presents with diarrhea, weight loss, abdominal pain, anorexia and weakness, alopecia, nail changes and hyperpigmentation of the skin.
- Histologic features of these polyps are identical to juvenile polyps with the exception of intervening stroma. Polyp is composed of tortuous and cystically dilated glands and present in the nonpolypoidal intervening mucosa.

NEOPLASTIC POLYPS

Adenomatous polyps are true neoplasms arising from the mucosal epithelium. These polyps are more common in men than women.

- Neoplastic polyps are distributed throughout the large intestine, i.e. right colon (40%), left colon (40%) and rectosigmoid region (20%). These are rarely seen in small intestine.
- Neoplastic polyps are subdivided into tubular adenomas (most common raspberry on a stalk), villus adenomas, tubulovillus (mixture of tubular and villus); and sessile serrated adenomas (serrated epithelium lining the crypts). Neoplastic polyps may be pedunculated (attached by stem) or sessile (broad base attachment). Differences between tubular and villus adenomas in colorectal regions are given in Table 20.58.
- All adenomas are precancerous lesions. The risk for malignant transformation parallels the percentage of the villus component (finger-like projections) in the polyp and size >2 cm increases the risk for developing colon carcinoma (e.g. rectosigmoid region) in villus adenoma. Patients are most often asymptomatic, but rectal bleeding may occur. Risk of colon carcinoma in neoplastic polyps is given in Table 20.59.

Table 20.59 Risk of colon carcinoma in neoplastic polyps

Neoplastic Polyp	Size of Neoplastic Polyp		
	(<1 cm)	(1–2 cm)	(>2 cm)
Tubular adenoma	1%	10.2%	34.7%
Tubulovillus adenoma	3.9%	7.4%	45.8%
Villus adenoma	9.5%	10.3%	52.8%

Risk of development of colon carcinoma is higher in villus adenoma.

Tubular Adenomas

Tubular adenomas are most common benign neoplastic polyps in the colon (90%) and rectosigmoid region (50%). Tubular adenomas may undergo malignant transformation to colon adenocarcinoma in 1–3% of cases. Risk for development of colon adenocarcinoma is proportional to the increasing size and number of polyps. Most tubular adenomas are excised through endoscopy in 99% of cases.

Surgical Pathology: Tubular Adenomas

Gross Morphology

Tubular adenomas are usually multiple and pedunculated attached to the large intestine by a stalk. These may be sessile. These are spherical in shape with shaggy surface. These are generally <2 cm in size with reddish or darker in color than the surrounding mucosa (Fig. 20.62A and B).

Light Microscopy

- Tubular adenoma is composed of closely packed tubular glands forming the head of the polyp lined by mucus-secreting columnar epithelium.
- More than 80% of tumor cells form glandular and tubular arrangement (Fig. 20.63).

Villus Adenomas

Villus adenomas account for 10% of neoplastic polyps in rectum and rectosigmoid region. These are >2 cm in size in diameter with velvety surface showing finger-like villus structures and high potential for malignant change. Large villus adenomas may secrete copious electrolyte-rich mucus, resulting in decreased serum potassium level and acute renal failure. Approximately 50% of all villus adenomas undergo malignant transformation to colon adenocarcinoma.

Surgical Pathology: Villus Adenomas

Gross Morphology

- Villus adenomas are solitary, sessile with broad base measuring ≥1–5 cm in diameter. These are most often located in the rectum extending over a wide area as thick, carpet-like growth.
- Finger-like projections (villi) protrude from the base of the polyps into the lumen of the intestine.

Light Microscopy

Villus adenomas are composed of villi (i.e. finger-like protrusions lined with columnar epithelium). More than 80% of tumor cells form villus projections (Fig. 20.64).

Tubulovillus Adenomas

Tubulovillus adenomas in large bowel constitute 15% of adenomatous polyps, which represent an intermediate

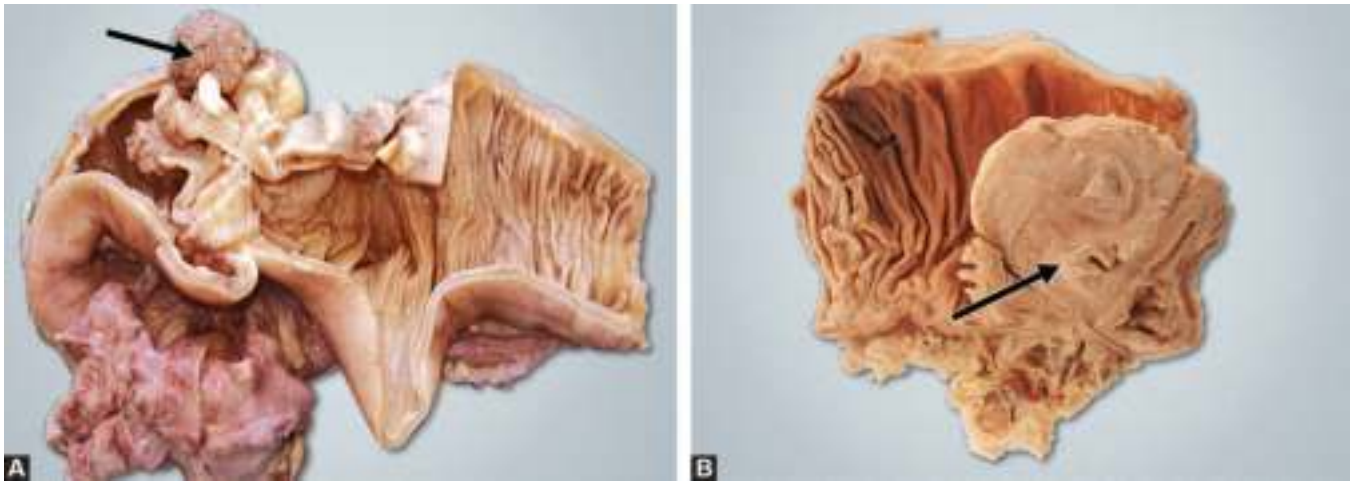

Fig. 20.62A and B: Tubular adenoma in large intestine shows pedunculated polyp (arrows). (*Courtesy:* Dr. Sujata Kanetkar, Professor and Head, Department of Pathology, Krishna Institute of Medical Sciences, Karad, Maharashtra.)

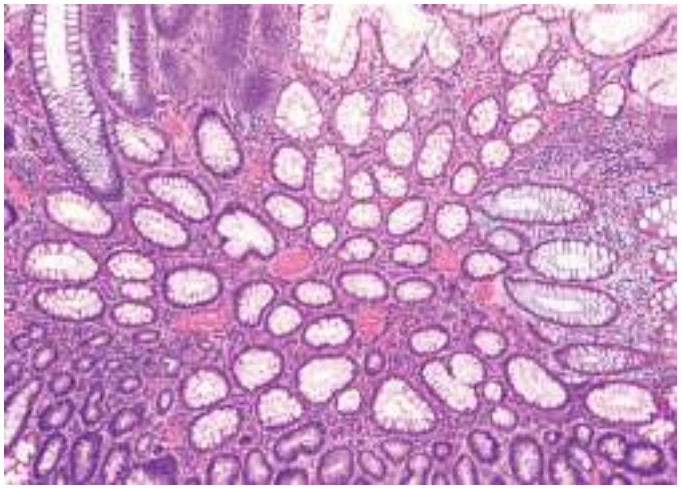

Fig. 20.63: Tubular adenoma in colon. It shows closely packed tubular glands lined by mucus-secreting columnar epithelium (100X).

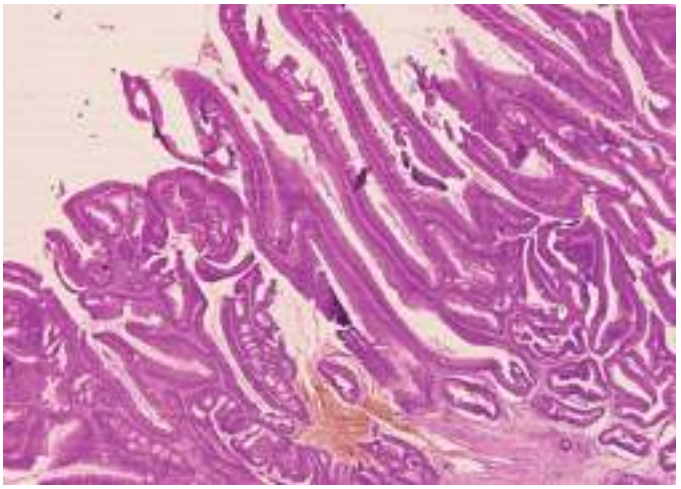

Fig. 20.64: Villus adenoma in colon. It shows finger-like protrusions lined with columnar epithelium (100X).

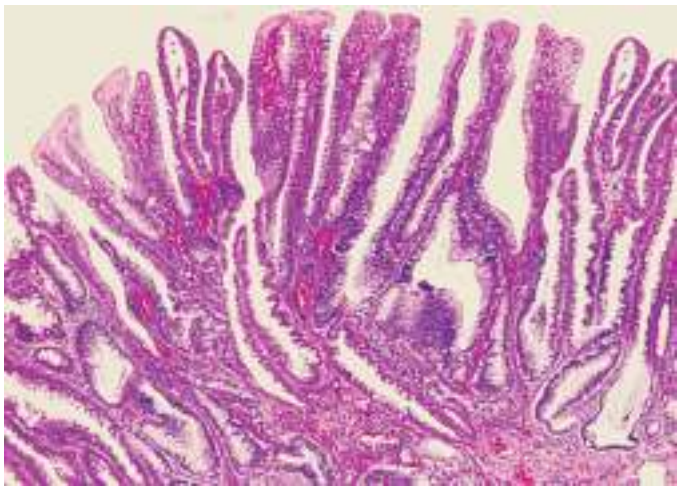

Fig. 20.65: Tubulovillus adenoma in colon. It shows tubular and villus components (100X).

step between tubular and villus adenomas in all respects. If the tubular adenoma component constitutes >40% of the total tumor mass or 20–80% villus component, it is known as tubulovillus adenoma. Tubulovillus adenoma shows tubular and villus components (Fig. 20.65).

Sessile Serrated Adenomas

Sessile serrated adenomas in colon resemble hyperplastic polyps, but unlike hyperplastic polyps, these may undergo malignant transformation. Sessile serrated adenomas most often occur in right colon and demonstrate microsatellite instability. Sessile serrated adenomas can be very subtle and are easily missed on endoscopy.

MULTIPLE POLYPOSIS SYNDROMES

Multiple polyposis syndromes are associated with a greatly increased risk for malignant transformation.

FAMILIAL ADENOMATOUS POLYPOSIS COLI

Familial adenomatous polyposis coli (FAP) is an autosomal dominant disorder associated with inactivation of the APC gene (adenomatous polyposis coli gene) located on chromosome 5q21.

- FAP is characterized by development of >100 tubular adenoma polyps (500–2500) in colon and rectum, particularly in the rectosigmoid region.
- Polyps are not present at birth. These appear in childhood and become clinically evident in second decade of life. Familial adenomatous coli with multiple polyps covering entire mucosa is shown in Fig. 20.66.

Molecular Genetic Alterations

Progression from adenoma to colon adenocarcinoma involves a series of steps in familial adenomatous

Fig. 20.66: Familial adenomatous coli. It shows multiple polyps covering virtually the whole of the mucosal surface of the colon >100 tubular adenoma polyps (ranging 500 to 2500).

polyposis coil. Patient with familial adenomatous polyposis coli has mutation in the APC tumor suppressor gene located on long arm of chromosome 5.

Further new mutations occur in 30–50% of patients, which include mutation of p53 tumor suppressor gene on chromosome 17 and point mutation of RAS oncogene.

Malignant Potential

The risk of malignant transformation approaches 100%. The risk of malignancy is related to the size of adenoma, amount of villus component, grade of epithelial dysplasia and family history.

Dysplastic foci in adenoma of FAP show stratification, hyperchromatic nuclei, mitotic figures in upper crypts and surface epithelium.

Management

By the age of 40 years, all the patients with FAP develop colon adenocarcinoma hence need prophylactic total colectomy.

Mortality in FAP

Noncolonic causes of death in patient with familial adenomatous polyposis (FAP) are pancreatic carcinoma, central nervous system tumors and complications of therapy.

GARDNER'S SYNDROME

Gardner's syndrome is a variant of familial polyposis syndrome due to APC gene mutation. It is an autosomal dominant disorder, which affects children 10–15 years of age.

Gardner's syndrome is associated with numerous adenomatous polyps in colon along with osteomas in the mandible and abdominal desmoid.

TURCOT'S SYNDROME

Turcot's syndrome is an autosomal dominant disorder due to APC gene mutation (5q21). It is characterized by multiple adenomatous polyps in colon with increased

risk for colorectal carcinoma and brain cancers (medulloblastoma or glioblastoma multiforme). Turcot's syndrome may be associated with familial adenomatous polyposis or Lynch syndrome.

Molecular Genetic Alterations

Molecular basis of Turcot's syndrome is either due to mutation of APC gene located on long arm of chromosome 5q21 or mutation in one of the mismatch repair genes associated with Lynch syndrome (MLH1 and PMS2). Medulloblastoma occurs due to mutation of APC gene and glioblastoma multiforme due to mutation of mismatch repair genes.

JUVENILE POLYPOSIS COLI

Juvenile polyposis coli is an autosomal dominant syndrome, which occurs due to mutation of PTEN gene. Patient develops >6 colorectal polyps.

TUBEROUS SCLEROSIS

Tuberous sclerosis is caused by mutation in the TSC1 or TSC gene, which encodes hamartin and tuberin proteins, respectively. Tuberous sclerosis is associated with multiple hamartomas in rectum, brain (as cortical tubers, subependymal hamartomas), face, and kidneys (renal angiomyolipoma in 80% cases).

MALIGNANT TUMORS OF COLON

HEREDITARY NONPOLYPOSIS COLON CANCER

Hereditary nonpolyposis colon cancer (HNPCC) is also known as Lynch syndrome. There is increased risk for development of carcinoma of endometrium (most common), right colon carcinoma, ovary, urothelium, brain and stomach in these patients.

Muir-Torre syndrome is an autosomal dominant syndrome that is thought to be subtype of HNPCC. Persons are prone to develop cancers of the colon, genitourinary tract tumors and skin (keratoacanthoma and sebaceous tumors).

Molecular Genetic Alterations

All hereditary nonpolyposis colorectal cancer (HNPCC or Lynch syndrome) occurs due to germline gene mutations in one of the MMRs DNA mismatch repair gene, i.e. MSH2, MSH6, MLH1, MLH3 and PMS2 genes. There may be mutation of TACSTD regulatory gene. These gene mutations cannot correct errors in the nucleotide pairing. Microsatellite instability (MSI) is demonstrated in 90% of the tumors that develop in these patients.

- Sessile serrated adenoma is the precursor lesion for HNPCC or Lynch syndrome.
- BRAF and K-RAS gene mutations never occur in HNPCC or Lynch syndrome.
- Sporadic colorectal carcinoma is usually caused by hypermethylation of the MLH1 promoter in 15% of cases.
- Microsatellite instability results from dysfunction of DNA mismatch repair genes, i.e. MSH2, MSH6, MLH1, MLH3 and PMS2. These genes are detected by immunohistochemistry, PCR-based genotyping and analysis of mononucleotide repeats (BAT25, BAT26) and dinucleotide repeats (D5S346, D2123, D17S250).

Location

HNPCC is frequently seen on the right-sided colon with expansile growth and mucin production.

Surgical Pathology: Hereditary Nonpolyposis Colon Cancer

Light Microscopy

- Histologic examination reveals mucinous or medullary features of colon carcinoma, infiltrated by lymphocytes.
- Crohn's-like lymphocytic reaction is demonstrated.

Management

Extensive clinical history and screening, i.e. genetic testing for microsatellite instability and expression of mismatch repair genes by immunohistochemistry technique for development of HNPCC is required in the surgical management of these patients.

COLORECTAL CARCINOMA

Colorectal carcinoma is the most common tumor, which affects both men and women. Most colorectal carcinomas develop as sporadic carcinomas in 99% of cases. Several hereditary cancer syndromes and other polyposis syndromes causing colorectal carcinoma are given in Table 20.60. Hereditary nonpolyposis colorectal cancer (HNPCC) represents 3–4% of colorectal carcinoma. Familial adenomatous polyposis (FAP) and remaining cancer syndrome represent are responsible for colorectal carcinoma <1% of cases.

Risk Factors

Risk factors for colorectal carcinoma are familial adenomatous polyposis, hereditary nonpolyposis colorectal cancer (HNPCC) or Lynch syndrome, inflammatory bowel disease (ulcerative colitis, Crohn's disease), history of colorectal cancer in first degree relatives, dietary factors (consumption of red meat, animal fat, saturated fat, refined carbohydrate, low fiber content), obesity, tobacco smoking, chronic alcoholism and excessive consumption of nonsteroidal anti-inflammatory drugs.

Table 20.60 Several hereditary cancer syndromes and other polyposis syndromes causing colorectal carcinoma

Polyposis Syndrome	Inheritance	Clinical Features	Gene and Location	Gene Product Function	Risk for Colorectal Carcinoma
Familial adenomatous polyposis (FAP) and variants	Autosomal dominant	>100 colonic and rectal adenomas (ranging 500–2500), nearly 100% lifetime risk for colorectal carcinoma by age of 40 years	APC gene	▪ MUTYH gene (normally codes for MYH glycosylase involved in repair) ▪ Growth inhibitory β-catenin sequestration; targeting of β-catenin for destruction	100%
Hereditary non-polyposis colorectal cancer (HNPCC) or Lynch syndrome	Autosomal dominant	70–80% lifetime risk for development of colorectal carcinoma; predisposition for extracolonic malignancies including endometrial carcinoma	▪ MLH1 ▪ MSH2 ▪ PMS2 ▪ MSH6 ▪ MLH3 ▪ BER-Ep4	DNA mismatch repair	10–50%
Juvenile polyposis syndrome	Autosomal dominant	Hamartomatous polyps in gastrointestinal tract, increased risk for development of colorectal carcinoma	SMAD4 (18q21.1)	▪ BMPR1A (bone morphogenetic protein receptor, type 1A on 19q23.2) ▪ TGF-β signaling	65%
MUTYH-associated polyposis	Autosomal recessive	Multiple polyps >100 in colorectal regions	MUTYH	Protein regulates MYH glycosylase enzyme	60–70%
Peutz-Jeghers syndrome	Autosomal dominant	Hamartomatous polyps in with or without adenomatous component in small intestine, large intestine and stomach in decreasing frequency, skin macules, and predisposition for extracolonic malignancies of thyroid, breast, lung, pancreas, gonads and urinary bladder	STK11/ LKB1 tumor suppressor gene	Serine threonine kinase	40%
Polymerase proofreading-associated polyposis	Autosomal dominant	Multiple adenomas in colon	▪ POLD1 ▪ POLE	Exonuclease proofreading domain	30–70%
Cowden syndrome and Bannayan-Ruvalcaba-Riley (BRR) syndrome	Autosomal dominant	Hamartomatous small, sessile polyps in gastrointestinal tract, no predisposition for colorectal cancer	PTEN (phosphatase and tensin homolog) on chromosome 10q23	Protein phosphatase and tensin homolog	10%
Gardener syndrome	Autosomal dominant	>100 colonic adenomas, congenital hypertrophy of the retinal pigment epithelium (CHRPE), osteomas in mandible, abdominal desmoid tumors	APC gene	Growth inhibitory: β-catenin sequestration; targeting of β-catenin for destruction	Unknown risk frequency
Turcot syndrome	Autosomal dominant	Familial adenomatous polyposis (>100 colonic adenomas) medulloblastoma or glioblastoma multiforme	APC gene	Growth inhibitory β-catenin sequestration; targeting of β-catenin for destruction	Unknown risk frequency
Attenuated familial adenomatous polyposis	Autosomal dominant	>15 but <100 colonic adenomas, >90% by age of 70 years	▪ APC gene ▪ MYH ▪ MUTYH	Growth inhibitory β-catenin sequestration; targeting of β-catenin for destruction	Unknown risk frequency

Contd...

Table 20.60 Several hereditary cancer syndromes and other polyposis syndromes causing colorectal carcinoma (*Contd...*)

Polyposis Syndrome	Inheritance	Clinical Features	Gene and Location	Gene Product Function	Risk for Colorectal Carcinoma
MYH-associated polyposis	Autosomal recessive	Familial adenomatous polyposis-like clinical presentation, and demonstration of APC gene mutation	MYH gene	DNA damage repair	Unknown risk frequency
Muir-Torre syndrome	Autosomal dominant	HNPCC syndrome features, sebaceous tumors and extrahepatic malignancies	▪ MLH1 ▪ MSH2 ▪ PMS2 ▪ MSH6 ▪ MLH3 ▪ BER-Ep4	DNA mismatch repair	Unknown risk frequency
Familial colorectal cancer type X (FCCTX)	Hereditary nonpolyposis disorder	Microsatellite stable disorder, predisposition to colorectal cancer in 50–90% by age of 70 years, no risk for extracolonic cancers	Unknown	No evidence of DNA mismatch repair deficiency	Unknown risk frequency
NTHL1-associated polyposis	Autosomal recessive	Multiple polyps in colorectal regions	NTHL1	Protein regulates DNA glycosylase 1 enzyme	Unknown risk frequency
Constitutional mismatch repair deficiency syndrome	Autosomal recessive	Multiple polyps in colorectal regions	▪ MLH1 ▪ MSH2 ▪ MSH6 ▪ PMS2	DNA mismatch repair	Unknown risk frequency
Hereditary mixed polyposis syndrome	Autosomal dominant	Multiple polyps in colorectal regions	GREM1	Protein encodes BMP (bone morphogenic protein)	Unknown risk frequency
MSH3-associated polyposis	Autosomal recessive	Multiple polyps in colon	MSH3	DNA mismatch repair	Unknown risk frequency
AXIN2-associated polyposis	Autosomal dominant	Multiple polyps in colon and stomach; tooth agenesis	AXIN2 (17q23-q24)	Wnt pathway inhibitor	Unknown risk frequency
Serrated polyposis	Unknown	Multiple polyps in distal colon and rectum	Unknown	Unknown	Unknown risk frequency

- Consumption of red meat, animal fat and saturated fat enhance bile acid synthesis, that get converted by gut bacteria to powerful carcinogenic agent.
- Consumption of diet low in fiber content decreases the stool bulk, increases fecal transit time and alters gut bacterial flora resulting in production of toxic oxidative products and then development of colorectal carcinoma. Consumption of diet rich in refined carbohydrate produces potential carcinogens. Low intake of vitamins A, C and B decrease oxygen-derived free radical scavenger activity and increase for colorectal carcinoma.
- High-fiber content in diet is protective, e.g. bran (the hard-outer layer of whole cereals such as oats, wheat, rice, and corn), fruits (apricot rich in calcium, potassium, phosphorus, iron, vitamin A and figs), nuts (coconuts, almonds) and boiled pea. Risk for colorectal carcinoma increases in immunocompromised state. Risk factors for colorectal carcinoma are given in Table 20.61.

Molecular Pathogenesis

In the sporadic colorectal carcinoma pathway, adenomas are characterized in the early stages by low-grade epithelial dysplasia precede the development of high-grade dysplasia, which may then progress to invasive colorectal carcinoma. There are two main types of precursor lesions for colorectal carcinoma: conventional

Table 20.61 Risk factors for colorectal carcinoma

Elderly persons
Familial adenomatous polyposis
Hereditary nonpolyposis colorectal cancer (HNPCC) or Lynch syndrome
Inflammatory bowel disease ▪ Ulcerative colitis ▪ Crohn's disease
History of colorectal cancer in first degree relatives
Dietary factors ▪ Red meat intake ▪ Saturated fat intake ▪ Animal fat intake ▪ Refined carbohydrate intake
Obesity
Tobacco smoking
Nonsteroidal anti-inflammatory drugs
Chronic alcoholism
Excessive consumption of nonsteroidal anti-inflammatory drugs

adenomas or adenomatous lesions (most common) and serrated polyps (second most common).

- The epithelium lining conventional colonic adenomas display cytologic features of dysplasia. In inflammatory bowel disease-associated neoplasia, the background colonic mucosa demonstrates variable degrees of chronic colitis, and eventually leads to low-grade epithelial dysplasia, which in turn may progress to high-grade dysplasia and invasive colon adenocarcinoma.
- The morphologic features of the neoplastic lesions significantly overlap in sporadic colorectal carcinoma and inflammatory bowel disease-associated neoplasia, but the inflammatory environment that characterizes chronic colitis dictates a number of different molecular mechanisms of neoplastic development and progression to colorectal carcinoma.
- Colorectal carcinoma that develops through the serrated pathway originates from the serrated polyps demonstrates epithelial dysplasia. Poorly differentiated colorectal carcinoma that develops through the microsatellite instability pathway demonstrates prominent intraluminal lymphocytes. The presence of microsatellite instability in the tumor DNA is analyzed by the microsatellite instability marker BAT25.
- Early detection of colonic adenomas and colorectal carcinoma in average-risk persons is done by performing flexible sigmoidoscopy, colonoscopy, double-contrast barium enema, CT colonography every 5–10 years. Tests that primarily detect colorectal carcinoma include annual examination of guaiac-based fecal occult blood test and fecal immunochemical test. Histologic examination of the biopsy is the gold standard for diagnosis.

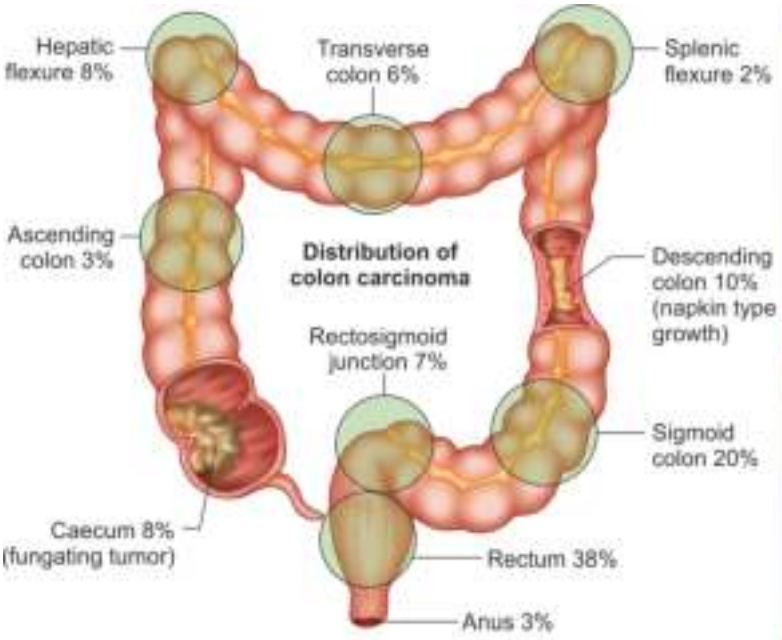
Table 20.62 Distribution of colorectal carcinoma in decreasing frequency

Location	Frequency
Rectosigmoid region	38%
Sigmoid colon	20%
Descending colon	10%
Cecum	8%
Hepatic flexure colon	8%
Transverse colon	5%
Ascending colon	3%
Anal canal	3%

Locations

Rectosigmoid is the most common site for colon carcinoma (38% of cases), sigmoid colon (20% of cases), descending colon (10% of cases), cecum (8% of cases), hepatic flexure (8% of cases), transverse colon (5% of cases), ascending colon (3% of cases), and anal region (3% of cases). Left-sided colon carcinoma most likely to obstruct lumen, while right-sided colon carcinoma more likely to bleed. Distribution of colorectal carcinoma in decreasing frequency is given in Table 20.62.

Pathology Pearls: Recent Advances of Colorectal Carcinoma Stem Cell (CRCSC) Biology



- Stem cell line includes totipotent stem cell in single cell embryo, embryonic stem cells derived from inner cell mass of the blastocyst (pluripotent) in 5–7 days embryo, cord blood stem cells (multipotent), placental stem cells (multipotent), and adult stem cells (multipotent) in infants and adults.
- Totipotent cells in single cell embryo have the potential to become any type in the adult body and any cell of the extraembryonic membranes (e.g. placenta).
- Pluripotent stem cells have the potential to make any differentiated cell in the body except placenta, which is derived from trophoblast (Fig. 20.67).
- Colorectal carcinoma demonstrates a variety of stem cells at various stages of differentiation within the tumor with enhanced self-renewal properties that drive long-term tumor growth, differentiation, chemotherapy resistance, relapse and metastasis.
- The maintenance of the stem cells and activation differentiation potential are fundamentally orchesterized by microenvironment stem cell niche-related cellular and humoral signaling pathways.
- Colorectal carcinomas can give rise to multiple lineages within the neoplasm. The resulting cellular plasticity contributes to tumor heterogeneity; hence it poses great difficulty in cancer therapy. Various functional clones of colorectal carcinoma stem cells can be present within a single tumor, further contributing to tumor heterogeneity. Colorectal carcinoma

stem cell markers, regulators and signaling pathways serve as important therapeutic targets. Colorectal carcinoma stem cells specific agents can be combined with chemotherapy to target both colorectal carcinoma stem cells and bulk tumor cells.

- Panel of immunomarkers used to analyze colorectal carcinoma includes CD11/Proml, Lgr5, CD44, Bmi1, CD166, CD26, ALDH1, EphB2 and Dclk1. Characteristics of colorectal carcinoma stem cells (CRCSCs) are given in Table 20.63.

Molecular Genetic Alterations

Colorectal carcinoma is a slow-growing tumor. It develops through a set of anatomic changes progressing from normal mucosa to adenomatous polyp carcinoma *in situ*, to invasive carcinoma to metastatic tumor. Combination of genetic and epigenetic abnormalities are observed in the development of colorectal carcinoma.

Risk factors: Colorectal carcinoma

- Age >50 years
- High fat, low fiber diet
- Ulcerative colitis and Crohn's disease
- Familial adenomatous polyposis (FAP)
- Hereditary nonpolyposis colorectal cancer (HNPCC)
- Adenomas (villous, tubular and tubulovillous)
- Peutz-Jeghers syndrome
- Family history of colorectal cancer

Immunohistochemistry: Colorectal carcinoma

Tumor markers	Expression
• Carcinoembryonic antigen (CEA)	Positive
• CK20	Positive
• CDX2 (transcription factor)	Positive
• SAT2 (transcription factor)	Positive
• p53	Positive
• β-Catenin	Positive
• CK7	Focally positive

Serum tumor markers used to detect colorectal carcinoma

Category	Tumor marker	Cancers	Category	Tumor markers	Cancers
Oncofetal proteins	Carcinoembryonic antigen (CEA)	• **Colon carcinoma** • NSGCT of testis • Gastric carcinoma • Pancreatic carcinoma • Lung carcinoma • Breast carcinoma	Mucins and glycoproteins	CA 19-9	• **Colon carcinoma** • Pancreatic carcinoma
				CA 72-4	• **Colon carcinoma** • Gastric carcinoma

Fig. 20.67: Colorectal carcinoma. Figure shows distribution, risk factors, serum tumor markers and immunohistochemistry.

Table 20.63 Characteristics of colorectal carcinoma stem cells (CRCSCs)

Categories	Comments
Properties of colorectal carcinoma stem cells (CRCSCs)	
Self-renewal	Self-renewal is a process by which stem cells divide and proliferate with maintenance of undifferentiated state throughout life
Differentiation	Stem cell differentiation involves the changes of a cell to more specialized cells by succession of alterations in cell morphology, membrane potential, metabolic activity and responsiveness to certain signals
Heterogeneity	Stem cell heterogeneity including genetic and nongenetic mechanisms refer to biological differences amongst normal and stem cells originated within the same tissue
Plasticity	Stem cell from one tissue may be able to give rise to cell types of completely different tissue, a phenomenon known as plasticity, e.g. hematopoietic stem cells developing into cardiac muscle and hepatocytes producing insulin

Contd...

Table 20.63 Characteristics of colorectal carcinoma stem cells (CRCSCs) (*Contd...*)

Categories	Comments
Therapy resistance	Cancer stem cells, a subset of cells within the colorectal carcinoma with the potential for self-renewal, differentiation and tumorigenicity, are thought to the major cause of cancer therapy failure
Metastasis	Cancer stem cells have potential for invasiveness and metastasis of colorectal carcinoma. Epithelial–mesenchymal transition (EMT) is a highly conserved cellular process that transforms epithelial cells into mesenchymal cells. Recent studies show that there is a link between EMT and colon carcinoma stem cells formation, which might have implications in tumor progression and therapeutic resistance
CRCSCs microenvironment	
Hypoxia: HIF1a	A major regulator of cellular adaptation to hypoxia is the hypoxia-inducible factor (HIF) family of transcription factors, which play important roles in angiogenesis, stem cell maintenance, metabolic reprogram mining resistance to apoptosis, autocrine growth factor signaling in colorectal carcinoma
Endothelium: Jagged 1	Endothelial cells promote colorectal carcinoma stem cell phenotype through a soluble form of Jagged 1. Without cell to cell contact, endothelial cells synthesize soluble factor Jagged 1, via ADAM17 proteolytic activity, that lead to NOTCH activation in colorectal carcinoma cells in a paracrine manner
HGF	Tumor derived human growth hormone (HGH) has been implicated in colorectal carcinoma development and progression. However, HGH role in colorectal carcinoma is yet to be established
CRCSCs and metastasis	
CD44	HNRNPLL, a newly identified colorectal carcinoma metastasis suppressor gene modulates alternative splicing of CD44 during epithelial–mesenchymal transition. CD44 mutation has been associated with colorectal metastasis
CD26	CD26, dipeptidyl peptidase IV is a multifunctional cell surface glycoprotein, that participates in colorectal cancer progression, tumor cell invasion and metastasis
EMT	Epithelial–mesenchymal transition (EMT) is a highly conserved cellular process that transforms epithelial cells into mesenchymal cells. Recent studies show that there is a link between EMT and carcinoma stem cells formation, which might have implications in tumor progression and therapeutic resistance
DICER1	Impaired function of DICER1 function causes upregulation of colon cancer stem cells and distant metastasis
MiR-146a-5p	MiR-146a-5p functions as tumor suppressor in various cancers. Epigenetic changes play an important role in the development of colorectal carcinoma. Overexpression of UHRF1, as an epigenetic regulator downregulates MiR-146a-5p tumor suppressor resulting in invasion and distant metastasis
HGF	Tumor derived human growth hormone (HGH) has been implicated in cancer development and progression
SDF-1	There has evidence showing that CXCR-4 chemokine receptor and its ligand, stromal cell derived factor 1 (SDF-1) plays an important role in colon carcinoma progression and metastasis
CCL9	BCL-9 promotes tumor progression by conferring enhanced proliferative, metastatic, and angiogenic properties of cancer stem cells in colon carcinoma
CRCSC signaling pathways	
Wnt/β-catenin pathway	Recent advances in high-throughput sequences revealed recurrent mutation in Wnt signaling pathway mutations in intestinal stem cell in addition to β-catenin in colorectal carcinoma (Table 20.64)
NOTCH miRNA-34a pathway	NOTCH signaling pathway promotes serrated neoplasia pathway in colorectal carcinoma through epigenetic modifications of EPHB2 and EPHB4
Micro-RNA-34a pathway	Micro-RNA-34a signaling pathway is tumor suppressor. Its dysregulation has been implicated in colorectal carcinoma
Hedgehog pathway	Hedgehog signaling pathway normally plays an important role in the embryogenesis and somatic development. Abnormal activation of this pathway has been linked to colorectal cancer
TGF-β pathway	TGF-β signaling pathway normally participates in cell proliferation, differentiation, migration and apoptosis. It is one of the most commonly altered cellular pathways in colorectal carcinoma (30%) and other human cancers
p53 pathway	The p53 signaling pathway is the most commonly mutated gene in colorectal cancer in proximal colon carcinoma (34%), distal colorectal carcinoma (42%) and other cancers. The p53 gene mutation plays an important role in the adenoma–carcinoma transition during tumor pathologic process

Contd...

Table 20.63 Characteristics of colorectal carcinoma stem cells (CRCSCs) (*Contd...*)

Categories	Comments
NF-κB pathway	The nuclear factor-kappa B (NF-κB) signaling pathway is a regulator of immune response and inflammation that has been implicated in the carcinogenic process of colorectal carcinoma
ID1/ID3 pathway	Activation of ID1/ID3 pathway governs colon carcinoma-initiating cell-renewal through cell-cycle restriction driven by the cell-cycle inhibitor. Additionally, silencing ID1/ID3 signaling pathway increases sensitivity of colon carcinoma-initiating cell to the chemotherapeutic agents
P13K pathway	Alterations of the P13K pathway are common in colorectal carcinoma, and the activation of the pathway either through PIK3A and PIK3CB, mutation or amplification of AKT, loss of function of PTEN and hyperactivation of mTORC1 could be contributory to the malignant transformation of benign lesions. One of the important current drug targets is the phosphatidylinositol 3-kinase (P13K) pathway to treat colorectal carcinoma

Table 20.64 The Wnt/β-catenin pathway and familial adenomatous polyposis linked to colorectal carcinoma

Signaling of the Wnt/β-catenin pathway is mediated through the ligands of Frizzled family of receptors, and the coreceptor LRP5 or LRP6. In the absence of the ligand, the Wnt pathway is inactive through the negative regulation of the downstream effector β-catenin
When β-catenin present in sufficient quantity in the nucleus, it stimulates transcription of target genes (c-Jun, c-Myc, cyclin D1)
Lack in Wnt/β-catenin signaling through the Frizzled receptor results in sequestration of β-catenin in a multiprotein complex including APC. Auxin and other proteins which exert a negative effect both through the cytoplasmic sequestration of β-catenin and by targeting it for destruction by proteasome through phosphorylation
In the presence of Wnt ligand, the Frizzled receptor and LRP5/LRP6 form a complex, which results in the recruitment and sequestration of Auxin at the cell surface, thereby inhibiting the kinase activity of APC complex. This results in the stabilization and nuclear translocation of β-catenin, thus resulting in transcription of target genes (c-Jun, c-Myc, cyclin D1)
In the setting of an APC gene mutation, the multiprotein APC/Auxin/β-catenin complex is disrupted, most commonly due to truncation of the APC protein in domains responsible for protein-protein interaction. This results in stabilization and nuclear transcription of β-catenin with the net effect of constitutively active transcription of growth-promoting genes and otherwise under tight regulation. Patient develops familial adenomatous polyposis with >500–2500 polyps in the colon linked to colorectal carcinoma

- Two distinct pathways have been described such as APC/β-catenin pathway and classic adenoma-carcinoma sequence with microsatellite pathway. Both pathways involve stepwise accumulation of multiple mutations. The Wnt/β-catenin pathway and familial adenomatous polyposis are given in Table 20.64.
- Oncogenes, their mode of activation and associated with colon carcinoma are given in Table 20.65. Tumor suppressor gene mutations associated with colon carcinoma are given in Table 20.66. Morphologic and molecular changes in the adenoma-colon carcinoma sequence are shown in Fig. 20.68.

APC/β-Catenin Signaling Pathway

The APC/β-catenin signaling pathway is essential for intestinal homeostasis. It is aberrantly activated in most colorectal carcinomas through a mutation of tumor suppressor APC gene mapped on chromosome 5q21. APC protein is an essential component of cytoplasmic protein complex that targets β-catenin is for destruction. β-Catenin is a multifunctional protein, which maintains intestinal homeostasis.

Table 20.65 Oncogenes, their mode of activation and associated with colon carcinoma (signal transduction proteins)

Category	Proto-oncogene	Mode of Activation	Associated Malignancies
GTP-binding (G) proteins	K-RAS gene	Point mutation	▪ *Colon carcinoma* ▪ Lung carcinoma ▪ Pancreas carcinoma
RAS signal transduction	BRAF gene	▪ Point mutation ▪ Translocation	▪ *Colon carcinoma* ▪ Melanoma ▪ Leukemia

Table 20.66 Tumor suppressor genes associated with colon carcinoma

Gene	Protein	Function	Familial Tumors	Sporadic Cancers
▪ SMADA-2 ▪ SMADA-4	▪ SMADA-2 protein SMADA-4 protein	▪ Both inhibit TGF-β signaling pathway. These repress CDK4 and MYC ▪ These also induce expression of CDK inhibitor	Juvenile polyposis	▪ *Colon carcinoma* ▪ Pancreas carcinoma
RB gene	▪ Retinoblastoma protein (locus 13p14) ▪ Mutation by deletion and nonsense	It codes for pRB protein, master brake on cell cycle by inhibiting nuclear transcription and G1 to S transition during cell cycle	▪ Retinoblastoma ▪ Osteosarcoma	▪ Retinoblastoma ▪ Osteosarcoma ▪ Breast carcinoma ▪ *Colon carcinoma* ▪ Prostate carcinoma ▪ Urinary bladder carcinoma ▪ Lung carcinoma
Angiogenesis inhibitors				
STK11	Liver kinase B1 (LKB1) or STK11	It activates AMPK family of kinases. It suppresses cell growth when cell nutrients and energy levels are low	*Peutz-Jeghers syndrome:* Cancers of GIT, pancreas	Diverse carcinomas in 5–20% cases

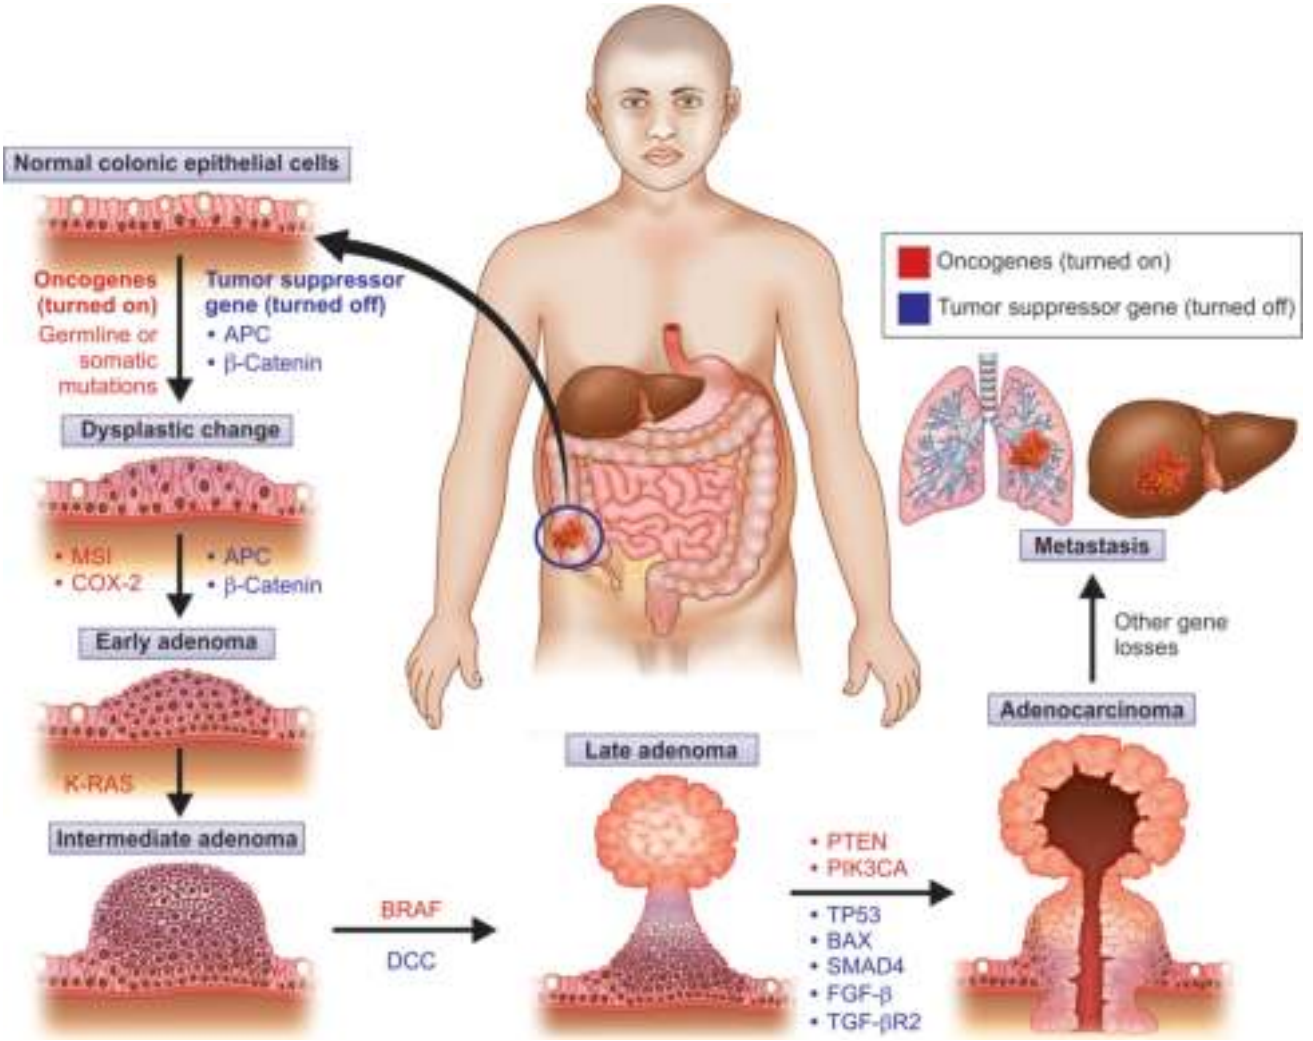


Fig. 20.68: Morphologic and molecular changes in the adenoma-colon carcinoma sequence. It is postulated by Knudson's hypothesis that loss of normal copy of tumor suppressor APC gene occurs early in life (first hit). This is the first hit. Loss of intact copy of APC gene follows (second hit). Other gene mutations include K-RAS, losses at 18q21 involving SMAD2 and SMADA4 and inactivation of tumor suppressor p53 gene. It leads to the emergence of colorectal carcinoma and metastases, in which additional gene mutations occur.

Classic Adenoma-Colon Carcinoma Sequence with Microsatellite Instability Signaling Pathway

Classic adenoma-carcinoma sequence with microsatellite pathway is associated with defects in DNA mismatch repair. It accounts for 80% of sporadic colorectal carcinomas.

- **First hit (normal mucosa to mucosa alteration):** Gene mutations in the development of colon carcinoma may be inherited (germline) or acquired (somatic).
  - Mutations of tumor suppressor APC gene (5q21) and mismatch repair genes such as MSH2 at 2p22 participate in alteration of normal mucosa.
  - APC is a key negative regular of β-catenin, a component of Wnt signaling pathway.
  - Mutation of APC gene has been demonstrated in sporadic cancers (colon, stomach and pancreas) and familial adenomatous polyposis.
  - Under physiologic state, APC gene prevents nuclear transcription by degrading β-catenin, an activator of nuclear transcription.
  - With loss of function of APC, accumulation of β-catenin activates transcription of genes encoding MYC and cyclin D1 leading to cell proliferation.
  - Additional mutations of K-RAS have been observed in adenomas and invasive colorectal carcinomas.
- **Second hit (altered mucosa to adenoma):** Methylation abnormalities, inactivation of normal alleles of APC, and MSH2 transform altered mucosa to adenoma.
- **Adenoma to colonic malignant transformation:** K-RAS proto-oncogene is located on chromosome 12p—a signal transducing protein. Point mutation of K-RAS has been identified in colon carcinoma in 50% of cases. There is as well as homozygous loss of additional cancer suppressor genes (DCC at 18p21, p53 at 17p13) participate in transformation of adenoma to colon carcinoma.
- **Microsatellite instability (MSI) mechanism:** Additional mutations and gross chromosomal alterations such as loss of DNA repair genes mutated TGF-β receptor gene and defective BAX gene produce marked changes in colon carcinoma growth.

Neoplastic progression is also associated with mutations of tumor suppressor genes encoding SMADA2 and SMADA4, which are effectors of TGF signaling. Under physiologic state, TGF signaling inhibits the cell cycle.

- **Defects in DNA mismatch repair genes:** DNA mismatch repair genes include principally MLH1, MSH2, MSH6, and PMS2. Normally, DNA repair genes correct errors in nucleotide pairing.
  - Mutations of DNA mismatch repair genes cannot correct errors in nucleotide pairing. There is increased risk of development of carcinoma of right colon, known as hereditary nonpolyposis colon cancer (HNPCC or Lynch syndrome). It is often preceded by serrated adenomas, rather than tubular adenomas seen in the traditional APC tumor pathway.
  - Extensive history of screening of early development of colorectal carcinoma is required in the management of these patients. Sporadic mismatch repair defects may also occur and are usually related to abnormal methylation.
- **TP53 tumor suppressor gene mutation:** TP53 mutation is associated with colon carcinoma. It is a gatekeeper tumor suppressor gene located on chromosome 17. The p53 gene product is a nuclear binding protein that halts cell cycle in G1 by inhibiting nuclear transcription factor, until the mutation is repaired.

Clinical Correlation

Left-sided colon carcinoma is most likely to obstruct lumen, while right-sided colon carcinoma is more likely to bleed. Many colorectal carcinomas are within the reach of the finger (during digital rectal examination) or the rectosigmoidoscope. Patient presents with occult bleeding, change in bowel habits, loss of weight, loss of appetite and anemia.

Clinical manifestations according to location of carcinoma in large bowel are given in Table 20.67. Differences between right-sided colon carcinoma and left-sided colorectal carcinomas are given in Table 20.68.

Table 20.67 Clinical manifestations according to location of carcinoma in large bowel

Symptoms	Right-sided Colon Carcinoma (Frequency %)	Left-sided Colon Carcinoma (Frequency %)	Carcinoma Rectum (Frequency %)
Pain abdomen	80	60	5
Mass abdomen	70	40	0
Rectal bleeding	20	20	60
Change in bowel habit	40	60	80
Weight loss	50	15	25
Vomiting	30	10	0
Obstruction	5	20	5

Table 20.68 Differences between right-sided colon carcinoma and left-sided colorectal carcinomas

Characteristics	Right-sided Colon Carcinoma	Left-sided Colorectal Carcinoma
Location of growth	Cecum and ascending colon	Descending colon and rectosigmoid region
Growth pattern	Usually fungating or polypoid large cauliflower-like, soft friable growth projecting into the lumen (rarely napkin-ring type)	Napkin-ring configuration as a result of fibrosis. It leads to obstruction of lumen
Invasion of growth	More invasive growth	Less invasive growth
Clinical correlation	Silent lesion and diagnosed later	Obstructive lesion, so diagnosed early
Histologic features	Similar	Similar
Involvement of other structures	More common such as mesentery, lymph nodes, distant metastases	Less common such as mesentery, lymph nodes, distant metastases
Prognosis	Good	Poor

Right-sided Colon Carcinoma

- Adenocarcinoma of ascending and transverse colon tend to be exophytic, polypoidal growth, or crater-like ulcerations with raised margins, and commonly present with bleeding per rectum. Right-sided colon carcinoma is more invasive and metastasizes early as compared to left-sided lesions.
- Patient presents with black, tarry stools, rectal bleeding, anemia, abdominal aching, pressure, or dull cramps, weakness, fatigue, exertional dyspnea, diarrhea, constipation, anorexia, weight loss and vomiting.

Left-sided Colorectal Carcinoma

- Adenocarcinoma of the descending colon, rectum or sigmoid colon often presents as a circumferential annular/napkin ring configuration mass narrowing the intestinal lumen. It produces early obstruction of colon and rectum lumen.
- Patient presents with black, tarry stools or rectal bleeding, intermittent abdominal fullness or cramping; rectal pressure, constipation, diarrhea or ribbon-like stool, and dark or bright red blood in stool; mucus in or on stool.

Surgical Pathology: Colorectal Adenocarcinoma

Gross Morphology

- Colorectal adenocarcinomas show wide range of gross appearances including fungating intraluminal growth, ulcerated growth with heaped up edges and circumferential growth.
- Tumor is firm with grey white appearance.
- Approximately 10% are mucinous adenocarcinomas (Figs 20.69 and 20.70).

Light Microscopy

- Classic colorectal adenocarcinoma is composed of irregularly distributed tubular structures in a desmoplastic stroma. There is presence of complex cribriform architecture and intraluminal necrosis. It shows abundant pool of mucin in 50% of the tumor area.
- Signet ring adenocarcinoma is rare in colon and composed of cells with abundant intracytoplasmic vacuoles arranged in diffuse infiltrative cords, nests and sheets (Fig. 20.71).

Immunohistochemistry Technique

Panel of immunomarkers is used to analyze expression in conventional colon adenocarcinoma (microsatellite stable) includes CEA, CK7, CK20, CDX2 (specific marker associated with poor prognosis), SAT, β-catenin and villin. TTF-1, PAX2 and WT1 markers are negative in conventional colon adenocarcinoma.

Markers	Expression
Carcinoembryonic antigen (CEA)	Positive
Cytokeratin 7 (CK7)	Positive
Cytokeratin 20 (CK20)	Positive
CDX2 (transcription factor)	Positive
SAT (transcription factor)	Positive
β-Catenin	Positive
p53	Positive
Villin	Positive
TTF-1	Negative
PAX2	Negative
WT1	Negative

Mode of Spread

Right-sided colon carcinoma is more invasive that metastasizes early as compared to left-sided colon carcinoma.

- **Lymphatic route:** Colorectal carcinoma invades lymphatic channels and initially involves the lymph nodes immediately underlying the tumor.
- **Hematogenous route:** Blood-borne metastases from colorectal carcinoma is usually seen in the liver and then lungs. Solitary liver metastasis may be treated by wedge resection giving months to years of symptom-free remission. Multiple liver metastases are not resectable. These patients may respond to chemotherapy for months/years.

Prognostic Factors

Poor prognostic factors of colorectal carcinoma include high tumor stage, poor differentiation of colon

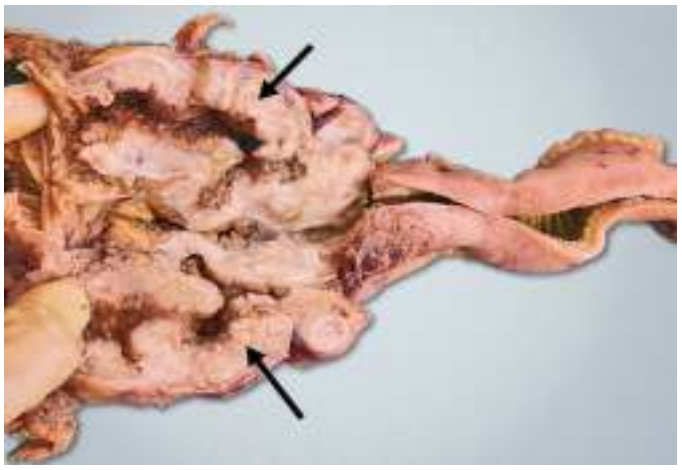

Fig. 20.69: Carcinoma in cecum. Tumor shows fungating intraluminal growth. Tumor is firm with gray white appearance. Cut surface is gray white (arrows). (*Courtesy:* Dr. Sujata Kanetkar, Professor and Head, Department of Pathology, Krishna Institute of Medical Sciences, Karad, Maharashtra.)

Fig. 20.70: Carcinoma in rectum. Tumor shows fungating and ulcerated intraluminal growth. Tumor is firm with grey white appearance. Cut surface is gray white with areas of necrosis (arrow).

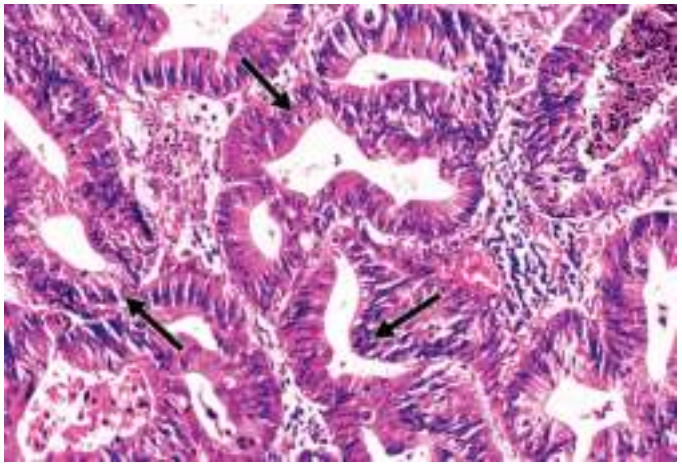

Fig. 20.71: Classic colorectal adenocarcinoma. Tumor is composed of irregularly distributed tubular structures in a desmoplastic stroma (arrows) (400X).

Table 20.69 Molecular genetic markers associated with good prognosis in colorectal carcinoma

Low recurrence score is analyzed by oncotype Dx colon cancer assay (current validated marker)
Low risk analyzed by color print (current validated marker)
No deletion of chromosomes 18q (DDC or SMAD4 genes in this region) is analyzed by cytogenetic study
No deletion of chromosomes 17p and 8 is analyzed by cytogenetic study
Absence of TP53 gene mutation
Loss of CDKN1B (p27) expression
High-frequency of mismatch repair status (deficient microsatellite instability) analyzed by immunohistochemistry
Absence of K-RAS and N-RAS gene mutation is associated with good prognosis. RAS gene mutations are demonstrated in 40–50% of colorectal carcinomas. Anti-EGFR therapy is ineffective in these colorectal carcinomas with RAS gene mutations
Absence of BRAF gene mutation is associated with good prognosis. BRAF gene mutation is demonstrated in colorectal carcinomas. Anti-EGFR therapy is ineffective in these colorectal carcinomas with RAS gene mutations. Anti-EGFR therapy is ineffective in these colorectal carcinomas with BRAF gene mutations

carcinoma, lymphovascular and/or perineural invasion and age group more than 40 years. By convention, signet ring cell carcinoma, small cell carcinoma and undifferentiated carcinoma are high-grade neoplasms associated with poor prognosis.

Complications

Complications of colorectal carcinoma include obstruction, hemorrhage, perforation and infection. Molecular genetic markers associated with good prognosis in colorectal carcinoma are given in Table 20.69.

Clinical Pearls: Diagnostic Modalities of Colon Carcinoma

- **Serum tumor markers:** Serum carcinoembryonic antigen (CEA), CA 19-9 and CA 72-4 levels are increased in colon carcinoma. Serum tumor markers used to detect colorectal carcinoma are given in Table 20.70.
- **Digital rectal examination:** Digital rectal examination is carried out to feel the growth in the rectum and anal canal.
- **Barium enema:** Barium enema with or without contrast media is used to visualize the local deformities of intestinal topography.
- **Sigmoidoscopy:** Sigmoidoscopy rigid or flexible fiber optic type is performed to visualize rectal tumors or routine screening.
- **Colonoscopy:** Colonoscopy is used to visualize the colon for detection of early polypoidal tumors during preoperative period and recurrences after surgical resection. Multiple biopsies may be obtained for histologic examination.
- **Computed tomography (CT):** Computed tomography is performed to stage disease and detection of metastases.

- **Magnetic resonance imaging (MRI):** Magnetic resonance imaging is performed to detect metastatic disease.
- **Transrectal ultrasonography:** Transrectal tomography is an excellent choice for staging rectal carcinoma.
- **Laparotomy:** Laparotomy is performed to detect metastases to abdominal regions especially liver and omentum, that often remains undetected by current imaging techniques.

Therapeutic Response

Epidermal growth factor receptor (EGFR) inhibitor drugs, e.g. cetuximab and panitumumab are effective thereby for EGFR positive colorectal carcinoma especially when the cancer stem cells are negative for both BRAF and K-RAS gene mutations.

Prognosis

The grade and stage of the tumor (Astler-Coller system) determine the prognosis of colorectal carcinoma. Location of the tumor, extent of bowel involvement, histologic grading and presence or absence of metastasis. The overall 5-year survival regardless of the stage is 35%.

Table 20.70 Serum tumor markers used to detect colorectal carcinoma

Category	Tumor Markers	Examples	
Oncofetal proteins	Carcinoembryonic antigen (CEA)	▪ *Colon carcinoma* ▪ Nonseminomatous germ cell testicular tumor ▪ Stomach carcinoma	▪ Pancreatic carcinoma ▪ Lung carcinoma ▪ Breast carcinoma
Mucins and glycoproteins	▪ CA 19-9 ▪ CA 72-4	▪ *Colon carcinoma* ▪ *Colon carcinoma*	▪ Pancreatic carcinoma ▪ Gastric carcinoma

DISORDERS OF APPENDIX

ANATOMY AND HISTOLOGY

The appendix is a tubular structure extending from the cecum. It has an average length 7–10 cm. It is lined by colonic-type mucosa, surrounded by submucosa and muscular coats.

- In children and young adults, the mucosa contains numerous lymphoid follicles. In the elderly persons, the lumen often shows fibrous obliteration.
- Appendix fills with food and empties regularly into the cecum. Because appendix empties insufficiently due to its small lumen, therefore, it is prone to obstruction and vulnerable to infection.

INFLAMMATORY DISORDERS

ACUTE APPENDICITIS

Acute appendicitis is bacterial infection associated with proximal obstruction of the lumen. It is a common cause of acute abdomen. It is most frequent in adolescents and young adults and has no sex predilection.

Etiopathogenesis

Appendix becomes inflamed and edematous as a result of lumen occlusion by fecolith or carcinoid tumor. It leads to increase in intraluminal pressure, ischemic mucosal injury, and secondary bacterial infection. Other causes of appendix lumen occlusion include submucosal lymphoid hyperplasia in the course of viral infection, pinworms, carcinoid tumor of appendix and barium from X-ray studies.

Clinical Features

Patient with acute appendicitis presents with pain in periumbilical region (central abdomen) radiating to right iliac quadrant. Systemic symptoms include fever, nausea and vomiting. Rebound tenderness may be demonstrated by pushing the abdominal wall at McBurney's point.

- Atypical presentation is encountered if the appendix is in retroperitoneal or intrapelvic location.
- Abdominal mass in the right lower quadrant may be palpated following a rupture of appendix and formation of a periappendiceal abscess. Pathologic disorders confused with acute appendicitis are given in Table 20.71.

Surgical Pathology: Acute Appendicitis

Gross Morphology

- External surface of appendix is congested appendix and distal half covered by purulent exudate.
- The lumen contains a purulent exudate and often a fecolith (Fig. 20.72).

Light Microscopy

- Diagnostic criteria of acute appendicitis include infiltration of muscular coat of appendix by polymorphonuclear infiltration.
- Acute inflammatory infiltrate extends from the mucosa through the full thickness of the appendiceal wall (Fig. 20.73).

Complications

If untreated by surgical resection, acute appendicitis most often leads to perforation or periappendiceal abscess, or both. Transmural necrotizing inflammation of the appendix results in peritonitis. Patient may develop septicemia resulting in pylephlebitis (inflamed thrombosis of the portal vein), liver abscess and subphrenic abscess.

Laboratory Diagnosis

Peripheral smear examination shows leukocytosis with increased neutrophil count. Ultrasound and X-ray are performed in atypical cases of appendicitis prior to surgery.

Table 20.71 Pathologic disorders confused with acute appendicitis

Mesenteric lymphadenitis
Acute salpingitis
Acute cholecystitis
Ectopic pregnancy
Ruptured ovarian follicle
Torsion ovarian cyst
Inflammatory bowel disease
Acute pyelonephritis and urinary tract infection

Fig. 20.72: Acute appendicitis. It shows congestion on the external surface of inflamed appendix.

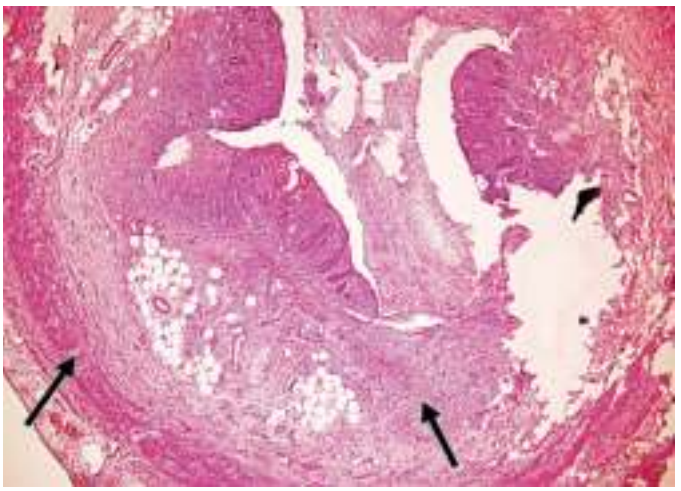

Fig. 20.73: Diagnostic criteria of acute appendicitis. It shows neutrophilic infiltration in the muscular coat (arrows) (100X).

Therapeutic Correlation

The inflamed appendix in acute appendicitis should be surgically removed because of possible devastating complications of perforation or abscess.

Precautions Prior to Surgery

Yersinia enterocolitica can cause mesenteric granulomatous lymphadenitis in children. Patient presents with pain in the right lower quadrant (pseudoappendicitis), diarrhea, reactive arthritis, erythema nodosum, and septicemia. Infected children frequently undergo laparotomy due to a mistaken diagnosis of appendicitis.

MUCOCELE OF APPENDIX

Mucocele of appendix refers to a dilated mucus-filled appendix and is based on the gross and microscopic appearance of appendix.

Pathogenesis

Mucocele of appendix occurs due to chronic obstruction and mucinous cystadenoma or mucinous cystadenocarcinoma.

Complications

Rupture of a neoplastic mucocele may seed the peritoneal cavity with mucus-secreting tumor cells, a condition referred to as pseudomyxoma peritonei.

NEOPLASTIC DISORDERS OF APPENDIX

CARCINOID TUMOR

Carcinoids are neuroendocrine tumors of low-grade malignancy. These are most commonly located in the submucosa of the intestines (e.g. appendix, terminal

ileum, and rectum). The most common appendiceal neoplasm is neuroendocrine (carcinoid) tumor, which is usually detected as an incidental finding. Tip of the appendix is the most common site. Common benign and malignant tumors of the appendix are given in Table 20.72.

Clinical Course

Clinical course of carcinoid tumor of appendix depends on size of the neoplasm.

- **Carcinoid tumor of appendix <2 cm:** It is considered benign. It rarely metastasizes. Perineural or lymphovascular is not indicative of malignant potential.
- **Carcinoid tumor of appendix >2 cm:** It invades mesoappendix and metastasizes to regional lymph nodes, liver, lungs and bones in 66% of cases.

Table 20.72 Common benign and malignant tumors of appendix

Benign Tumors of Appendix	
Adenoma	
▪ Villus adenoma	▪ Tubulovillus adenoma
▪ Tubular adenoma	▪ Cystadenoma
Serrated lesions	
▪ Hyperplastic polyp	▪ Traditional serrated adenoma
▪ Sessile serrated adenoma	
Carcinoid tumor (neuroendocrine tumor)	
Malignant Tumors of Appendix	
Mucinous adenocarcinoma	
Neuroendocrine carcinoma	
Goblet cell carcinoid	
Mixed adenoneuroendocrine carcinoma (also known as adenocarcinoma ex-goblet cell carcinoid)	

DISORDERS OF ANUS AND PERIANAL REGION

ANATOMY AND HISTOLOGY

Anal canal is present at the terminal end of gastrointestinal tract. It measures 3–4 cm in length. The mucosal lining the upper region of the anal canal is extension of rectal mucosa. The mucosa lining the middle region of the anal canal is known as transition zone measuring 0.5–1 cm above the dentate line has features of both metaplastic squamous mucosa and urothelium.

The mucosa of distal portion of anal canal extending from the dentate line to the anal verge, is composed of specialized nonkeratinizing squamous epithelium with melanocytes. Important disorders of anorectal region are shown in Fig. 20.74.

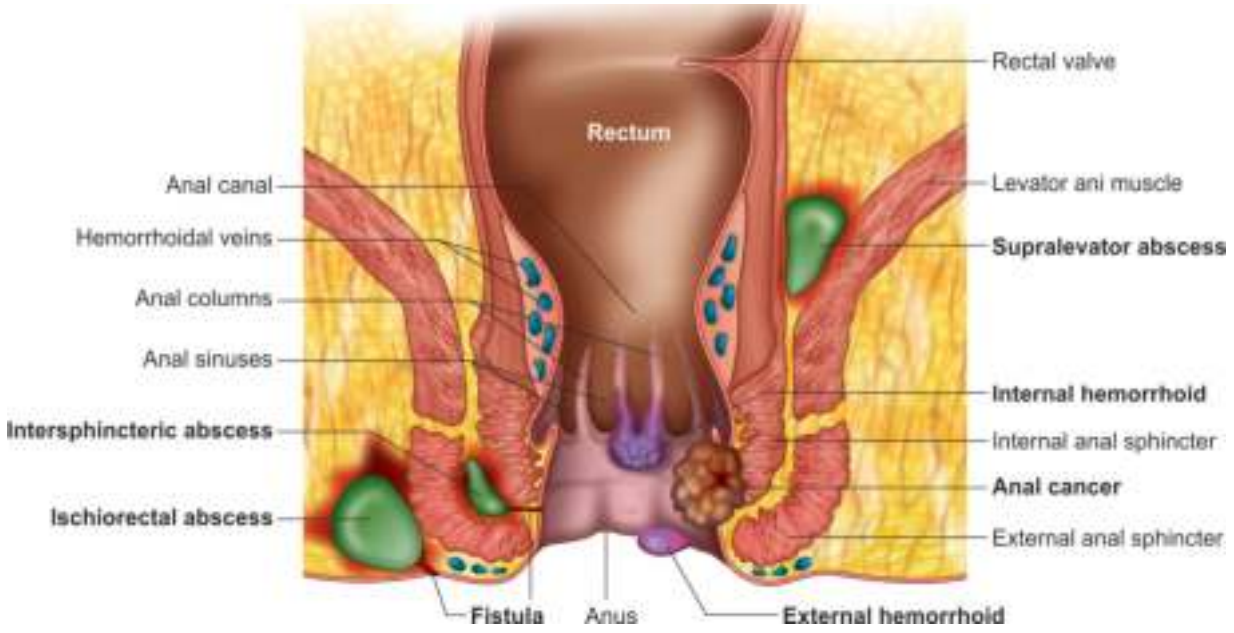

Fig. 20.74: Anatomy of anal canal and important disorders. The upper portion of the anal canal consists of colorectal-like columnar epithelium. The middle portion of the anal canal above dentate line is lined by transitional epithelium, which is squamous metaplasia of the columnar epithelium. The lower portion of the anal canal is lined by nonkeratinized stratified squamous epithelium devoid of epidermal appendages (hair follicles, apocrine glands and sweat glands). Beyond the anal verge, perianal skin is hair-bearing keratinizing squamous epithelium.

VASCULAR DISORDERS OF ANAL CANAL

HEMORRHOIDS

Hemorrhoids are painless dilated venous plexuses in the anal canal. All hemorrhoids result from increased portal venous pressure.

- Precipitating factors for hemorrhoids include chronic constipation, straining at stool, pregnancy, obesity, chronic liver disease and low fiber diet.
- Hemorrhoids should not be diagnosed unless prolapse or bleeding per rectum is a dominant symptom. Classification of hemorrhoids is given in Table 20.73. Investigation of rectal bleeding is given in Table 20.74.

External Hemorrhoids

External hemorrhoids originate from below the anorectal junction. It is covered by anal skin. It occurs as a result of dilation of inferior hemorrhoidal veins.

- These are predisposed by a low fiber diet. When thrombosed, these contain clotted blood.
- These become painful, swollen, shiny blue and itchy resulting in bleeding during defecation. Resolution of external hemorrhoids leaves a painless flabby skin sac around the anal orifice.

Table 20.73 Classification of hemorrhoids

Degree	Features
First degree	Bleeding
Second degree	Prolapse and reducing spontaneously
Third degree	Prolapse needing pushing back
Fourth degree	Prolapse permanent

Treatment of hemorrhoids is based on symptoms rather than appearances.

Table 20.74 Investigation of rectal bleeding

Symptoms (Bright Red Blood)	Diagnostic Tools
Bright red blood seen only on paper	▪ Inspection of stool ▪ Rectal examination ▪ Proctoscopy ▪ Rigid sigmoidoscopy
Bright red blood drippling into pain	▪ Proctoscopy ▪ Rigid sigmoidoscopy
Bright red blood mixed with motion	▪ Proctoscopy ▪ Rigid sigmoidoscopy ▪ Flexible sigmoidoscopy
Dark red blood	▪ Proctoscopy ▪ Rigid sigmoidoscopy ▪ Flexible sigmoidoscopy ▪ Barium meal
Anyone over 40 years of age and family history of colorectal anaplasia	Flexible sigmoidoscopy

Internal Hemorrhoids

Internal hemorrhoids originate from dilatation of superior hemorrhoidal veins above the anorectal junction and are covered by mucous membrane.

When the person performs Valsalva maneuver, internal hemorrhoids appear as red mucosal mass may protrude from anus. Internal hemorrhoids are not palpable.

NON-NEOPLASTIC DISORDERS OF ANAL CANAL

PILONIDAL SINUS

Pilonidal sinus is hair containing cyst or sinus located in the midline over the coccyx or lower sacrum.

- On clinical examination, it opens up as a dimple with visible hair and possibly, an erythematous halo.
- Pilonidal sinus may appear as a palpable cyst. When pilonidal sinus is enlarged, it has a palpable sinus tract. Although it is congenital disorder, yet the lesion is diagnosed between the ages of 15 or 30 years.

ANORECTAL FISTULA

Chronic inflammation in anorectal region creates an abnormal passage from inner anus or rectum out to skin surface surrounding anus, which is known as anorectal fistula. It most often occurs due to local abscess. Patient presents with serosanguineous or purulent discharge from red raised tract opening anorectal fistula on applying pressure. Bidigital palpation may reveal an indurated cord.

ANAL FISSURE

Anal fissure is a longitudinal tear in the superficial mucosa at the anal margin. More than 90% of anal fissures are located in the posterior midline area, which are accompanied by hyperplastic papule known as sentinel tag. Anal fissure most often results from trauma due to passage of hard stool or irritable diarrheal stool.

Patient presents with pain during and after bowel action, minor bleeding, itching, constipation, and painful spasm of sphincter.

RECTAL MUCOSAL PROLAPSE

The rectal mucosa protruding through the anus is known as rectal mucosal prolapse, which appears as moist red doughnut with radiating lines.

- **Incomplete rectal mucosal prolapse:** When prolapse is incomplete, only the mucosa is bulging.
- **Complete rectal mucosal prolapse:** When complete rectal mucosal prolapse occurs, which includes the anal sphincter following Valsalva maneuver such as straining at stool or exercise.

Predisposing Factors

Predisposing factors for rectal mucosal prolapse include constipation, excessive straining at defecation, deep pouch of Douglas, redundant sigmoid colon, decreased sigmoid colon, decreased anal canal sphincter tone and reduced pelvic support.

Other conditions causing rectal mucosal prolapse are large hemorrhoids, prolapsing rectal tumor, anal warts and polyps.

Surgical Pathology: Rectal Mucosal Prolapse

Light Microscopy

Histologic examination shows mucosal surface erosion, epithelial hyperplasia, mixed inflammatory infiltrates and lamina propria fibromuscular hyperplasia.

Clinical Features

Patient presents with rectal mucosal prolapse related symptoms, i.e. defecation, mucus discharge, bleeding, and incontinence.

PRURITUS ANI

Pruritus ani is characterized by sensation of itch, burning or pain. It is more common in men than women.

Etiopathogenesis

Pruritus ani is idiopathic in 50% of cases. Anorectal causes of pruritus ani include fissures, fistula, papilloma, skin tags, hemorrhoids and prolapse. Dermatological causes are psoriasis, lichen planus, Paget's disease, candidiasis and thread worms. Dietary factors implicated in pruritus ani include coffee, tea, spices, pork, alcohol, tomatoes and drugs (e.g. antibiotics, laxatives, colchicine, and quinidine).

Clinical Features

Patient presents with slight itch in perianal skin that may progress to severe itch especially during summer.

Management

Secondary causes of pruritus ani should be identified and treated. Patient should be advised about personal hygiene.

NEOPLASTIC DISORDERS OF ANAL CANAL

Anal cancer is relatively uncommon. It accounts for about 4% of anorectal malignancies. Various anal neoplasms include squamous cell carcinoma, malignant melanoma, lymphoma and anal gland adenocarcinoma. Overall anal cancers are more common in women. Lesions at the anal margins are more common in men. Revised (2019) WHO classification of tumors of the anal canal is given in Table 20.75.

Table 20.75 Revised (2019) WHO classification of tumors of the anal canal

Benign Epithelial Tumors and Precursor Lesions
▪ Squamous intraepithelial neoplasia, low-grade
▪ Squamous intraepithelial neoplasia, high-grade
Malignant Epithelial Tumors
▪ Squamous cell carcinoma, NOS
• Verrucous squamous cell carcinoma
▪ Adenocarcinoma, NOS
Neuroendocrine Tumors
▪ Neuroendocrine tumor, NOS
• Neuroendocrine tumor, grade 1
• Neuroendocrine tumor, grade 2
• Neuroendocrine tumor, grade 3
▪ Neuroendocrine carcinoma, NOS
• Large cell neuroendocrine carcinoma
• Small neuroendocrine tumor carcinoma
Mixed Neuroendocrine–Non-neuroendocrine Neoplasm (MiNEN)

Term NOS, not otherwise specified.
Adapted from 2019 WHO classification of tumors of the anal canal.

ANAL CARCINOMA

Anal carcinoma arises at or above the dentate line and not visible at the anus. Anal carcinoma arising below the dentate line is visible at the anus. Anal carcinoma behaves like basal cell carcinoma and has favorable prognosis.

Etiopathogenesis

There is increased incidence of anal cancer among male homosexuals. Approximately 50% of anal cancers are associated with human papillomavirus infection.

Clinical Features

Patient presents with bleeding, pain, swelling and ulceration around anus. As the anal cancer advances, patient suffers worsening pain, disturbed bowel habit, urinary incontinence and rectovaginal fistula.

- Approximately, 50% of anal cancers are diagnosed before the malignancy has spread beyond primary site.
- About 13–25% are diagnosed after the anal cancer has spread to inguinal lymph nodes and 10% to distant organs. Delay in presentation and diagnosis cause direct as well as distant metastases.
- Early anal cancers may be confused with warts, fissures, hemorrhoids leading to delayed diagnosis.

Epidermoid Carcinoma

Epidermoid carcinoma accounts for about 80% of anal cancers. The tumor is most frequently encountered in the anus at anorectal junction in the male homosexual population. HPV types 16 and 18 are linked to epidermoid carcinoma.

Surgical Pathology: Anal Carcinoma
Gross Morphology
Anal cancers appear as ulcers or proliferative growth with ulcerated areas.
Light Microscopy
On histologic examination, tumor varies predominantly well-differentiated keratinizing large cell carcinoma at the anal margin to less differentiated nonkeratinizing to small cell carcinoma in the upper anal canal (Fig. 20.75).

Basaloid Carcinoma

Basaloid carcinoma occurs at the squamocolumnar junction or transitional zone, sometimes called cloacogenic carcinoma.

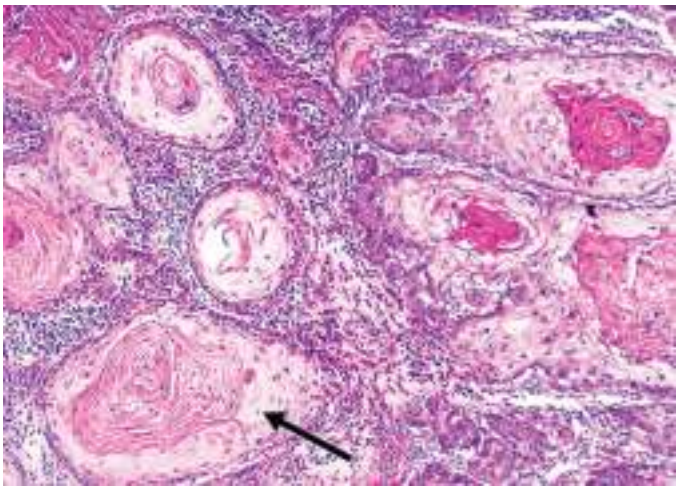

Fig. 20.75: Well-differentiated squamous cell carcinoma of anus (arrow) (400X).

DISORDERS OF PERITONEUM

ANATOMY AND HISTOLOGY

Serosal membranes are derived from the mesoderm, which form the visceral and parietal surfaces of pleural, pericardial and peritoneal cavities including tunica vaginalis. On histologic examination, serous membranes are lined by flat mesothelial cells resting on a basement membrane, below which lies a poorly delimited connective tissue layer.

NON-NEOPLASTIC DISORDERS OF PERITONEUM

ACUTE PERITONITIS

Acute peritonitis is caused due to perforation of gastric, biliary, intestine or pancreas. Spontaneous bacterial peritonitis most often occurs in children, immunocompromised persons or patients with cirrhosis.

GRANULOMATOUS SEROSITIS

Granulomatous serositis presents as small nodules in the setting of disseminated cancers. It may be caused by infections, noninfectious causes, autoimmune and meconium induced. Causes of granulomatous serositis are given in Table 20.76.

Table 20.76 Causes of granulomatous serositis

Categories	Disorders
Infectious causes	▪ Fungal infections (histoplasmosis, Cryptococcus) ▪ Parasites (Schistosomiasis, Echinococcus or Ascaris)
Noninfectious causes	▪ Sutures or starch ▪ Implants of keratin derived from mature cystic teratoma, endometrioid adenocarcinoma with squamous differentiation, squamous cell carcinoma of cervix
Autoimmune disorders	Crohn's disease or sarcoidosis
Meconium	Meconium in neonate inducing peritonitis

METAPLASIA OF PERITONEUM

Metaplasia of peritoneum most often occurs in women in the abdomen and pelvic region due to its close embryologic relationship with Müllerian ducts. Its pathogenesis is discussed below.

- **Endometriosis:** When endometriosis develops in the wall of intestine, ureter or urinary bladder, the woman presents with signs and symptoms resembling malignancy. On histologic examination, endometriosis lesion is composed of endometrial glands with stroma, dense fibrosis and adhesions. Endometriosis can induce metaplasia of peritoneum.
- **Endocervicosis:** Endocervicosis comprises benign glands resembling endocervical type of epithelium leading to metaplasia of peritoneum.
- **Ectopic decidual metaplasia:** Ectopic decidual metaplasia of peritoneum occurs in pregnant women. There is presence of small gray white nodules on the peritoneal surfaces.

- **Walthard nests:** Walthard nests appear as yellow-white nodules on the serosal surface of fallopian tubes. These may undergo cystic change. Histologic examination reveals transitional metaplasia of peritoneum.
- **Disseminated peritoneal leiomyomatosis:** It is uncommon multifocal proliferation of smooth muscle-like cells thought to represent hormone-induced metaplasia of peritoneum.

FIBROSIS OF PERITONEUM

Reactive peritoneal fibrosis occurs in the setting of recurrent peritonitis often associated with long-term peritoneal dialysis, cirrhosis, or surgery.

Sclerosing peritonitis occurs as a result of hyperplasia of submesothelial mesenchymal cells covering small intestine, diaphragm, liver, spleen in the setting of peritoneal dialysis, autoimmune disorders and carcinoid tumors.

EOSINOPHILIC PERITONITIS

Eosinophilic peritonitis occurs in the settings of childhood atopy, autoimmune collagenous disorders, hypereosinophilic syndrome, lymphomas and metastatic carcinoma.

NEOPLASTIC DISORDERS OF PERITONEUM

PRIMARY NEOPLASMS

WHO classification of tumors of peritoneum is given in Table 20.77.

Well-differentiated Papillary Mesothelioma

Well-differentiated papillary mesothelioma is a low-grade tumor associated with asbestos exposure. It most often occurs in women during reproductive period in 80% of cases. Clinical course is indolent.

Surgical Pathology: Well-differentiated Papillary Mesothelioma

Gross Morphology

Tumor is solitary or multifocal <2 cm in diameter. Cut surface is gray white exhibiting nodules and papillary structures.

Light Microscopy

Tumor is composed of papillary fronds with fibrovascular core covered by single layer of bland cuboidal to flattened mesothelial cells.

Immunohistochemistry Technique

Panel of immunomarkers is used to analyze expression in diffuse malignant mesothelioma on histologic sections.

Markers	Expression
▪ Calretinin	▪ Positive
▪ Thrombomodulin	▪ Positive
▪ WT1	▪ Positive
▪ Cytokeratin 5/6	▪ Positive

MOC-31, Ber-EP4, CA19-9 and CD15 (LeuM1) markers are negative in diffuse malignant mesothelioma. These are used to distinguish peritoneal epithelioid mesothelioma from peritoneal and ovarian serous carcinomas.

Multicystic Mesothelioma

Multicystic mesothelioma is a low-grade neoplasm also known as multicystic peritoneal inclusion cyst. On histologic examination, multilocular cysts are lined by mesothelium with bland cytologic features harboring areas of conventional malignant mesothelioma.

Diffuse Malignant Mesothelioma

Diffuse malignant mesothelioma of peritoneum is a rare neoplasm. On histologic examination, tumor resembles ectopic decidual reaction.

Table 20.77 WHO classification of tumors of peritoneum

Categories	Tumors
Mesothelial tumors	▪ Well differentiated papillary mesothelioma (low-grade tumor associated with asbestos exposure) ▪ Multicystic mesothelioma (low-grade tumor also known as multilocular peritoneal inclusion cyst) ▪ Diffuse malignant mesothelioma ▪ Adenomatoid tumor
Smooth muscle cell tumors	Leiomyomatosis peritonealis disseminata
Tumors of uncertain origin	Desmoplastic small round cell tumor
Epithelial tumors	▪ Primary peritoneal adenocarcinoma ▪ Primary peritoneal borderline tumor

SECONDARY NEOPLASMS

Secondary peritoneal metastasis is most common malignant process caused by invading cancer stem cells (CSCs) from malignant tumors involving ovary, colorectal region, stomach, breast and lung including melanoma. Metastasis from ovarian, gastric, and colorectal malignancies is associated with increased risk of recurrence and mortality. Primary tumors metastasizing to the peritoneum are given in Table 20.78.

Pseudomyxoma Peritonei

Pseudomyxoma peritonei (PMP) is a clinical term used to designate diffuse intra-abdominal gelatinous ascites with jelly-like mucinous implants on peritoneal surfaces from mucinous neoplasm of appendix, stomach, ovary, pancreas, and hepatobiliary system.

Table 20.78 Metastases to the peritoneal serosal surface

Primary Tumors Metastasizing to the Peritoneal Serosal Surface
Ovarian carcinoma
Cervical carcinoma
Breast carcinoma
Biliary tract carcinoma
Upper gastrointestinal tract carcinoma
Sarcomas of female reproductive tract
Endometrial carcinoma
Fallopian tube carcinoma
Pancreatic carcinoma
Lung carcinoma
Lower gastrointestinal tract carcinoma

GASTROINTESTINAL TRACT DISORDERS: DIAGNOSTIC APPROACH

Distribution of carcinomas in upper gastrointestinal tract is shown in Fig. 20.76. *Helicobacter pylori*-induced gastrointestinal disorders are shown in Fig. 20.77. Appendix disorders include acute appendicitis and carcinoid tumor. Important disorders of large bowel are shown in Fig. 20.78. Symptoms of colorectal disorders are given in Table 20.79. Differential diagnosis of lower abdominal mass is given in Table 20.80.

Large bowel disorders include hyperplastic polyps, neoplastic polyps, neoplasms, inflammatory bowel disease, diverticula, infectious colitis, drug-induced colitis and irritable bowel syndrome. Investigations of colorectal disorders include detailed clinical history, abdominal examination, anorectal examination, digital examination, proctoscopy, sigmoidoscopy, colonoscopy, barium enema, imaging techniques and feces examination.

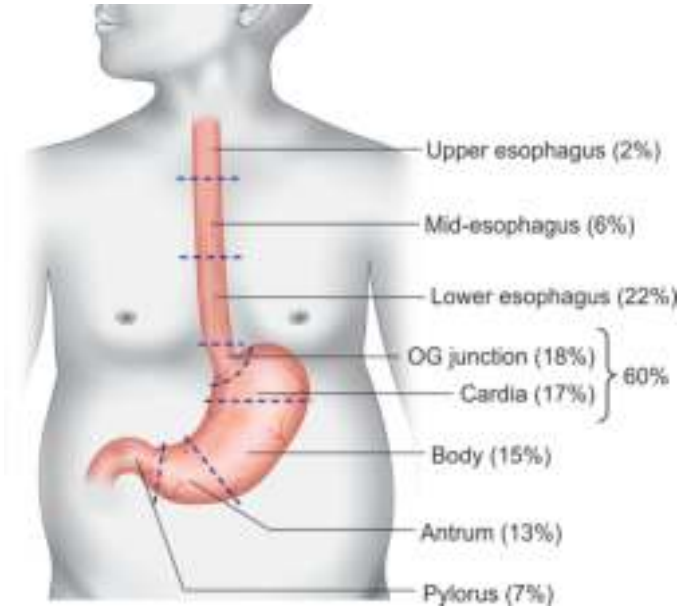

Fig. 20.76: Distribution of carcinomas in upper gastrointestinal tract.

- **Abdominal examination:** Abdomen should be inspected for visible peristalsis and distension. Palpable sigmoid colon is observed in constipated patients. Palpable liver may disclose metastatic deposits from colorectal carcinoma.
- **Anorectal examination:** Rectum and anus are readily accessible. Anorectal examination can detect pruritus ani, perianal warts, perianal abscess, perianal hematoma, prolapsing hemorrhoids, thrombosed hemorrhoids, anal fistula, anal fissures, anal cancer, rectal prolapse, rectocele and fecal soiling of perineum.
- **Digital examination:** Digital examination helps in diagnosing skin tags and Crohn's disease. On straining, prolapsing hemorrhoids, rectal prolapse and tumors are detected.
- **Proctoscopy:** Fiberoptic proctoscopy helps in visualization of rectal prolapsing mucosa, hemorrhoids, dentate line and anal epithelium.
- **Flexible sigmoidoscopy:** Flexible sigmoidoscopy permits examination up to 60 cm from the anal margin. It is performed without sedation in <10 minutes. Approximately, 70% of colorectal carcinomas are within reach of flexible sigmoidoscope.
- **Colonoscopy:** Patient should take a low residual diet followed by clear fluids for 48 hours and strong purgative before colonoscopy. Colonoscopy is more

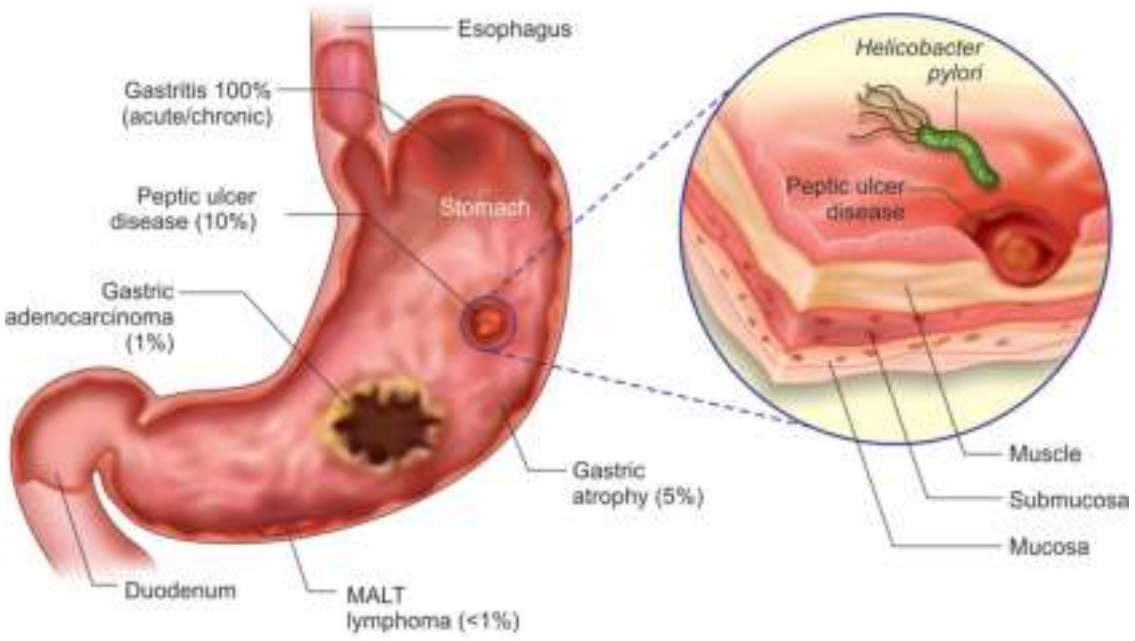

Fig. 20.77: *Helicobacter pylori*-induced gastrointestinal disorders.

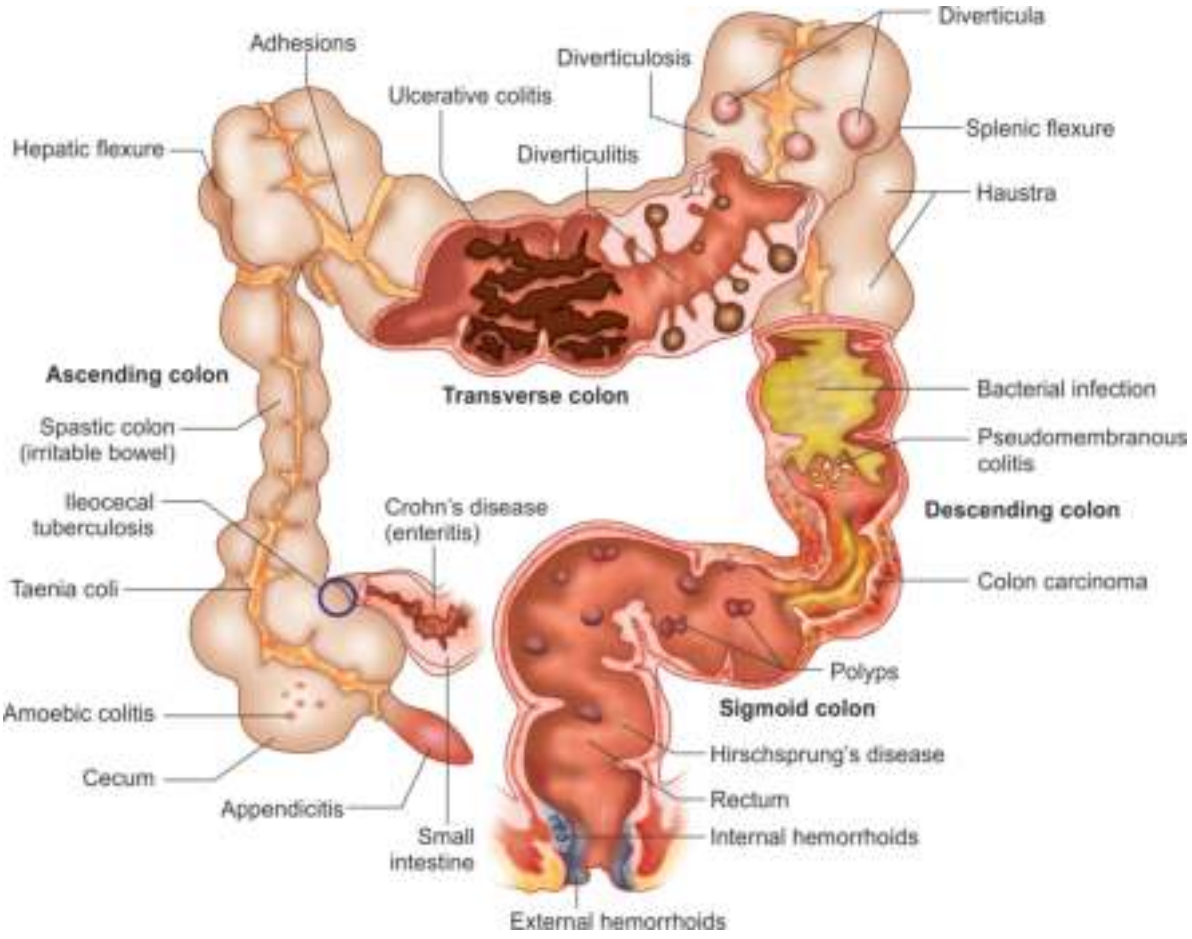

Fig. 20.78: Important disorders of large bowel.

Table 20.79 Symptoms of colorectal disorders

Parameters	Symptoms
Nonspecific symptoms	▪ Malaise ▪ Vomiting ▪ Weight loss
Abdominal pain	▪ Constant pain or colic ▪ Distension ▪ Borborygmi
Bowel habits	▪ Altered frequency ▪ Constipation or diarrhea ▪ Bleeding (bright red or mixed with mucus, dark or altered)
Anal and perianal	▪ Pruritus ▪ Pain related to defecation ▪ Prolapse ▪ Incontinence ▪ Discharge ▪ Tenesmus ▪ Swelling (painful or painless)

Table 20.80 Differential diagnosis of lower abdominal mass

Location	Disorders
Right iliac fossa	▪ Carcinoma of cecum ▪ Crohn's disease ▪ Appendicular abscess ▪ Ileocecal tuberculosis ▪ Actinomycosis ▪ Intussusception
Left iliac fossa	▪ Carcinoma of sigmoid colon ▪ Diverticular disease
Either iliac fossa	▪ Ovarian mass ▪ Ectopic pregnancy ▪ Transplanted kidney

sensitive for detecting fine mucosal abnormalities, biopsy sampling and therapeutic procedures such as polypectomy.

- **Double contrast barium enema:** In double contrast barium enema, air is pushed after evacuation of barium, which discloses gross anatomy, extracolonic abnormalities such as fistulas.
- **Imaging modalities:** Imaging techniques used to detect colorectal disorders include ultrasonography, CT scan and MRI scan.
  - Ultrasonography: It may demonstrate clinically inapparent metastases in patients with colorectal carcinoma.
  - CT and MRI scans: Preoperative computed tomography and magnetic resonance scanning give more accurate information in detection of local extent of rectal carcinoma and hepatic metastases than ultrasonography. MRI scanning is useful in the assessment of complex anal fistulas.
- **Feces examination:** Detection of occult blood in the feces is important in the investigation of patients with unexplained iron deficiency anemia.
  - Occult blood: Feces of patient smeared on a filter paper is impregnated with guaiac acid and then added hydrogen peroxide. Hematin from hemoglobin in the feces catalyzes the oxidation of guaiac acid giving characteristic color change to blue. Immunologic tests for human hemoglobin may prove to be more sensitive.
  - 24 hours fecal fat and D-xylose tests: Diagnostic modalities include 24 hours fecal fat excretion. D-xylose test, anti-tissue transglutaminase circulating autoantibodies and intestinal biopsy. The autoantibody test may also be used for screening prior to definitive diagnosis by biopsy.
  - Culture and sensitivity: It is done if infection is suspected such as *Entamoeba histolytica* and toxins of *Clostridium difficile* in patients with pseudomembranous colitis.
- ***Helicobacter pylori* tests:** In the advanced stage of *Helicobacter pylori*-induced gastrointestinal tract disorders; urea breath test or antibody test for *Helicobacter pylori* must be performed.
- **Serum tumor markers:** Serum carcinoembryonic antigen (CEA), CA 19-9 and CA 72-4 levels are increased in colon carcinoma.
- **Sampling of tissue biopsy:** Tissue biopsy is obtained by several procedures:
  - Endoscopic biopsy: Small fragments of mucosal tissue are obtained for histologic examination.
  - Suction biopsy: It makes possible to obtain submucosa for study.
  - Polypectomy: The specimen is bisected or serial sections depending on size of polypoid mass.
  - Endoscopic mucosal resection: Mucosal resections are obtained by this method.

Table 20.81 Panel of immunohistochemical markers applied in Barrett's esophageal intestinal metaplasia at the gastroduodenal junction and tumors of gastrointestinal tract

Immunohistochemical Markers	Expression
Barrett's esophageal intestinal metaplasia at the gastroduodenal junction	
Cytokeratin 7 (CK7) surface and deep region	Positive
Cytokeratin 20 (CK20) surface region only	Positive
DAS-1	Positive
MUC1	Positive
MUC2	Positive
Gastric adenocarcinoma (intestinal type)	
Cytokeratins (CKs)	Positive
Epithelial membrane antigen (EMA)	Positive
Carcinoembryonic antigen (CEA)	Positive
CDX2	Positive (specific marker)
Colorectal adenocarcinoma	
Carcinoembryonic antigen (CEA)	Positive
Cytokeratin 7 (CK7)	Positive
Cytokeratin 20 (CK20)	Positive
CDX2 (transcription factor)	Positive (specific marker associated with poor prognosis)
SAT (transcription factor)	Positive
β-Catenin	Positive
p53	Positive
Villin	Positive
Gastrointestinal stromal tumors	
c-KIT (CD117) encoding tyrosine kinase	Positive (strong staining in membranous, cytoplasmic or perinuclear globular patterns in 90%)
DOG1	Positive (most specific marker)
PDGFA	Positive
CD34	Positive (75%)
Smooth muscle actin	Positive (40%)
Protein kinase c-theta	Positive
Vimentin	Positive
Smooth muscle actin encoded by ACTA2 gene	Positive
Desmin	Positive (5%)
S-100 protein	Negative
Gastrointestinal carcinoid (neuroendocrine) tumors	
Synaptophysin	Positive (cytoplasmic staining)
Chromogranin A	Positive (cytoplasmic staining)
Neuron-specific enolase (NSE)	Positive (cytoplasmic staining)
CD56 (neuronal cell adhesion molecule—NCAM) neuroendocrine marker	Positive (membranous staining)
Cytokeratins (AE1/AE3 and CAM 5.2 epithelial marker)	Positive (cytoplasmic staining)
CDX2	Positive (50%)

Contd...

Table 20.81 Panel of immunohistochemical markers applied in Barrett's esophageal intestinal metaplasia at the gastroduodenal junction and tumors of gastrointestinal tract (*Contd...*)

Immunohistochemical Markers	Expression
Gastrointestinal tract mucosa-associated lymphoid tissue (MALT) lymphoma	
CD20	Positive
CD43	Positive
IgM > IgA > IgG	Positive
IgD	Negative
CD5	Negative
CD10	Negative
BCL-16	Negative
Cyclin D1	Negative

There is no definite immunohistochemical marker for gastric MALT lymphoma. Panel of immunohistochemical markers are appile to assess architecture of infiltration lymphoid cells, immunophenotype and chain restriction.

- Bowel resection: Portion of bowel resection is obtained to study various gastrointestinal disorders. Serosal surface is examined to study involvement by tumor. Bowel wall is inspected for tumor involvement, perforation and adhesion.

  Mesentery and soft tissue are dissected to obtain lymph nodes. A minimum of 12 lymph nodes is required for establishing staging criteria.

- **Immunohistochemistry technique:** Immunohistochemistry has now become the most powerful and widely used ancillary diagnostic tool in surgical pathology, especially in the diagnosis of undifferentiated tumors. Panel of immunohistochemical markers applied in Barrett's esophageal intestinal metaplasia at the gastroduodenal junction and tumors of gastrointestinal tract is given in Table 20.81.

DISORDERS OF EXOCRINE PANCREAS
- Exocrine pancreas: structure
  - Anatomy and physiology
- Pancreatitis: overview
  - Acute pancreatitis
  - Chronic pancreatitis
  - Autoimmune pancreatitis
- Cystic fibrosis of pancreas
- Exocrine and endocrine pancreatic tumors
- Islet cell tumors
- Metastatic pancreatic tumors

DISORDERS OF LIVER

ANATOMY AND PHYSIOLOGY

NORMAL STRUCTURE

The liver and pancreas are derived as glandular outgrowths of the primitive foregut. The liver is the largest parenchymal organ weighing about 1000–1500 g. It lies just below the diaphragm. The right lobe liver is larger than the left lobe. The falciform ligament is the rough dividing line between the two lobes. External surface is smooth and brown. Cut surface is brown.

Anatomy of the liver and its relationship to the gallbladder, pancreas and duodenum is shown in Fig. 21.1.

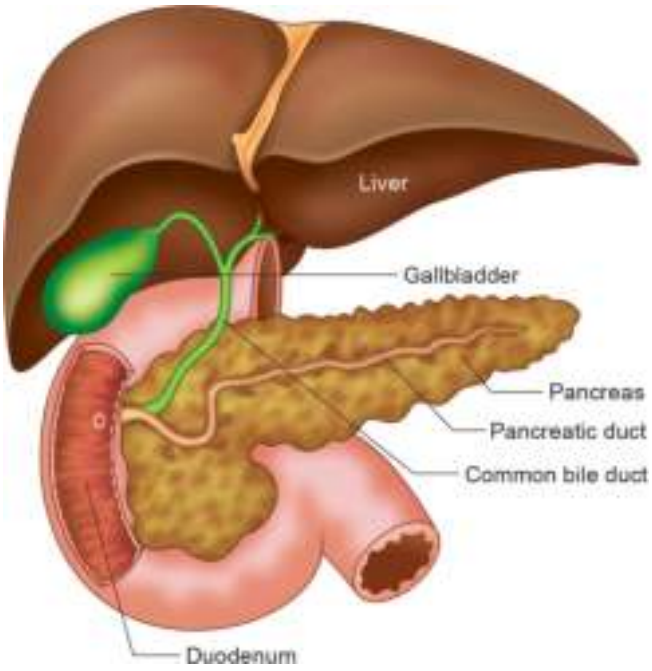

Fig. 21.1: Anatomy of the liver and its relationship to the gallbladder, pancreas and duodenum.

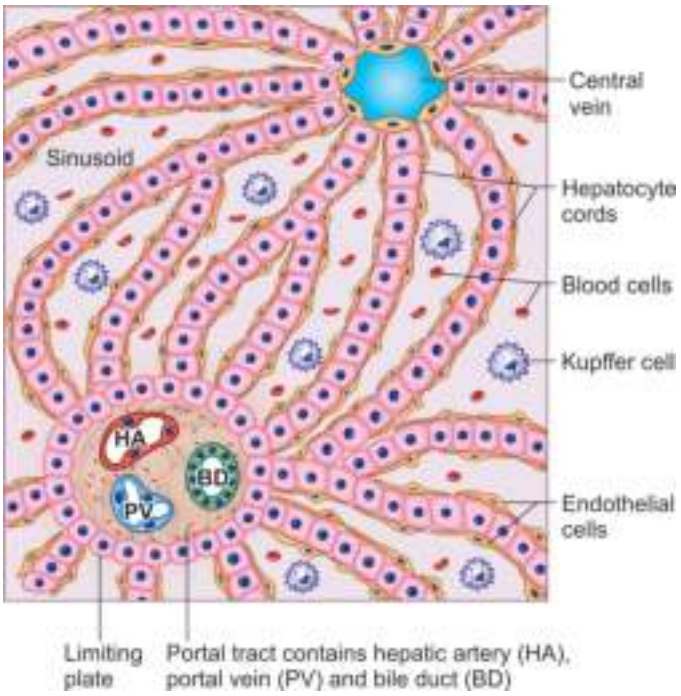

Fig. 21.2: Schematic representation of the normal liver lobule. The portal tract contains branches of the hepatic artery, portal vein, and interlobular bile duct. The liver cell plates converge to the terminal hepatic venule.

Liver Acinus (Lobule)

Liver is divided histologically into hexagonal or polyhedral lobules. The center of the liver lobule (acinus) has central vein. Portal triads are present at the periphery of the liver lobule. Portal triad consists a branch of hepatic artery, portal vein and bile duct (Figs 21.2 and 21.3).

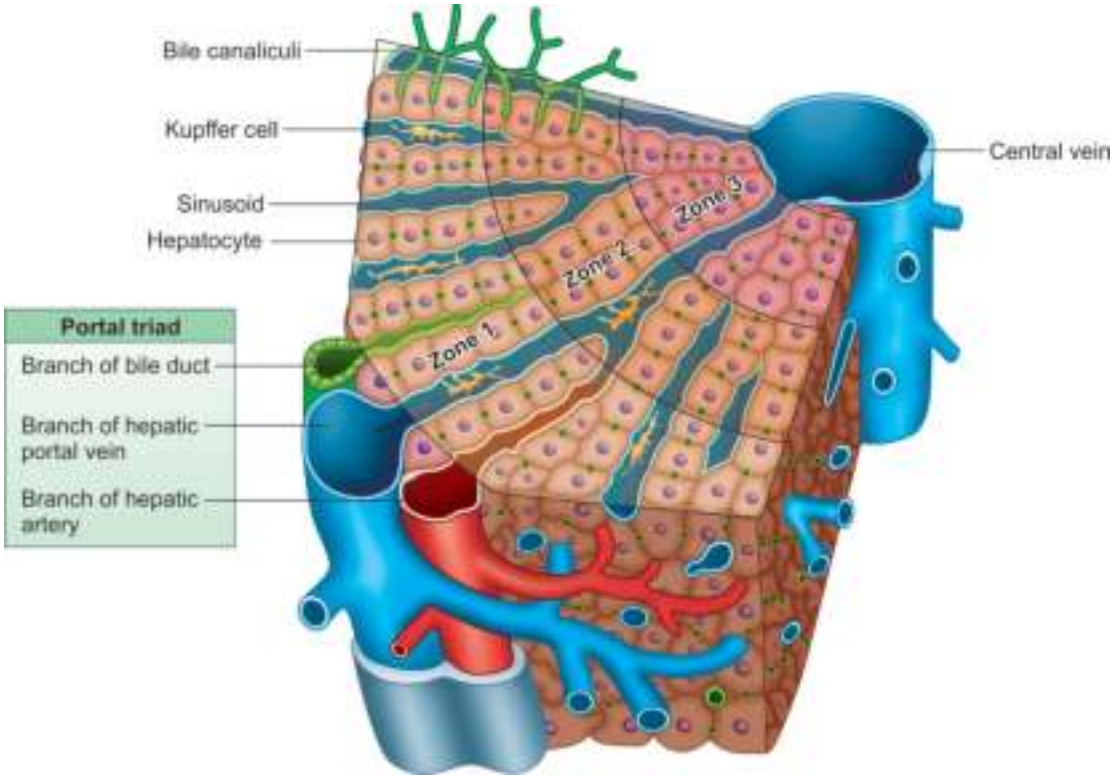

Fig. 21.3: Liver lobule shows cords of hepatocytes, sinusoids and bile ducts in the liver. Blood flows in sinusoids towards the center of the lobule (terminal hepatic vein) and bile in opposite direction draining in the bile ducts.

Portal Triad

Portal triad consists of branch of bile duct, portal vein and hepatic artery surrounded by fibrocollagenous tissue. The area surrounding central vein is known as centrilobular area. The area surrounding portal triad is known as periportal area.

Hepatocytes

Hepatocytes radiate from the portal tracts towards the terminal hepatic venules. Hepatocytes are arranged in one-cell thick columns. Sinusoid is present between each of these columns.

Limiting Plates

Portal tract is bound by a row of hepatocytes known as limiting plate. The liver cell plates are two-cell thick in babies and small children. By attaining the age of 5 years the normal one-cell thick pattern is established. Destruction of limiting plates in hepatitis is known as piecemeal necrosis.

FUNCTIONAL ZONES OF LIVER ACINUS (LOBULE)

Functionally, the liver can be divided into three zones between the portal triad and central vein; based on supply of oxygen and nutrients. Lobular and acinar regions of liver terminology are given in Table 21.1.

Pathology Pearls: Functional Zones of Liver Acinus

Zone 1 of Liver Acinus

- Zone 1 of liver acinus encircles the portal tracts (periportal zone). It receives richest oxygen and nutrients from hepaticartery.
- Zone 1 of liver acinus hepatocytes are specialized for oxidative liver functions such as gluconeogenesis, synthesis of glycogen from lactate, β-oxidation of fatty acids, catabolism of amino acids, urea synthesis, cholesterol synthesis, secretion of bile salts and acid; and sodium-dependent bile acid uptake.

Zone 2 of Liver Acinus

- Zone 2 of liver acinus is located between zone 1 and zone 3. It has moderate supply of oxygen and nutrients.

Zone 3 of Liver Acinus

- Zone 3 of liver acinus is located in most distant region from the portal tract around central vein (perivenular zone). It has poor supply of oxygen and nutrients.
- Zone 3 hepatocytes are important for glycolysis, synthesis of glycogen from glucose, lipogenesis, cytochrome P-450 based drug and toxins detoxification, removal of ammonia from blood by glutamine, ketogenesis, secretion of bile salts and acid; and sodium-dependent bile acid uptake.
- There is increased phagocytic activity of Kupffer cells. Necrosis of hepatocytes in Zone 3 of liver acinus associated with lymphocytic infiltration should raise concern for autoimmune hepatitis, liver transplant rejection and hepatocellular injury induced by alcohol and drugs.

Table 21.1 Lobular and acinar regions of liver terminology

Lobular	Acinar	Description
Periportal region	Zone 1	Area around the portal tract
Midzonal region	Zone 2	Parenchyma between central venule and portal tract
Centrilobular, central, centrizonal region	Zone 3	Area around central venule

Hepatic Vasculature

Near the hilum, portal tract contains portal vein, branch of hepatic artery and interlobular bile ducts. Liver receives blood supply from portal vein and hepatic artery. The liver cell plates converge to the terminal hepatic venule (Fig. 21.4).

Portal Vein

Liver receives 70–75% of blood flow from portal vein. Portal vein is formed by joining of the superior mesenteric vein and splenic vein. Normal portal vein pressure is 5–10 mm Hg.

Hepatic Artery

Liver receives 25–30% of oxygenated blood flow from hepatic artery. Hepatic artery occlusion does not cause necrosis of hepatocytes except in transplanted liver.

Hepatic Vein

Hepatic vein drains blood from the liver to the inferior vena cava. Hepatic abnormalities include disturbance of blood flow and portal hypertension.

Hepatic Sinusoids

Liver Sinusoids

The liver sinusoids are lined by endothelial cells. Underneath the endothelium, there is a row of hepatocytes. Sinusoidal endothelium lacks tight junctions between endothelial cells and basement membrane of the endothelium.

This anatomical arrangement permits free access of plasma from sinusoidal blood to the hepatocytes, thus facilitating two-way exchange of molecules between hepatocytes and blood.

Clinical Pearls: Diseases that can Affect Sinusoidal Blood Flow

- Sickle cell disease
- Cirrhosis
- Metastatic deposits in liver
- Chemotherapy
- Cytotoxic drug in preparation of bone marrow transplantation.

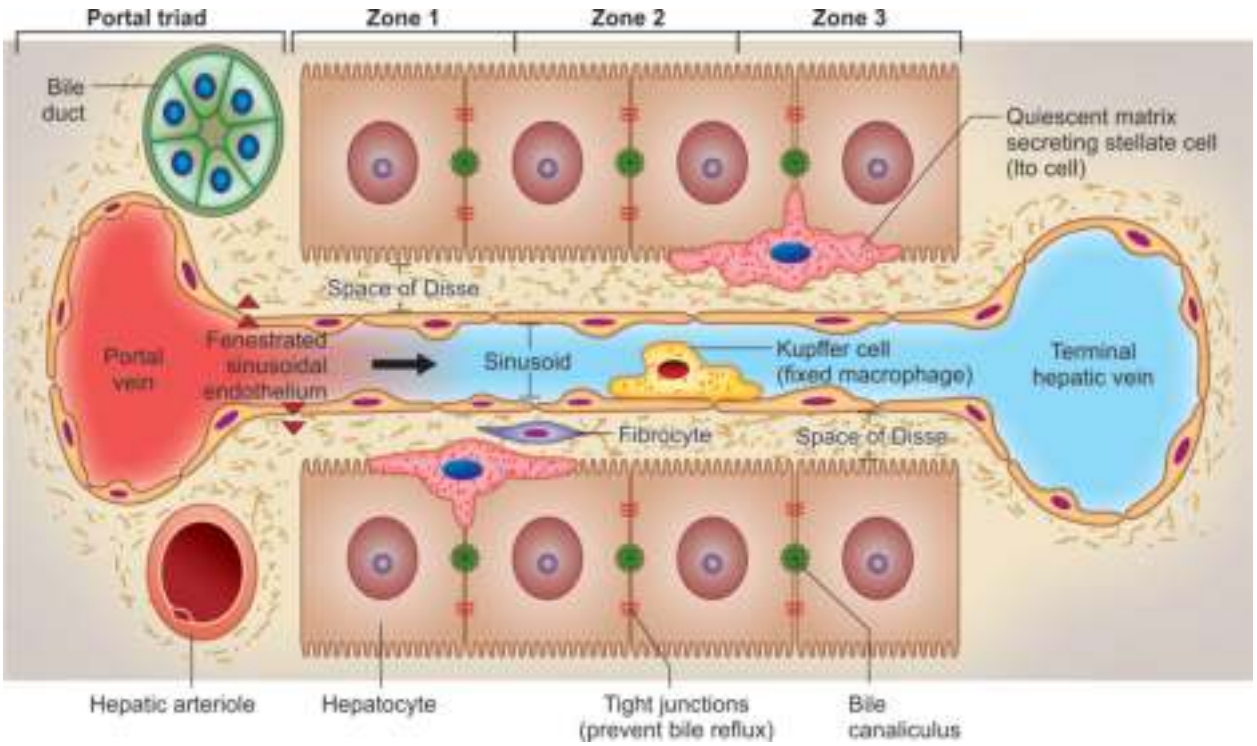

Fig. 21.4: The hepatic sinusoid and perisinusoidal space. Tight junction between hepatocytes prevents escape of bile.

Space of Disse

The space between the endothelium and hepatocytes is known as '**space of Disse**'. It contains collagen fibers especially type 3, proteoglycans and some fibronectin. Space of Disse consists of Kupffer cells and perisinusoidal stellate cells (Ito cells).

Kupffer Cells

Kupffer cells are adherent to sinusoidal endothelial cells inside sinusoid, which function as fixed tissue macrophages and participate in the phagocytosis of gut-derived bacteria. The Kupffer cell population is greatest in zone 1 of the liver acinus. Kupffer cells help in metabolism of vitamin A.

Perisinusoidal Stellate Cells (Ito Cells)

Perisinusoidal stellate cells (Ito cells) are in close contact with the liver cells, which may extend into small recesses between hepatocytes. Most of them contain vitamin A. These cells have myofibroblastic properties and participate in synthesis of collagen fibers during inflammation.

Bile Canaliculi

Bile canaliculi are present in between hepatocytes. Bile from bile canaliculi is drained into the bile ducts in portal triad and ultimately into the common bile duct. The canalicular microvilli are surrounded by a meshwork of contractile proteins, which maintain tone within the canalicular system. From the canaliculi, the bile flows into the periductules known as **canals of Hering**.

PHYSIOLOGY

Liver participates in excretion of substances, detoxification of substances, synthesis of vitamin K-dependent clotting factors (II, VII, IX, X), proteins, metabolism of carbohydrates, lipids and proteins; and storage of iron. Functions of the liver are given in Table 21.2. Functions of the liver and clinical manifestations due to altered function are given in Table 21.3.

Carbohydrate Metabolism

Liver participates in conversion of carbohydrates and proteins into triglycerides and fatty acids. It regulates blood glucose concentration by glycogenesis, glycogenolysis and gluconeogenesis. Hepatic pathway of carbohydrate metabolism is shown in Fig. 21.5.

Protein Metabolism

Liver participates in synthesis of plasma proteins (albumin, α and β globulins and fibrinogen), vitamin K-dependent coagulation factors (II, VII, IX, X), and nonessential amino acids. It also synthesizes α_1-antitrypsin and ceruloplasmin (Fig. 21.6).

- Decreased synthesis of albumin in liver leads to edema.

Table 21.2 Functions of the liver

Parameters	Liver functions
Lipid metabolism	▪ Oxidation of triglycerides into the fatty acids, further conversion into ketone bodies for fuel, glucose and cholesterol ▪ Synthesis and excretion of lipoproteins into the blood ▪ Synthesis of cholesterol and phospholipid ▪ Synthesis of bile acids ▪ Synthesis and excretion of cholesterol and bile acids
Carbohydrate metabolism	▪ Conversion of carbohydrates and proteins into triglycerides and fatty acids ▪ Regulation of blood glucose by glycogenesis, glycogenolysis and gluconeogenesis
Protein metabolism	▪ Synthesis of plasma proteins including albumin, α- and β-globulins ▪ Synthesis of nonessential amino acids ▪ Synthesis of coagulation factors (II, VII, IX, X)
Waste management, detoxification and drug metabolism	Detoxification of metabolic waste products (e.g. deamination of amino acids and production of urea)
Storage	Storage of vitamins, iron, carbohydrate (glycogen) and lipids
Intermediate metabolism	Clearance and excretion of drugs, toxins, metabolic byproducts (bilirubin, ammonia and estrogen hormone)
Secretion	Synthesis and secretion of bile

Bile juice contains many of the products of the above processes, i.e. bile salts, bilirubin, cholesterol, phospholipid, amino acids, steroids, enzymes, vitamins and porphyrins.

Table 21.3 Functions of the liver and clinical manifestations due to altered functions

Metabolism	Liver Functions	Clinical Manifestations due to Altered Function
Carbohydrate metabolism	Glycogen storage and synthesis of glucose derived from amino acids, lactic acid and glycerol	Hypoglycemia due to impaired glycogenolysis and gluconeogenesis. Abnormal glucose tolerance due to impairment of uptake and release of glucose by the liver
Fat metabolism	▪ Lipoproteins synthesis ▪ Conversion of proteins and carbohydrates to fat; synthesis, recycling and elimination of cholesterol; formation of ketone bodies from fatty acids	▪ Impaired synthesis of lipoproteins ▪ Altered serum cholesterol level
Proteins metabolism	▪ Deamination of proteins and synthesis of urea from ammonia ▪ Synthesis of plasma proteins ▪ Synthesis of coagulation factors (fibrinogen, prothrombin, factors V, VII, IX and X) ▪ Synthesis of bile salts ▪ Elimination of bilirubin by hepatocytes	▪ Increased blood ammonia level ▪ Decreased serum proteins especially albumin resulting in edema (transudate) ▪ Bleeding tendencies due to decreased synthesis of coagulation factors ▪ Malabsorption of fats and fat-soluble vitamins ▪ Increased serum bilirubin and jaundice
Metabolism of steroid hormones	▪ Sex hormones ▪ Glucocorticoids ▪ Aldosterone	▪ Gonadal dysfunction including gynecomastia in male ▪ Increased cortisol concentration (Cushing's syndrome) ▪ Manifestations of hyperaldosteronism (sodium retention and hypokalemia)
Metabolism of drugs	Drugs metabolism taking place in liver	Decreased metabolism of drug and its binding due to decreased synthesis of albumin
Vitamins and minerals	Storage of vitamins and minerals	Clinical manifestations of fat-soluble vitamins due to deficiency of storage in liver
Filtration and removal of bacteria	Liver Kupffer cells filter and remove bacteria	Increased exposure of coelomic cavities

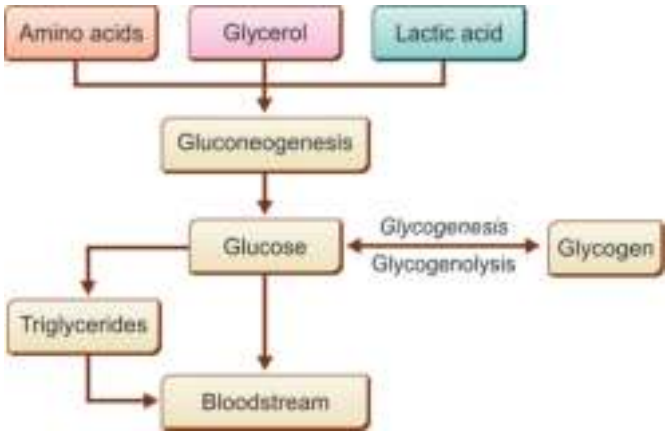

Fig. 21.5: Hepatic pathway of carbohydrate metabolism (storage and synthesis of glucose and conversion of glucose to fatty acids).

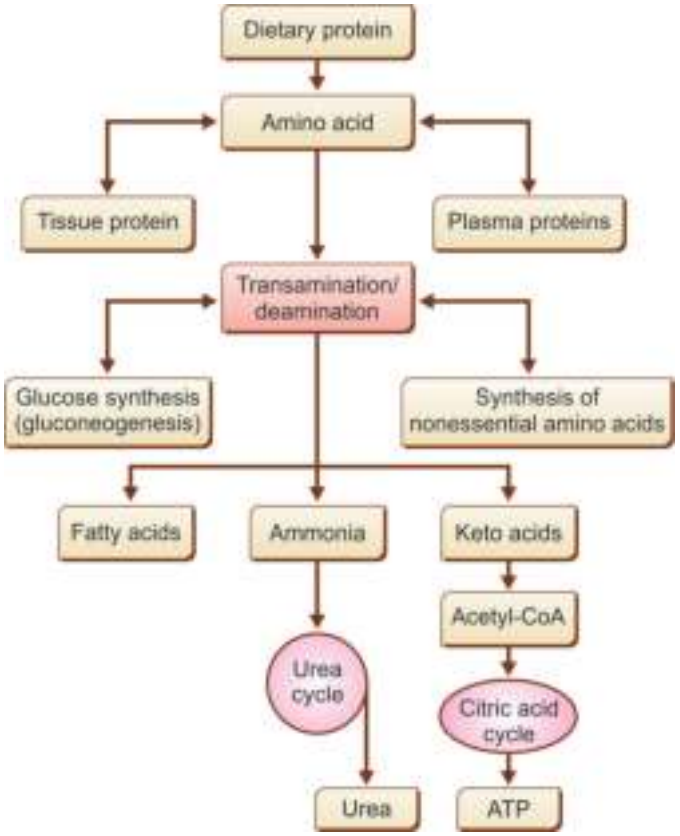

Fig. 21.6: Hepatic pathway of protein metabolism shows conversion of amino acids to proteins, nucleic acids, keto acids and glucose. The urea cycle converts ammonia generated by the deamination of amino acids to urea (acetyl-CoA, ATP and adenosine triphosphate).

- Decreased synthesis of fibrinogen and vitamin K-dependent coagulation factors (II, VII, IX, X) leads to coagulation disorders.
- The α_1-antitrypsin deficiency causes **panacinar emphysema** and **cirrhosis**.
- Deficiency of copper transporting ceruloplasmin protein results in **Wilson's disease**.

Lipid Metabolism

Liver oxidizes triglycerides into the fatty acids, which can be further metabolized into ketone bodies for fuel, glucose and cholesterol. Liver synthesizes and excretes lipoprotein into the blood. It participates in synthesis and excretion of cholesterol, phospholipid and bile acids. Hepatic lipid metabolism is shown in Fig. 21.7.

Intermediate Metabolism of Substances

Liver participates in the clearance and excretion of drugs, toxins metabolic byproducts (bilirubin, ammonia and estrogen hormone).

Detoxification of Metabolic Waste Products

Liver participates in detoxification of metabolic waste products (e.g. deamination of amino acids and production of urea).

Storage Function

Liver stores fat soluble vitamins (A, E, D and K), iron, carbohydrate (glycogen) and fat.

Secretion of Bile Juice

Liver participates in synthesis and secretion of bile. Bile juice contains water (95%), bile salts, bilirubin, phospholipid, cholesterol, amino acids, steroids, enzymes, vitamins and porphyrins.

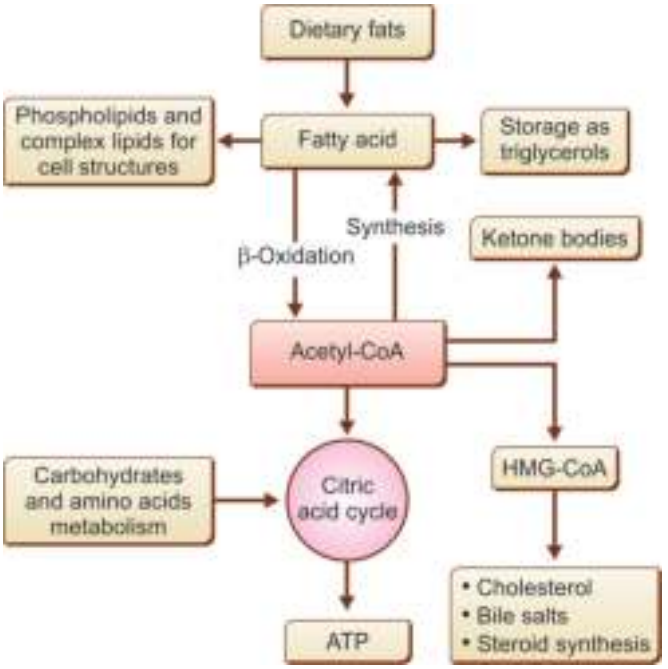

Fig. 21.7: Hepatic lipid metabolism shows β-oxidation breaking fatty acids into two-carbon acetyl-CoA units, which are used in the citric acid cycle to generate ATP or synthesis of cholesterol of keto acids leading to their release into blood for utilization by the tissues for energy purpose.

HEPATOCELLULAR DISEASE

Acute hepatocellular disease persists for <6 months. Chronic hepatocellular disease persists for >6 months. Causes of hepatocellular disease are given in Table 21.4. Enzymes indicative of liver plasma membrane integrity are given in Table 21.5.

PATTERNS OF LIVER NECROSIS

Focal Hepatic Necrosis

Focal necrosis of liver involves single cell or small group of cells in any area of lobules. But all liver lobules are not affected. Focal liver necrosis is caused by viral hepatitis, toxic agents and bacteria.

Table 21.4 Causes of hepatocellular disease

Duration of Hepatocellular Disease	Causes
Acute hepatocellular disease persists for <6 months	▪ Common causes: HBA, HBV, HBC, alcoholic hepatitis, toxic injury, ischemic injury ▪ Less common causes: HDV, HEV, CMV, EBV, Herpes virus, autoimmune hepatitis, Wilson disease, liver disease of pregnancy
Chronic hepatocellular disease persists for >6 months	▪ Common causes: HBV, HCV, alcoholic liver disease, nonalcoholic fatty liver (NAFL), drug toxicity, autoimmune hepatitis ▪ Inborn errors of metabolism: Hemochromatosis, α_1-antitrypsin deficiency, Wilson disease, glycogen storage disease, Gaucher's disease

In hepatocellular disease, the relative elevation of ALT and AST exceed the relative elevation in alkaline phosphatase (ALP).

Surgical Pathology: Focal Necrosis of Liver

Light Microscopy

- Histologic examination of liver biopsy shows Councilman's bodies (apoptotic bodies) in viral hepatitis.
- Kupffer cells hyperplasia is seen around necrotic cells.

Zonal Hepatic Necrosis

Zonal liver necrosis is characterized by involvement of identical region of all hepatic lobules. There are three types of zonal necrosis.

- **Centrilobular necrosis:** It most often occurs due to cardiac failure, hypotensive shock, viral hepatitis, carbon tetrachloride toxicity and chloroform toxicity.
- **Midzonal necrosis:** It is seen in yellow fever.
- **Periportal necrosis:** It occurs due to phosphorus poison and eclampsia of pregnancy.

Submassive Hepatic Necrosis

An entire hepatic lobule shows necrosis involving 26–75% of liver parenchyma.

Massive (Fulminant) Hepatic Necrosis

Fulminant acute liver failure is also known as *massive hepatic necrosis* involving >75% of liver parenchyma due to hepatotropic viruses, drugs, toxins and chemicals. Fulminant acute hepatitis may progress to hepatic encephalopathy within 2–3 weeks of onset of jaundice. Causes of fulminant hepatitis are given in Table 21.6. Clinical features of fulminant acute liver failure are given in Tables 21.7A and B.

Table 21.5 Enzymes indicative of liver plasma membrane integrity

Indicative of Hepatocellular Disease	Indicative of Biliary Tract Disease
Alanine aminotransferase (ALT)	Alkaline phosphatase (ALP)
Aspartate aminotransferase (AST)	Gamma-glutamyltransferase (GGT)
Lactate dehydrogenase (LDH)	5'-Nucleotidase (5'-NT)

Biliary tract disease produces relatively greater increase in alkaline phosphatase (ALP) than increase in ALT, AST or LDH. Alkaline phosphatase (ALP) is associated with plasma membrane of hepatocytes adjacent to the biliary tract.
Enzymes indicative of hepatocellular disease are alanine aminotransferase (AST). Alkaline phosphatase (ALP) elevations relate to biliary tract disease.

Table 21.6 Etiology of massive (fulminant) hepatic necrosis

Categories	Examples
Hepatotropic viruses	HBV, HDV, HEV (20% in pregnant women) and HCV (rare)
Therapeutic drugs	Acetaminophen, methyldopa, isoniazid, halothane, and antidepressants
Toxins	Myotoxin
Chemicals	Carbon tetrachloride and phosphorus

Table 21.7A Clinical features of fulminant acute liver failure

Fulminant Liver Failure	Clinical Manifestations
Hepatic encephalopathy	▪ Grade I: Mild confusion, euphoria or depression ▪ Grade II: Drowsy and semi-comatose ▪ Grade III: Stupor (marked confusion but rousable) ▪ Grade IV: Coma (unrousable)
Jaundice	Yellow discoloration of eyes
Bleeding tendency	Oozing from gastrointestinal tract
Asterixis (flapping tremors)	Demonstrated with the arms outstretched and hands dorsiflexed reflecting uremia

Table 21.7B Clinical features of liver disease

Clinical Signs and Symptoms	Mechanism	Clinical Features
Jaundice	Failure of uptake, conjugation and excretion of bilirubin	Yellow discoloration of tissues (sclera) due to deposition of bilirubin pigment
Bleeding manifestations	Failure of synthesis of vitamin K-dependent coagulation factors (II, VII, IX, X)	Easy bruising and prolonged clotting time of blood
Edema (transudate)	Failure of synthesis of albumin causing decreased oncotic pressure exerted by plasma proteins	Swelling in the dependent part of body due to accumulation of fluid (water) in extracellular compartment
Ascites	Portal hypertension and decreased hepatic synthesis of albumin	Accumulation of fluid in peritoneal cavity (ascites), demonstrated by shifting dullness
Gynecomastia	Failure to detoxify endogenous or exogenous estrogens	Enlargement of bilateral breasts
Hepatic encephalopathy	Occurs due to failure to detoxify ammonia and excitatory amino acids derived from protein breakdown	Altered consciousness, lack of coordination, coma and flapping tremors
Hematemesis and melena	Portal hypertension	Blood loss in vomitus and stool

Clinical Pearls: Liver Transplantation

Liver transplantation has emerged as an established and well-accepted therapeutic option for patients with acute and chronic hepatocellular failure and hepatocellular carcinoma. The indication for liver transplantation should be assessed independently of etiology. Aim of liver transplantation is to prolong patient's life and improve quality of life.

- **Specific indications:** Specific indications of liver transplantation include acute hepatic fulminant failure, chronic hepatic failure, hepatocellular carcinoma, cirrhosis, extrahepatic biliary atresia, inborn errors of metabolism including α-antitrypsin deficiency, sclerosing cholangitis, and hepatic vein thrombosis (Budd-Chiari syndrome).
- **Prognosis of liver transplantation:** Acute hepatic fulminant failure continues to be associated with high mortality rate and emergency liver transplantation is often the only life-saving. Survival after liver transplantation for acute fulminant hepatocellular failure has been reported to less favorable survival for patients with chronic liver disease.
- **Liver transplantation evaluation processes:** Liver transplantation evaluation processes include hematology evaluation, laboratory biochemical investigations (serum bilirubin, AST, ALT, prothrombin time and international normalized ratio, liver function tests, renal function tests, thyroid profile, ceruloplasmin, viral hepatotropic viruses and autoantibodies), hepatic imaging (sonography with Doppler, MS—CT/dynamic MRT), cardiopulmonary evaluation, and pathogens evaluation (CMV, EBV, Mycobacterium tubercle bacilli).
- **Absolute contraindications:** Absolute contraindications for hepatic transplantation include severe cardiopulmonary disease, severe pulmonary arterial hypertension (mean pulmonary artery pressure (PAP) $\geq$25 mm Hg in right heart), hepatocellular carcinoma with extrahepatic metastasis and current extrahepatic malignancies.
- **Complications:** Most common complications include acute graft rejection, vascular thrombosis, biliary leakage or stricture, infections, malignancy and adverse effects of immunosuppressive drugs. Graft-versus-host disease causes damage to interlobular ducts of liver.

Clinical Features

Patient of massive liver necrosis presents with jaundice, bleeding, confusion and disorientation. Marked elevation of ALT and AST are characteristic findings. Serum bilirubin rises rapidly. There is prolonged prothrombin time and international normalized ratio (PT–INR).

Surgical Pathology: Massive Hepatic Necrosis

Gross Morphology

- Liver is soft flabby shrunken in size one-third of its normal weight (500 g) with wrinkled Glisson's capsule.
- There is presence of patches of greenish bile stained areas.
- Cut surface shows areas of necrosis and patches of bile stain.

Light Microscopy

- Liver biopsy reveals necrotic liver lobules, leaving a collapsed collagenous and reticulin framework.
- Necrosis and collapse of reticulin framework are responsible for shrinkage of liver.
- The portal tracts appear to be close to each other.
- There may be slight infiltration by chronic inflammatory cells in the portal areas (Fig. 21.8).

Prognosis

Mortality rate is very high in >80% of massive hepatic necrosis cases. These patients die unless an emergency liver transplantation is performed. Rest of the patients recover due to regeneration of hepatocytes.

Hepatic Necrosis: Histologic Patterns

Liver cell injuries may occur in isolated or group of hepatocytes, periportal piecemeal necrosis and bridging necrosis described as under.

- **Single cell or group of cells necrosis of hepatocytes:** This pattern of necrosis of hepatocytes is seen around terminal hepatic venule. Necrosis of hepatocytes occurs due to viral hepatitis, toxins or obstruction to venous drainage of liver or congestive heart failure (Fig. 21.9).
- **Periportal piecemeal necrosis of hepatocytes:** Periportal piecemeal necrosis of hepatocytes is seen around portal tract. It occurs in chronic active hepatitis, autoimmune hepatitis and active cirrhosis (Fig. 21.10).

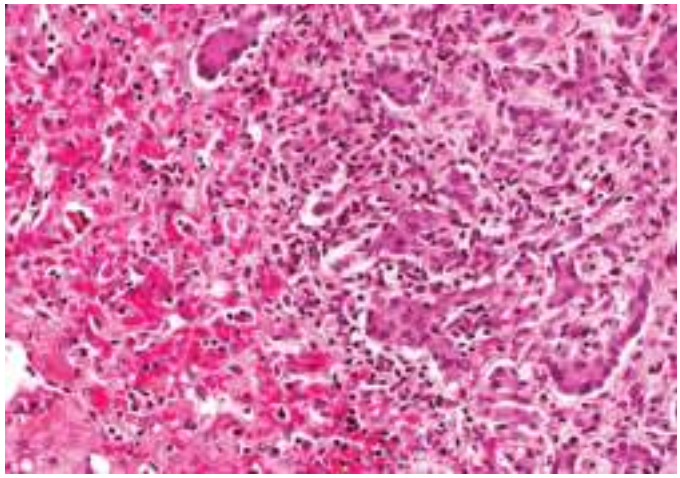

Fig. 21.8: Massive liver necrosis (acute liver failure). There is extensive hepatocyte necrosis seen here in a case of acetaminophen overdose. The hepatocytes at the right are dead, and those at the left are dying. This pattern can be seen with a variety of hepatotoxins. Acute liver failure leads to hepatic encephalopathy (400X).

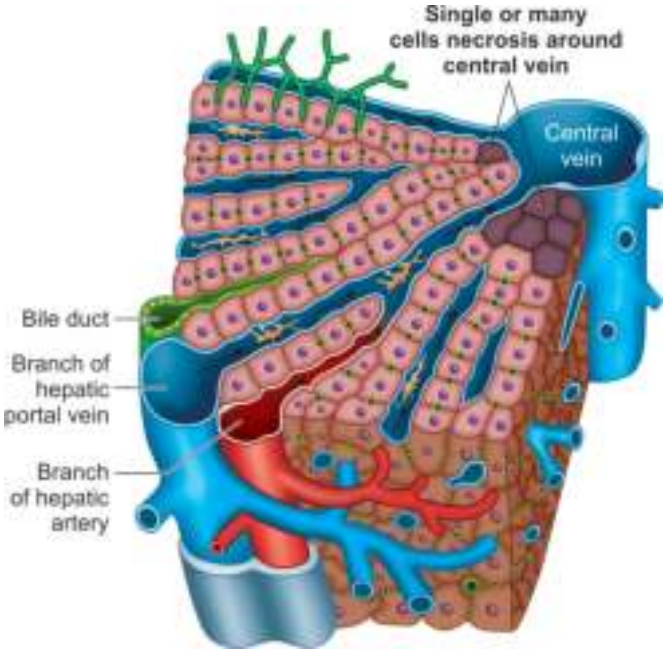

Fig. 21.9: Single cell or group of liver cells necrosis around terminal hepatic venule. This pattern of necrosis of hepatocytes occurs due to viral hepatitis, toxins or obstruction to venous drainage of liver or congestive heart failure.

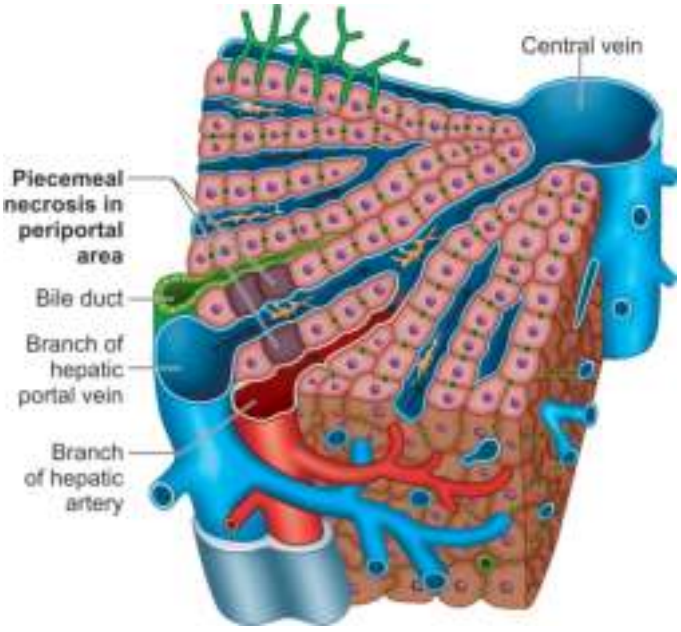

Fig. 21.10: Piecemeal necrosis around periportal area. It occurs in chronic active hepatitis, autoimmune hepatitis and active cirrhosis.

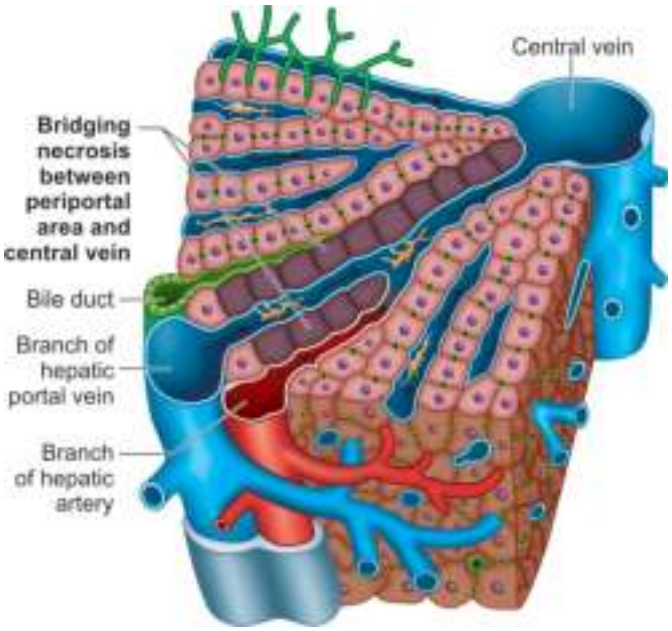

Fig. 21.11: Bridging necrosis of hepatocytes between portal triad and terminal hepatic venule. It occurs in severe viral infection.

- **Bridging necrosis of hepatocytes:** Bridging necrosis of hepatocytes occurs between portal tract and terminal hepatic venule in severe viral infection (Fig. 21.11).

CLINICAL FEATURES

Patient with liver disease shows various clinical manifestations described as under.

Jaundice

Jaundice refers to yellow discoloration of tissues (sclera) due to deposition of bilirubin pigment as a result of raised serum bilirubin concentration.

Bleeding Tendencies

Patient presents with easy bruising and prolonged clotting time of blood due to failure of synthesis of vitamin K-dependent coagulation factors (II, VII, IX, X).

Edema Legs

Patient presents with edema in dependent parts of lower limb due to decreased synthesis of albumin.

Ascites

Patient presents with ascites due to portal hypertension and decreased albumin synthesis by liver.

Gynecomastia

Patient presents with bilateral gynecomastia due to failure of detoxification of estrogens.

Hepatic Encephalopathy

Patient with hepatic encephalopathy presents with altered consciousness, lack of coordination, coma and flapping tremors due to failure of detoxification of ammonia and excitatory amino acids derived from protein breakdown.

Blood Loss in Vomitus and Melena

Patient with portal hypertension presents with bleeding from esophageal varices and melena.

LABORATORY DIAGNOSIS OF LIVER DISORDERS

Liver function tests frequently give an idea of the likely cause of liver disease. Routine and special laboratory tests in evaluation of liver disorders are given in Table 21.8. Laboratory investigations in liver disorders are given in Table 21.9. Diagnostic utility of serum

Table 21.8 Routine and special laboratory tests in evaluation of liver disorders

Liver Function Tests	Reason for Abnormal Results	Liver Disorders
AST (aspartate transaminase)	High value due to hepatocellular injury	Acute and chronic hepatic disorders
ALT (alanine transferase)	High value due to hepatocellular injury	Acute and chronic hepatic disorders
Alkaline phosphatase	High value due to cholestatic injury, bile duct injury, infiltrative processes	Biliary tract disorders, liver transplantation, granulomatous hepatitis, primary and secondary liver tumors
Total bilirubin and direct bilirubin	High value due to functional hepatocellular injury, cholestatic injury, bile duct injury	Acute hepatitis, chronic hepatitis, Dubin-Johnson syndrome, Gilbert syndrome, advanced liver disease with hepatocellular failure
Serum albumin	Values parallel synthetic function of hepatocytes	Cirrhosis (hepatocytes failure to synthesize albumin)
Serum globulins	Values parallel hepatocellular injury	Cirrhosis and autoimmune hepatitis (serum globulins increased level)
PT–INR	High value due to hepatocellular dysfunction	Severe hepatitis, cirrhosis (high value of PT–INR)
Blood test: γ-glutamyl transferase	High value due to injury to biliary ducts	Biliary tract disorders

Contd...

Table 21.8 Routine and special laboratory tests in evaluation of liver disorders (*Contd...*)

Liver Function Tests	Reason for Abnormal Results	Liver Disorders
Blood test: 5-nucleosidase	High value due to injury to biliary ducts	Biliary tract disorders
Blood test: lactic dehydrogenase (LDH)	High value due to hepatocellular injury	Liver cell ischemia and drug-induced hepatocellular injury
Blood test: α_1-antitrypsin	Value varies, increased in inflammatory diseases, decreased in inherited disorder	Infections (high value) and α_1-antitrypsin deficiency (low value)
Blood test: α-fetoproteins (AFP)	High value in liver cell neoplasms, increased liver cell regeneration	Hepatocellular carcinoma
Serum iron	High value due to increased iron uptake by hepatocytes; and hemolytic process	Hemochromatosis, hemolytic anemia and ineffective hematopoiesis
Serum ceruloplasmin	Low value in copper storage diorders, copper deficiency	Wilson disease, Menkes disease, complete deficiency of ceruloplasmin
Hepatic tissue iron quantitation	High value due to deposition of iron in tissues in primary and secondary iron deposition	Primary or secondary hemochromatosis
Hepatic tissue copper quantitation	High value due to deposition of copper in tissues	Wilson disease and Indian childhood cirrhosis

Table 21.9 Laboratory investigations in liver disorders

Liver Disorders	Laboratory Investigations	Interpretation
Hepatocellular failure	▪ Serum albumin ▪ Prothrombin time (normal <15 seconds) measures coagulation factors II, V, VII, X	↓ ↓
Hepatocellular injury	▪ Alanine aminotransferase (ALT) normal <40 IU/L (hepatocellular enzyme) ▪ Aspartate aminotransferase (AST) normal <40 IU/L (hepatocellular enzyme) ▪ LDH (hepatocellular enzyme) ▪ γ-Glutamyl transferase (γ-GT) normal <50 IU/L (plasma membrane enzyme from damage to bile canaliculi) ▪ 5'-Nucleotidase (plasma membrane enzyme from damage to bile canaliculi) ▪ Serum alkaline phosphatase (plasma membrane enzyme from damage to bile canaliculi)	↑ ↑ ↑ ↑ ↑ ↑
Hepatocellular injury, biliary obstruction, liver failure, hemolysis, congenital hyperbilirubinemia	Serum bilirubin (normal 5–12 µmol/L)	↑
Hepatitis A infection	IgM anti-HAV antibody	↑
Hepatitis B infection or carrier state	HBsAg	↑
Chronic active hepatitis (HBV infection)	HBeAg	↑
HCV exposure	Anti-HCV antibody	↑
HCV-induced hepatitis	HCV RNA	↑
Alcoholic cirrhosis	IgA and γ-glutamyl transferase	↑
Autoimmune hepatitis	IgG, anti-smooth muscle antibody and antinuclear factor	↑
Primary biliary cirrhosis	▪ IgM, anti-mitochondrial antibody ▪ Antismooth muscle antibody ▪ Anti-nuclear antiboty ▪ Bile canalicular antibody	↑ ↑ ↑ ↑
Wilson's disease	Ceruloplasmin	↓
Hemochromatosis	Ferritin	↑
Hepatocellular carcinoma	α-Fetoproteins (normally undetectable)	↑
α_1-Antitrypsin deficiency	α_1-Antitrypsin	↓

Table 21.10 Diagnostic utility of serum autoantibodies in liver disorders

Autoantibodies	Result	Liver Disorders
Antimitochondrial antibody	Present	▪ Primary biliary cirrhosis (80–90%) ▪ Chronic active hepatitis (10–25%)
Anti-smooth muscle antibody	Present	▪ Chronic active hepatitis (20–60%) ▪ Primary biliary cirrhosis (10–30%) ▪ Alcoholic liver disease (10–15%)
Antinuclear antibody	Present	▪ Chronic active hepatitis (20–50%) ▪ Primary biliary cirrhosis (15–40%) ▪ Drug-induced chronic active hepatitis (10–30%)
Anti-DNA antibody	Present	All types of liver disorders (30–60%)
Hepatocyte membrane antibody	Present	▪ Chronic active hepatitis (40%) ▪ Cirrhosis (60%) ▪ HBsAg negative acute hepatitis (15%)
Bile canalicular antibody	Present	▪ Chronic active hepatitis (20–40%) ▪ Primary biliary cirrhosis (20–40%)

autoantibodies in liver disorders are given in Table 21.10. Certain patterns of abnormalities suggest a particular type of liver disease, but none is specific to establish diagnosis.

Serum Alkaline Phosphatase

Alkaline phosphatase enzyme is located on the cell membrane of biliary canaliculi.

- Marked increase in level of serum alkaline phosphatase indicates disease of the biliary system (intrahepatic cholestasis, extrahepatic biliary obstruction, or primary biliary cirrhosis).
- Moderate increased levels of alkaline phosphatase are less useful in preceding cause of liver disease.

Serum Transaminases

Transaminases are enzymes located in the hepatocyte cytoplasm.

- Marked increase in level of serum transaminases reflects active necrosis of hepatocytes from any cause. ALT (alanine aminotransferase) is more specific for the liver than AST (aspartate aminotransferase).
- Mild increase in serum transaminases may be seen in cholestasis, as well as following administration of drugs such as anticonvulsants.
- Elevated glutamyl transpeptidase level is a sensitive index of hepatocellular damage.

Serum Conjugated and Unconjugated Bilirubin

Bilirubin is predominantly derived from hemoglobin in the normal turnover of red blood cells, and to a lesser extent, from myoglobin in skeletal muscle.

- Serum bilirubin analysis is useful to classify hyperbilirubinemia as predominantly unconjugated or conjugated. When the ratio of conjugated to total bilirubin is 0.4 or greater, predominantly conjugated hyperbilirubinemia is present.
- Biliary duct obstruction can be intrahepatic or extrahepatic. The most common cause of extrahepatic tract obstruction after the neonatal period is cholelithiasis.
- Recommended ranges for bilirubin, types of hyperbilirubinemia, unconjugated hyperbilirubinemia without hemolysis, unconjugated hyperbilirubinemia with hemolysis and commonly used methods to measure bilirubin are given in Tables 21.11 to 21.15.

Serum Albumin

Serum albumin reflects synthetic properties of the liver. Because of its half-life, low levels of albumin reflect long-standing liver disease, particularly cirrhosis.

Serum Ceruloplasmin

Ceruloplasmin levels are reduced in Wilson's disease. In Wilson's disease mutation of ATP7B gene located on chromosome 13 leads to deficiency of a copper transporting ATPase resulting in decreased copper transport into bile and impairs its incorporation into ceruloplasmin.

Table 21.11 Recommended normal ranges for bilirubin

Analyte	Bilirubin Range
Total bilirubin	0.2–1.0 mg/dl
Conjugated bilirubin	0.0–0.2 mg/dl

Table 21.12 Types of hyperbilirubinemia

Hyperbilirubinemia	Characteristics	Congenital Causes	Other Causes	Excretion of Bilirubin in Urine
Conjugated bilirubin (direct)	Water soluble, loosely bound to albumin	▪ Dubin-Johnson syndrome ▪ Rotor syndrome	▪ Hepatocellular damage ▪ Gallbladder stones ▪ Pancreatic cancer ▪ Biliary cirrhosis ▪ Biliary atresia	Present
Unconjugated bilirubin (indirect)	Insoluble, tightly bound to albumin	▪ Gilbert syndrome ▪ Crigler-Najjar syndrome type 1 (severe) and type 2 (mild)	▪ Hemolytic anemia ▪ Physiological jaundice of the newborn ▪ Hepatocellular disease	Absent

Table 21.13 Unconjugated hyperbilirubinemia without hemolysis in various age groups

Newborns
Mild to moderate and transient unconjugated hyperbilirubinemia
Physiological jaundice
Breast milk jaundice
Persistent unconjugated hyperbilirubinemia
Crigler-Najjar syndrome type 1 (severe) and type 2 (mild)
Children and Adults
Gilbert syndrome

- Accumulated copper causes toxic injury to organs by oxygen-derived free radicals, which displace metals from metalloenzymes.
- Decreased serum ceruloplasmin, increased hepatic copper (>250 µg/1 g dry weight of liver) and increased urinary copper are consistently seen in Wilson's disease.

Serum Transferrin

Serum transferrin level is increased in hemochromatosis.

Prothrombin Time–INR Test

Serum coagulation (clotting) abnormalities are commonly seen in liver disease due to failure of hepatic synthesis of

Table 21.14 Unconjugated hyperbilirubinemia with hemolysis

Schistocytes Present in Peripheral Blood	
Microangiopathic hemolytic anemia	Rule out disseminated intravascular coagulation (DIC), thrombotic thrombocytopenic purpura (TTP), hemolytic uremic syndrome (HUS)
Artificial cardiac valve	History of cardiac valve replacement
Autoimmune hemolytic anemia	Perform Coomb's test
Schistocytes Absent in Peripheral Blood	
Hemolysis in bone marrow	Rule out vitamin B_{12} deficiency
Red blood cell membrane defects	Examine peripheral blood smear for spherocytes, elliptocytes and stomatocytes
Red blood cell enzyme defects	Examine peripheral blood smear for bite cells in G6PD deficiency
Hemoglobinopathies	Perform hemoglobin electrophoresis

Table 21.15 Commonly used methods to measure bilirubin

Method	Principle	Comments
Total bilirubin	Bilirubin + Diazotized sulfanilic acid + Accelerator → Azodipyroles (reddish purple)	Classic diazo reaction described by Ehrlich; accelerator is caffeine and sodium benzoate. All fractions of bilirubin react with this method
Direct bilirubin	Bilirubin + Diazotized sulfanilic acid → Azodipyrole (reddish purple)	Classic diazo reaction minus accelerator, only conjugated and δ-bilirubin reacts with this method
Indirect bilirubin	Indirect bilirubin = Total Bilirubin – Direct bilirubin	Calculation done

vitamin K-dependent clotting factors. This is a feature of liver failure, as consequence of the end-stage of chronic liver disease such as cirrhosis. The one-step prothrombin time and international normalized ratio is a sensitive index of vitamin K-dependent clotting factors (II, VII, IX and X).

Serum Autoantibodies

Several liver diseases are associated with abnormal immunological parameters (autoantibodies).

- Primary biliary cirrhosis is associated with anti-mitochondrial autoantibodies and elevated serum IgM levels.
- Autoimmune chronic hepatitis is associated with anti-smooth muscle antibodies.

Table 21.16 Indications of liver biopsy

Persistent abnormal liver function tests
Jaundice of unclear origin
Portal hypertension and ascites
Grading and staging of chronic hepatitis
Grading and staging of chronic biliary diseases
Confirmation of fatty liver and grading and staging of steatohepatitis
Fever of unknown origin
Hereditary liver diseases
Metabolic liver diseases
Abnormal serum iron study
Diagnosis of space-occupying lesion in liver
Evaluation of transplanted liver
Unexplained splenomegaly

Imaging Studies

Imaging studies are valuable in patients with jaundice or tumors and space occupying lesions as part of pre-operative assessment.

Liver Biopsy

Percutaneous Vim Silverman needle used for liver biopsy is usually performed to diagnose liver diseases. Blind biopsy of right side of the liver is used to assess probable diffuse disease processes. CT or ultrasound-guided needle biopsy may be used to sample discrete lesions.

- Some liver diseases are diagnosed by considering clinical features, blood tests (LFT), serological tests for viral hepatitis and urine analysis.
- Indications of liver biopsy methods, complications and routine and special histochemical stains; immuno-histochemical stains and molecular techniques used in interpretation of liver biopsy are given in Tables 21.16 to 21.19.

Table 21.17 Complications of liver biopsy

Pain abdomen (>50%) subsides in 1–2 days
Hemorrhage from punctured site (less frequent)
Hemoperitoneum
Subcapsular hematoma in liver
Hemobilia (bleeding in biliary tree)
Bile leakage with peritonitis associated with severe obstruction of the large bile ducts
Lacerations of gallbladder, kidney, pancreas and other internal organs
Pneumothorax right side
Arteriovenous fistula

Table 21.18 Liver biopsy methods

Liver Biopsy Methods	Technique	Advantages	Comments
Percutaneous liver biopsy	Cutting needle (Vim Silverman, trucut), suction needle (Jamshidi, Klatskin, Menghini)	Most common, least invasive technique for histologic evaluation	Puncture or lacerations of adjacent organs by inexperienced
Transjugular liver biopsy	Catheter through the internal jugular vein	Liver biopsy in patients with severe coagulation disorders, fulminant hepatocellular failure, massive ascites or severe obesity	Smaller and fragmented biopsy specimens
Laparoscopic (open liver biopsy)	Laparoscopic open biopsy is taken	Provides largest liver biopsy specimens in cirrhosis, chronic liver diseases such as viral hepatitis, primary sclerosing cholangitis and nodular regenerative hyperplasia	Most invasive and expensive technique
Computed tomography or ultrasound-guided liver biopsy	CT- or ultrasound-guided liver biopsy performed	<1 mm bore needle used for fine needle aspiration under CT or ultrasound guided performed to visualize hepatic lesion and to avoid intersecting blood vessels	Reduced risk for hemorrhage of cirrhotic patient compared with transcutaneous biopsy

Table 21.19 Routine and special stains; immunohistochemical stains and molecular techniques used in interpretation of liver biopsy

Stain	Histologic Features	Clinical Correlation
Routine and special stains		
Hematoxylin and eosin	Routine assessment of liver histology	Liver architecture
PAS (periodic acid–Schiff) stain	▪ Glycogen ▪ Neutral polysaccharides	▪ Glycogen storage disease ▪ Gaucher disease ▪ Niemann-Pick disease
PAS (periodic acid–Schiff) stain after diastase digestion	▪ Lipochrome pigment in perivenular hepatocytes ▪ α_1-Antitrypsin inclusions in portal hepatocytes ▪ Lysosomal activity of Kupffer cells in portal tract region ▪ Basement membrane of interlobular ducts ▪ Fungi	▪ Elderly persons ▪ α_1-antitrypsin deficiency (homozygous or heterozygous state) ▪ Areas of cell necrosis in acute and chronic hepatitis ▪ Biliary disorders ▪ Diagnosis of fungal infection
Masson trichrome stain	▪ Collagen fibers ▪ Hepatocytes lobular confluent necrosis	▪ Chronic liver disease ▪ Fulminant hepatitis (severe massive necrosis of hepatocytes)
Von Gieson stain	Elastic fibers of large- and medium-sized blood vessels	Fibrointimal thickening, vascular occlusion, non-cirrhotic portal fibrosis and allograft vascular rejection
Reticulin stain	▪ Assessment of basic hepatic cord sinusoid reticulin, collagen III framework, liver architecture, thickness of hepatic plates, ducts and ductules ▪ Fibrosis ▪ Confluent necrosis of condensed fibers	▪ Evaluation of hepatic cords thickness (normal thickness of hepatic cord 1–2 cells; while in hepatocellular carcinoma thickness of hepatic cord >2–3 cells); reticulin is decreased or absent in hepatocellular carcinoma ▪ Chronic liver disease ▪ Fulminant hepatitis (severe massive necrosis of hepatocytes)
Perls Prussian blue	Hemosiderin	Primary hemochromatosis (iron deposition in hepatocytes), hemolytic anemia (iron deposition in Kupffer cells); and blood transfusion reactions (iron deposition in Kupffer cells)
Fouchet stain and Hell's bilirubin stain	Demonstration of bile	Cholestatic liver disease
Serius red stain	Direct staining of mature collagen type 1 fibers	Fibrosis in chronic liver disease
Congo red stain	Amyloid	Amyloid gives salmon-pink under LM and green birefringence under polarized microscope
Grocott's methenamine silver (GMS) stain	Fungi, microorganisms and parasites	Candida, Aspergillus, Cryptococcus, *Pneumocystis jerovecii*
Ziehl-Neelsen stain	Mycobacterium tubercle bacillus	Mycobacterium tubercle bacillus (human strain) and *Mycobacterium avium-intracellulare* complex
Rubeanic acid and rhodamine stains	Copper	Wilson disease
Orcein (Shikata) and Victoria blue stains	▪ Copper binding protein (granular staining) ▪ Hepatitis B surface antigen (diffuse cytoplasmic stain) ▪ Elastic fibers	▪ Indian childhood cirrhosis and primary biliary cirrhosis ▪ Chronic viral hepatitis type B ▪ Differentiation of old and new fibrosis
Warthin-Starry stain	Spirochetes (*Treponema pallidum*)	Syphilis
Oil red O and Sudan black stains	Neutral fats on frozen sections	Fatty liver disease
Phosphotungstic acid hematoxylin (PTAH) stain	Fibrin deposits in sinusoids and blood vessels	Toxemia of pregnancy, humoral allograft rejection, Q-fever and HELLP syndrome

Contd...

Table 21.19 Routine and special stains; immunohistochemical stains and molecular techniques used in interpretation of liver biopsy (*Contd...*)

Stain	Histologic Features	Clinical Correlation
Immunohistochemical stains		
HBsAg	Cytoplasmic staining of hepatocytes	Chronic viral hepatitis (HBV)
HBcAg	Nuclear staining of hepatocytes	Chronic viral hepatitis (HBV)
HCV	Cytoplasmic staining of hepatocytes	Chronic viral hepatitis (HCV)
Delta antigen	Nuclear staining of hepatocytes	Chronic viral hepatitis delta virus
Ubiquitin	Mallory-Denk bodies	Active fatty liver (alcoholic or nonalcoholic), chronic biliary tract disease
Cytokeratins 7,19	Epithelium of bile duct and ductules	Cytokeratin staining absent due to loss of interlobular bile duct in primary biliary disease and chronic allograft rejection
α-Antitrypsin	Presence of intracytoplasmic inclusions in periportal area	α-Antitrypsin deficiency
Cytomegalovirus (CMV)	Presence of CMV giving nuclear staining in hepatocytes	Cytomegalovirus (CMV) infection (active or latent)
Molecular techniques		
Polymerase chain reaction (PCR)	Demonstration of viruses and other infectious agents; and gene mutations	▪ Chronic viral hepatitis (HBV) ▪ Chronic viral hepatitis (HCV) ▪ HFE gene in hemochromatosis
Gene microarray analysis	Gene mutation	HFE gene in hemochromatosis
Epstein-Barr virus encoded RNA (EBER) probe	Epstein-Barr virus	Lymphoma and post-transplant lymphoproliferative disorders

Purpose of Liver Biopsy

Liver biopsy is examined to diagnose disease, its severity and progression. Prior to liver biopsy, PT–INR estimation is essential to distinguish between hepatocellular jaundice and obstructive jaundice.

Laboratory Investigations

Prior to liver biopsy, screening laboratory studies must be carried out 24–48 hours in advance such as complete blood counts, PT–INR, activated partial thromboplastin time (APTT), bleeding time and cross-matching for possible transfusion.

- After liver biopsy, pulse, blood pressure and abdominal girth should be monitored to rule out bleeding.
- Liver biopsy in a case of viral hepatitis is performed to confirm the disease, ascertain etiology, staging fibrosis and rule out superimposed disease process.
- For most chronic liver disease, a minimum of 1.5 cm in length and 6 portal tracts is usually sufficient to analyze liver biopsy specimen.

JAUNDICE AND CHOLESTASIS

JAUNDICE AND CHOLESTASIS: OVERVIEW

Jaundice is also called icterus. Clinical jaundice appears when serum bilirubin exceeds 2.5 mg/dl. It causes yellow discoloration of sclerae, skin, and mucous membranes due to accumulation of bilirubin, the catabolic product of the heme moiety of hemoglobin. It is most often associated with hepatocellular disease, biliary obstruction, or hemolytic anemia.

BILIRUBIN METABOLISM

After life span of RBCs 100–120 days, these cells are destroyed by reticuloendothelial system and liberate hemoglobin, which dissociates to form heme and globin. Simplified pathway of bilirubin metabolism is shown in Fig. 21.12. Pathophysiology of jaundice is shown in Fig. 21.13.

- Heme consists of porphyrin and iron. Globin goes to amino acid pool. Iron goes to iron storage

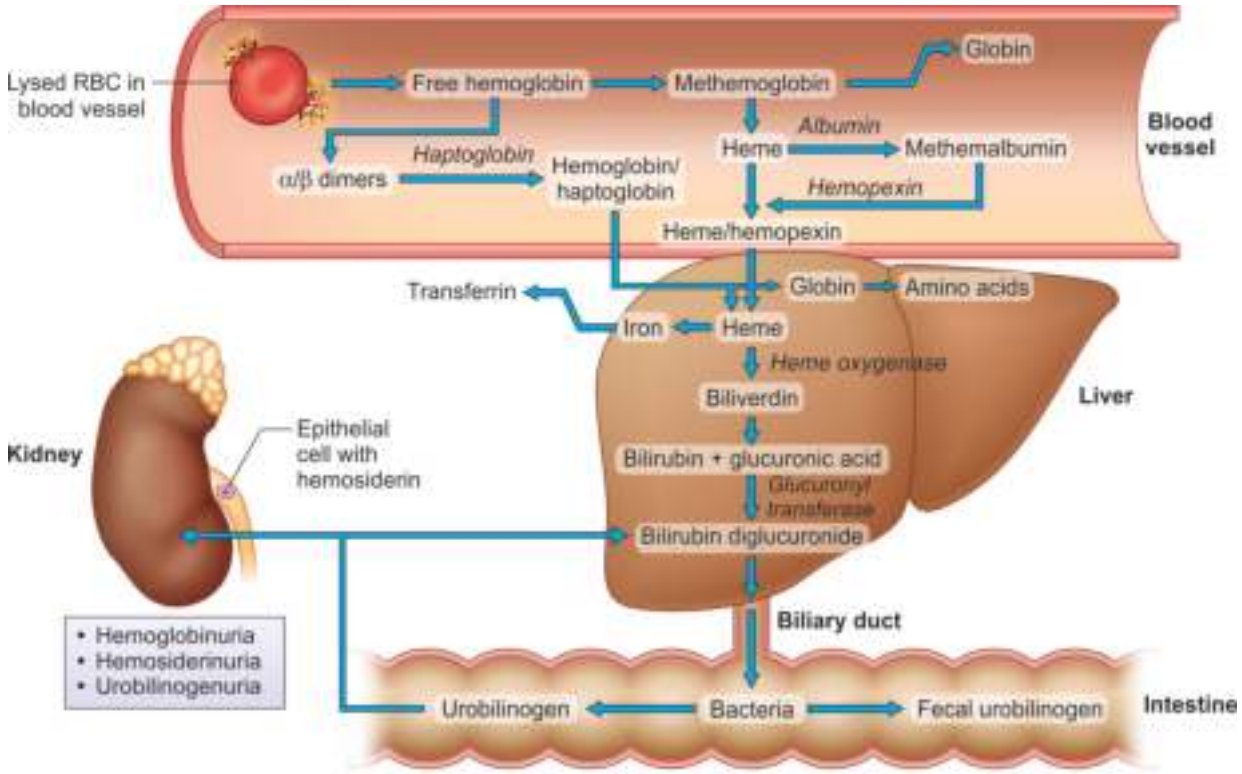

Fig. 21.12: Simplified pathway of bilirubin metabolism. Hemolytic anemia leads to increased biliary excretion of bilirubin. Obstruction of biliary passages will cause regurgitation of conjugated, water-soluble bilirubin into the blood which is then excreted in the urine. Hepatocellular damage in hepatitis will cause impaired biliary excretion of urobilinogen and conjugated bilirubin; these are excreted in the urine, causing it to darken. The enterohepatic circulation returns *cholic acid* and *chenodeoxycholic acid* to the liver; this enhances bile secretion.

sites, e.g. bone marrow, spleen and liver for reutilization.

- Porphyrin is converted into biliverdin and then unconjugated bilirubin (water insoluble), which goes to liver to form conjugated bilirubin by glucuronyl transferase. Conjugated bilirubin enters bile duct and enters small intestine and excreted in feces.
- Part of bilirubin in intestine is absorbed and goes to liver, which is called enterohepatic circulation.
- Rest of conjugated bilirubin is excreted as stercobilinogen in feces. Total normal bilirubin level is 0.3–1.0 mg/dl. Differences between direct and indirect bilirubin are given in Table 21.20. Deranged bilirubin metabolism in various disorders is given in Table 21.21.

PHYSIOLOGICAL JAUNDICE OF NEWBORN

Physiological jaundice of newborn is also called neonatal jaundice. It is common but clinically insignificant characterized by unconjugated hyperbilirubinemia observed during the first week of life.

- Transient jaundice results from both increased bilirubin production and relative deficiency of enzyme glucuronyl transferase in the immature liver especially in premature infants. It is known as physiological jaundice of newborn.
- It must be distinguished from neonatal cholestasis due to extrahepatic biliary atresia, α_1-antitrypsin deficiency and cytomegalovirus infection.

CHOLESTASIS

Failure to drain bile juice leads to the appearance in the plasma of increased concentrations of all constituents of bile such as bilirubin, alkaline phosphatase, IgA and less often cholesterol.

Causes of cholestasis are given in Table 21.22. Cholestasis due to intrahepatic and extrahepatic causes is given in Table 21.23.

Secondary Changes in Liver Resulting from Cholestasis

- **Scattered liver cell necrosis:** Increased concentration of bile causes scattered liver cell injury.
- **Cellular debris in macrophages:** Macrophages contain bile pigment and cellular debris.
- **Periportal fibrosis and proliferation of bile ductules:** These histologic findings are nonspecific.
- **Feathery degeneration of hepatocytes:** Hepatocytes are swollen due to accumulation of water and bile pigment.

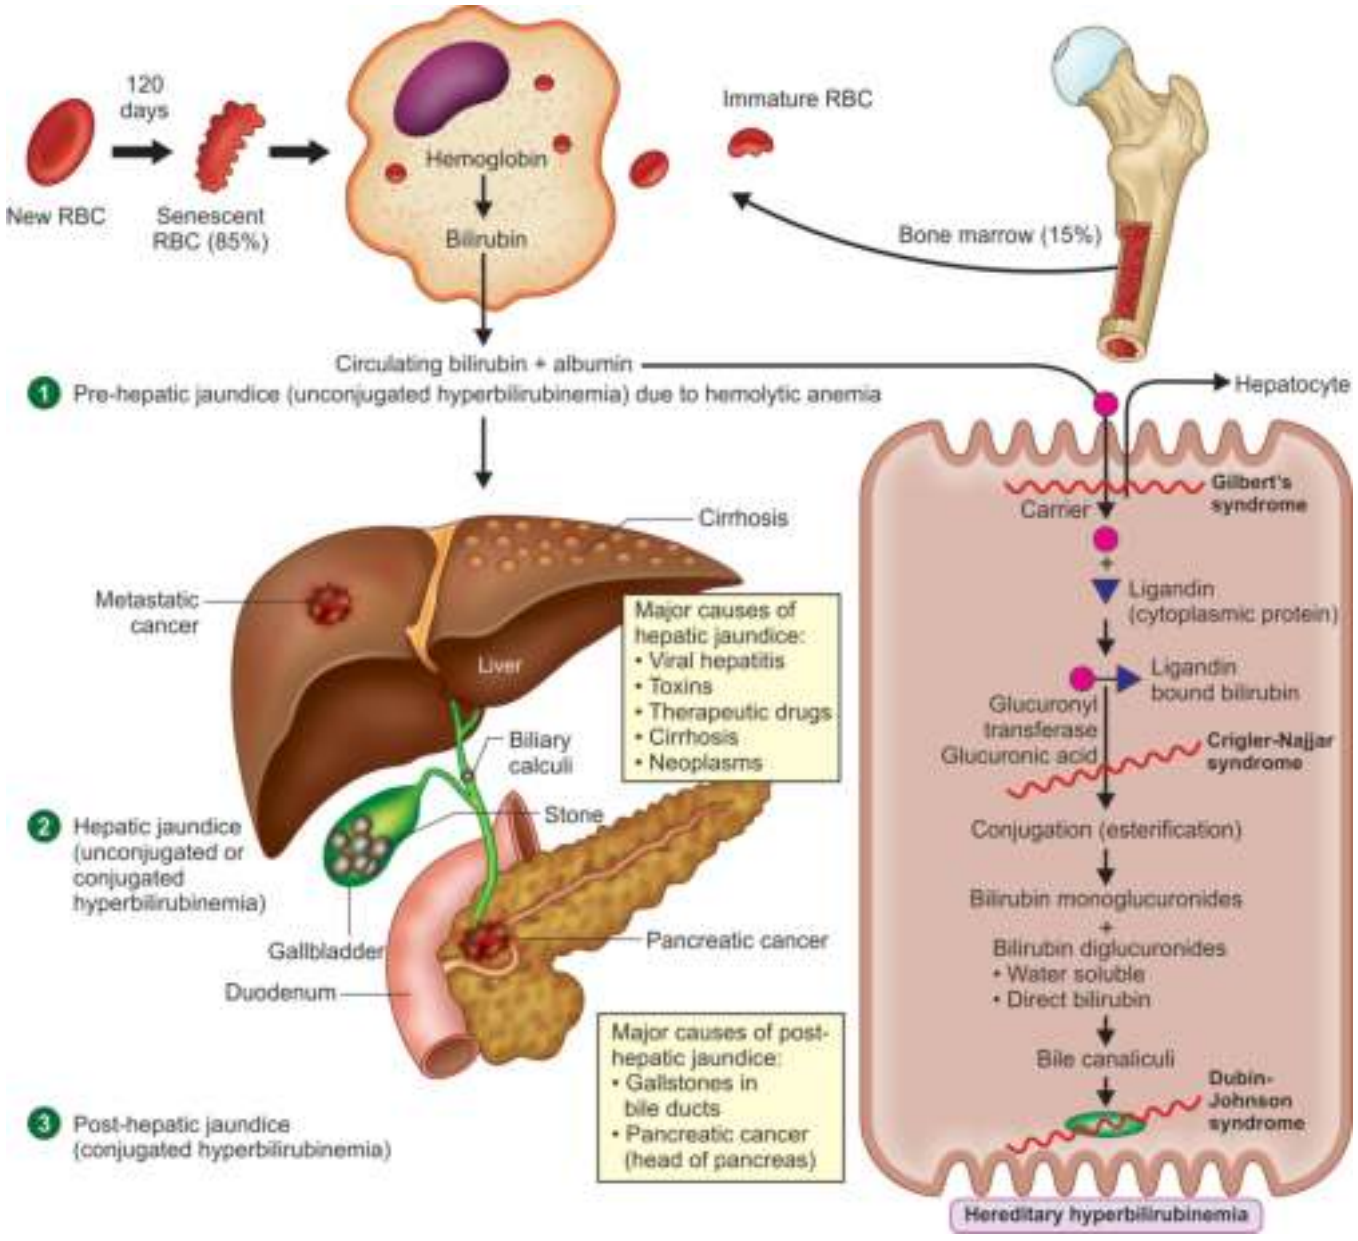

Fig. 21.13: Pathophysiology of jaundice.

Table 21.20 Differences between direct bilirubin and indirect bilirubin

Direct Bilirubin	Indirect Bilirubin
Normal range (0–0.2 mg/dl)	Normal range (0.3–0.7 mg/dl)
Conjugated bilirubin (direct reacting)	Unconjugated bilirubin (indirect reacting)
Water soluble	Lipophilic and water insoluble
Loosely bound to albumin	Tightly bound to albumin
Easily filtered by glomeruli and excreted in urine	Not filtered by glomeruli, hence not excreted in urine
Unable to cross blood–brain barrier	Able to cross blood–brain barrier and damages brain of the newborn (kernicterus) with erythroblastosis fetalis

Total serum bilirubin normal range (0.3–10. mg/dl).

- **Formation of bile lakes:** Long-standing cholestasis may cause hepatocellular injury. Extravasated bile pigments form brownish-yellow masses admixed with cellular debris.

Table 21.21 Deranged bilirubin metabolism in various disorders

Pathophysiology of Hyperbilirubinemia	Causes
Prehepatic causes (increased bilirubin production)	▪ Hemolytic anemia ▪ Aortic aneurysm rupture ▪ Massive intestinal hemorrhage ▪ Blood resorption from large hematoma
Hepatic causes (decreased uptake of bilirubin)	▪ Gilbert's syndrome* ▪ Diffuse hepatocellular injury by HBV and HCV ▪ Chloramphenicol drug ▪ Flavaspidic drug used in tapeworm infestations (drug inhibiting uptake of bilirubin by binding to the ligand) ▪ Contrast media used for cholecystography
Hepatic impaired conjugation of bilirubin (unconjugated hyperbilirubinemia)	▪ Neonatal jaundice ▪ Crigler-Najjar syndrome (types 1 and 2)* ▪ Gilbert's syndrome ▪ Hepatic impaired excretion of bilirubin (conjugated hyperbilirubinemia) ▪ Dubin-Johnson syndrome* ▪ Rotor's syndrome* ▪ Hepatitis ▪ Pregnancy associated cholestasis (recurrent jaundice of pregnancy) ▪ Drugs causing intrahepatic cholestasis such as oral contraceptives and anabolic hormones ▪ Alcoholic cirrhosis ▪ Primary biliary cirrhosis ▪ Hepatic infiltration ▪ Sepsis
Posthepatic obstruction of bilirubin outflow in extra-hepatic biliary passages (conjugated hyperbilirubinemia)	▪ Primary sclerosing cholangitis ▪ Gallstones ▪ Cholangiocarcinoma ▪ Portahepatitis lymph nodes ▪ Biliary atresia ▪ Surgical-induced biliary stenosis ▪ Carcinoma of head of pancreas ▪ Carcinoma of ampulla of Vater ▪ Pancreatitis

**Gilbert's syndrome, Crigler-Najjar syndrome, Dubin-Johnson syndrome, and Rotor's syndrome are examples of hereditary hyperbilirubinemia.*

Table 21.22 Causes of cholestasis

Pathophysiology of Cholestasis	Causes
Extrahepatic mechanical obstruction	▪ Primary sclerosing cholangitis ▪ Gallstones ▪ Cholangiocarcinoma ▪ Portahepatitis lymph nodes ▪ Biliary atresia ▪ Surgical induced biliary stenosis ▪ Carcinoma of head of pancreas ▪ Carcinoma of ampulla of Vater ▪ Pancreatitis
Intrahepatic mechanical obstruction	▪ Granulomas ▪ Metastatic neoplasms in liver ▪ Cystic fibrosis

Contd...

Table 21.22 Causes of cholestasis (*Contd...*)

Pathophysiology of Cholestasis	Causes
Mechanical obstruction in infancy	Biliary atresia (extrahepatic or intrahepatic)
Intrahepatic cholestasis without obstruction	▪ Certain infections ▪ α-Antitrypsin deficiency ▪ Part of paraneoplastic syndromes in renal cell carcinoma ▪ Pregnancy ▪ Viral hepatitis ▪ Hepatotoxic drugs ▪ Idiopathic recurrent cholestasis ▪ Familial progressive cholestasis (Byler's disease) ▪ Primary biliary cirrhosis ▪ Other types of cirrhosis

Table 21.23 Cholestasis due to extrahepatic and intrahepatic causes

Liver Biopsy (LM)	Extrahepatic Cholestasis	Intrahepatic Cholestasis
Cholestasis	Severe degree	Mild degree
Bile pigments present	▪ Ducts and ductules ▪ Rupture of bile canaliculi leading to bile lake formation	Hepatocytes and Kupffer cells
Acute inflammation (PMN cells) in bile ducts	Present surrounding bile duct and canaliculi	Absent surrounding bile duct and canaliculi
Feathery degeneration of hepatocytes	Unremarkable	Marked

RECURRENT JAUNDICE DURING PREGNANCY

Recurrent jundice most often occurs in the third trimester of pregnancy, after seven months of gestation. Biochemical findings mimic extrahepatic biliary obstruction. Jaundice clears after delivery, which may recur with subsequent pregnancy. Etiology is related to increased levels of estrogens. Complications include stillbirths, prematurity and fetal distress.

HEREDITARY HYPERBILIRUBINEMIA

Under physiologic state, after a span of 100–120 days, red blood cells release unconjugated bilirubin. Hepatocytes participate in conjugation of bilirubin and its excretion in biliary ducts.

- Three steps in bilirubin metabolism include: uptake of unconjugated bilirubin by hepatocytes, conjugation of bilirubin by glucuronyl transferase enzyme in hepatocytes and excretion of conjugated bilirubin in biliary ducts. Defects at any level may result in congenital hyperbilirubinemia.
- Examples are Gilbert's syndrome, Crigler-Najjar syndrome, Dubin-Johnson syndrome and Rotor syndrome. Comparison of various types of hereditary hyperbilirubinemias is given in Table 21.24.

Clinical Pearls: Hereditary Hyperbilirubinemia

- **Gilbert syndrome:** It is an autosomal or recessive disorder that results in an unconjugated hyperbilirubinemia due to a partial deficiency of glucuronosyltransferase enzyme used to metabolize bilirubin.
- **Crigler-Najjar syndrome:** It is an autosomal disorder characterized by the absence of bilirubin conjugating enzymes in the liver.
  - Crigler-Najjar syndrome type 1 is an autosomal recessive disorder characterized by complete absence of glucuronosyltransferase enzyme leading to elevated levels of unconjugated bilirubin, kernicterus and death within the first 18 months of life.
  - Crigler-Najjar syndrome type 2 is an autosomal dominant disorder, less severe, nonfatal form of disease with partial defect in the conjugating glucuronosyltransferase enzyme.
- **Dubin-Johnson syndrome:** It is an autosomal recessive disorder that results from a defect in glucuronide transport proteins which carry bilirubin from the liver into the biliary system. Patient presents with conjugated hyperbilirubinemia, hepatomegaly, and dark pigmentation of the liver. Staining for melanin is negative.
- **Rotor syndrome:** It is a variant of Dubin-Johnson syndrome characterized by chronic conjugated hyperbilirubinemia and defective excretion of organic ions into the bile. It requires no treatment. It has excellent prognosis. Hepatocytes lack dark pigmentation.

Table 21.24 Comparison of various types of hereditary hyperbilirubinemias

Disorder	Inheritance	Bilirubin Metabolism Defects	Serum Bilirubin	Clinical Course	Prognosis
Unconjugated hyperbilirubinemia					
Gilbert's syndrome	Autosomal dominant	UDP-glucuronyl transferase activity decreased	<6 mg/dl	Episodic hyperbilirubinemia (marked jaundice)	Excellent
Crigler-Najjar syndrome type 1	Autosomal recessive	UDP-glucuronyl transferase activity absent	>20 mg/dl	Fatal outcome during neonatal period (mild jaundice)	Poor
Crigler-Najjar syndrome type 2	Autosomal dominant	UDP-glucuronyl transferase activity decreased	<20 mg/dl	Mild course (mild jaundice)	Good
Conjugated hyperbilirubinemia					
Dubin-Johnson syndrome	Autosomal recessive	Impaired bilirubin excretion due to mutation of canalicular multidrug resistance protein 2 (MRP2)	<5 mg/dl	Intermittent mild jaundice, mild hepatomegaly (brown-to-black in hepatocytes)	Excellent
Rotor's syndrome	Autosomal recessive	Decreased hepatic uptake and storage. Decreased biliary excretion	<6 mg/dl	Benign course (mild jaundice)	Good

GILBERT'S SYNDROME

Gilbert's syndrome is an autosomal dominant or recessive disorder characterized by mild, recurrent, unconjugated hyperbilirubinemia (<6 mg/dl) due to impaired clearance of bilirubin in the absence of significant liver disease. This disease is usually detected in later life. Aside from jaundice, patient is asymptomatic. No treatment is usually necessary.

- The cause is a combination of decreased bilirubin uptake by hepatocytes and reduced activity of glucuronyl transferase enzyme.
- Patient presents with episodic hyperbilirubinemia precipitated by stress, fatigue, alcohol use, or recurrent infection.

Surgical Pathology: Gilbert Syndrome

Light Microscopy

- The liver architecture appears normal except for mild non-specific accumulation of lipofuscin pigment in the centrilobular zones.
- There are other mild abnormalities, which can be seen in electron microscopy.

Clinical Pearls: Gilbert Syndrome

- Bilirubin has antioxidant property, and in persons with mildly increased bilirubin levels in Gilbert syndrome may offer a protective effect.
- Patients with Gilbert syndrome have a lower incidence of ischemic heart disease due to decreased production of advanced glycation end products, which prevents endothelial dysfunction and reduces progression of atherosclerosis.
- Patients with Gilbert syndrome have lower incidence of Hodgkin disease, endometrial carcinoma and cancer-related mortality.
- Patients with Gilbert syndrome are at higher risk for developing pigment stones in gallbladder (cholelithiasis) in the settings of hemolytic disorders such as β-thalassemia major, sickle cell disease and hereditary spherocytosis.

CRIGLER-NAJJAR SYNDROME

Crigler-Najjar syndrome is an autosomal dominant/recessive disorder characterized by unconjugated hyperbilirubinemia due to lack of glucuronyl transferase enzyme or its decreased activity in hepatocytes. Differences between Crigler-Najjar syndrome types 1 and 2 are given in Table 21.25. Crigler-Najjar syndrome has two variants described as under:

- **Crigler-Najjar syndrome type 1:** It is most severe form of autosomal recessive disorder. A total lack of glucuronyl transferase results in early death from kernicterus; damage to the basal ganglia and other parts of the central nervous system caused by unconjugated bilirubin.
- **Crigler-Najjar syndrome type 2:** It is less severe form of autosomal dominant disorder and compatible with life. It responds to phenobarbital therapy, which decreases the serum concentration of unconjugated bilirubin.

DUBIN-JOHNSON SYNDROME

Dubin-Johnson syndrome is an autosomal recessive familial disorder. Conjugated hyperbilirubinemia occurs due to defective bilirubin transport. Liver biopsy shows conspicuous deposition of melanin-like pigment.

Table 21.25 Differences between Crigler-Najjar syndrome types 1 and 2

Characteristics	Crigler-Najjar Syndrome	
	Type 1	Type 2
Inheritance	Autosomal recessive disorder	Autosomal dominant disorder
Glucuronyl transferase enzyme	Complete deficiency	Deficiency varying from one person to another
Kernicterus	Common	Rarely
Clinical course	Severe type	Mild type
Bilirubin	Unconjugated hyperbilirubinemia	Bile consisting of unconjugated as well as conjugated hyperbilirubinemia
Prognosis	Death during first year	Life is compatible depending on content of glucuronyl transferase enzyme
Response to phenobarbital therapy	No response	Responds well results in synthesis of glucuronyl transferase enzyme

Molecular Genetic Alterations

Dubin-Johnson syndrome occurs due to ABCC2 gene mutation that codes for canalicular multidrug resistance protein 2 (MRP2). MRP2 participates in ATP-dependent excretion of bilirubin mono- and diglucuronides across the canalicular membrane into the bile canaliculi.

Clinical Features

Patient presents with intermittent mild jaundice, hepatomegaly and nonspecific gastrointestinal symptoms.

Surgical Pathology: Dubin-Johnson Syndrome

Gross Morphology

Gross examination reveals blackish discoloration of liver due to accumulation of polymerized epinephrine metabolites.

Light Microscopy

- Liver architecture is normal and shows deposition of brown-to-black melanin-like pigment in hepatocytes and Kupffer cells mainly in centrilobular region (Fig. 21.14).
- Melanin-like pigment in hepatocytes feature differentiates from other congenital conjugated hyperbilirubinemia.

Histochemistry

The chemical nature of this pigment is not clear. The dark melanin-like pigment is demonstrated by Masson-Fontana stain.

Laboratory Investigations

Serum bilirubin level is raised between 2 and 5 mg/dl. Serum liver transaminases (ASI and ALT) and alkaline phosphatase are within normal limits. Bromsulphthalein excretion is a diagnostic test for Dubin-Johnson syndrome.

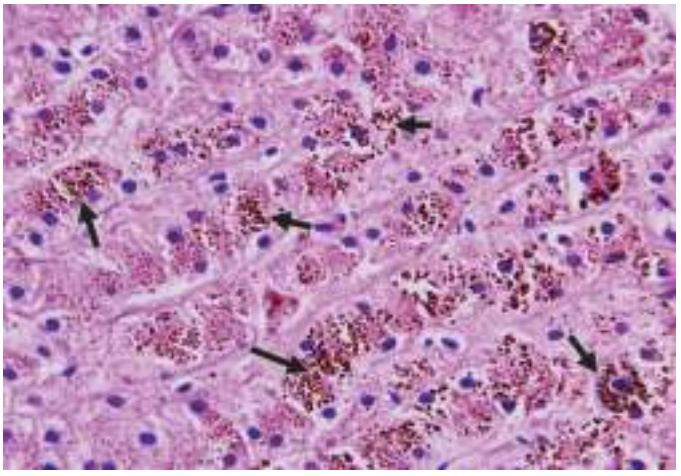

Fig. 21.14: Dubin-Johnson syndrome. Liver shows deposition of brown-to-black melanin-like pigment in hepatocytes and Kupffer cells mainly in centrilobular region (arrows) (400X).

ROTOR SYNDROME

Rotor's syndrome is a relatively benign disorder characterized by conjugated hyperbilirubinemia. It is similar to Dubin-Johnson syndrome, but abnormal melanin-like pigment is not present. Both Dubin-Johnson syndrome and Rotor syndrome cause conjugated hyperbilirubinemia (serum bilirubin ≤6 mg/dl).

NEONATAL CHOLESTASIS

Neonatal cholestasis occurs due to various disorders is given as follows (Table 21.26).

Table 21.26 Major causes of neonatal cholestasis

Categories	Etiological Agents
Bile duct obstruction	Extrahepatic biliary atresia/stenosis
Neonatal infection	Cytomegalovirus, bacterial sepsis, syphilis or urinary tract infection
Toxic substances	Drugs like acetaminophen, methyldopa, halothane, antidepressants and isoniazid
Metabolic disorders	Niemann-Pick disease, tyrosinemia, galactosemia, cystic fibrosis, α_1-antitrypsin deficiency or defective bile acid synthetic pathways
Miscellaneous disorders	Indian childhood cirrhosis, Alagille syndrome (paucity of bile ducts) or hypotensive shock
Idiopathic neonatal hepatitis	Unknown

EXTRAHEPATIC BILIARY ATRESIA/STENOSIS

Extrahepatic biliary atresia is defined as portal or total absence of permeable bile duct between porta hepatis and the duodenum. Cholestasis is total and permanent. Needle liver biopsy allows correct identification of the disorder.

- Extrahepatic biliary atresia is most common cause of pathologic infant jaundice; common reason for pediatric liver transplantation.
- Stenotic or atretic portions of extrahepatic biliary tree cause chronic extrahepatic large duct obstruction.
- Disorder may occur in two forms: (a) fetal/embryonic (congenital) and (b) perinatal/acquired. Acquired extrabiliary stenosis occurs as a result of progressive inflammation leading to obstruction of the biliary tree. It results in marked cholestasis, intrahepatic bile duct proliferation, fibrosis and cirrhosis. The liver becomes rocky hard.

Surgical Pathology: Extrahepatic Biliary Atresia/Stenosis

Light Microscopy

- Histologic examination of liver biopsy shows lobular cholestasis, numerous brown-green bile plugs, portal neutrophilic infiltrate, bile ductular proliferation with elongated and angulated ductules (Fig. 21.15).
- Later, fibrosis or cirrhosis occurs.

ALAGILLE SYNDROME

Alagille syndrome is an autosomal dominant disorder, which can affect the liver, heart and other organs. Alagille syndrome is characterized by abnormalities in the bile ducts leading to liver damage. Mutation in NOTCH signaling pathway is involved in the development of Alagille syndrome.

Patient presents with mild to severe symptoms such as jaundice, pruritus, xanthomas, congenital heart defects, butterfly shape of vertebral column and other bones demonstrated on radiographs.

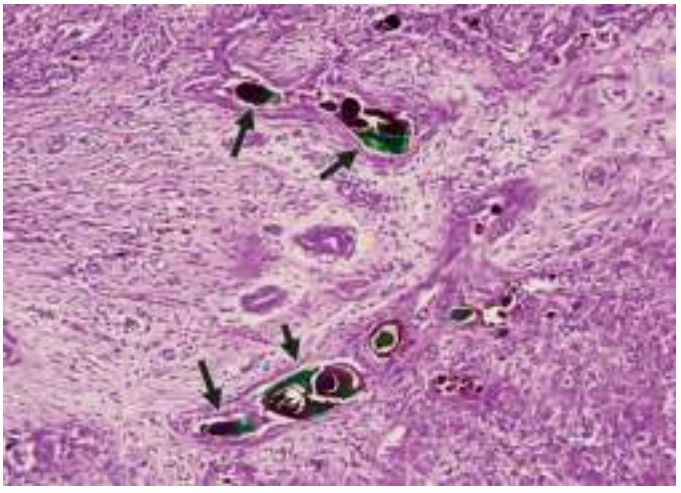

Fig. 21.15: Extrahepatic biliary atresia. Two months old infant presents with jaundice, pale stools, dark colored urine, and hepatomegaly. Microscopically, it shows numerous brown-green bile plugs, bile duct proliferation, and extensive fibrosis (arrows) (100X).

DRUG-INDUCED HEPATITIS

Various therapeutic drugs may cause drug-induced hepatitis, which include acetaminophen, methyldopa, halothane, antidepressants and isoniazid. Liver biopsy shows presence of eosinophils in the portal tracts, evidence of cholestasis, and sometimes granulomas.

CAROLI DISEASE

Caroli disease is an autosomal dominant trait disorder. Mutation of PKHD1 gene linked to ARPKD has been demonstrated in patient with Caroli disease. There is history of liver and kidney disease. It is characterized by segmental dilatation of larger intrahepatic ducts associated with bile inspissation and cholestasis.

It is frequently complicated by cholelithiasis and hepatic abscess. There is increased risk for development of cholangiocarcinoma.

NEONATAL HEPATITIS OF UNKNOWN ETIOLOGY

Neonatal hepatitis is of unknown etiology in 50% of cases. Approximately 30% of cases are assigned to α_1-antitrypsin deficiency alone. Most of the other known causes can be attributed to chromosomal abnormalities or intrauterine infections or biliary atresia.

Clinical Features

Neonatal hepatitis may cause jaundice during the first few weeks of life. Most infants with uncomplicated neonatal hepatitis eventually recover. Untreated biliary obstruction causes progressive fibrosis resulting in secondary biliary cirrhosis.

Surgical Pathology: Neonatal Hepatitis

Light Microscopy

- Liver biopsy in neonatal hepatitis shows presence of multinucleated giant cells (characteristic finding).
- Multinucleated giant cells contain as many as 40 nuclei and may appear detached from other cells in the liver plate.
- Hepatocytes may contain bile pigment due to prolonged cholestasis and hemosiderin (Fig. 21.16).

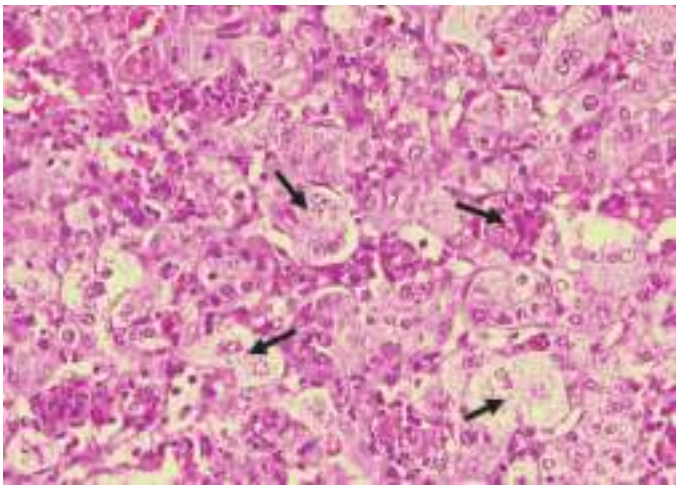

Fig. 21.16: Neonatal hepatitis. Seen here is the major differential diagnosis of biliary atresia: This is neonatal giant cell hepatitis. There is lobular disarray with focal hepatocyte necrosis, giant cell transformation, lymphocytic infiltration, Kupffer cell hyperplasia, and cholestasis (not seen here). Neonatal hepatitis may be idiopathic or of viral origin. Many neonates recover in a couple of months (arrows) (400X).

JAUNDICE: DIFFERENTIAL DIAGNOSIS

Differential diagnosis of jaundice (Table 21.27) and disorders causing type of hyperbilirubinemia is given in Table 21.28.

HEMOLYTIC JAUNDICE

Hemolytic jaundice occurs due to rapid destruction of red blood cells resulting in production of excess of bilirubin. Liver is not able to conjugate excess of bilirubin. Hemolytic disease of the newborn most commonly occurs with Rh blood group incompatibility between mother and fetus.

Clinical Features

Patient presents with jaundice due to excess of unconjugated bilirubin in blood. Hemolytic jaundice is seen in sickle cell disease, mismatched blood transfusions and some infections.

Urine Analysis

Urine analysis in hemolytic jaundice shows increased urobilinogen and absence of bilirubin (acholuria). Degree of urine urobilinogen increase is directly related to increased hemoglobin catabolism.

HEPATOCELLULAR JAUNDICE

Hepatocellular jaundice occurs due to hepatitis, congenital hyperbilirubinemia due to malfunction of glucuronyl transferase enzyme and hepatocellular

Table 21.27 Differential diagnosis of jaundice

Etiology	Serum	Urine	Stool Color
▪ Hemolytic anemia ▪ Hepatocellular jaundice (e.g. acute hepatitis)	▪ Unconjugated hyperbilirubinemia ▪ Mixed hyperbilirubinemia ▪ Increased transaminases	▪ Normal ▪ Dark	▪ Dark ▪ Pale
Extrahepatic obstructive jaundice (e.g. cholestasis)	▪ Conjugated hyperbilirubinemia ▪ Increased alkaline phosphatase ▪ Increased transaminases	Dark	Pale
Congenital hyperbilirubinemia (e.g. Gilbert's syndrome)	▪ Unconjugated or conjugated hyperbilirubinemia ▪ Other liver function tests: normal ▪ No evidence of hemolysis	Variable	Variable

Table 21.28 Disorders causing type of hyperbilirubinemia

Causes	Alkaline Phosphatase and AST/ALT	Hyperbilirubinemia
▪ Gallstone, carcinoma of common bile duct obstruct the bile flow ▪ Pancreatic head carcinoma ▪ Viral hepatitis induced hepatocellular damage	▪ Alkaline phosphatase level >AST/ALT occurs in obstructive jaundice ▪ Alkaline phosphatase level <AST/ALT	Direct (conjugated) bilirubin >15% of total bilirubin
▪ Physiological jaundice of newborn ▪ Hemolytic anemia ▪ Breast milk jaundice due to presence of β-glucuronidase in milk ▪ Diffuse hepatocellular damage due to cirrhosis, viruses and drugs ▪ Gilbert's syndrome ▪ Crigler-Najjar syndrome (types 1 and 2)	Not applicable	Indirect (unconjugated) bilirubin <15% of total bilirubin

carcinoma. Patient presents with jaundice due to excess of conjugated and unconjugated bilirubin in blood. Urine analysis may show normal or decreased urobilinogen.

EXTRAHEPATIC OBSTRUCTIVE JAUNDICE

Extrahepatic obstructive jaundice is related to mechanical obstruction of bile flow outside the liver due to gallstones or pancreatic tumors obstructing pancreatic biliary duct.

Clinical Features

Patient presents with jaundice due to excess of conjugated bilirubin in blood passage of clay-colored stools.

Urine Analysis

Urine analysis shows decreased urobilinogen. Serum ALT and AST enzyme levels are variable.

Blood Biochemistry

Alkaline phosphatase and cholesterol are increased.

HEPATITIS

HEPATITIS: OVERVIEW

Hepatitis refers to inflammation of the liver caused by viruses, autoimmune mechanisms, drugs, toxins or secondary to other systemic disorders.

- The known hepatotropic viruses primarily affecting hepatocytes include hepatitis A virus (HAV), hepatitis B virus (HBV), hepatitis B-associated delta virus (HDV), hepatitis C virus (HCV), and hepatitis E virus (HEV). HAV and HEV transmit via fecal–oral route. HBV, HCV and HDV transmit via parenteral/sexual route.
- Viruses causing systemic disease can involve the liver, which include yellow fever virus (mid-zonal necrosis), Epstein-Barr virus, Ebola virus (mild hepatitis during the acute phase); cytomegalovirus (particularly in newborns and immunosuppressed persons); herpesviruses; and enteroviruses.
- HAV infection has direct cytopathic effect on hepatocytes. Hepatocellular injury occurs due to attack by CD8+ cytotoxic T cells and natural killer cells; and antibodies formed against viral antigens on infected hepatocytes.
- Extent of inflammation and hepatocellular necrosis in HBV infection depends on the immune response of the person.
  - Prompt immune response in HBV infection may cause hepatocellular injury to eliminate HBV. Marginal immune response in HBV infection fails to eliminate HBV, hence persistence of HBV antigens in hepatocytes results in chronic hepatitis or carrier state. Accelerated immune response in HBV infection can cause fulminant hepatitis.
- Infection with hepatotropic viruses may produce clinical manifestations of varying grades of severity ranging from mild jaundice, nausea and anorexia to fulminating illness (acute liver failure) associated with fatal outcome.
- Some cases may progress to cirrhosis with increased risk of development of hepatocellular carcinoma.
- Classification of hepatitis based on etiology, histologic activity (necrosis and inflammation) and degree of fibrosis (progression of disease) according to METAVIR scoring system is given in Table 21.29.
- Acute and chronic hepatitis may be caused by hepatotropic viruses (HAV, HBV, HCV, HDV and HEV). Acute hepatitis is characterized by jaundice, elevation of serum AST (aspartate transaminase) and ALT (alanine transferase), nausea and vomiting.
- Histologic features in acute hepatitis are evidence of hepatocellular injury and regeneration, chronic inflammatory infiltrate but **absence of fibrosis**.

Table 21.29 Classification of hepatitis based on etiology, histologic activity (necrosis and inflammation) and degree of fibrosis (progression of disease) according to METAVIR scoring system

Classification of Hepatitis Based on Etiology	
Hepatotropic viruses	HAV, HBV, HCV, HDV, HEV
Uncommon viruses	Cytomegalovirus and herpesvirus (immunocompromised state), yellow fever virus (mid-zonal necrosis), Epstein-Barr virus, rubella virus, Ebola virus, adenovirus, enterovirus
Parasites	*Entamoeba histolytica*, *Echinococcus granulosus*, *Schistosoma japonicum*, *Schistosoma mansoni*
Leptospira species	Weil's disease (jaundice, hemorrhagic fever and renal failure)
Autoimmune hepatitis	Nitrofurantoin, methyldopa, statins, methotrexate, oxyphenisatin acetate (laxative), α or β interferon, phenothiazines, infliximab
Classification of Hepatitis Based on Histologic Activity (Necrosis and Inflammation)	
Portal tract inflammation	Inflammation confined to portal tract region
Periportal tract inflammation	Inflammation extending from portal area to surrounding periportal tract region
Piecemeal necrosis (now known as interface necrosis)	Loss of hepatocytes between hepatic lobule and limiting plates of portal tracts demonstrated in viral hepatitis, autoimmune hepatitis and steatohepatitis
Bridging necrosis	Confluent necrosis of hepatocytes bridging adjacent central vein of hepatic lobules and limiting plates of portal tracts
Classification of Hepatitis Based on Activity Grade	
Grade 0	No activity in liver
Garde A1	Mild activity in liver
Garde A2	Moderate activity in liver
Grade A3	Severe activity in liver
Classification of Hepatitis Based on Degree of Fibrosis (Progression of Disease)	
Stage 0	No evidence of fibrosis in liver
Stage 1	Mild fibrosis confined to portal tracts
Stage 2	Moderate fibrosis in portal tract and periportal region
Stage 3	Severe fibrosis with bridging necrosis between central vein of hepatic lobules and limiting plates of portal tracts
Stage 4	Massive fibrosis (e.g. cirrhosis)

The METAVIR scoring system is a system used to assess the extent of fibrosis by histologic evaluation in a liver biopsy of patients with hepatitis. The grade indicates the activity or degree of inflammation while the stage represents the amount of fibrosis or scarring.

- Chronic hepatitis (chronic portal hepatitis, chronic lobular hepatitis, chronic active hepatitis) is caused by hepatotropic viruses such as HBV (10%), HCV (80%), and HDV (10%).
- Histologic features in chronic hepatitis are evidence of hepatocellular injury and regeneration, chronic inflammatory infiltrate but **presence of fibrosis**. Clinical course of the following viral hepatitis is given in Table 21.30. Differentiating Histologic features of acute and chronic viral hepatitis are given in Table 21.31. Histologic features of liver with specific hepatotropic viruses are given in Table 21.32.

Table 21.30 Clinical course of the following viral hepatitis

Clinical Patterns of Hepatitis	Hepatotropic Virus
Asymptomatic hepatitis	HAV (most often), HBV, HCV, HDV, HEV
Acute hepatitis without jaundice (anicteric hepatitis) or with jaundice (icteric jaundice)	HAV, HBV, HCV, HDV, HEV
Chronic hepatitis (chronic portal hepatitis previously known as chronic persistent hepatitis, chronic lobular hepatitis, chronic active hepatitis)	HBV (10%), HCV (80%), HDV (10%)
Chronic carrier state	HBV, HCV, HDV
Massive liver necrosis with acute hepatocellular failure	HAV, HBV, HCV, HDV, HEV

HAV and HEV transmit via fecal–oral route. HBV, HCV and HDV transmit via parenteral/sexual route.

Table 21.31 Differentiating histologic features of acute and chronic viral hepatitis

Hepatocellular Injury Parameters	Acute Viral Hepatitis	Chronic Viral Hepatitis
Hepatotropic viruses	▪ HAV (most often) ▪ HBV ▪ HCV ▪ HDV ▪ HEV	▪ NA ▪ 10% ▪ 80% ▪ 10% ▪ NA
Hallmark characteristics	▪ Prominent portal lymphocytic infiltrates, normal interlobular bile ducts ▪ Diffuse necro-inflammatory change in the perivenular zone in early stage of disease, apoptosis, Kupffer cell reaction ▪ Cholestasis (presence of bile plugs) in more severe cases ▪ Fibrosis in hepatic lobule absent	▪ Periportal interface inflammatory activity in active stage ▪ Lobular necro-inflammatory change irregularly distributed in active stage disease ▪ Cholestasis present ▪ Variable portal fibrosis with eventual bridging fibrosis between hepatic central vein and portal tract and development of cirrhosis
Liver architecture	Disrupted	Disrupted
Hepatic lobule involvement pattern	Centrilobular zone of liver	Throughout hepatic lobule
Ballooning swelling (degeneration) of hepatocytes	Present	Present
Regeneration of hepatocytes	Present	Present
Hepatocytes loss	Isolated hepatocytes or cluster of hepatocytes	Isolated hepatocytes or cluster of hepatocytes
Fibrosis in hepatic lobule	Absent	Present (portal and periportal fibrosis with bridging fibrosis between hepatic central vein and portal tract)
Spill over inflammation from portal tract to hepatic acinus	Uncommon	Common
Piecemeal necrosis	Piecemeal necrosis absent	Piecemeal necrosis present (hallmark of progressive disease)
Councilman hyaline bodies (apoptotic bodies) in sinusoids	Present	Absent
Ground glass appearance of hepatocytes	Absent	Present in HBV infection
Fatty change	Present in HCV infection	Present in HCV infection
Bile duct proliferation and lymphoid aggregates	Present	Present in HCV infection
Reactive changes in sinusoids	Kupffer cells laden with phagocytosed cellular debris; and chronic inflammatory cells infiltrate in sinusoids	Kupffer cells laden with phagocytosed cellular debris; and chronic inflammatory cells infiltrate in sinusoids
Cirrhosis	Absent	Progresses to cirrhosis
Hepatocellular carcinoma	Absent	Increased risk

Histologic features shared by acute and chronic viral hepatitis are hepatocellular injury, necrosis of hepatocytes, apoptosis of hepatocytes, regeneration hepatocytes and sinusoidal changes.

Table 21.32 Histologic features of liver with specific hepatotropic viruses

Hepatotropic Viruses	Acute Viral Hepatitis	Chronic Viral Hepatitis
HAV	Increase in plasma cells in portal region, periportal inflammation, cholestasis	No chronic viral hepatitis
HBV	Emperipolesis (presence of an intact cell within the cytoplasm of another cell)	Hepatocytes show ground glass appearance (endoplasmic reticulum synthesizing HBsAg) in 50–66% of cases, hepatocytes can show dysplasia in advanced disease
HBV + HDV	Microvesicular steatosis, hepatitis often with severe confluent hepatocellular necrosis	Microvesicular steatosis
HCV	Sinusoidal lymphocytosis, granulomatous necrosis	Portal lymphoid aggregates (≤50%), sinusoidal lymphocytosis, granulomatous necrosis, mild microvesicular steatosis in <25% of hepatocytes
HEV	Bile duct proliferation, bile duct ectasia, cholestasis with an acinar arrangement of hepatocytes	No chronic forms (rare exception is post-transplant cases)
HGV	Syncytial giant cells of hepatocytes, usually mild necroinflammatory change	No chronic viral hepatitis

VIRAL HEPATITIS

ACUTE VIRAL HEPATITIS

Incubation period of acute viral hepatitis (HAV, HBV, HCV, HDV, HEV, HGV) is the period from the time of infection and the first symptoms appear. Acute viral hepatitis has three phases: preicteric phase (prodromal phase), icteric phase (jaundice) and recovery phase (convalescence phase).

Preicteric Phase

The period of prodromal period and clinical symptoms vary with each of the hepatotropic virus.

- In acute hepatitis, patients may present with malaise, flu-like symptoms, anorexia, low-grade fever, arthralgia, myalgia with jaundice and passage of dark-colored urine and clay-colored stools in about 20% of cases most often paralleling the severity of the disease or specific hepatotropic virus involved. Right upper quadrant tenderness due to hepatomegaly may be present.
- Extrahepatic manifestations may also occur such as serum sickness manifestations (rash, urticaria, angioneurotic edema), polyarteritis nodosa (HBV infection), cryoglobulinemia, and renal disease (mild proteinuria, abnormal urinary sediments, rarely glomerulonephritis).
- Majority of cases with HCV infection may be asymptomatic or have vague non-specific symptoms.
- Patient with HAV infection may demonstrate hepatomegaly. Approximately 10% of patients with HBV infection show signs of serum sickness, characterized by skin rash, arthralgia, myalgia or mild proteinuria. Serum transaminases aspartate transaminase (AST) and alanine aminotransferase (ALT) increase steadily and attain peak before clinical jaundice appears. Peripheral blood smear reveals atypical lymphocytosis.

Icteric Phase (Jaundice)

The icteric phase is variable depending on the type of hepatitis. Patient develops itching, jaundice, abdominal pain and tenderness.

- Liver function tests demonstrate elevations of aspartate transaminase (AST) and alanine aminotransferase (ALT) usually >500 IU/L and most often over 1000 IU/L (ALT more specific for hepatocellular injury). Alkaline phosphatase value is usually normal or elevated about two times of normal values.
- Urine analysis shows darkening of urine due to increased excretion of bilirubin and urobilinogen. Jaundice is usually accompanied by improvement of constitutional symptoms.
- When hyperbilirubinemia and jaundice occur, the serum bilirubin value ranges from 5 to 20 mg/dl, depending on the degree of hepatotropic virus infection and necroinflammatory changes. Importantly, the PT–INR and serum albumin levels are generally normal in uncomplicated cases.

Recovery Phase

- Recovery phase is also known as convalescence phase. Symptoms are subsiding like return of appetite and resolution of jaundice.
- Recovery is the rule in the majority of cases. Liver function tests return to normal within few weeks after clinical presentation, although a prolonged clinical course lasting a few months can occur with acute HAV infection.

Table 21.33 Patterns of acute viral hepatitis

Pattern	Comments
Inflammatory-predominant pattern (with variable necrosis)	▪ Acute viral hepatitis ▪ Autoimmune hepatitis ▪ Wilson disease ▪ Celiac disease ▪ Idiosyncratic drug reaction
Cholestasis pattern (nonspecific)	▪ Acute viral hepatitis (HAV, HEV) ▪ Acute hepatitis (drug-induced)
Toxic pattern (direct hepatocellular injury)	▪ Halothane ▪ Acetaminophen ▪ Cocaine ▪ MDMA (3,4-methylenedioxy-N-methamphetamine) ▪ Organic solvents ▪ Toxic mushrooms ▪ Some herbal medications ▪ Herpes simplex virus ▪ Adenovirus ▪ Acute vascular injury/ischemia
Resolving pattern (nonspecific)	▪ Idiosyncratic drug reaction ▪ Systemic autoimmune disorders ▪ Systemic inflammatory disorders
Giant cell pattern (nonspecific in adults)	Autoimmune hepatitis
Mild nonspecific pattern	Early acute viral hepatitis versus biliary injury requires clinical and laboratory correlation

- In 1–2% of cases, fulminant clinical course can occur with any of the hepatotropic viruses.
- Pregnant women with HEV and patients with coexisting acute HBV and HDV coinfection present with jaundice, hepatic encephalopathy (lethargy, drowsiness and asterixis), ascites, gastrointestinal tract symptoms, renal failure and disseminated intravascular coagulation (DIC). Patterns of acute viral hepatitis are given in Table 21.33.

Pathology Pearls: Pathophysiology of Viral Hepatitis

The basic pathophysiologic processes of acute and chronic viral hepatitis are complex. The hepatotropic viruses first bind to the hepatocyte cell membranes.

- Prompt humoral antibody-mediated response clears the hepatotropic virus or inhibits penetration and viral replication. The hepatotropic viruses that penetrate into the hepatocytes may elicit an immune mediated response, resulting in viral clearance by way of necrosis of the infected hepatocytes and removal of infected hepatocytes by CD8+ cytotoxic T cells or inhibition of viral replication as a result of synthesis of anti-viral cytokines.
- Infection can persist with resultant hepatitis when the immune-mediated response is only partial/marginal (eliciting an active stage of chronic hepatitis) or totally absent (carrier state). Fibrogenesis from activation of stellate cells plays a crucial role in the pathogenesis of the ongoing disease.

Surgical Pathology: Acute Viral Hepatitis

Gross Morphology

- Acute viral hepatitis progressing to fulminant acute hepatocellular failure leads to reduction in size of the liver. Liver capsule shows wrinkling indicating rapid reduction of liver cell mass. Cut surface of liver exhibits red appearance. It may greenish due to cholestasis.
- In some cases, there is evidence of commencing regeneration of hepatocytes in the form of rounded yellowish areas scattered against the red background of necrotic liver.

Light Microscopy

Structural changes in acute viral hepatitis comprise evidence of hepatocellular necrosis in centrilobular zone, inflammation within the liver acini and portal tract connective tissue. Changes in the connective tissue framework most often occur as a result of extensive severe loss of hepatocytes. Acute viral hepatitis has two major features: lobular disarray and chronic inflammatory infiltrate. Ballooning degeneration of hepatocytes and Councilman bodies in sinusoids are prominent features. Morphologic features of acute viral hepatitis are shown in Figs 21.17 and 21.18 and Table 21.34.

- **Ballooning degeneration of hepatocytes:** Hepatocytes show degeneration with empty appearance and granules around nucleus, which correlates with intracellular edema and consequent dilatation of the endoplasmic reticulum, loss of ribosomes and swelling of the mitochondria. The cytoplasm

of hepatocytes does not bind eosin hence giving empty appearance. Ballooning degeneration may cause necrosis of some hepatocytes and this change may be reversible.

- **Biliary cholestasis:** Bile accumulates in the biliary canaliculi which causes feathery appearance of hepatocytes.
- **Fatty change:** Mild fatty change is seen in hepatocytes especially with HCV infection.
- **Hepatic lobular disarray:** Normal architecture of liver is disrupted.
- **Hepatocellular necrosis:** Isolated cell or clusters of hepatocytes may undergo irreversible cell necrosis. Apoptosis removes viral infected scattered hepatocytes. Apoptotic cells represent membrane-bound cellular chromatin remnants that are extruded into the hepatic sinusoids in cases of viral hepatitis, which are called 'Councilman bodies', which appear as eosinophilic stained structures in hematoxylin and eosin-stained sections seen under light microscope.
- **Bridging necrosis:** Severe hepatocellular injury may lead to bridging necrosis (portal-portal, central-central or portal-central).
- **Regenerative changes:** Hepatocytes may show regenerative changes. Sinusoidal cell reactive changes: Kupffer cells are prominent and increased in number in the sinusoids, which contain phagocytosed cellular debris, bile pigments and lipofuscin pigment. There is influx of lymphocytes, plasma cells and macrophages into sinusoids.
- **Inflammatory response with influx of mononuclear cells:** Portal tract is also the site of inflammation. Connective tissue of portal tract shows infiltration by lymphocytes, macrophages and plasma cells. Presence of neutrophils and eosinophils are not uncommon. Persistent inflammation and fibrosis is an unfavorable sign of chronic viral hepatitis progressing to post-necrotic cirrhosis. Spill over of chronic inflammatory cells (lymphocytes, macrophages and plasma cells) from portal tract into liver acinus causes liver cell necrosis. Inflammation is most severe in the perivenular region of acinar zone.
- **Changes in the connective tissue framework:** In majority of cases, there is insufficient hepatocellular necrosis exhibiting normal architecture of liver cell plates. In more severe cases with extensive hepatocellular necrosis exhibit bridging necrosis extending from central vein to portal tract. There is collapse of reticulin fiber framework in this area. Bridging necrosis is the most serious development, because there is increased risk of subsequent cirrhosis.

CHRONIC VIRAL HEPATITIS

Chronic viral hepatitis is defined as persistently abnormal liver function tests greater than six months after the acute viral hepatitis occurs with hepatotropic HBV and HCV.

- Hepatitis C causes chronic hepatitis in 80% of cases. Hepatitis B causes chronic hepatitis in 10% of cases. Liver may show mild, moderate, or severe injury depending on the extent of injury, inflammation and repair.
- Depending on clinical course, hepatotropic viruses may cause portal hepatitis (previously known as chronic persistent hepatitis), chronic lobular hepatitis and chronic active hepatitis.

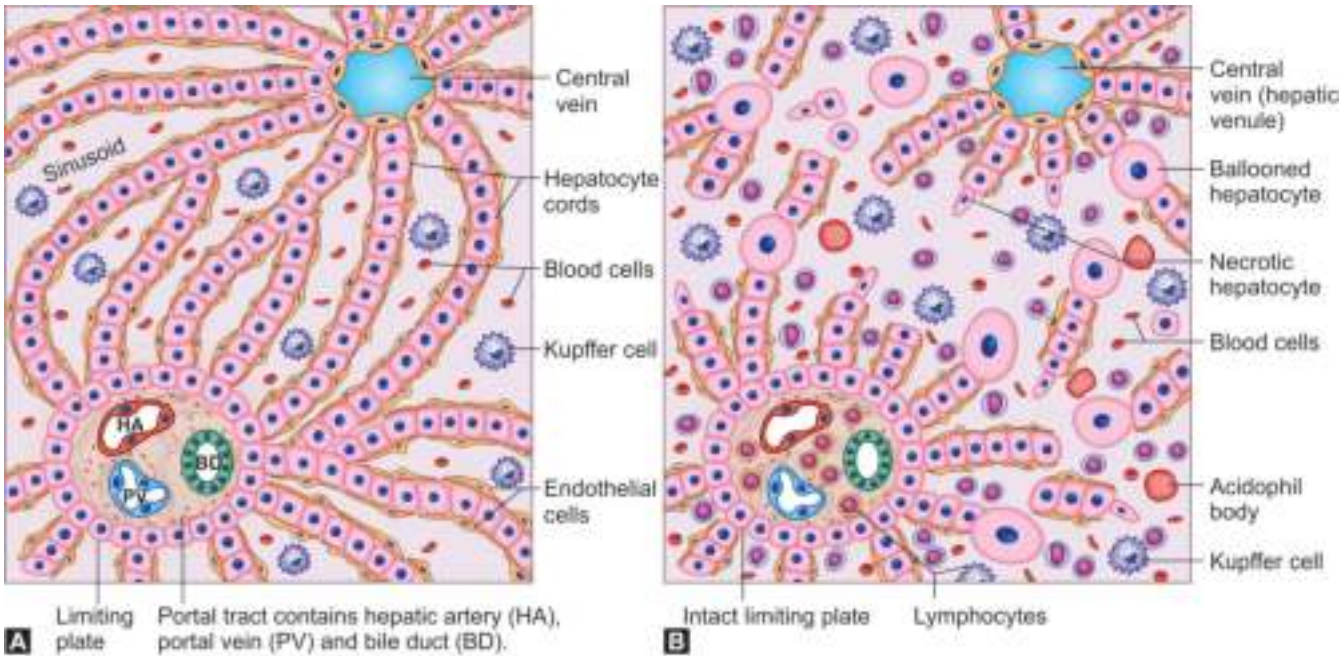

Fig. 21.17A and B: (A) Normal liver acinus contains a small portal tract at the center and terminal hepatic venules at the periphery, (B) acute viral hepatitis is diffuse inflammation caused by specific hepatotropic viruses. It shows spotty necrosis of hepatocytes (single/clusters), ballooning degeneration of hepatocytes, apoptosis of hepatocytes (Councilman bodies in sinusoids) and intrasinusoidal inflammation chiefly lymphocytes and a few macrophages.

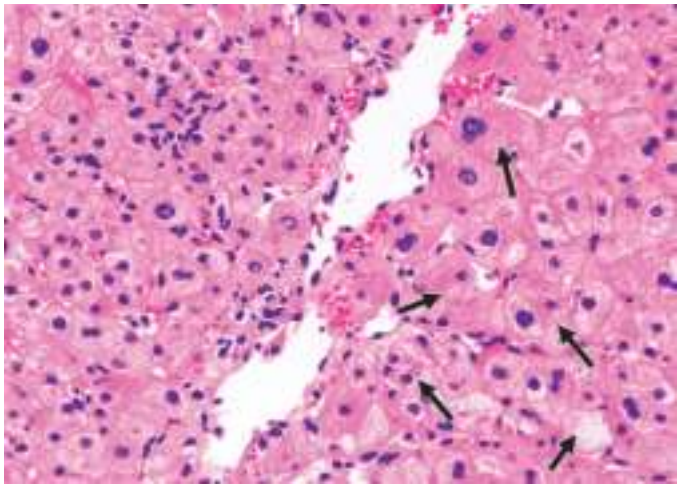

Fig. 21.18: Acute viral hepatitis. It shows spotty necrosis of hepatocytes, ballooning degeneration of hepatocytes, Councilman bodies in sinusoids and numerous lymphocytic infiltrate (arrows) (400X).

- Clinically, the patients are symptomatic in the early stages. The patients are diagnosed on the basis of abnormal liver function tests with appropriate viral serological analysis of chronic viral hepatitis.
- With time, patients develop advanced liver disease with portal hypertension manifested by splenomegaly, ascites, and/or esophageal varices.
- The serum aspartate transaminase (AST) and alanine aminotransferase (ALT) enzymes are usually elevated to various degrees but often fluctuate at times. Prolonged PT–INR and decreased serum albumin are indicators of advanced liver disease and hepatocellular impairment. In addition, marked elevations of serum aspartate transaminase (AST) and alanine aminotransferase (ALT) enzymes occur in patients with reactivation of chronic HBV infection.
- Advanced liver disease cases may demonstrate thrombocytopenia, leukopenia, low serum cholesterol values, and high ammonia level. Outcome of chronic viral hepatitis depends on anti-viral therapy, age of the patient and associated coexisting medical illness. Prognosis is poor in patients in human immunodeficiency virus (HIV) coinfection.

Portal Hepatitis

Portal hepatitis was previously known as chronic persistent hepatitis. It occurs only in HBV and HCV infections.

Light Microscopy

Liver biopsy in portal hepatitis shows following features (*refer* to Figs 21.19 and 21.20).

- Liver acinar architecture is preserved.
- Chronic inflammation is confined to portal tracts without damaging limiting plates. Connective tissue of portal tracts is infiltrated by lymphocytes, plasma cells and macrophages. Limiting plates are intact.
- Hepatocytes do not show evidence of patchy necrosis or piecemeal necrosis.

Table 21.34 Morphologic features of acute hepatitis

Morphologic Changes	Light Microscopy
Hepatocellular injury	▪ Liver cell swelling (ballooning degeneration) ▪ Cholestasis (bile plugs) ▪ Fatty change due to HCV
Hepatocellular necrosis	▪ Liver cell necrosis (isolated or clusters) ▪ Bridging necrosis in severe inflammation (portal-portal, central-central, portal-central) ▪ Lobular disarray (loss of normal architecture)
Hepatocytes regeneration	Proliferation of hepatocytes
Sinusoidal cell reactive changes	▪ Accumulation of phagocytosed cellular debris in Kupffer cells ▪ Influx of mononuclear cells in sinusoids
Portal tracts	▪ Mononuclear inflammatory infiltrate in portal tracts ▪ Spill over of inflammatory cells into adjoining parenchyma may show liver cell necrosis

Chronic Lobular Hepatitis

Chronic lobular hepatitis has been regarded by some authors as a variant of portal hepatitis.

Surgical Pathology: Chronic Lobular Hepatitis

Light Microscopy

- **Preservation of normal liver acinar architecture:** Liver acinar architecture is preserved in most part of liver. Collapse of the reticulin framework may be demonstrated in the region of the terminal hepatic venule. There may be clustering of Kupffer cells containing ceroid pigment. Ceroid pigment is partly oxidized lipid. These histologic findings suggest that loss of hepatocytes has taken place.
- **Evidence of patchy hepatocellular damage:** Hepatocytes show ballooning degeneration and acidophilic change. There is absence of piecemeal necrosis. Periportal fibrosis is minimal or absent. It rarely progresses to chronic active hepatitis and cirrhosis.

Chronic Active Hepatitis

Chronic active hepatitis is the most serious progressive liver disease characterized by a marked inflammatory response with concurrent evidence of long-standing

fibrosis disease that results in severe hepatocellular failure. Patient presents with nonspecific symptoms such as fatigue, anorexia and malaise. During carrier state, serum transaminase (AST and ALT) levels are normal; and histologic examination shows ground glass hepatocytes, but absence of inflammation.

Surgical Pathology: HBV Replication in Chronic Viral Hepatitis

Light Microscopy

Liver biopsy shows chronic inflammation in portal tracts, damaging the limiting plates and extending into liver lobule. There is presence of bridging necrosis and periportal fibrosis. Chronic viral hepatitis most often progresses to cirrhosis.

- **Ballooning degeneration of hepatocytes:** The hepatocytes show ballooning with scattered apoptotic cells. It depends on whether or not viral replication is occurring. Hepatocytes show ground glass appearance due to accumulation of HBsAg in the cytoplasm.
- **Biliary cholestasis:** Biliary cholestasis may be severe as a result of fibrosis or secondary to cirrhosis.
- **Kupffer cell hyperplasia:** Kupffer cells are also prominent and increased in number in the sinusoids, which contain phagocytosed cellular debris, bile pigments and lipofuscin pigment.
- **Piecemeal necrosis:** Hepatocellular necrosis in periportal region is known as piecemeal necrosis. It is observed in immunocompetent persons.
- **Bridging necrosis with periportal fibrosis:** In very severe cases, there may be presence of bridging necrosis with periportal fibrosis of connecting vascular structures of portal tract to terminal hepatic venules by thick band of collapsed reticulin. Collagen fibers are laid down to replace injured hepatocytes. Fibrous septa may extend into lobules. Coalescence of fibrous strands, associated with regeneration of hepatocytes may lead to cirrhosis.
- **Portal tract-chronic inflammation:** It is similar to that seen in portal hepatitis. Portal tracts are infiltrated by large number of lymphocytes, macrophages, and plasma cells. These inflammatory cells erode limiting plates and extend into lobular parenchyma. It is accompanied by periportal fibrosis. The expanded portal tracts often display proliferated bile ductules. Histology of portal hepatitis is shown in Figs 21.19 and 21.20.
- **Segmental bile duct lesions:** Both large and interlobular ducts undergo epithelial hyperplasia resulting in narrowing or occlusion of bile ducts. Histology of chronic active hepatitis is shown in Figs 21.21 and 21.22.

Pathology Pearls: Ground Glass Hepatocytes in Various Disorders

- HBV infection
- Lafora's disease (myoclonal epilepsy)
- Phenobarbital induced hypertrophy of smooth endoplasmic reticulum
- Glycogen storage disease type 4
- Multidrug intake

Viral Hepatitis: Biochemical Abnormalities

Biochemical abnormalities include serum enzymes, serum bilirubin, urine analysis and serological tests described as follows:

- **Serum transaminase enzymes:** There is increased level of transaminases (ALT and AST) three to five times. It may be over 1000 IU/L in severe hepatitis. Transaminases return to normal level over a period of several months. There is modest increase of alkaline phosphatase.
- **Serum bilirubin:** There is variable increase in serum bilirubin concentration.
- **Urine analysis:** Bilirubin is present in urine.
- **Serologic tests:** These must be performed to determine which virus has caused the disease. Serological markers in viral hepatitis are given in Table 21.35.

HEPATOTROPIC VIRUSES

HEPATITIS A VIRUS (HAV) INFECTION

Hepatitis A virus is single-stranded spherical unenveloped RNA icosahedral virus measuring 27 nm in diameter. HAV is inactivated by boiling for one minute or formaldehyde and chlorine. It is resistant to heat, acid and ether. HAV infection is usually a benign self-limiting disease, although it can cause acute fulminant hepatitis and death or need for liver transplantation in

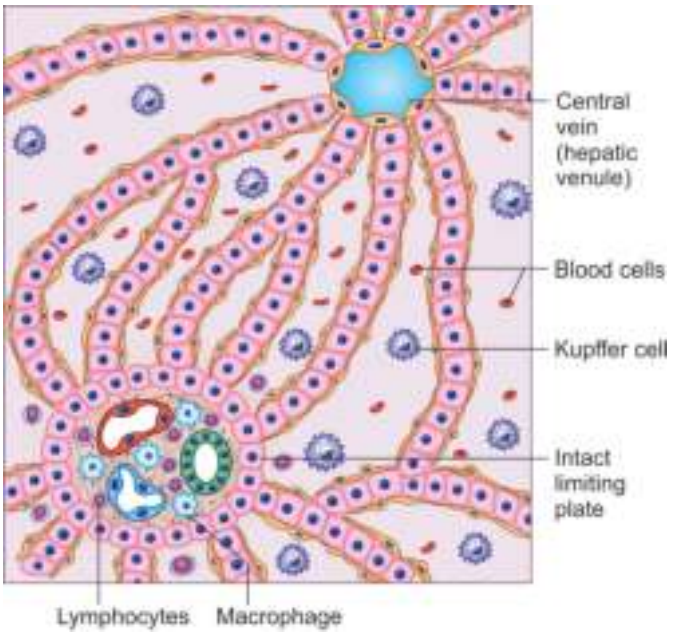

Fig. 21.19: Portal hepatitis (previously known as chronic persistent hepatitis). Chronic inflammation is confined to the portal tracts. Limiting plate is intact. Liver parenchyma appears normal.

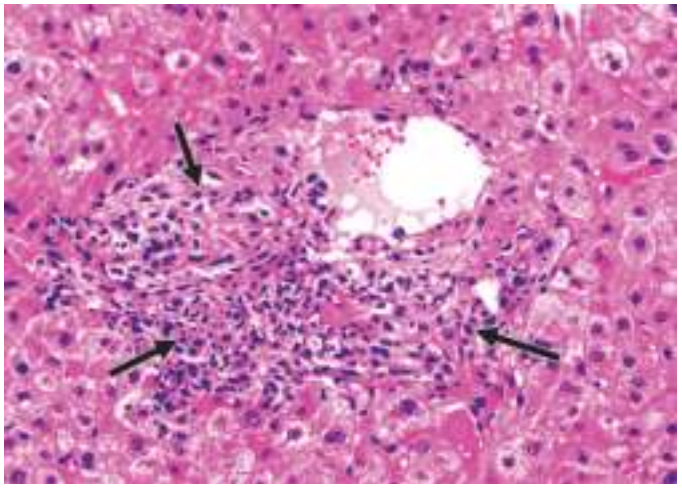

Fig. 21.20: Portal hepatitis. Chronic inflammation is confined to portal tracts. Lobular parenchyma appears normal. Hepatocytes show ballooning degeneration (arrows) (400X).

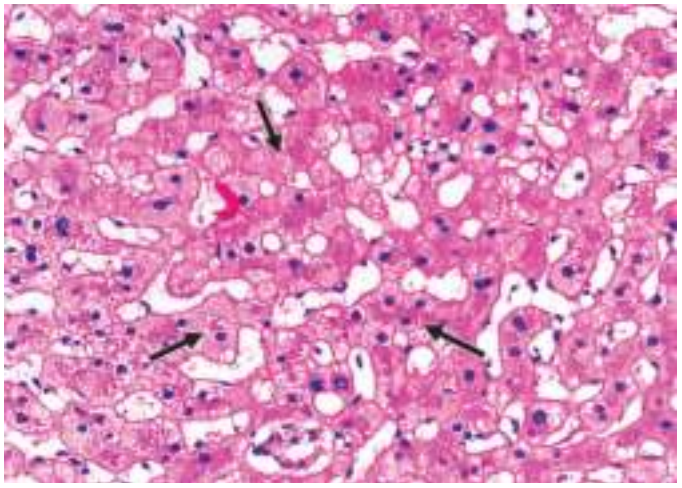

Fig. 21.22: Chronic active hepatitis. Ground-glass hepatocytes in chronic hepatitis. Smooth endoplasmic reticulum of hepatocytes distended with virions (HBsAg) gives ground-glass appearance of hepatocytes (arrows) (400X).

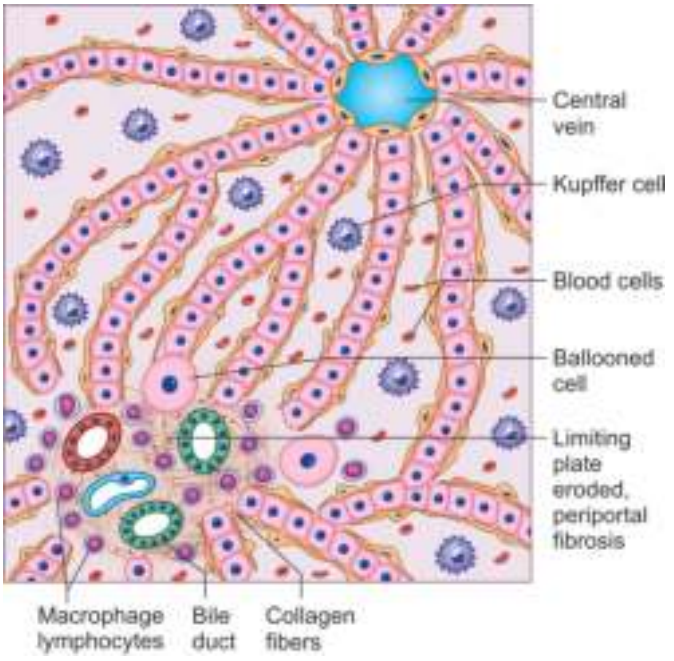

Fig. 21.21: Chronic active hepatitis is marked by severe chronic inflammation in the portal tracts. Periportal necrosis of hepatocytes is conspicuous, ballooned cells are present, and limiting plate is eroded. The inflammation extends into the lobular parenchyma and is accompanied by periportal fibrosis. The expanded portal tracts often display proliferated bile ductules and collagen fibers.

0.15–0.2% of cases. There is no carrier state or chronic state in HAV infection.

Etiology

Hepatitis A is contracted primarily by the **fecal–oral route**. Parenteral infection does not occur. Edible shellfish concentrate the virus in contaminated waters and may also transmit the infection especially in USA. Anal intercourse in homosexuals increases risk for hepatitis A. It has a brief incubation period of 15–45 days.

Pathogenesis

Hepatitis A virus replicates in the liver, and is excreted in the bile, and shed in the stool. There is only one antigenic type of HAV. The fecal shedding of HAV occurs during the first 2–3 weeks of the illness before and one week after onset of jaundice. Exposure to HAV gives lifelong immunity. Pathogenesis of HAV-induced hepatitis is shown in Fig. 21.23.

Age Group

The clinical presentation of symptoms is dependent upon age of the patients. Severity of symptoms is increasing in older age groups.

Children below 6 years most often remain asymptomatic. Older children and adults are symptomatic with clinical jaundice in 70% of cases. Symptoms usually last for approximately 2 months but can last longer.

Clinical Features

There are three phases of hepatitis induced by HAV—preicteric, icteric and recovery phases described as under:

- **Preicteric phase:** HAV is present in liver, bile, stool and blood. Patient is asymptomatic in this phase.
- **Icteric phase:** Patient presents with mild jaundice, malaise, nausea, anorexia and fever. Jaundice appears one week after the onset of symptoms with peak at around 10 days.
  - On clinical examination, liver may become enlarged and tender.

Table 21.35 Serological markers in viral hepatitis

Hepatotropic Hepatitis	Serology	Interpretation
HAV	▪ Anti-HAV IgG ▪ Anti-HAV IgM	▪ Past infection and lifelong immunity ▪ Acute HAV infection
HBV	▪ HBsAg ▪ HBeAg ▪ Anti-HBc IgG ▪ Anti-HBs antibody ▪ HBV-DNA qualitative ▪ HBV-DNA quantitative	▪ Acute and chronic HBV infection ▪ High degree of HBV infectivity and replication ▪ Past infection; acute and chronic HBV infection ▪ Past HBV infection and immunity; immunization ▪ Acute and chronic HBV infection ▪ Acute and chronic HBV infection; viral replication
HDV	▪ Anti-δ IgM and IgG ▪ HDV-RNA	▪ Acute HDV infection (high IgM and low IgG) ▪ Chronic HDV infection (high IgG and low to immeasurable IgM) ▪ Acute and chronic HDV infection
HCV	▪ Anti-HCV antibody ▪ HCV qualitative ▪ HCV quantitative	▪ Acute and chronic HCV infection ▪ Acute and chronic HCV infection ▪ Acute and chronic HCV infection; viral replication
HEV	▪ Anti-HEV IgM and IgG ▪ Anti-HEV IgG ▪ HEV-RNA	▪ Acute HEV infection (high IgM and low IgG) ▪ Past HEV infection and immunity ▪ Acute HEV infection
HGV	▪ Anti-HGV antibody ▪ HGV-RNA	▪ Acute and chronic HGV infection ▪ Acute and chronic HGV infection

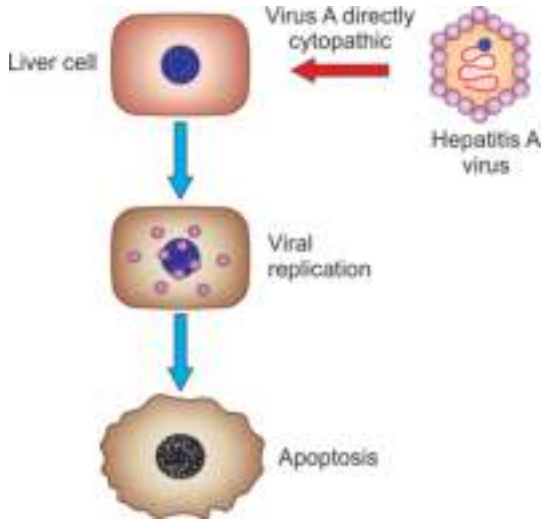

Fig. 21.23: Pathogenesis of HAV-induced hepatitis. HAV in contrast to HBV appears to be directly cytopathic.

- At this stage, liver function tests demonstrate elevations of aspartate transaminase (AST) and alanine aminotransferase (ALT) usually greater than 500 IU/L and most often over a 1000 IU/L, with ALT more specific for hepatocellular injury.
- Alkaline phosphatase value is usually normal or elevated about two times of normal values. When hyperbilirubinemia and jaundice occur, the serum bilirubin value ranges from 5 to 20 mg/dl, depending on the degree of HAV infection and necroinflammatory changes.
- Importantly, the PT–INR and serum albumin levels are generally normal in uncomplicated cases.
- Coagulation tests may be abnormal. One stage prothrombin time is sensitive indicator of severity of liver disease. HAV appears in stool 2–3 weeks before jaundice and one week after icteric phase.

- **Recovery phase:** Signs and symptoms in HAV infection generally disappear over a period of 3–8 weeks. Complete recovery occurs in most patients with mortality in <1%. Majority of patients recover without progressing to chronic hepatitis. HAV infection is not associated with cirrhosis or hepatocellular carcinoma. HAV infection has no carrier state.
- **Fulminant hepatitis:** Only a few patients may develop fulminant hepatitis with mortality in 0.1% of cases.

Serological Studies

The presence of IgM anti-HAV is indicative of acute hepatitis A, whereas IgG anti-HAV merely documents past infection indicating lifelong immunity (Fig. 21.24).

- **Anti-HAV of IgM antibody:** Initially, increased titer of anti-HAV of IgM antibody indicates active infection. It is a reliable diagnostic marker for acute HAV infection. Anti-A of IgM antibody appears in the blood, when patient becomes symptomatic. IgM antibody starts decreasing in a few months to one year.
- **IgG antibody:** Increased titer of anti-HAV of IgG antibody appears soon after IgM antibody in blood.

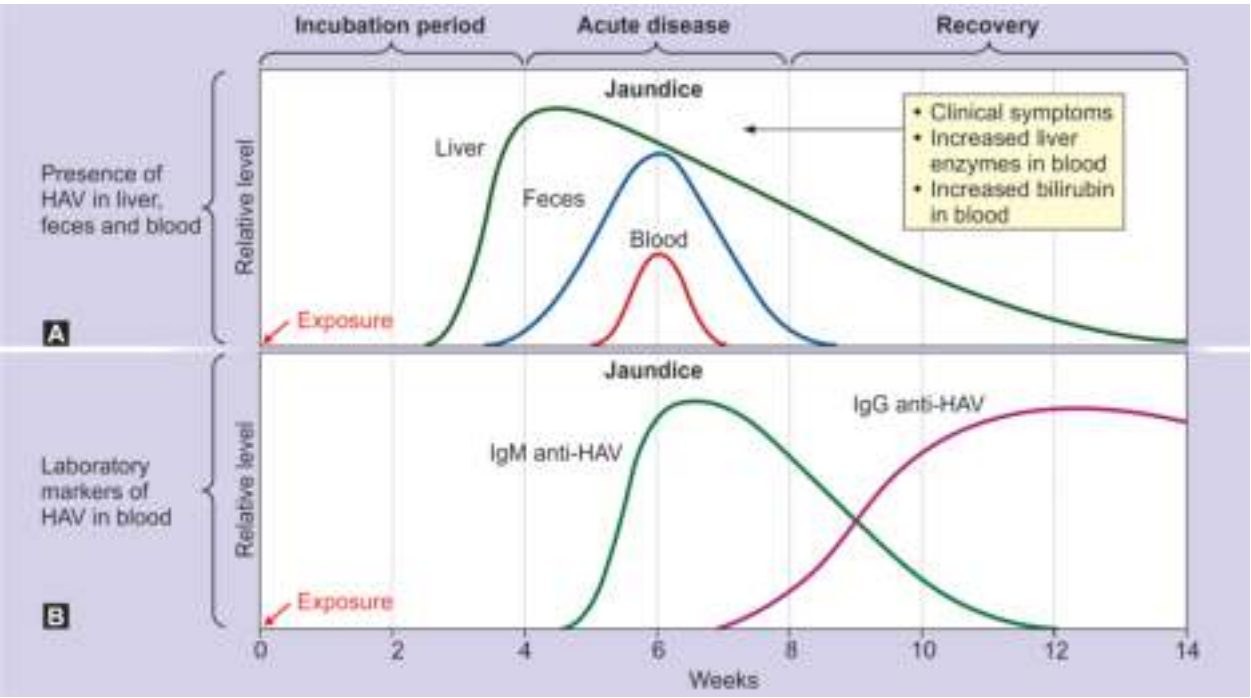

Fig. 21.24A and B: Serological studies in acute viral hepatitis due to HAV. The presence of IgM anti-HAV is indicative of acute hepatitis A, whereas IgG anti-HAV merely documents past infection indicating lifelong immunity. Presence of IgM antibodies coincides with a decline in fecal shedding of the virus.

It indicates exposure to HAV and recovery from infection or vaccination. It is a protective antibody giving lifelong immunity.

In patients with HAV infection, chronic hepatitis never occurs. There is lifelong immunity. Viral elimination is total without a carrier state.

Surgical Pathology: Acute Viral Hepatitis (HAV)
Light Microscopy
Histologic examination of liver biopsy in acute viral hepatitis (HAV) shows disarray of the liver cell plates accompanied by inflammatory infiltrate and liver cell necrosis.

Vaccination

The vaccine against HAV is available and highly effective. Vaccination is of a little benefit in prevention of hepatitis in people with known HAV exposure. It is intended to replace the use of immunoglobulin in people at high-risk for HAV.

HEPATITIS B VIRUS (HBV) INFECTION

HBV is complete virion measuring 42 nm in diameter known as **Dane particle**. It is hardy virus, which can withstand extremes of temperature and humidity. HBV consists of lipoprotein coat with central core (nucleocapsid).

- **Viral lipoprotein coat:** HBV consists of central core surrounded by lipoprotein coat containing the hepatitis B surface antigen (HBsAg).
- **Central core (nucleocapsid):** It is hexagonal in shape, which contains double-stranded circular DNA, DNA polymerase, hepatitis B core antigen (HBcAg), and hepatitis Be antigen (HBeAg).

  Presence of HBeAg in the serum indicates active viral replication, infectivity of serum and progression of liver cell damage (Figs 21.25 and 21.26).

Mode of Transmission

HBV is transmitted via transfusion of blood or blood products, hemodialysis, accidental needle-stick in health workers, intravenous drug abuse, homosexual activity, contact with body fluids by shedding of HBV in saliva, tears, and breast milk and transplacental transmission from mother to neonate.

Incubation Period

Incubation period of HBV infection is 4–26 weeks (average 60–90 days or 8 weeks).

Pathogenesis

HBV virions are not directly cytopathic, which integrate into the host DNA and induce hepatic inflammation leading to hepatocellular injury. Smooth endoplasmic reticulum of hepatocytes distended with HBV virions

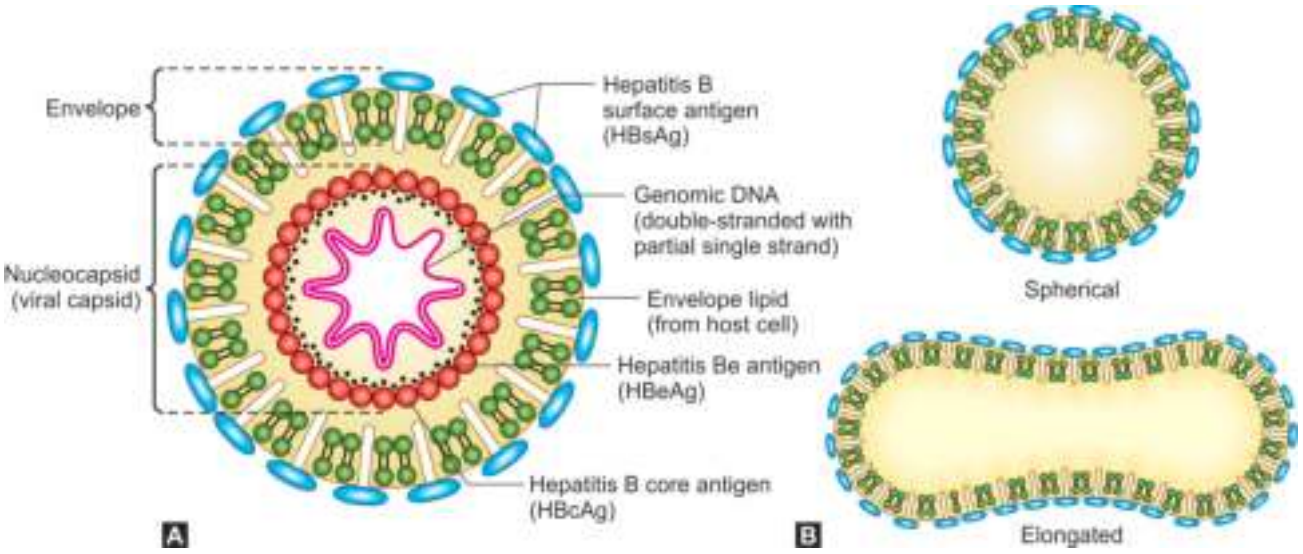

Fig. 21.25: Structure of hepatitis B virus. (A) Hepatitis B virus (Dane particles), (B) viral envelope particles containing HBsAg.

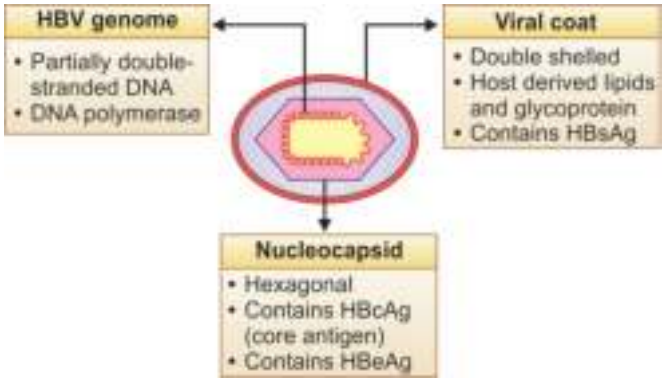

Fig. 21.26: Structure of hepatitis B virus shows HBV genome, viral coat and nucleocapsid.

gives ground glass appearance of hepatocytes. It indicates chronic carrier state.

Increased titers of HBeAg, HBV DNA and HBV DNA polymerase enzyme indicate active viral replication in blood and correlates with infectivity of the blood. Pathogenesis of HBV hepatitis is shown in Fig. 21.27.

- **Entry of HBV into the hepatocytes:** HBV entry into the hepatocytes may depend on polymerized human serum albumin (PHSA) serving as a linkage between the putative receptors of HBV and hepatocytes. Hepatitis B virus enters the host hepatocytes. HBV virion multiplication occurs in hepatocytes as a result of proliferation of HBV DNA.
- **Processing of HBV DNA:** HBV DNA of virus acts as the template for the formation of RNA, which is termed pregenomic. This term 'pregenomic' is given because RNA forms the template for the formation of viral DNA through the medium of virally encoded reverse transcriptase. It leads to formation of complete virions.

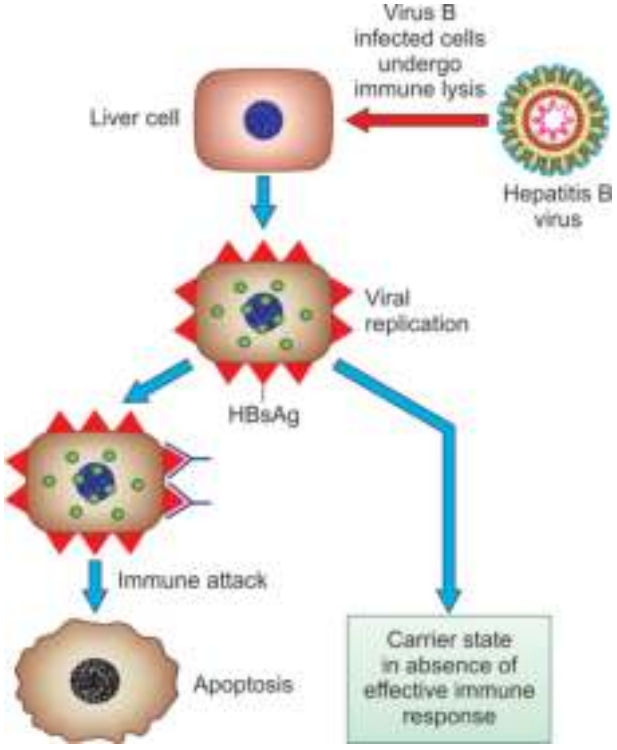

Fig. 21.27: Pathogenesis of HBV hepatitis. The HBV causes liver cell injury due to expression of HBsAg on surface of hepatocytes. The infected liver cells are eliminated by immune-mediated mechanism. Asymptomatic carrier state can ensure in the absence of specific immunity.

- **Integrative phase of HBV:** During integrative phase, virions are not produced; and there is absence of antigens and antibodies.

Hepatocellular Response to Virions

- **Weak hepatocellular response to CD8+ cytotoxic T cells:** There is formation of HBsAg and HBcAg,

which sensitize CD8+ cytotoxic T cells. Weak response of CD8+ cytotoxic T cells results in chronic hepatitis.

- **Strong hepatocellular response:** Strong response of CD8+ cytotoxic T cells causes hepatocellular injury. Excess of HBsAg is accumulated in smooth endoplasmic reticulum producing ground glass appearance of hepatocytes.

Extrahepatic Manifestations

HBsAg and anti-HBsAb form immune complex resulting in deposition in blood vessels, which activates complement system resulting in angioedema, arthritis, skin rashes, fever and glomerulonephritis.

Serological Assays in Acute HBV Infection

Serological assays may be employed to distinguish between acute and chronic hepatitis due to HBV infection.

- Most sensitive and specific commercial methods used in diagnosis of HBV infection are radioimmunoassay (RIA) and enzyme-linked immunosorbent assay (ELISA) by using specific antibodies against various HBV proteins. Both these methods can detect HBsAg as low as 0.25 ng/ml and anti-HBs antibodies.
- Polymerase chain reaction (PCR) is used to detect low concentration of HBV DNA present in both blood and tissue samples (Table 21.36 and Fig. 21.28A and B).

Table 21.36 Serological events in HBV infection

HBsAg	HBeAg	Anti-HBe	Anti-HBc	Anti-HBc IgM	Anti-HBs	Significance
+	+/–	+/–	+	+	–	Acute HBV infection
+	+	–	+	–/Weak positive	–	HBV carrier (high infectivity)
+	–	+	+	–	–	HBV carrier (low infectivity)
–	–	+/–	+	–	+	Past HBV infection
–	–	–	–	–	+	Past HBV immunization

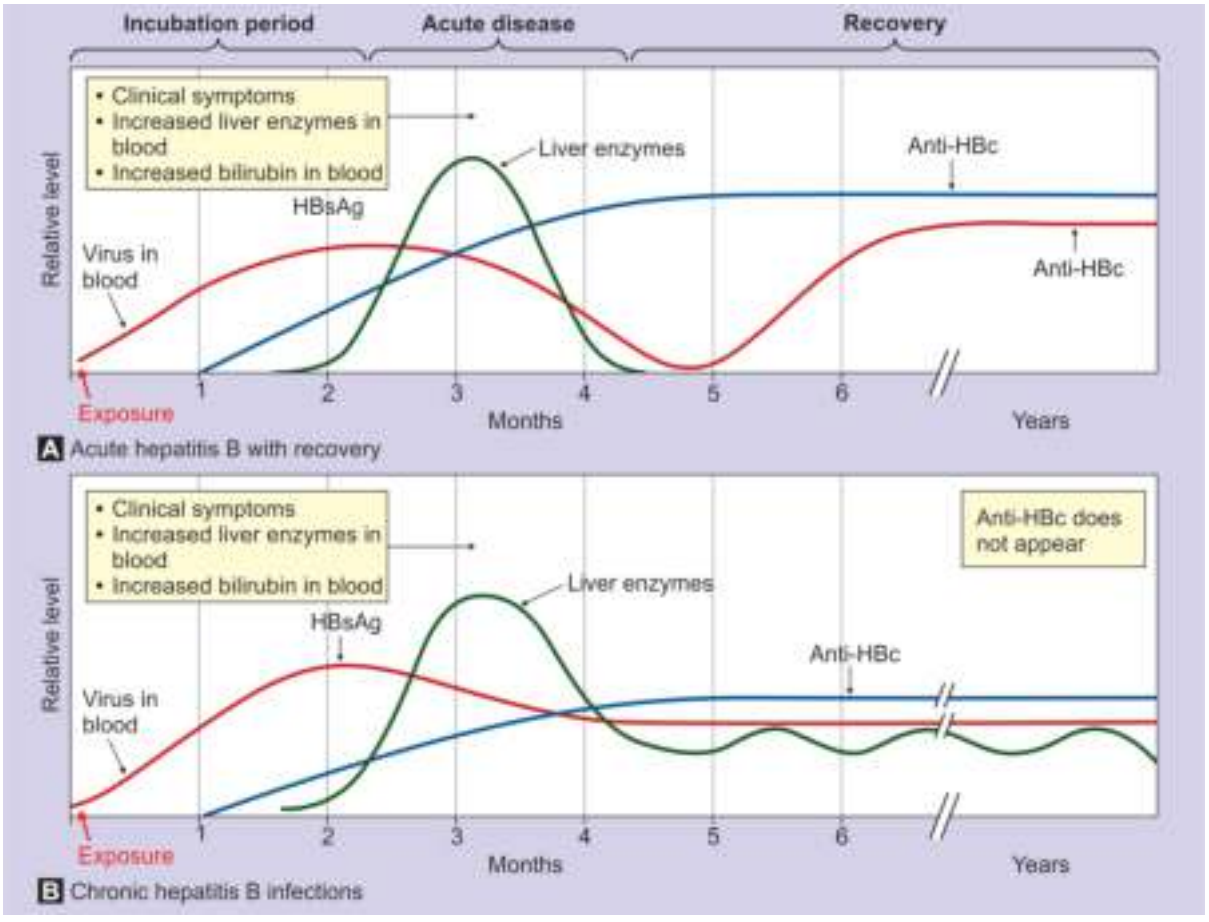

Fig. 21.28: Hepatitis B. (A) Clinical phases and serological markers. Acute infection is characterized by rapid appearance of viremia before clinical symptoms appear. There is disappearance of HBV from the blood and appearance of antibodies against hepatitis B surface antigen (HBsAg). (B) Chronic hepatitis is signaled by continuing onset of jaundice or presence of viremia.

- **HBsAg first marker in serum:** Hepatitis B surface antigen (HBsAg) is the first marker appearing in the serum and is demonstrated in the serum between 1 week and 2 months after exposure and before the appearance of clinical symptoms. It disappears from the blood during convalescence. Persistence of HBsAg is being used to differentiate acute from chronic viral hepatitis. HBsAg persists up to 4 months in acute hepatitis. Persistence of HBsAg >6 months defines chronic hepatitis.
- **HBeAg second marker in serum:** Presence of HBeAg in the serum indicates maximum infectivity and intense viral replication. As with surface antigen (HBsAg), 'e' antigen (HBeAg) appears before the onset of clinical manifestations and disappears from the serum in two weeks. As the 'e' antigen is cleared from the serum, the antibody to 'e' antigen appears in the serum. But there is a gap between disappearance of the 'e' antigen and demonstration of antibody.
- **Anti-HBc IgG and IgM markers in serum:** With the onset of clinical manifestations, anti-HBc IgG and IgM most often appear in the serum and remain in low concentration for life, which do not play significant role in viral elimination and rather serve as marker for infection. It is important to mention that HBcAg is not detectable in serum.
- **Anti-HBs antibody last marker in serum:** Last marker to appear in serum is anti-HBs antibody. It is measured if present in excess concentration. Anti-HBs antibody forms immune complexes with the circulating HBsAg. These antigen–antibody complexes may produce extrahepatic complications such as glomerulonephritis, necrotizing vasculitis and serum sickness like syndrome. The antibody to HBsAg participates in elimination of HBsAg.

There is a window period between the appearance of HBsAg and corresponding antibody. IgG anti-HBs is protective antibody to subsequent HBV infection. Its persistence indicates either active or passive immunization against HBV. Recombinant vaccine consists of HBsAg alone.

- **HBV DNA marker in serum:** The presence of viral DNA (HBV DNA) in the serum is the most certain indicator of hepatitis B virus (HBV) infection, which indicates viral burden and active replication. It evaluates recovery from infection after antiviral therapy. It helps in differentiation of inactive carrier state and chronic hepatitis in HBV infection. Serological markers and interpretation for hepatitis B virus infection are given in Table 21.37.

Hallmark of Chronicity of HBV Infection

Failure to clear HBsAg from serum after 6 months is the hallmark of chronicity due to HBV infection, which occurs in <5% of cases. Presence of HBeAg, HBV DNA or polymerase in the serum either singly or together indicates active HBV replication. In patients where there is no HBV replication, the continuing presence of HBsAg correlates with integration of the viral genome into the genome of host hepatocytes.

Clinical Course of HBV Infection

Majority of cases are subclinical (65%). Approximately 35% of cases develop acute fulminant viral hepatitis or chronic viral hepatitis. Approximately 10–30% cases of chronic hepatitis cases develop confluent hepatic necrosis, cirrhosis (<1%) and hepatocellular carcinoma.

Clinical course of hepatitis B infection is shown in Fig. 21.29. Differences between hepatitis induced by HAV and HBV are given in Table 21.38.

Table 21.37 Serological markers and interpretation for hepatitis B virus infection

Presence/Absence			Interpretation
HBsAg	Anti-HBsAb	Anti-HBcAb	
Positive	Negative	Negative	Early acute HBV infection
Positive	Positive or negative	Positive	Either acute or chronic HBV infection
Negative	Positive	Positive	Previous HBV infection and current immunity to the virus
Negative	Negative	Positive	Not clear interpretation either due to HBV infection in the remote past, low-level HBV infection, or false-positive/nonspecific reactions. If present, anti-HBs helps to validate anti-HBc reactivity
Negative	Negative	Negative	These results suggest that liver toxicity is due to some other agents other than HBV
Negative	Positive	Negative	These results are typical of a vaccinated individual

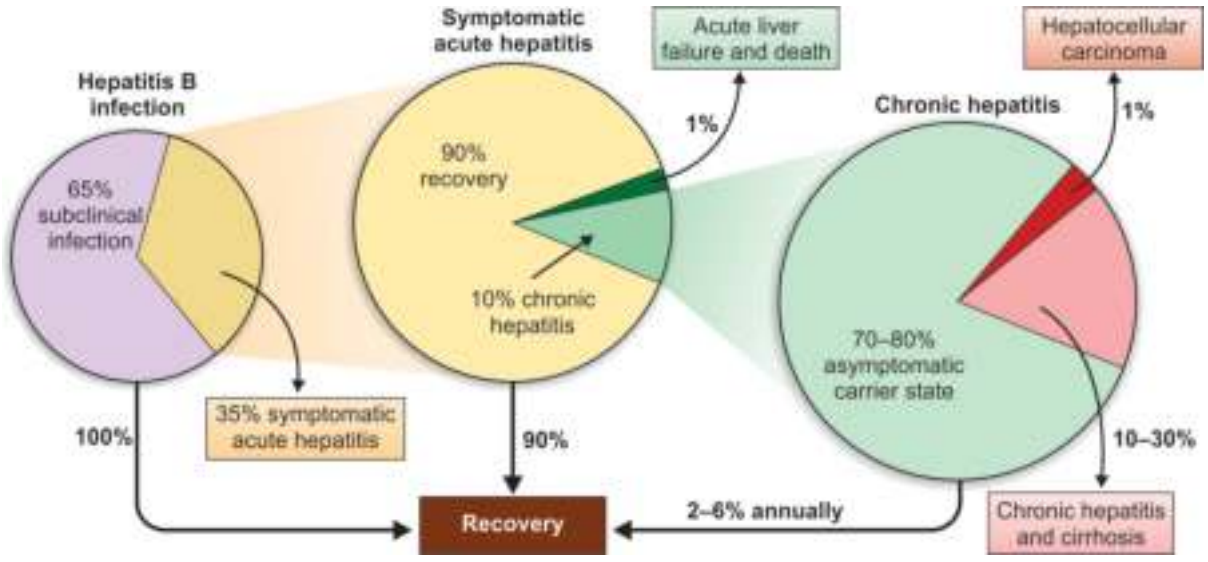

Fig. 21.29: Clinical course of hepatitis B infection. It has subclinical, acute hepatitis, chronic hepatitis or asymptomatic chronic carrier. Fulminant acute hepatitis with massive liver cell necrosis may be seen in 1% of cases. There is increased risk of development of cirrhosis and hepatocellular carcinoma.

Table 21.38 Differences between hepatitis induced by HAV and HBV

Parameters	Hepatitis A Infection	Hepatitis B Infection
Mode of transmission	Fecal–oral route	Parenteral route and close contact
Carrier state	Absent	Present
Chronic viral hepatitis	Absent	Present
Age	Children and adolescents	All age group
Viruses in stool and body secretions	Viruses are present in stool 2–3 weeks after onset of jaundice	Viruses are not excreted in stool. But these are present in body secretions
Viremia	Transient excretion	Viruses remain for prolonged period starting from incubation period, acute hepatitis to chronic hepatitis. Infection transmitted by such blood administration to other persons
Vertical transmission	Absent	Present
Fulminant viral hepatitis	Rare	More frequent
Risk for hepatocellular carcinoma	Absent	Present
Clinical course	Usually self-limited	Variable, it may be severe with fatal outcome

Pathology Pearls: Summary of Serological Studies in HBV-induced Hepatitis

- HBsAg is demonstrated in acute or chronic HBV-induced hepatitis.
- Demonstration of IgG anti-HBs and IgG anti-HBc indicates previous exposure to HBV.
- Demonstration of anti-HBs IgG indicates that the person is immunized.
- Anti-HBc IgM is the only serological marker demonstrated during window period.
- Window period is a period in which HBsAg and anti-HBsAb is not detectable in the serum, but anti-HBcAb and anti-HBeAb are the only markers of the disease. HbsAg, HBV DNA, and HBeAg are absent. It (anti-HBC-IgM) converts to anti-HBc IgG in 6 months.
- Qualitative marker of HBV replication is HBeAg.
- Quantitative (definite) marker of HBV replication is HBV DNA > HBV DNA polymerase.
- Inactive HBV carrier refers to HBeAg negative with normal ALT levels and undetectable or low level of HBV DNA (<2000 IU/ml).

Pathology Pearls: Precore or Basic Core Mutant HBV

- Patient with precore or basic core mutant HBV develops severe and progressive liver disease. There is increased risk for cirrhosis and hepatocellular carcinoma.
- Serological assays reveal HBeAg negative but positive anti-HBe. HBV DNA levels are >10,000 copies/ml.
- Blood biochemistry analysis reveals persistent or intermittent elevations in ALT (alanine aminotransferase) activity.

Clinical Manifestations of HBV Infection

- **Subclinical acute hepatitis:** Patient is asymptomatic or clinically unrecognized.
- **Acute icteric hepatitis:** HBsAg is the first marker of infection. It appears 2–8 weeks after exposure, and persists up to 4 months.
- **Fulminant acute hepatitis with massive hepatic necrosis:** It develops in <1% of clinically diagnosed HBV infections. Markedly elevation of ALT and AST are characteristic findings. Gross examination reveals soft flabby shrunken liver, and wrinkled Glisson's capsule. Histologic examination shows necrotic liver lobules, leaving a collapsed collagenous framework. These patients die unless an emergency liver transplantation is performed.
- **Chronic hepatitis:** Persistence of abnormal liver function tests and HBsAg in cytoplasm of hepatocytes for >6 months is considered chronic hepatitis.
  - Chronic carriers: These are otherwise healthy carriers. HBsAg persists longer than 6 months. There is absence of infective particles in 10–15% cases. Anti-HBc IgM converts to anti-HBc IgG.
  - Chronic active hepatitis: It occurs in 33% cases of chronic carriers. There is presence of infective particles. There is increased risk for post-necrotic cirrhosis (33%) and hepatocellular carcinoma (10%).

Surgical Pathology: Liver Biopsy in HBV Infection

Clinical indication for liver biopsy in HBV infection is to determine active viral hepatitis. In patient's serological or biochemical tests are inconclusive of clear picture of the disease activity.

Light Microscopy

- Liver biopsy in patient with chronic active hepatitis is performed to assess evidence of fibrosis and inflammatory grade of the disease.
- Liver shows infiltration of connective tissue of portal tracts by lymphocytes, plasma cells and macrophages.
- There is presence of fibrosis and piecemeal necrosis of the limiting plate of hepatocytes close to the portal tracts.
- Hepatocytes with HBsAg show cytoplasmic ground-glass appearance and sanded nuclei (Fig. 21.30).

Immunohistochemistry Technique

- Immunohistochemistry technique reveals HBsAg in cytoplasm. HBsAg is demonstrated by Shikata's orcein stain, Victoria blue and aldehyde fuscin stain.
- HBcAg is expressed in cytoplasm, membrane or nucleus and its presence indicates active HBV replication and infectivity of the virus.

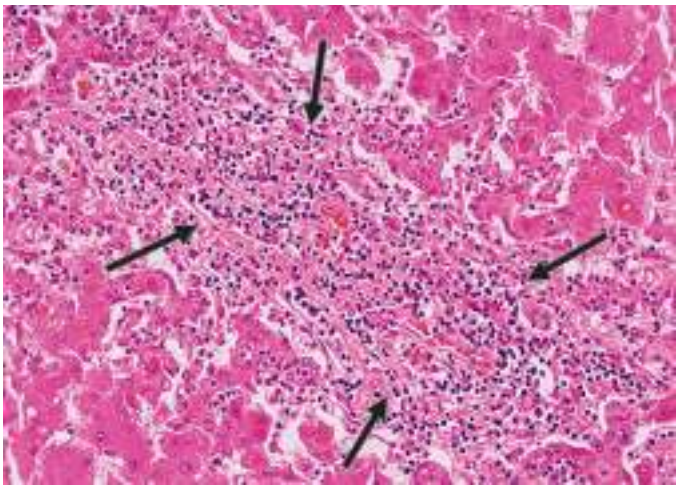

Fig. 21.30: Chronic active hepatitis. Chronic viral hepatitis leads to liver cell destruction. A mononuclear inflammatory cell infiltrate extends from portal areas and disrupts the limiting plate of hepatocytes which are undergoing necrosis, the so-called piecemeal necrosis of chronic active hepatitis. In this case, the hepatitis B surface antigen (HBsAg) and hepatitis B core antibody (HBcAb) were positive (arrows) (400X).

HEPATITIS C VIRUS INFECTION

Hepatitis C virus (HCV) is 30–60 nm enveloped single-stranded RNA flavivirus. About 50% of affected persons develop biochemical evidence of the chronic liver disease.

- Approximately 10% of HCV infected cases develop chronic active viral hepatitis or cirrhosis.
- Coexistent conditions such as hepatitis B infection, alcoholism, hemochromatosis and α_1-antitrypsin deficiency adversely affect the clinical course of HCV infection.
- Factors associated with spontaneous clearing of HCV infection appear to include younger age, female sex, and certain histocompatibility genes. Outcome of untreated hepatitis C infection is shown in Fig. 21.31.

Incubation Period

Incubation period of HCV infection is similar to HBV, i.e. 4–26 weeks.

Mode of Transmission

Hepatitis C virus is transmitted by blood-borne parenteral route, sexual contact, transplacental infection of the fetus and co-infection with HBV described as under:

- **Blood and its products transfusion (parenteral route):** HCV is transmitted by blood-borne parenteral route with sharing of needles in drug addicts and transfusion of blood and its products. About 60–90% of intravenous drug users are infected with HCV.
- **Sexual contact:** HCV can also be transmitted by sexual intercourse with infected partner.

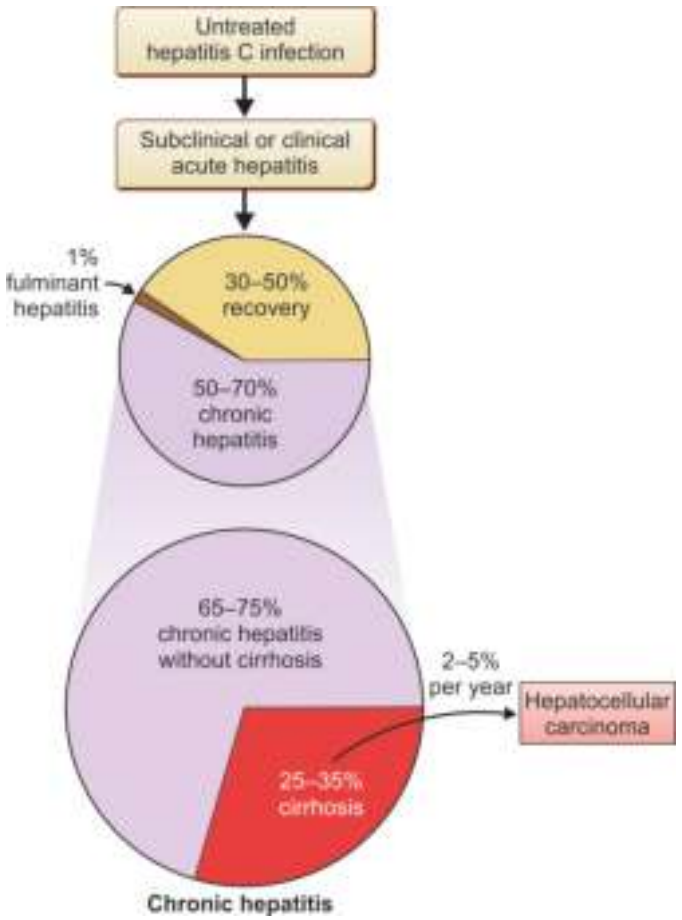

Fig. 21.31: Outcome of untreated hepatitis C infection.

- **Transplacental route:** Mother transmits HCV infection to fetus via transplacental route.
- **Co-infection:** Persons with HBV and HCV co-infection are also affected.

Clinical Features

Most people infected with HCV have a normal life span. It is persistent infection due to recurrent relapses as a rule in >85% of cases and usually mild. The most serious consequences of chronic HCV infection are progressive liver fibrosis leading to cirrhosis over 10–30, end-stage liver disease, and hepatocellular cancer.

Extrahepatic Manifestations

- **Cryoglobulinemia:** Immune response to HCV leads to cryoglobulinemia. IgM cryoglobulins precipitate at 4°C and dissolve again at 37°C. These are demonstrated in 35% of patients. Mixed cryoglobulinemia (IgM and IgG) is demonstrated in some of patients with hepatitis C infection. These cryoglobulins induce glomerular and vascular injury.
- **Membranous glomerulonephritis:** Membranous glomerulonephritis is also mediated by cryoglobulins. Patient may develop **nephrotic syndrome** characterized by massive proteinuria, hypoproteinemia, hyperlipidemia, lipiduria and generalized edema.
- **Raynaud phenomenon:** Vasculitis mediated by deposition of cryoglobulins in the blood vessel wall is associated with purpura termed Raynaud phenomenon.

Surgical Pathology: Liver Biopsy in HCV Infection

Light Microscopy

In addition to the features common to viral hepatitis, HCV infection may produce the following histologic changes:

- **Cytopathic changes in the hepatocytes:** Histologic examination shows scattered hepatocytes with intense degree of eosinophilia indicating damage to hepatocytes by HCV. There is no evidence of inflammation.
- **Presence of inflammatory cells within sinusoids:** The sinusoids show infiltration by lymphocytes and macrophages. The intensity of inflammation is out of proportion to the relatively small amount of hepatocytic damage.
- **Presence of inflammatory cells within portal tracts:** Connective tissue of hepatocytes may show lymphoid aggregates.
- **Evidence of intrahepatic bile ducts damage:** Presence of inflammatory infiltrate in bile duct epithelium causes destruction of intrahepatic bile duct in 30% of cases.
- **Focal fatty change:** Sublethal liver cell injury is seen in the form of small droplet fatty change (Fig. 21.32).

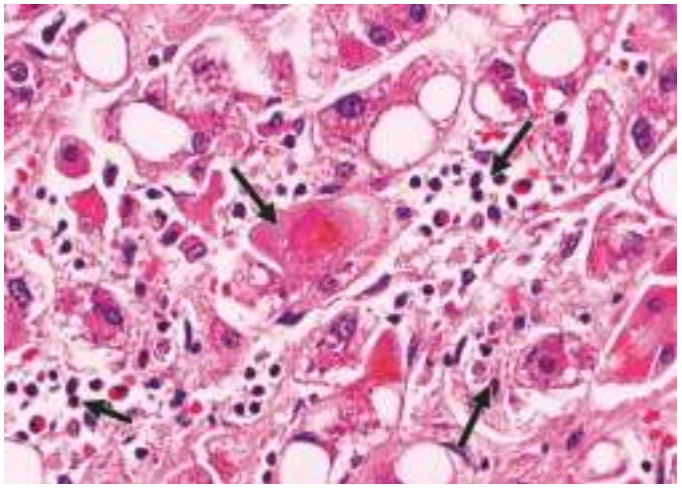

Fig. 21.32: Viral hepatitis C. This is a case of viral hepatitis C, in which half of cases leads to chronic liver disease. The extent of chronic hepatitis can be graded by the degree of activity (necrosis and inflammation) and staged by the degree of fibrosis. In this case, necrosis and inflammation are prominent, and there is some steatosis as well. Regardless of the grade or stage, the etiology of the hepatitis must be sought, for the treatment may depend upon knowing the cause, and chronic liver diseases of different etiologies may appear microscopically and grossly similar (arrows) (400X).

Pathology Pearls: Steatosis in HCV Infection

- Steatosis favors HCV genotype 3 replication, since lipid droplets in hepatocytes provide a scaffold for viral replication. It is most often associated with more inflammation activity and rapid fibrosis.
- Steatosis may represent superimposed disease processes, e.g. obesity, diabetes mellitus and alcoholism.

Serological Assays

Initially IgM anti-HCV antibody appears, which is followed by appearance of IgG anti-HCV antibodies. Chronic HCV infection shows episodic elevations in serum transaminases with persistent HCV RNA in blood.

- Anti-HCV IgG does not provide immunity due to antigenic variability and genome instability seen in HCV. Direct measurement of HCV in the serum remains the most accurate test for infection.
- The viral tests are highly sensitive and specific, but more costly than antibody tests.
  - **Screening with enzyme immunoassay:** Presence of anti-HCV IgG indicates infection or recovery. It is not a protective antibody.
  - **Confirmatory tests:** These include recombinant immunoblot assay (RIBA) and HCV RNA using polymerase chain reaction (Fig. 21.33A and B).

Treatment

α-Interferon is administered in HCV infected patients.

HEPATITIS D VIRUS INFECTION

Hepatitis D virus (HDV) is single-stranded spherical RNA virus containing delta protein antigen (HDAg), and surrounded by a proteinaceous coat of HBsAg. It requires co-infection or superinfection with HBV for replication. It is infective only when encapsulated by HBV. Incidence with HDV infection is especially high in intravenous drug users.

Pathology

Hepatitis D virus (HDV) has direct cytopathic effect on hepatocytes in contrast to HBV. HDV produces extensive hepatocellular injury. Liver shows microvesicular fatty change and many acidophilic '**Councilman bodies**' in sinusoids. Chronicity is very rare. Incubation period of HDV infection is 4–7 weeks in superinfection with HBV.

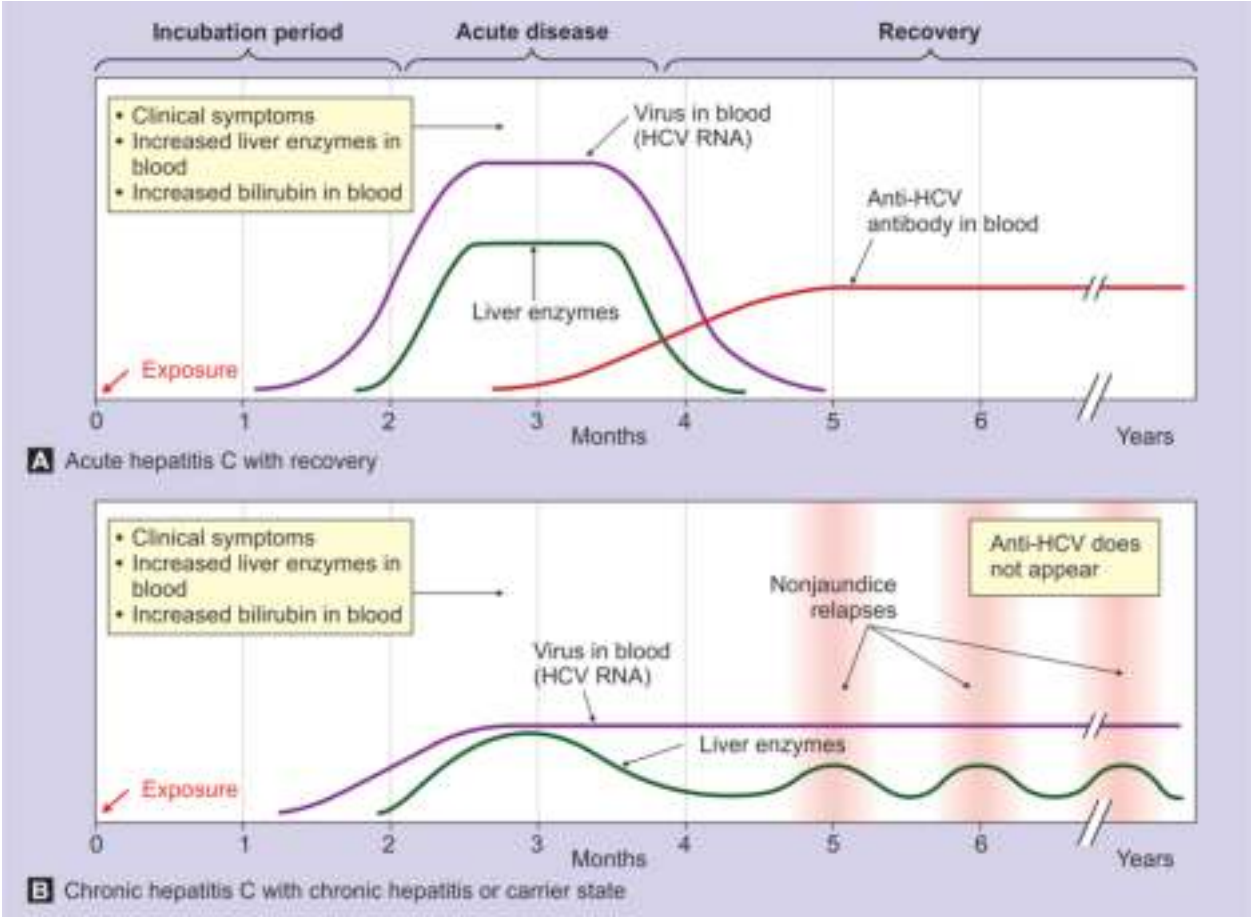

Fig. 21.33: Chronic hepatitis C. (A) Acute hepatitis C with recovery, (B) chronic hepatitis C with chronic hepatitis or carrier state.

Mode of Transmission

Mode of transmission of HDV can be acquired simultaneously with HBV (co-infection) or it may secondarily infect HBV carriers (superinfection). Both co-infection and superinfection may be followed by acute viral hepatitis (Table 21.39 and Fig. 21.34A and B).

- **Co-infection:** Person receiving infected blood transfusion with HBV and HDV develops acute hepatitis.
- **Superinfection:** Carriers of HBV develop superinfection with HDV.

Serological Studies

Anti-HDV IgM is most reliable marker of acute HDV infection. Anti-HBc IgM is also demonstrated. IgG is not a protective antibody.

HEPATITIS E VIRUS INFECTION

Hepatitis E virus (HEV) has now been cloned and sequenced. It is single-stranded RNA virus measuring 32–34 nm. HEV infection is contracted with recent travel to endemic areas, i.e. Africa, Asia, or Central America.

HEV infection resembles HAV infection, but it is more common in young adults rather than children. No vaccine has been developed for HEV prophylaxis.

Mode of Transmission

Hepatitis E virus is transmitted by fecal–oral route. Incubation period is 35–40 days.

Clinical Features

Like hepatitis A, hepatitis E usually presents as an acute self-limited illness with low mortality in 1–12% of cases. Patient presents with mild viral hepatitis with jaundice, fever and arthralgia that lasts about 6 weeks.

It does not progress to chronic liver disease. For unknown reasons, infection during pregnancy is associated with high mortality due to fulminant hepatic failure in 20% of cases.

Serological Assays in Hepatitis E Virus

Presence of anti-HBe IgM indicates active HEV infection. Anti-HEV IgG (protective antibody) indicates recovery.

Table 21.39 Co-infection and superinfection in relation to hepatitis D infection

Parameters	Co-infection	Superinfection
Status of patient before infection with HDV	HDV and HBV in healthy carrier	HDV infection in HBV carrier
Recovery from acute viral hepatitis with immunity	90%	10–15%
Risk of fulminant viral hepatitis and death	3–4%	7–10%
Risk of developing chronic viral hepatitis resulting in cirrhosis	Rare	80%

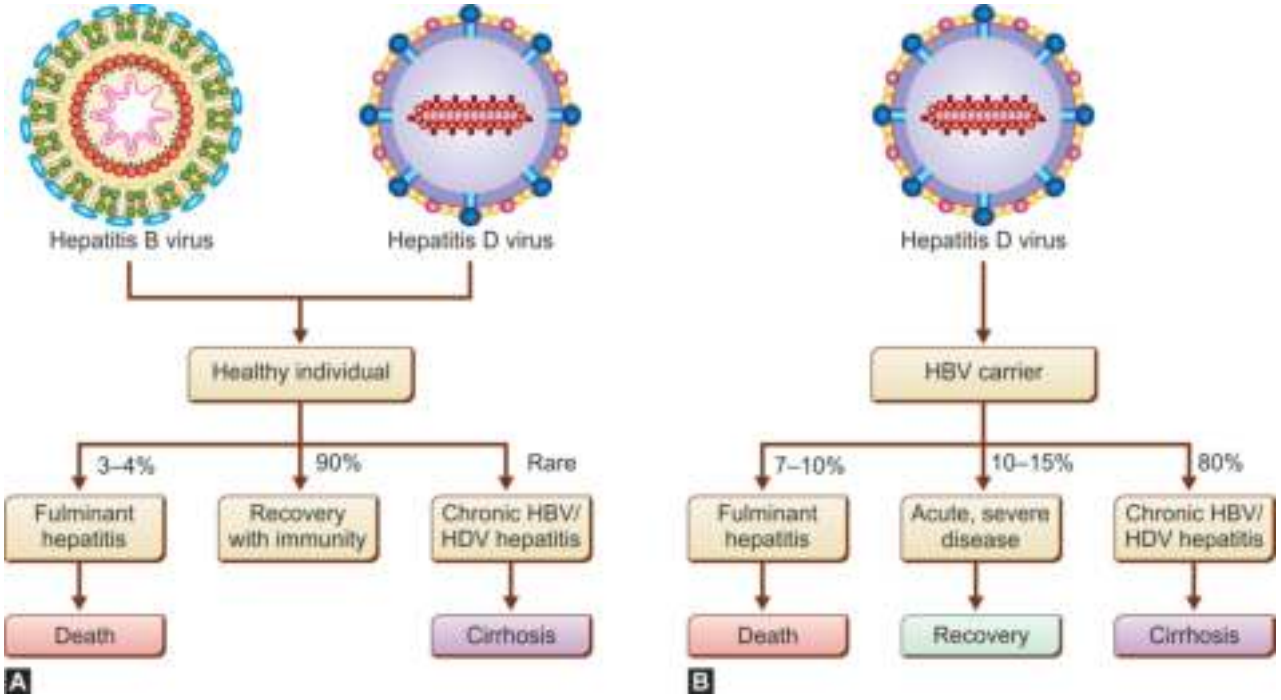

Fig. 21.34: (A) Co-infection, (B) superinfection in relation to hepatitis D infection.

HEPATITIS G VIRUS INFECTION

Hepatitis G virus (HGV) is a viral agent similar to HCV, which has been cloned and identified as HGV. Hepatitis G virus is a flavivirus transmitted parenterally by blood and found in 1–2% of blood donors and at a much higher rate among intravenous drug abusers. It does not lead to chronic viral hepatitis. It has no known relationship to hepatocellular carcinoma. Comparison of hepatotropic viruses is given in Table 21.40.

Table 21.40 Comparison of hepatotropic viruses

Characteristics	Hepatitis A (HAV)	Hepatitis B (HBV)	Hepatitis C (HCV)	Hepatitis D (HDV)	Hepatitis E (HEV)
Family	Picornavirus	Hepadnavirus	Flavivirus	Unknown	Calciviridae
Year of identification	1973	1965	1989	1977	1995
Genetic material	ssRNA	ssDNA	ssRNA	ssRNA	ssRNA
Morphology	Icosahedral capsid	Double shelled enveloped	Enveloped	Enveloped replication defective	Icosahedral unenveloped
Size of virus	27 nm	42 nm	30–60 nm	35 nm	32–24 nm
Transmission	▪ Fecal–oral route ▪ Male homosexuals	▪ Parenteral route ▪ Sexual contact ▪ Mother to fetus ▪ Breastfeeding	▪ Parenteral route ▪ Sexual contact	▪ Parenteral route ▪ Sexual contact	Fecal–oral route
Incubation period	2–6 weeks	4–26 weeks	2–26 weeks	4–7 weeks	2–8 weeks
Age group	Children and adolescents	Any age	Adults	Any age	Young adults
Onset	Acute onset	Insidious onset	Insidious onset	Insidious onset	Acute onset
Prevalence	Worldwide	Worldwide	Probably worldwide	Endemic region	Only in developing countries
Antigen	HAV (viremia transient)	▪ HbsAg ▪ HbcAg ▪ HbeAg	▪ HCV, C100-3 ▪ C-33c, and NS-5 –	▪ HbsAg ▪ HDV –	HEV – –
Antibodies	Anti-HAV	Anti-Hbs	Anti-HCV	Anti-HbsAg	Anti-HAV
Nature of illness	Mild	Occasionally severe	Moderate	Occasionally severe	Mild except during pregnancy
Fulminant hepatitis	0.1–0.4%	<1%	Rare	3–4%	0.3–3% (20% in pregnant women)
Carrier state	None	0.1–1%	0.2–0.4%	0.1–10%	No carrier state
Chronic hepatitis	Absent	5–10%	>70% cases	<5% (co-infection) and 80 (superinfection)	None
Cirrhosis	None	Yes	Yes	+/–	None
Hepatocellular carcinoma	No	Yes	Yes	Unknown	Unknown
Prognosis	Excellent	Poor	Moderate	Variable	Good
Associated findings	None	Serum sickness (5–10%), polyarteritis nodosa and membranous glomerulonephritis	Post-transfusion hepatitis, MPGN-1, and porphyria cutanea tarda	None	None
Specific prophylaxis	Immunoglobulin administration and vaccination	Immunoglobulin administration and vaccination	Nil	HBV vaccine	Nil

AUTOIMMUNE HEPATITIS (LUPOID HEPATITIS)

Autoimmune hepatitis is most common autoimmune chronic progressive disorder of liver especially in young women. It occurs due to reduction in number of CD8+ suppressor T cells. Women with autoimmune hepatitis show circulating antinuclear autoantibodies and elevated serum IgG concentration. But there are no serum markers to diagnose this disorder.

ETIOPATHOGENESIS

Autoimmune hepatitis is caused by viruses, drugs and in the settings of autoimmune disorders like rheumatoid arthritis, ulcerative colitis and Sjögren's syndrome. A pathogenetic role for immune-mediated mechanisms in autoimmune hepatitis is suggested by the presence of following:

- Positive LE cell phenomenon is demonstrated in 10% cases of systemic lupus erythematosus.
- Anti-nuclear antibodies are observed in >50% of cases.
- Smooth muscle cell autoantibodies are observed in 40–60% of cases.
- Autoantibody against receptor on cell membrane of hepatocytes is observed. Autoantibodies against microsomes are demonstrated.
- There is reduction in number of CD8+ suppressor T cells and their functional ability in autoimmune hepatitis.
- Heavy plasma cell infiltrate in liver is present.
- Rapid response to treatment with immunosuppressive agents has good response.

Classification

Autoimmune hepatitis is classified into two categories (types 1 and 2) based on the basis of autoantibodies (Table 21.41).

Table 21.41 Autoantibodies formed in autoimmune hepatitis types 1 and 2

Autoimmune Hepatitis Types	Autoantibodies
Autoimmune hepatitis type 1	▪ ANA (antinuclear antigen) most common ▪ SMA (smooth muscle actin antigen) most specific ▪ SLA (soluble liver antigen) ▪ LPA (soluble pancreas antigen)
Autoimmune hepatitis type 2	▪ LKM1 (liver, kidney microsome) ▪ LC-1 (liver cytosol 1 antigen)
Autoimmune hepatitis type 3	Antisoluble liver antigen

Clinical Features

Patient presents with jaundice, acne, amenorrhea and hepatosplenomegaly.

Surgical Pathology: Autoimmune Hepatitis

Light Microscopy

- Liver shows characteristic infiltration of plasma cells in periportal regions.
- Entire spectrum of hepatitis is demonstrated.

Prognosis

Untreated patient of autoimmune hepatitis may develop hepatocellular failure and cirrhosis having fatal outcome.

Management

Patients of autoimmune hepatitis are treated by immunosuppressive therapy. Liver transplantation is recommended for end-stage disease or history of recurrence.

BACTERIAL INFECTIONS AND PARASITIC INFESTATIONS OF LIVER

BACTERIAL LIVER INFECTIONS

Bacterial infections of the liver occur in many ways, in the setting of liver abscess, acute hepatitis, granulomatous hepatitis, hepatic tuberculosis, peritonitis, empyema, syphilitic hepatitis, and hepatic brucellosis. Right lobe of the liver is the most common sites of abscess formation and frequently observed in older patients or immunocompromised young individuals. Liver function test abnormalities and jaundice frequently accompany a variety of bacterial infections, especially sepsis. Bacterial infections can trigger acute decompensation of cirrhosis associated with development of organ dysfunction.

PYOGENIC LIVER ABSCESS

Pyogenic liver abscess is defined as a pus-filled mass in the liver caused by Staphylococci, Streptococci, and gram-negative enterobacteria, i.e. anaerobic inhabitants of the gastrointestinal tract. The bacteria gain access to the liver by direct extension from contiguous organs or through the portal vein or hepatic artery, bile ducts or by direct invasion or inoculation through the Glisson's capsule. Bacterial infections can originate in the biliary system, bacterial endocarditis, or pyelonephritis to produce pyogenic liver abscess. The routes of bacterial infection spread to liver are described as follows:

- **Arterial route of infection:** Bacteria reach the liver through hepatic artery during sepsis or in septic thromboemboli in bacterial endocarditis. Liver abscess may be caused by a variety of bacteria, such as Streptococci, Staphylococci, and gram-negative bacteria.
- **Portal vein infection:** Bacteria may originate in infected diverticula or mucosal abscesses. In pre-antibiotic era, bacterial appendicitis was a common cause of liver abscess; today it is uncommon.
- **Ascending biliary infection:** Bacteria ascending into the liver from the duodenum are most often gram-negative. Such infections usually occur in patients who have biliary duct stones or other diseases of biliary tract.
- **Direct invasion of liver:** Bacterial infection of the gallbladder may extend to liver transdiaphragmatic infection or direct entry of bacteria into liver from the infected peritoneum. It is a rare complication of severe infection and usually found in terminally ill patients or those who have had extensive surgery.
- **Direct inoculation of bacteria:** This type of infection is typically found in wounded people.

Surgical Pathology: Pyogenic Liver Abscess
Gross Morphology
Microabscesses are formed in the liver resulting in hepatomegaly (Fig. 21.35).
Light Microscopy
▪ On histologic examination, microabscess of liver contains numerous neutrophils. ▪ The beginning of an organizing abscess wall shows some pink fibrin (Fig. 21.36A and B).

Fig. 21.35: Liver abscesses. This patient died from gram-negative septicemia and the abscesses are a complication of this. The site of the original infection was not found (arrows).

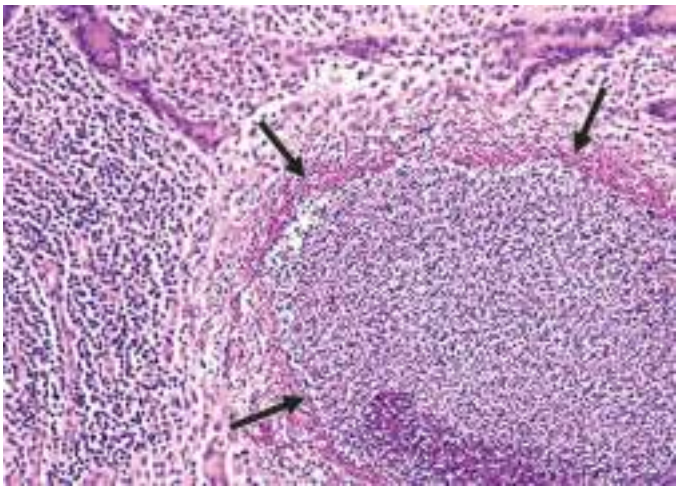

Fig. 21.36A: Pyogenic liver abscess. Microscopically, a microabscess of liver contains numerous neutrophils in the center. The beginning of an organizing abscess wall with some pink fibrin is seen here (arrows) (100X).

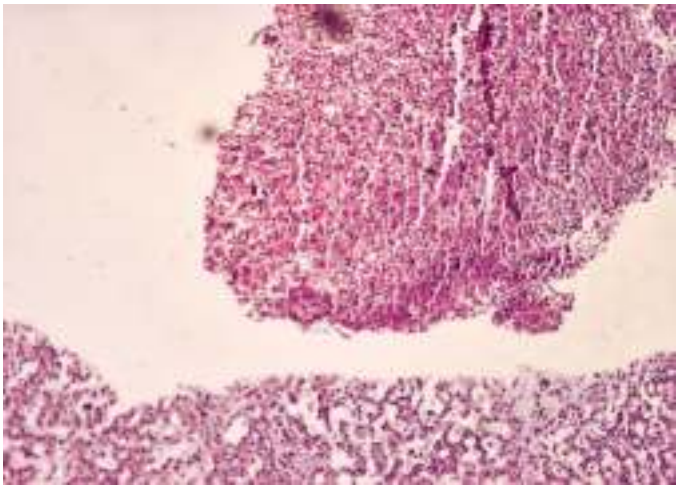

Fig. 21.36B: Pyogenic liver abscess. It is defined as pus-filled mass in the liver that can develop from injury to the liver of intra-abdominal infection disseminated from the portal vein. Histologic examination of pyogenic liver abscess reveals numerous neutrophils (400X).

GRANULOMATOUS LIVER ABSCESS

Granulomatous liver abscess occurs in the settings of tuberculosis, fungal infections and brucellosis. Tuberculous liver abscess most often occurs in developing countries. Tuberculosis is worldwide health problem caused by tubercle bacilli. It is transmitted by inhalation of droplets (most common), ingestion (infected milk) and skin inoculation (handling infected specimens). It may involve multiple systems.

Tubercle bacilli may disseminate via systemic circulation to seed distant organs such as bone marrow, liver, spleen, adrenal glands, retina, meninges, kidneys, fallopian tubes, and epididymis. Light microscopy of tuberculoses of liver is shown in Fig. 21.37.

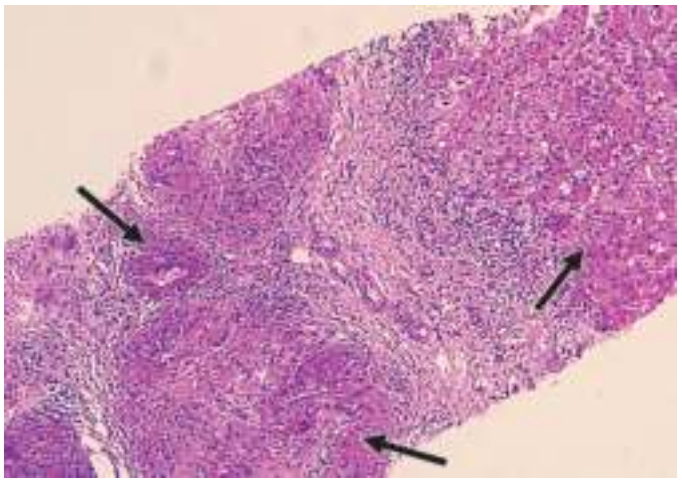

Fig. 21.37: Tuberculosis (TB) of liver. Liver biopsy is considered the most specific diagnostic test for hepatic TB. Caseating epithelioid cell granulomas are observed 50–85% of cases with miliary TB. Histologic examination shows multiple epithelioid cell granulomas (arrows) (100X).

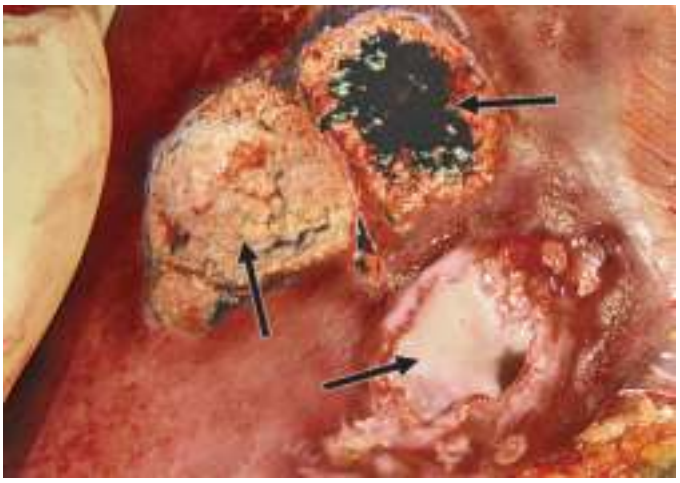

Fig. 21.38: Amoebic liver abscess. This is an amoebic abscess of liver. Abscesses may arise in liver when there is seeding of infection from the bowel, because the infectious agents are carried to the liver from the portal venous circulation (arrows).

PARASITIC LIVER INFECTIONS

Parasitic and helminthic infections are important in tropical countries. Such infections include malarial parasite, *Entamoeba histolytica, Leishmania donovani,* liver fluke (e.g. *Fasciola hepatica* and *Clonorchis sinensis*) and *Echinococcus granulosus*.

AMOEBIC LIVER ABSCESS

Amoebic liver abscess is the most common form of extraintestinal amoebiasis. It most often occurs in posterosuperior region of right lobe of liver.

Etiology

Amoebic liver abscess is caused by *Entamoeba histolytica*. Approximately, 30% of patients have a history of antecedent intestinal amoebiasis. It occurs most often in men than women and rare in children. Large amoebic abscess presses upon liver capsule resulting in pain.

Clinical Features

Patient presents with abrupt onset of fever and dull aching abdominal pain in the right upper quadrant or epigastrium, usually lasting <10 days duration. Jaundice is unusual.

Surgical Pathology: Amoebic Liver Abscess
Gross Morphology
Necrosed hepatocytes are admixed with blood resembling anchovy sauce (Fig. 21.38).
Light Microscopy
Abscess material from liver on histologic examination shows necrotic material with a few neutrophils with clusters of trophozoites of amoeba.

Laboratory Diagnosis

The diagnosis of amoebic liver abscess is most often made by radiological or ultrasound in conjunction with serological testing for antibodies to *Entamoeba histolytica*.

Complications

Amoebic liver abscess may be secondarily infected, which can extend and perforate into pleuropulmonary structures, subphrenic space, peritoneal cavity and pericardial sac. There may be dissemination of amoebic liver abscess to brain or kidney. Differences between amoebic and pyogenic liver abscesses are shown in Table 21.42.

HYDATID CYST IN LIVER

Hydatid cyst in liver is caused by *Echinococcus granulosus* and common in India. Right lobe of liver is the commonest site of hydatid cyst followed by lung. Accidental spillage during fine needle aspiration may cause anaphylactic shock.

- Hydatid disease is caused by larval or cystic stage of *Echinococcus granulosus* tapeworm or *Echinococcus multilocularis*. Adult parasites are found in dogs and sheep. Humans are infected after ingestion of eggs. The eggs hatch in the small intestine and their larvae pass to the liver by portal circulation. Most commonly the right lobe of liver is affected. However, any lobe of liver can be affected.
- Echinococcus multilocularis is less common. Cysts are multilocular containing thick pasty material, and surrounded by a fibrous wall. It has a more aggressive clinical course in comparison to *Echinococcus granulosus*.

Table 21.42 Differences between amoebic and pyogenic liver abscesses

Characteristics	Amoebic Liver Abscess	Pyogenic Liver Abscess
Causative organism	*Entamoeba histolytica*	*Escherichia coli*, Pseudomonas and Klebsiella
Liver lobe involved	Posterosuperior part of right lobe	Posterior part of right lobe
Abscess	Single abscess of variable size	Single or multiple abscesses
Gross morphology	The center of abscess has necrotic area containing reddish brown thick pus resembling anchovy or chocolate sauce. Abscess is surrounded by necrotic liver parenchyma	The center of abscess contains pus. Abscess is surrounded by fibrous capsule
Light microscopy	It shows leukocytes, RBCs, necrotic debris and *Entamoeba histolytica*	It shows infiltration by neutrophils
Septicemia	Absent	It may occur due to dissemination of pathogens
Jaundice	Rare	Always present

Surgical Pathology: Hydatid Cyst in Liver

Gross Morphology

Liver contains multiple hydatid cysts of various sizes. Color of the cysts is white of an boiled egg (Fig. 21.39).

Light Microscopy

- The hydatid cyst is filled with colorless fluid containing daughter cysts and brood capsules with scolices.
- The cyst wall shows an inner germinal layer (endocyst), outer chitinous (fibrous lamina) ectocyst layer surrounded by either granulation tissue or a fibrous capsule (pericyst).
- The adjacent liver shows eosinophilic infiltrate in portal tracts. The scolices having hooklets of 20–40 μm length (Fig. 21.40A and B).

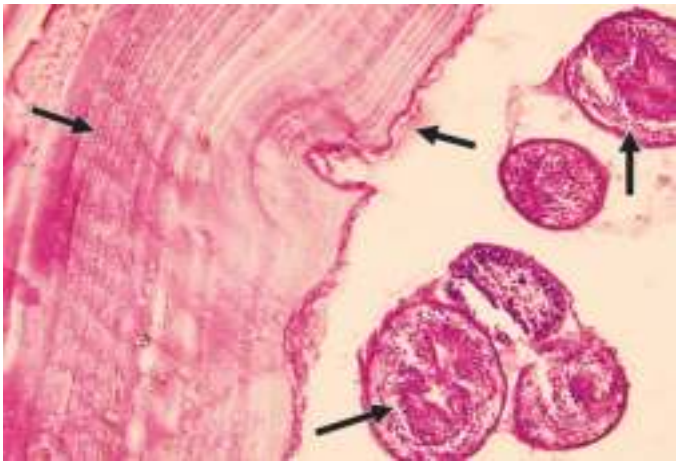

Fig. 21.40A: Hydatid cyst of liver. The cyst wall shows an inner germinal layer (endocyst), outer chitinous (fibrous lamina) ectocyst layer surrounded by either granulation tissue or a fibrous capsule (pericyst). Scolices having hooklets are also seen (arrows) (400X).

Fig. 21.39: Hydatid cyst of liver. Ingestion of eggs of *Echinococcus granulosus* in contaminated feces can infect humans. Hydatid cyst with multiple daughter cysts consists of outer thick fibrotic wall layer, middle layer of hyalinized, laminated, and acellular material, and inner layer of adult tapeworm heads (arrows)

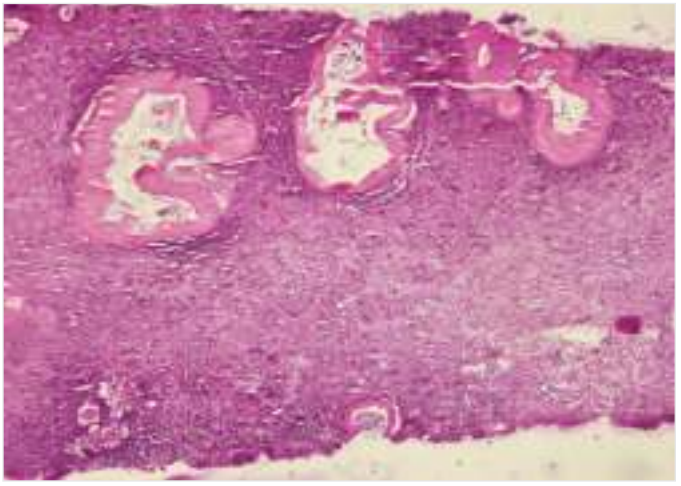

Fig. 21.40B: Hydatid cyst of liver. Disease is caused by *Echinococcus granulosus*. The principal complications are infection, biliary duct fistula and rupture into the peritoneum or chest. Diagnosis has become easier with advances in ultrasonography and computed tomography scanning. Histologic examination reveals multiple hydatid cysts within liver (400X).

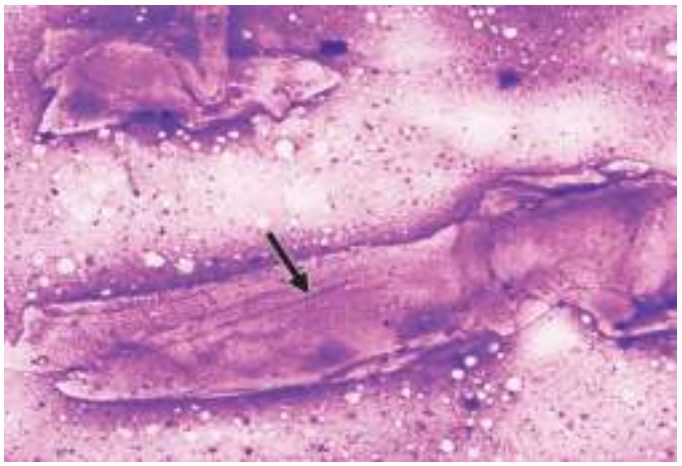

Fig. 21.41: FNAC of hydatid cyst of liver. Smear shows laminated membranous structures resembling ectocyst of hydatid cyst. Claw-like refractile hooklets are demonstrated in the background. PAS stain highlights the laminated membranous structures as magenta-colored structures and Gomori methenamine stain black. Hooklets are demonstrated by Ziehl-Neelsen stain as bright purple (arrow) (400X).

Cytologic Smear Examination

Cytologic smear shows laminated membranous structures resembling ectocyst of hydatid cyst. Claw-like refractile hooklets are demonstrated in the background (Fig. 21.41).

Periodic acid–Schiff (PAS) stain highlights the laminated membranous structures as magenta-colored structures and black hooklets by Gomori methenamine stain. Hooklets are demonstrated by Ziehl-Neelsen stain as bright purple.

Complications

Rupture of hydatid cyst into the peritoneal cavity results in fatal anaphylactic reaction. Rupture of cyst can involve into the gallbladder or through the diaphragm into the pleural space and lung.

HEPATOMEGALY DUE TO MALARIAL PARASITE

Hepatic involvement by malarial parasite causes hepatomegaly secondary to hypertrophy and hyperplasia of Kupffer cells.

SCHISTOSOMIASIS IN LIVER

Schistosomiasis in liver is caused by *Schistosoma mansoni* or *Schistosoma japonicum*. The adult worms lodge in the portal vein and its branches.

The eggs are highly antigenic and stimulate formation of granuloma, tissue destruction, scarring, and portal hypertension.

ASCENDING CHOLANGITIS AND LIVER ABSCESS

Ascending cholangitis after percutaneous ablation therapy of liver tumors often disseminates to liver resulting in liver abscess.

SUPPURATIVE THROMBOSIS OF PORTAL VEIN

Portal vein thrombosis most often occurs due to intra-abdominal sepsis following perforated appendix, peritonitis or diverticulitis. Infection from portal vein spreads to liver.

Patient presents with fever, rigors and abdominal pain in right upper quadrant. Liver functions are abnormal but clinical jaundice is uncommon. Portal vein thrombosis may cause portal hypertension.

DRUGS AND TOXINS INDUCED HEPATOCELLULAR INJURY

Exposure to drugs and industrial chemicals may cause acute hepatocellular injury. Chemicals act as systemic poisons and get converted to toxic intermediate leading to centrilobular hepatocellular injury. Drugs and toxic chemicals may affect one or more of the liver lobular structures such as hepatocytes, bile ductules, bile ducts, blood vessels and mononuclear phagocytes. Drugs and toxins causing hepatocellular injury are given in Table 21.43. Drugs and toxins affecting bile ductules and bile ducts are given in Table 21.44.

Table 21.43 Drugs and toxins causing hepatocellular injury

Pathological Findings	Mode of Action	Drugs and Toxins
Toxic hepatic coagulative necrosis in zone 3	Reactive metabolites	Paracetamol, carbon tetrachloride poisoning and mushroom *Amanita phalloides* poisonings
Cytosolic spotty necrosis producing intralobular inflammation	Formation of neoantigens as a result of hapten linkage with liver cell proteins	Halothane, erythromycin, isoniazid and α-methyldopa
Acute hepatitis like morphology with cholestasis	Immune-mediated mechanism	Sulphonylureas, phenothiazines and tricyclic antidepressants
Chronic hepatitis like morphology	Immune-mediated mechanism	Methotrexate, α-methyldopa, nitrofurantoin and oxyphenisatin

Contd...

Table 21.43 Drugs and toxins causing hepatocellular injury (*Contd...*)

Pathological Findings	Mode of Action	Drugs and Toxins
Macrovesicular fatty change	Due to decreased proteins synthesis, lack of apoprotein B-100, damage to endoplasmic reticulum, Golgi apparatus or plasma membrane of hepatocytes	Alcohol and methotrexate
Microvesicular fatty change	Reflecting impaired mitochondrial oxidation of fatty acids	Tetracycline, valproic acid (anticonvulsant), Reye's syndrome and poisoning by ingestion of unripe ackee fruit in Jamaica patients
Phospholipid accumulation in lysosomes	Due to inhibition of phospholipase by drugs	Amiodarone
Granulomatous hepatitis	Cell-mediated mechanism	Sulphonamide, allopurinol, carbamazepine, phenylbutazone and quinine
Cirrhosis	Direct toxicity	Ethanol, methotrexate and carbon tetrachloride
Hepatocellular adenoma, hepatocellular carcinoma	Carcinogenic agent	Estrogens and thorotrast contrast dye
Angiosarcoma	Carcinogenic agent	Vinyl chloride and inorganic arsenic

Table 21.44 Drugs and toxins affecting bile ductules and bile ducts

Pathological Findings	Mode of Action	Drugs and Toxins
Acute cholestasis	Estrogen binding with 17β-glucuronides causing cholestasis	Oral contraceptives, anabolic and androgenic steroids
Prolonged cholestasis with destruction of small bile ducts	Immune-mediated mechanisms	Chlorpromazine, paraquat poisoning and arsenic derivatives
Intrahepatic and extrahepatic stricture resembling sclerosing cholangitis	Mechanism unknown	Infusion of floxuridine into the hepatic artery in the treatment of liver metastases from colorectal carcinoma

Pathogenesis

Pathogenesis of hepatocellular injury by drugs occurs either by direct or idiosyncratic mechanisms.

Direct Hepatocellular Injury

Direct hepatocellular injury is dose-dependent. Drugs may produce intermediate metabolites and oxygen-derived free radicals and cause adverse effects on hepatocytes by peroxidation of cell membrane lipids leading to hepatocellular injury. Metabolic intermediates may also block the biochemical pathways by impairing mitochondrial oxidation of fatty acids. Therefore, hepatocytes show fatty change.

Idiosyncrasy Mechanism of Drugs

Idiosyncrasy mechanism of drugs causing hepatocellular injury is not dose-dependent.

- **Hypersensitivity:** Metabolites of isoniazid and halothane may cause hepatocellular injury by hypersensitivity reaction.
- **Autoantibody synthesis:** Autoantibody synthesized against drug produce adverse effects on cytochrome P450 enzyme.
- **Hapten formation:** Drug or its metabolite binds to cellular proteins and forms a hapten. This hapten acts as antigen leads to hepatocellular injury.

Surgical Pathology: Drug-induced Hepatocellular Injury

Light Microscopy

Drug-induced hepatocellular damage shows histologic changes, i.e. eosinophilic infiltrate, central lobular necrosis, noncaseating epithelioid cell granulomas, cholestasis and giant cell hepatitis.

ACETAMINOPHEN INDUCED HEPATOCELLULAR INJURY

Acetaminophen is an important analgesic recommended by the clinicians. Excessive consumption of acetaminophen is highly toxic to the liver. The toxic dose of acetaminophen after a single acute ingestion is in the range of 150 mg/kg in children and 7 g in adults. Drug toxicity should be suspected in all cases of acute hepatitis. Drug-induced hepatocellular injury can be either direct or indirect. Indirect hepatocellular injury is caused by metabolites and oxygen-derived free radicals that are produced as byproducts of xenobiotic metabolism.

Physiologic state

Normal dose of acetaminophen is rapidly absorbed from the stomach and small intestine and become conjugated in the liver to form nontoxic metabolite, then eliminated in the urine.

Pathologic state

In case of acute drug overdose, normal pathways of acetaminophen metabolism become saturated. Excess acetaminophen is then metabolized in the liver via the mixed function oxidase P450 system located in the smooth endoplasmic reticulum of the hepatocytes, yielding oxidative metabolites leading to centrilobular necrosis. Patient may later develop hepatocellular necrosis.

CARBON TETRACHLORIDE-INDUCED HEPATOCELLULAR INJURY

Carbon tetrachloride (CCl_4) is well-studied hepatotoxin. Immune reactions against a chemical or its metabolites also cause of indirect liver damage. Chemically-induced hepatocellular injury is classified as predictable when toxicity is immediate and dose-dependent and as unpredictable or idiosyncratic when toxicity occurs without explanation.

Exposure to industrial solvents, such as carbon tetrachloride, causes predictable toxic hepatocellular injury, characterized by centrilobular necrosis and elevated serum levels of transaminases (ALT and AST).

Pathogenesis

Carbon tetrachloride (CCl_4) is metabolized via the mixed function oxygenase (P450) system located in the smooth endoplasmic reticulum of the liver to a chloride ion and a highly reactive trichloromethyl free radical. Like the hydroxyl radical, this radical is a potent initiator of lipid peroxidation, which damages the plasma membrane and leads to hepatocellular necrosis.

Surgical Pathology: Carbon Tetrachloride (CCl_4)-induced Hepatocellular Injury

Light Microscopy

Acute, chemically-induced hepatocellular injury shows the entire spectrum of liver disease, from transient cholestasis to massive hepatic necrosis.

LIVER CIRRHOSIS AND PORTAL HYPERTENSION

LIVER CIRRHOSIS

Cirrhosis is end-stage liver disease with disruption of entire normal hepatic architecture, replaced by bridging fibrosis, presence of parenchymal regenerative nodules by proliferating hepatocytes, disruption of normal architecture of the entire liver with interference with its normal functioning and varying degree of portosystemic shunting.

- **Etiology:** Most common causes of cirrhosis are alcohol abuse, viral hepatitis (HCV, HBV), nonalcoholic steatosis, secondary biliary cirrhosis, hemochromatosis, drug (methotrexate), and chemical agent (carbon tetrachloride). Less common causes of cirrhosis are primary biliary cirrhosis, Wilson disease, autoimmune hepatitis, primary sclerosing cholangitis, and inborn errors of metabolism.
- **Complications:** Complications of liver cirrhosis are portal hypertension with subsequent sequelae, e.g. esophagogastric varices, ascites, hepatic encephalopathy, hepatocellular carcinoma, coagulopathy, jaundice, pruritus, hepatorenal syndrome and hepatobiliary syndrome. Liver cirrhosis is more prevalent among malnourished alcoholic people over 50 years of age.
- **Portal hypertension:** Portal hypertension is a vascular disorder of the liver characterized by increased resistance to portal blood flow at the level of sinusoids with the development of venous collaterals and ascites. It is classified based on site of portal venous obstruction: prehepatic, hepatic and post-hepatic.
  - Prehepatic portal hypertension occurs due to obstruction of portal and splenic vein secondary to thrombosis.
  - Intrahepatic portal hypertension is caused by vascular obstruction secondary to liver cirrhosis, metastatic tumors, or schistosomiasis.
  - Post-hepatic portal hypertension occurs due to venous chronic congestion secondary to constrictive pericarditis, tricuspid valvular insufficiency, congestive heart failure or hepatic vein occlusion (Budd-Chiari syndrome).
  - Portosystemic shunting is characterized by abnormal vascular connections between the hepatic portal vein and the systemic circulation. Clinical consequences of portosystemic shunt are esophagogastric varices, periumbilical collaterals (caput medusae), splenomegaly and hemorrhoids.

Pathology Pearls: Diagnostic Histologic Criteria for Cirrhosis

- Presence of bridging fibrosis in liver.
- Formation of parenchymal nodules due to proliferation of hepatocytes.
- Disruption of normal architecture of liver.

ETIOLOGIC CLASSIFICATION

Liver cirrhosis can be classified based to the etiology and morphologic appearance of liver in cirrhosis. Cirrhosis is classified according to etiology. Based on the etiology, cirrhosis is sub-classified as follows: viruses (HBV, HCV), toxins (alcohol abuse, drugs, i.e. acetaminophen, some antibiotics, antidepressants), nonalcoholic steatohepatitis, autoimmune hepatitis, cholestasis (primary biliary sclerosis, primary sclerosing cholangitis), vascular etiology (Budd-Chiari syndrome, sinusoidal obstruction syndrome, cardiac cirrhosis), and metabolic disorders (hemochromatosis, Wilson disease, α_1-antitrypsin deficiency). Etiological classification of cirrhosis is given in Table 21.45.

Alcoholic (Laennec or Nutritional) Cirrhosis

Alcoholic cirrhosis is an advanced stage of alcoholic liver disease that happens after years of drinking too much of alcohol. Alcoholic liver disease comprises liver steatosis, steatohepatitis, alcoholic cirrhosis. Liver shows micronodular pattern evolving in late stages to typical hobnail liver with large and irregular regenerative nodules.

Post-necrotic Cirrhosis

Post-necrotic cirrhosis is also called macronodular cirrhosis due to hepatitis B and C viruses, which involves areas of scarring in liver forming large and irregular nodules, that are >3 millimeters in diameter. Liver cirrhosis is an irreversible scarring of liver that can lead to hepatocellular failure and hepatocellular carcinoma more often than in other forms of liver cirrhosis. Clinicians usually prescribe antiviral drugs to prevent hepatotropic viruses (HBV and HCV) from causing more liver damage. One can prevent hepatitis B virus infection by getting vaccinated for hepatitis B vaccine.

Biliary Cirrhosis

Primary biliary cirrhosis is of probable autoimmune origin caused by anti-mitochondrial antibodies; obstructive jaundice. Secondary biliary cirrhosis is the result of long-standing extrahepatic biliary obstruction due to stone, stricture, pancreatitis or pancreatic carcinoma and congenital malformation.

Hemochromatosis-induced Cirrhosis

Primary hemochromatosis is familial defect in regulation of iron absorption resulting in massive accumulation of hemosiderin in hepatic and pancreatic parenchymal cells, myocardium, and other sites. Classic triad of bronze diabetes include diabetes mellitus, hemochromatosis, and skin pigmentation. Secondary hemochromatosis is caused by chronic iron overload of diverse etiology.

Wilson's Disease-induced Cirrhosis

Wilson's disease is an autosomal recessive disorder of copper metabolism, in which excess of copper is deposited in the liver, kidney tubular cells (amino aciduria and glycosuria), brain (basal ganglia especially the putamen of the lenticular nucleus impairing extrapyramidal motor functions), and 'Descemet membrane of the cornea' (Kayser-Fleischer ring). Ceruloplasmin levels are decreased in Wilson's disease secondary to copper deposition in various organs. Cirrhosis can be micronodular or macronodular in Wilson's disease.

Table 21.45 Etiological classification of cirrhosis

Common Causes of Cirrhosis	Rare Causes of Cirrhosis
Alcohol related liver disease (Laennec's cirrhosis, portal cirrhosis or hobnail cirrhosis)	Primary biliary cirrhosis (PBC)
HBV and HCV (most common in India)	Wilson's disease
Nonalcoholic liver disease	Autoimmune hepatitis
Secondary biliary cirrhosis (e.g. obstruction of the common bile duct by stone, stricture and pancreatitis or pancreatic carcinoma)	Primary sclerosing cholangitis
▪ Hemochromatosis ▪ Methotrexate drug-induced cirrhosis ▪ Carbon tetrachloride and ethanol induced cirrhosis	Inborn errors of metabolism (α_1-antitrypsin deficiency, galactosemia, glycogen storage disease, fructose intolerance and acid cholesterol ester hydrolase deficiency)

Inborn Errors of Metabolism Induced Cirrhosis

Persons with inborn errors of metabolism such as α_1-antitrypsin deficiency, galactose-1-phosphate uridyl-transferase deficiency (galactosemia) and glycogen storage disease are linked to development of liver cirrhosis. About 15% of adults with α_1-antitrypsin deficiency develop cirrhosis. α_1-Antitrypsin deficiency, an autosomal recessive disorder is the leading cause of liver disease. Most of the liver disease is associated with homozygosity for the Z mutant allele, the so-called PiZZ. It is a protein-folding disorder in which toxic insoluble ATZ proteins aggregate in endoplasmic reticulum of hepatocytes leading to endoplasmic reticulum stress, mitochondrial depolarization, and caspase cleavage, inflammation, fibrosis, liver cirrhosis, and increased risk for hepatocellular carcinoma.

MORPHOLOGIC CLASSIFICATION

Morphologic classification of cirrhosis is purely descriptive. It has no relevance to the clinical presentation and management of these patients. Based on the morphology, liver cirrhosis can be sub-classified as micronodular cirrhosis (uniform regenerating nodules <3 mm in diameter), macronodular cirrhosis (irregular regenerative nodules with a variation >3 mm in diameter), or mixed cirrhosis (when features of both micronodular and macronodular cirrhosis are present).

Micronodular Cirrhosis

Micronodular cirrhosis is characterized by regenerative nodules measuring <3 mm in size. Liver shows more irregular pattern. Micronodular cirrhosis occurs due to alcohol abuse, hemochromatosis, hepatic venous outflow obstruction, chronic biliary obstruction, jejunoileal bypass, and Indian childhood cirrhosis. Etiology, frequency, and light microscopic features in micronodular cirrhosis are given in Table 21.46.

Macronodular Cirrhosis

Macronodular cirrhosis is characterized by regenerative nodules measuring >3 mm in size. Liver shows more irregular pattern. Macronodular cirrhosis occurs due to hepatitis B, α_1-antitrypsin deficiency, and primary biliary cholangitis. Etiology, frequency, and histologic features in macronodular cirrhosis are given in Table 21.47.

Table 21.46 Etiology, frequency and light microscopic features in micronodular cirrhosis

Etiology	Frequency	Light Microscopy
Alcoholic cirrhosis	60–70%	Fatty change, neutrophilic infiltration and Mallory's bodies
Primary biliary cirrhosis	5%	Portal tract inflammation (early stage) and granulomas, medium-sized bile duct destruction, cholestasis in zone 1 in periportal region, Mallory's bodies in some cases
Large bile duct obstruction induced cirrhosis	<5%	Marked cholestasis and bile cell proliferation; and irregular outlines of cirrhotic nodules
Hemochromatosis induced cirrhosis	5%	Marked deposition of hemosiderin in hepatocytes, Kuppfer cells and epithelium of ducts
Intestinal bypass	Rare	Marked fatty change, and Mallory's bodies in some cases
Cystic fibrosis induced cirrhosis	Rare	Periodic acid–Schiff material present in proliferated ductules in portal tracts
Indian childhood cirrhosis	Rare	Mallory's bodies

Table 21.47 Etiology, frequency and histologic features in macronodular cirrhosis

Etiology	Frequency	Light Microscopy
Chronic viral hepatitis (HBV or HCV)	10–20%	Hepatocytes show ground glass appearance and viral antigens are demonstrated by immunohistochemistry technique
Cryptogenic cirrhosis	Common	Macronodular cirrhosis of unknown etiology
Wilson's disease	Rare	Excess deposition of copper in hepatocytes demonstrated by rubeanic acid, fatty change and sometimes Mallory's bodies
α_1-Antitrypsin deficiency	Rare	Periodic acid–Schiff stain positive and diastase resistant globules in hepatocytes demonstrated by immunohistochemistry technique
Drugs and toxins	Rare	Macronodular cirrhosis
Hereditary hemorrhagic telangiectasia	Rare	Large dilated blood vessels in fibrous septa of liver

Micronodular and Macronodular Cirrhosis

Micronodular and macronodular cirrhosis is characterized by presence of regenerative nodules ranging from <3 to >4 mm in diameter. Some portal tracts and central veins are spared. Mixed cirrhosis progresses into macronodular cirrhosis over time, indicative of incomplete expression of micronodular cirrhosis.

PATHOPHYSIOLOGY OF LIVER CIRRHOSIS

Liver is formed by hepatocytes (parenchymal cells), other non-parenchymal cells and hepatic sinusoids. The walls of hepatic sinusoids are lined by hepatic stellate cells (HSCs), liver sinusoidal endothelial cells (LSECs), and Kuffer's cells (KCs). Both hepatocytes (parenchymal cells) and cells lining hepatic sinusoids, cytokines, and microRNAs are involved in the initiation and progression of liver fibrosis and cirrhosis.

- Most important pathways leading to cirrhosis are chronic active hepatitis, steatohepatitis (fatty change with evidence of inflammation), portal fibrosis and fibrosis occurring in acinar zone 3.
- Chronic active hepatitis and alcohol liver disease are the most important causes of liver cirrhosis accounting >60% of cases. Pathologic changes that occur in cirrhosis, include irreversible hepatocellular injury, extensive fibrosis, and nodular tissue growth, resulting from hepatic parenchymal cell death; collapse of liver's supporting structure, distortion of the vascular bed, and nodular regeneration of remaining liver tissue. Toxins stimulate sinusoidal endothelial cells and Kupffer cells. Normal liver morphology and pathogenesis of cirrhosis are given in Fig. 21.42A and B.

Role of Activated Kupffer Cells

Activated Kuffer's cells present in the sinusoidal endothelium destroy hepatocytes by production of harmful chemical mediators, growth factors (PDGF, TNF-α, TGF-β, ET-1 and MCP-1. PDGF and TNF-α), which also stimulate the activation of hepatic stellate cells (HSCs). PDGF and MCP-1 released by activated Kupffer cells participate in chemotaxis of neutrophils and lymphocytes. Hepatocytes undergo dysfunction and apoptosis. Repeated cycles of apoptosis and regeneration of hepatocytes contribute to pathogenesis of liver cirrhosis.

Role of Liver Sinusoidal Endothelial Cells

Perisinusoidal endothelial cells synthesize endothelin 1 and platelet activating factor. Edothelin 1 (ET-1) stimulates quiescent extracellular matrix (ECM) synthesizing stellate cells (Ito cells). Liver sinusoidal endothelial cells (LSECs) constitute the sinusoidal endothelium. It is known that retinol deficiency can activate and transform hepatic stellate cells (HSCs) into myofibroblasts with an enhanced extracellular matrix (ECM) production, resulting in perisinusoidal fibrosis, and ultimately to liver cirrhosis. HSCs can synthesize cytokine IL-33 that activates HSCs and promote hepatic fibrosis. On the contrary, differentiated LSECs can promote reversion of activated LSECs to quiescent state thereby preventing progression to fibrosis through vascular endothelial growth factor (VEGF)-stimulated nitrous oxide production.

Role of Hepatic Stellate Cells

Hepatic stellate cells, also called Ito cells, reside in the space of Dissie in the normal liver and their main function is storage of vitamin A and other retinoids. Following multiple injurious insults and/or exposure to inflammatory cytokines such as platelet-derived growth factor (PDGF), transforming growth factor-β (TGF-β), tumor necrosis factor-α (TNF-α), and interleukin-1 (IL-1), HSCs undergo the transition from a quiescent state to activated state. Contraction of stellate cells causes decreased sinusoidal perfusion resulting in hypoxia. Activated HSCs play important role in initiation and progression of hepatic fibrosis, and synthesis of large amount of collagen and other ECM ultimately leading to hepatic fibrosis.

Role of Cytokines

At the molecular level, multiple cytokines are involved in regulation of signaling pathways that mediate activation of HSCs, fibrogenesis and development of cirrhosis.

- PDGF is the strong mitogen to HSCs. Transforming growth factor-α (TGF-α) is the strongest known inducer of fibrogenesis in liver by stimulating HSCs. TGF-β induces expression of the matrix-producing genes and inhibits degrading of ECM by downregulating expression of matrix metalloproteinases (MMPs) and promoting tissue inhibitor matrix proteinases (TIMP) resulting in excessive deposition of collagen fibers, promoting fibrogenesis and development of liver cirrhosis.
- Tumor necrosis factor-α (TNF-α) is mainly secreted by monocytes, macrophages, HSCs and Kupffer's cells. TNF-α plays an important role in the activation of HSCs and synthesis of ECM.
- Interferons (IFNs) downregulate fibrogenesis via triggering the apoptosis of HSCs. Similarly, interferon-γ (IFN-γ) downregulates extracellular matrix deposition by inhibiting activation of HSCs via TGF-β1/SMAD3 signaling pathways.
- Interleukins (ILs) are group of cytokines are secreted by leukocytes (monocytes/macrophages, CD4+ helper T cells, endothelial cells). ILs play important

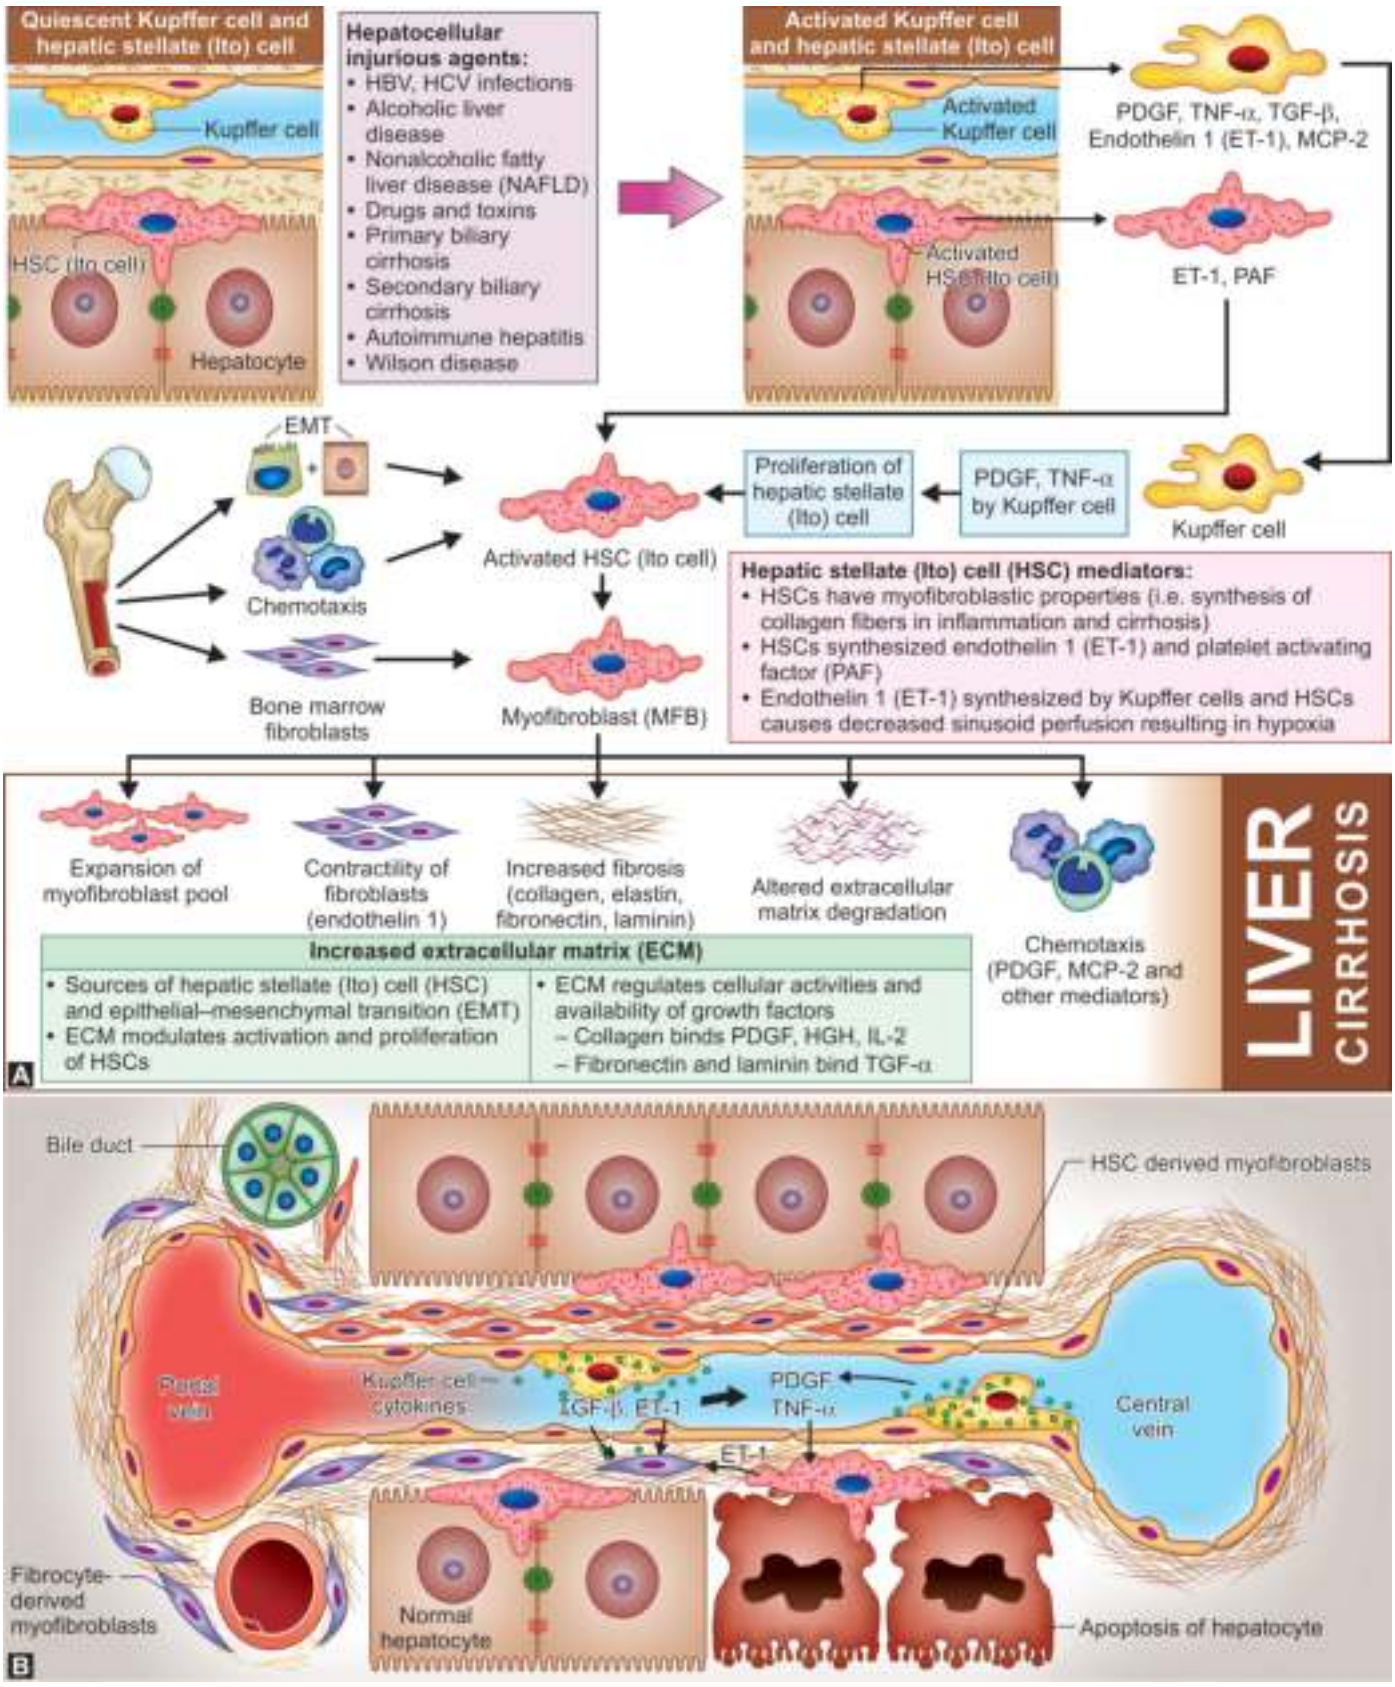

Fig. 21.42: (A) Normal liver morphology, (B) pathogenesis of cirrhosis. Kupffer cell activation and platelet activating factor synthesized by endothelial cells produce cytokines leading to influx of PMNs cells. Endothelial cells synthesize endothelins, which stimulate myofibroblast like Ito cells to synthesize collagen. Contraction of Ito stellate cells results in decreased sinusoidal perfusion and thus cause hypoxia.

role in inflammation, immune response, and liver fibrogenesis.

- **Pro-fibrogenic interleukins:** Kupffer cells and liver sinusoidal endothelial cells (LSECs) secrete interleukins in response to liver tissue damage. IL-1 stimulates hepatocyte stellate cells (HSCs) to secrete MMP-9, MMP-13 and TIMP-1 involved in hepatic fibrogenesis. IL-17 transforms HSCs to myofibroblasts, and upregulates TNF-α, TGF-β and collagen-1α involved in promoting hepatic fibrogenesis.
- **Antifibrogenic interleukins:** IL-10 downregulates the proinflammatory response and has modulatory effect on liver fibrogenesis. IL-22 promotes tissue repair, induces HSCs senescence, and restricts hepatic fibrinogenesis. Pretreatment of fibrotic liver with IL-6 improves hepatic microenvironment and primes it for mesenchymal stem cell transplantation resulting in improvement in hepatocellular injury after hepatic fibrosis.

Role of MicroRNAs

Recently, microRNAs as a regulator at post-transcription level, plays a pivotal role in hepatic fibrogenesis and development of cirrhosis. MicroRNAs can serve as biomarkers for HSCs activation and progression of hepatic fibrinogenesis, and may represent therapeutic targets for liver fibrosis and cirrhosis.

- **Pro-fibrogenic microRNAs:** MicroRNA-21 promotes liver fibrogenesis by downregulating TGF-β and HSCs activation. TGF-β induces expression of microRNAs (miR-18b) that can promote HSCs proliferation by regulating p27 and the cell cycle. Elevation of serum miR-18b level is suggestive of diagnostic biomarker for patients with liver cirrhosis. MicroRNAs (miR-214-5p) can increase the expression of fibrosis-related genes encoding MMP-2, MMP-9, TGF-β1, α-SMA, which activate HSCs leading to hepatic fibrinogenesis.
- **Antifibrogenic microRNAs:** MicroRNAs (miR-150, miR-194) can inhibit HSCs activation and extracellular matrix (ECM) deposition in the liver.

Surgical Pathology: Liver Cirrhosis

Gross Morphology

- **Early cirrhosis:** Liver may weigh >2 kg. External surface of liver may show diffuse nodularity. Cut surface shows yellow discoloration (Fig. 21.43).
- **Late cirrhosis:** Liver is shrunken in size weighing <1 kg. External surface of liver shows regenerative nodules (micronodules <3 mm or macronodules >3 mm or mixed pattern). Cut surface shows brown discoloration (Fig. 21.44A and B).

Light Microscopy

- Liver architecture is disrupted showing regenerating nodules of hepatocytes separated by fibrous bands of variable thickness resulting in disruption of architecture of entire liver.
- Fibrosis occurs as a result of synthesis of collagen by perisinusoidal hepatic stellate cells (Figs 21.45 and 21.46). Differences between cirrhosis and hepatic fibrosis are given in Table 21.48.

Pathology Pearls: Differential Diagnosis of Cirrhosis

- Cirrhosis should be differentiated from hepatocellular necrosis and nodular regenerating nodule:
  - Cirrhosis shows collagen deposition with regenerative nodules.
  - Hepatocellular necrosis shows a collapsed reticulin framework with lack of regenerative nodule.
  - Nodular regenerative hyperplasia lacks fibrous septa.
- Active cirrhosis should be differentiated from inactive cirrhosis:
  - Active cirrhosis shows presence of ongoing hepatocellular damage or interface hepatitis or steatohepatitis.
  - Inacative cirrhosis lacks liver cell necrosis, inflammation activity, and a sharp delineation of paucicellular septa and liver cell nodule.

CLINICAL FEATURES

Patient with a prior history of blood transfusion during surgical procedure presents with anorexia, fatigue, nausea, vomiting, weight loss, mild pain abdomen on right side, and varicose veins. Later, patient develops jaundice (yellow discoloration of sclera and skin), bruising (bleeding), ascites, splenomegaly, and edema in the lower extremities. Patient with cirrhosis can be

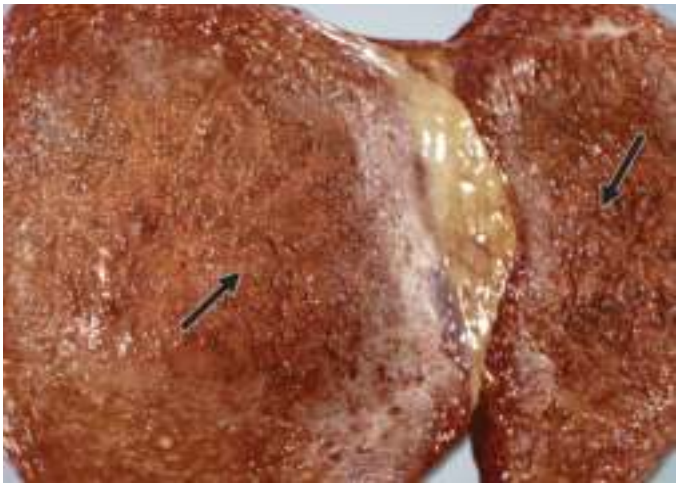

Fig. 21.43: Micronodular cirrhosis. This is an example of a micronodular cirrhosis. The regenerative nodules are quite small, averaging <3 mm in size. The most common cause for this is chronic alcoholism. The process of cirrhosis develops over many years (arrows).

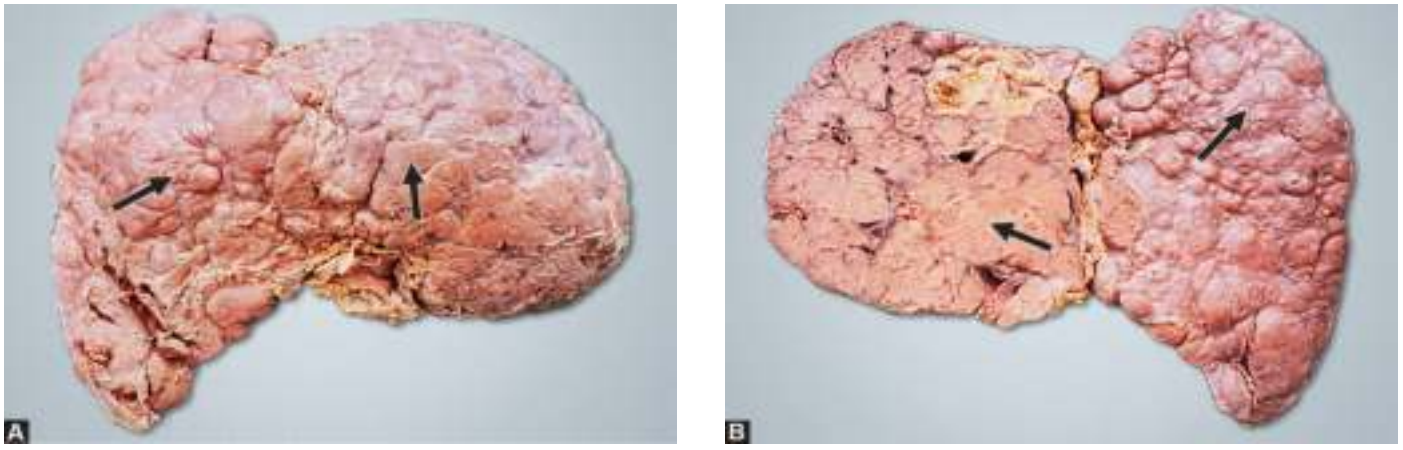

Fig. 21.44A and B: Macronodular cirrhosis. External as well as cut surface of liver shows large regenerative nodules >3 mm in diameter. HBV or HCV is the most common cause for macronodular cirrhosis. Cirrhosis may be linked to alcoholic liver disease, Wilson's disease and α_1-antitrypsin deficiency (arrows). (*Courtesy:* Dr. Sujata Kanetkar, Professor and Head, Krishna Institute of Medical Sciences, Karad, Maharashtra.)

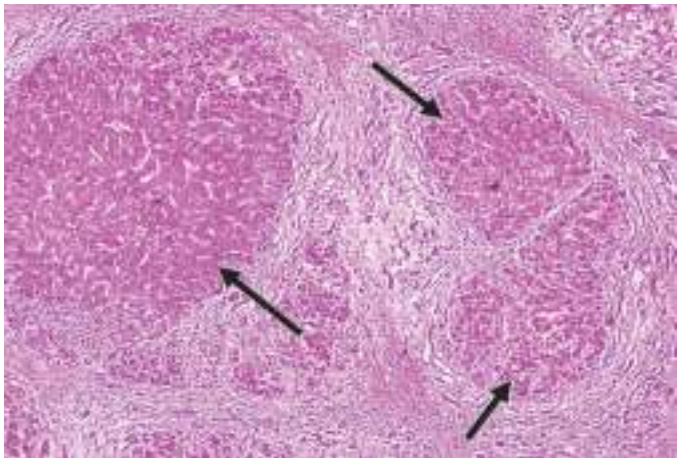

Fig. 21.45A: Liver cirrhosis. It shows parenchymal regenerative nodules surrounded by fibrous connective tissue that bridges between portal tracts. Within this collagenous tissue is scattered lymphocytes as well as a proliferation of bile ducts (arrows) (400X).

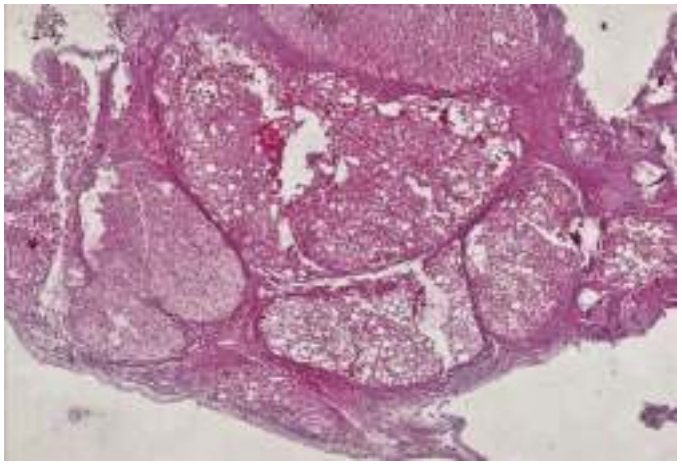

Fig. 21.45B: Liver cirrhosis. Histologic examination of nonbiliary cirrhotic liver reveals diffuse disruption in architecture of the entire liver (i.e. loss of normal central–portal relationship), bridging fibrous septa and rounded parenchymal nodules of regenerating hepatocytes (400X).

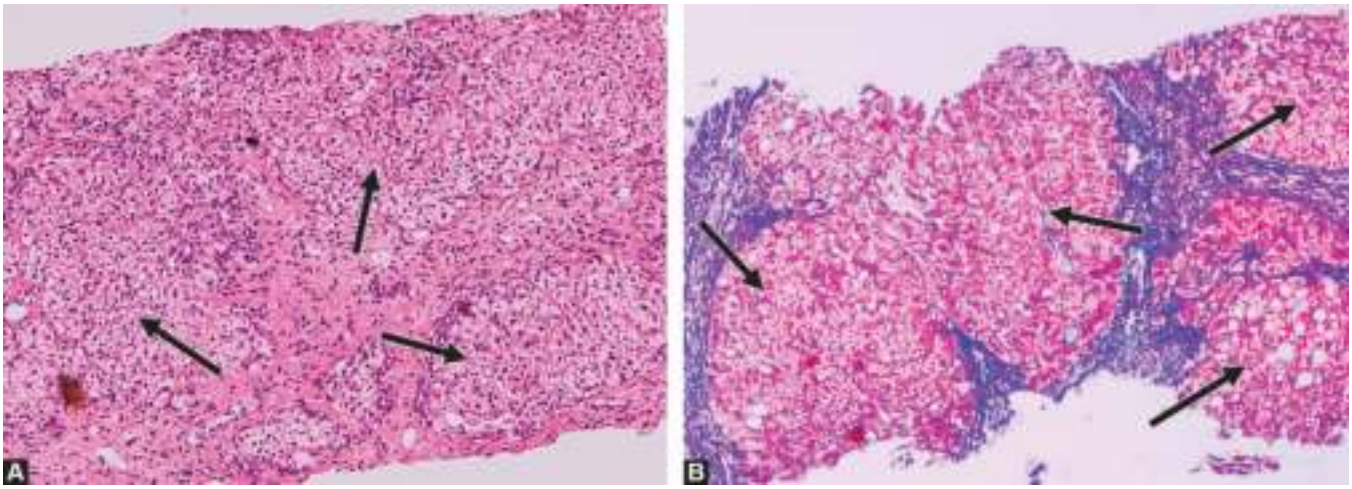

Fig. 21.46: (A) Liver cirrhosis. It shows regenerative nodules of hepatocytes surrounded by fibrous connective tissue that bridges between portal tracts. Within this collagenous tissue scattered lymphocytes as well as a proliferation of bile ducts (arrows), (B) regenerative nodules surrounded by dense connective tissue stained by Masson trichrome (arrows) (100X). Table 21.48 Differences between cirrhosis and hepatic fibrosis

Parameters	Cirrhosis	Hepatic Fibrosis
Portal hypertension	Present	Present (marked)
Intrahepatic shunts contributing to portosystemic shunts	Present	Absent
Impaired hepatocyte functions	Present	Absent
Increased risk of development of hepatocellular carcinoma	Present	Absent

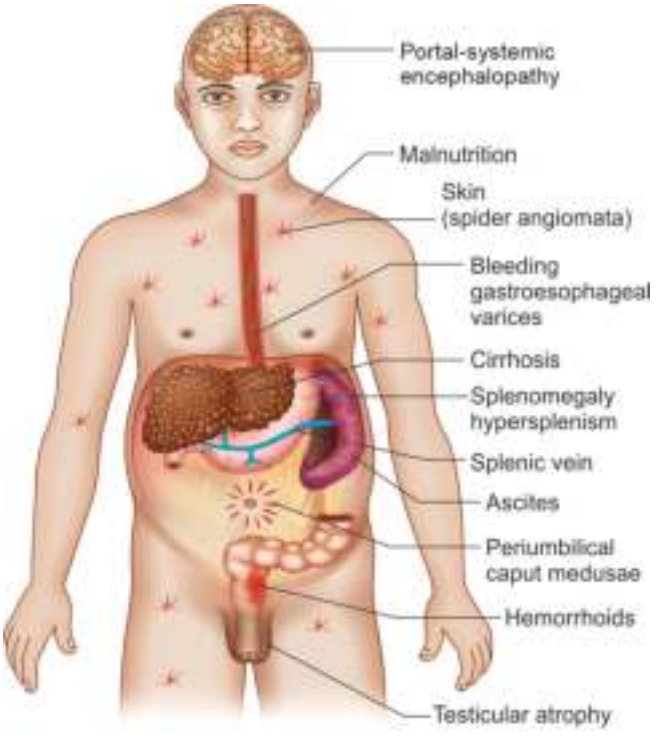

Fig. 21.47: Cirrhosis. It shows clinical manifestations.

asymptomatic or symptomatic, depending on whether cirrhosis is clinical compensated or decompensated. Clinical manifestations of liver cirrhosis are shown in Fig. 21.47.

Compensated Liver Cirrhosis

Patient with compensated cirrhosis is usually asymptomatic and detected incidentally on physical examination (hepatosplenomegaly), laboratory investigations (mild to moderate elevation of aminotransferases or gamma-glutamyl-glutamyl transpeptidase), and imaging.

Decompensated Liver Cirrhosis

Patient with decompensated cirrhosis presents with wide range of signs and symptoms arising from a combination of liver dysfunction and portal hypertension. Transition from compensated cirrhosis to decompensated cirrhosis is driven by the severity of portal hypertension with subsequent sequalae due to increased resistance to portal blood flow at the level of the sinusoids with development of venous collaterals (jaundice, esophageal varices, distended abdominal veins, i.e. caput medusae, splenomegaly, ascites, and edema in the lower extremities), hepatic encephalopathy (confusion, asterixis, i.e. flapping tremor on extension and dorsiflexion of hands, and '**fetor hepaticus**', i.e. sweet, musty smell due to high levels of ketones and dimethyl sulfide in the blood), spontaneous bacterial peritonitis, hepatocellular carcinoma, hyperdynamic circulation, and hepatorenal syndrome.

Physical Examination

Physical examination in patients with cirrhosis may reveal signs of chronic liver disease (jaundice, hypertrophic arthropathy, Dupuytren's contracture, and impaired estrogen metabolism related gynecomastia, hypogonadism, testicular atrophy, spider telangiectasias, palmer erythema), signs of portal hypertension (ascites, splenomegaly, caput medusae), and consequences of increased portal venous pressure (esophageal varices, distended abdominal veins (caput medusae), splenomegaly, and consequences of hypoalbuminemia (ascites, peripheral edema), a firm nodular liver edge just below the right costal margin, and soft protuberant abdomen with a shifting dullness on percussion, signs of hepatic encephalopathy (confusion, asterixis, i.e. flapping tremor on extension, and dorsiflexion of hands, and fetor hepaticus, i.e. sweet, musty smell due to high-levels of ketones and dimethyl sulfide in the blood), and scant chest/axillary hair. Liver cirrhosis may lead to hepatocellular failure and hepatocellular carcinoma in regenerating nodules.

- Liver cirrhosis can lead to hyperdynamic circulation, reduction in lean skeletal muscle, muscle cramps, and umbilical hernia. Spider nevi (central arteries surrounded by multiple small-sized vessels) are observed secondary to hyperesterogenemia.
- Peripheral blood smear examination reveals macrocytic anemia, and pancytopenia due to hypersplenism.

IMAGING TECHNIQUES

Abdominal ultrasonography with sonoelastography is commonly used to detect and characterize hepatic focal and diffuse fibrotic/cirrhotic lesions depending on the morphologic pattern.

- Abdominal ultrasonography reveals mild hepatosplenomegaly, nodular liver surface with heterogenous echotexture, loss of parenchymal uniformity, segmental atrophic right lobe, diffusely increased echogenicity of liver parenchyma, dilated portal vein

with slow venous blood flow, dilated splenic vein, and ascites consistent with cirrhosis.

- Sonoelastography is done to evaluate tissue stiffness and elasticity with high predictive value of 22.5 kilopascals indicative of cirrhosis (reference range 4.1–5.5).

LABORATORY DIAGNOSIS

A comprehensive work-up is performed to study electrocardiogram, B-type natriuretic peptide (BNP), complete blood count (CBC), serum alanine aminotransferases (ALT) and aspartate aminotransferases (AST); coagulation panel to evaluate the integrity of the patient's coagulation cascade [prothrombin time and international normalized ratio (PT–INR), and activated partial thromboplastin time (APTT)], and complete metabolic panel (serum albumin and total proteins—indicators of the synthetic activity of liver). Serum albumin and PT–INR are true indicators of synthetic hepatic function. Electrocardiogram findings are within normal limits. Appropriate laboratory investigations in patients with liver cirrhosis include hepatotropic virus serologies and liver biopsy.

Serum Hepatocellular Enzymes

Aminotransferases are usually elevated with AST greater that ALT; however, normal levels do not exclude cirrhosis. In chronic hepatitis except alcoholic hepatitis, the AST/ALT ratio is <1. As chronic viral hepatitis progresses to cirrhosis, there is reversal of this AST/ALT ratio. Alkaline phosphatase, gamma-glutamyl transferase (GGT) and 5′-nucleotide are elevated in cholestatic disorders.

Coagulation Profile Test

Prothrombin time and international normalized ratio (PT–INR) measures the activity of coagulation factors II, V, VIII and X involved in extrinsic and common pathways of coagulation system. Prothrombin time and international normalized ratio (PT–INR) is elevated in the settings of vitamin K deficiency, warfarin pharmacotherapy, liver disease, and disseminated intravascular coagulation. International normalized ratio (INR) is calculated standardization of the prothrombin time, used for assessment of extrinsic pathway and common pathway of coagulation system for monitoring the response to warfarin pharmacotherapy. Activated partial thromboplastin time (APTT) measures the activity of coagulation factors II, V, VIII, IX, X, XII involved in the intrinsic pathway of coagulation system. APTT is elevated in the settings of von Willebrand disease, antiphospholipid syndrome, in the presence of inhibitors, and disseminated intravascular coagulation.

Serum Proteins

Serum albumin is true indicator of synthetic hepatic function. Albumin synthesis is impaired in liver cirrhosis. Immunoglobulins, especially the gamma fraction, are usually elevated due to impaired clearance by the liver.

Complete Blood Count

Peripheral blood smear shows normocytic normochromic anemia, however macrocytic anemia can be seen in alcoholic liver cirrhosis. Leukopenia and thrombocytopenia are observed secondary to sequestration by splenomegaly as well as alcoholic suppression effect on the bone marrow.

Specific Tests in Newly Diagnosed Case of Cirrhosis

Serology and polymerase chain reaction techniques are used for viral hepatitis (HBV, HCV), autoimmune hepatitis (anti-nuclear antibodies, anti-smooth muscle antibodies) and primary biliary cirrhosis (anti-mitochondrial antibody).

- Serum ferritin and transferrin saturation is analyzed for hemochromatosis. Ceruloplasmin and urinary copper are analyzed for Wilson disease. A young patient with elevated liver enzymes, increased copper in the urine and Kayser-Fleischer rings in periphery of cornea on slit lamp eye examination has degeneration of the putamen in the brain.
- HCV most likely develop chronic viral hepatitis in patients requiring repeated blood transfusion over years for aplastic anemia. Serum α_1-antitrypsin level and protease inhibitor phenotype are analyzed for α_1-antitrypsin deficiency. Serum α-fetoprotein level is performed for hepatocellular carcinoma.

Liver Biopsy: Gold Standard for Cirrhosis Diagnosis

Liver biopsy is the gold standard for diagnosing liver cirrhosis as well as assessing the degree of inflammation (grade) and fibrosis (stage) of the disease.

- Liver biopsy in HBV is the indication to determine active hepatitis in patients, whose serological or biochemical tests do not paint a clear picture of disease status.
- Histologic examination of liver biopsy shows bridging fibrous septa surrounding parenchymal regenerative nodules, disruption of the architecture of the entire liver, steatosis, and portal inflammation.
- Histochemical trichrome stain is used to visualize connective tissues, particularly collagen, in tissue sections, which highlights as blue, circumferential bands of fibrosis surrounding regenerating parenchymal nodules (micronodular, macronodular, or mixed micronodular pattern of liver cirrhosis

elevating hepatic venous gradient). Reticulin stain enhances the fibrous septa dividing the hepatic regenerative nodules.

TREATMENT

Damage to the liver is permanent in liver cirrhosis. Further injury to the liver should be avoided to halt the progression of the liver disease. Chronic liver disease can be prevented by avoidance of alcohol, vaccination for hepatotropic viruses (HBV and HCV), good nutrition with a balanced diet, weight reduction, and early treatment of precipitating factors. Specific therapy most often targets the etiology such as antiviral mediations in viral hepatitis (HBV and HCV), corticosteroids and immunosuppressive agents in autoimmune disease, copper-chelating agents in Wilson disease, iron-chelating agents, and phlebotomy in hemochromatosis. Alcohol abstinence is beneficial in alcoholic cirrhosis. Weight reduction of at least 7% is beneficial in nonalcoholic steatohepatitis (NASH).

PORTAL HYPERTENSION

Portal hypertension is characterized by development of venous collaterals with varices in the submucosal veins of the esophagus, hemorrhoidal plexus, and other sites.

- Patient with portal hypertension has fatal outcome due to development of hepatic encephalopathy, massive bleeding in GIT, recurrent infection, hepatorenal syndrome and hepatocellular carcinoma.
- Normal pressure in portal vein is 7 mm Hg. As in other vascular bed, pressure in portal vein results from the interaction between the amount of blood flowing through the system and resistance to the blood flow.
- Portal hypertension occurs due to increased resistance to blood flow anywhere in the portal system or increased blood flow through the systemic circulation or combination of both mechanisms.

  In majority of cases, portal hypertension occurs due to resistance to blood flow in prehepatic, hepatic or posthepatic vascular tree.
- Portal hypertension causes significant diversion of blood from the portal circulation into the systemic circulation.

ETIOLOGIC CLASSIFICATION

At a functional level, portal hypertension may be divided into three main groups based on site of portal venous obstruction (pre-sinusoidal, sinusoidal and post-sinusoidal) as shown in Fig. 21.48 and Table 21.49.

- In pre-sinusoidal portal hypertension, hepatic venous pressure is normal even though increased

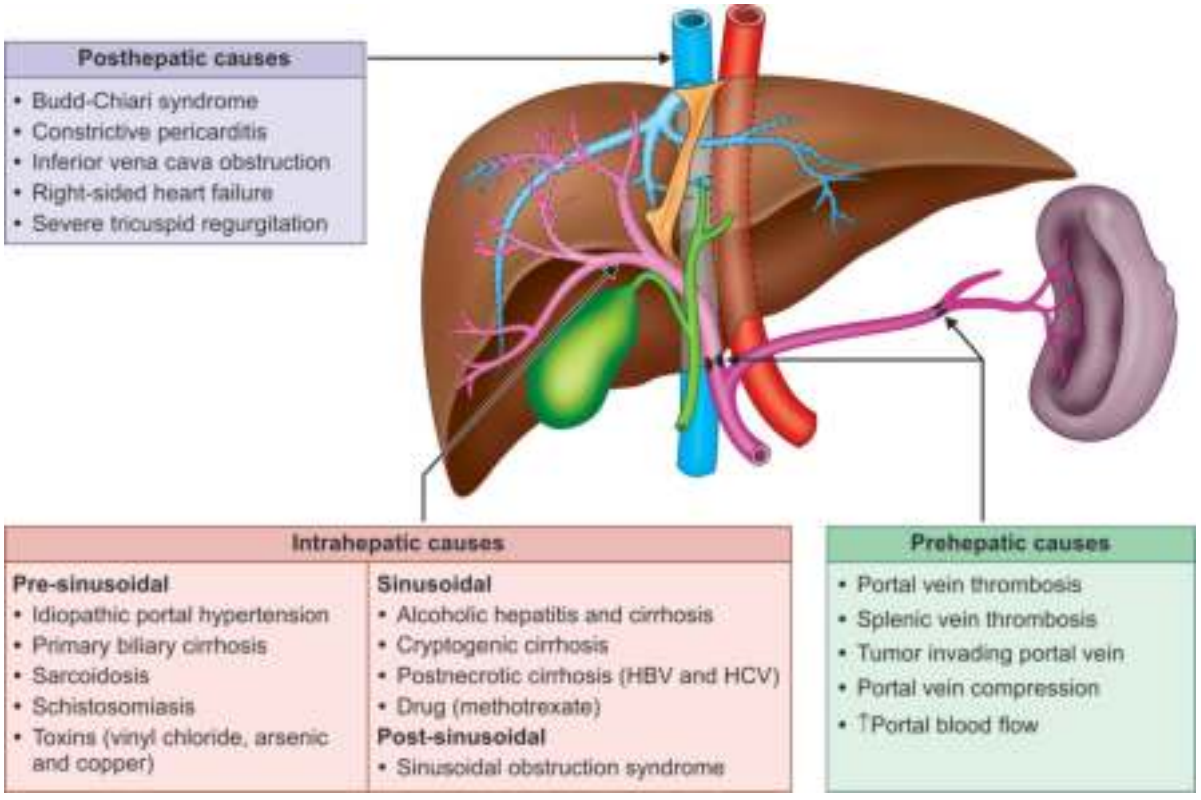

Fig. 21.48: Portal hypertension. It shows prehepatic, intrahepatic and posthepatic causes.

Table 21.49 Etiological classification of portal hypertension

Site of Lesions	Causes
Post-sinusoidal etiology	
Heart	Constrictive pericarditis and congestive heart failure
Inferior vena cava	Fibrous tissue webs, thrombosis and malignant tumor invasion
Large extrahepatic veins	Thrombosis (Budd-Chiari syndrome), tumor invasion and fibrous webs
Small intrahepatic veins	Veno-occlusive disorder, alcoholism and central hyaline sclerosis
Sinusoidal etiology	
Intrahepatic lesions	Cirrhosis (most common), acute alcoholic hepatitis, viral hepatitis (HBV and HCV), cytotoxic drug (methotrexate), vitamin A intoxication
Pre-sinusoidal etiology	
Portal tract lesions	Schistosomiasis, early primary biliary cirrhosis, congenital hepatic fibrosis, chronic active hepatitis, toxins (vinyl chloride, arsenic, copper), sarcoidosis, tuberculosis, and idiopathic
Portal and splenic veins	Thrombosis, compression and tumor invasion
Increased portal blood flow	Idiopathic tropical splenomegaly and arteriovenous fistula

pressure in portal vein. Liver functions are normal. Bleeding episode as a rule is not followed by hepatocellular failure.

- In sinusoidal as well as post-sinusoidal portal hypertension, the resistance to blood flow extends from the central hepatic veins. Hence, pressure in both hepatic and portal veins is increased. Patient with sinusoidal portal hypertension in cirrhosis frequently develops hepatocellular failure following a variceal bleed.

Portal Hypertension with Portal Vein Obstruction

Thrombosis in portal vein is the principal pathologic cause of extrahepatic portal vein obstruction.

- **In neonates**, infection may spread along umbilical vein to reach the left portal vein resulting in its obstruction.
- **In children**, intra-abdominal sepsis such as appendicitis may be responsible for portal vein thrombosis. Probable predisposing factors include dehydration associated with gastroenteritis and infection.
- **In adults**, portal vein thrombosis may occur in ulcerative colitis, Crohn's disease, sclerosing cholangitis, postoperative period, hypercoagulable state in myeloproliferative disorder and tumor invasion in portal vein especially hepatocellular carcinoma.

Portal Hypertension without Portal Vein Obstruction

Pre-sinusoidal portal hypertension is characterized by splenomegaly, functional evidence of hypersplenism without portal vein obstruction in non-cirrhotic liver. Portal blood pressure rises due to increased hepatic resistance to portal blood inflow, which probably occurs as a result of injury to the endothelial lining of intrahepatic portal vein radicles and sinusoids. This entity is common in middle-aged Japanese women.

CLINICAL FEATURES

In cirrhosis, liver is unable to receive blood from the gastrointestinal tract and accessory organs. As the pressure in the portal vein rises; blood flows back into the spleen and flows through collateral channels to the venous system, bypassing the liver. Liver fails to synthesize essential vital blood components, filter substances or neutralize toxic substances.

- Patient with portal hypertension presents with jaundice, hypoalbuminemia, hyperammonemia (hepatic encephalopathy), fetor hepaticus, palmar erythema, spider angiomas, caput medusae, gynecomastia, respiratory renal failure and bleeding diathesis. Death occurs due to hepatic coma, massive GIT bleeding, hepatorenal syndrome and hepatocellular carcinoma (Table 21.50).
- Clinical manifestations of portal hypertension are portosystemic shunts, massive splenomegaly and ascites. Later, patient develops various complications associated with fatal outcome.

Portosystemic Shunts

Pressure in the venous system causes distension and varicosity of the veins in esophagus and around umbilicus. Varicose veins can hemorrhage during vomiting, resulting in bloody vomit, internal hemorrhage, and shock associated with fatal outcome.

Table 21.50 Clinical manifestations in cirrhosis

Clinical Sequelae	Clinical Findings
Portal hypertension	Esophageal varices, splenomegaly, caput medusae, ascites, ankle edema, hypersplenism (anemia, leukopenia and thrombocytopenia) anemia, and hemorrhagic tendencies
Hyperestrinism	Spider nevi, pectoral alopecia, gynecomastia, altered hair distribution, palmar erythema, testicular atrophy
Hepatic encephalopathy	Jaundice, hemorrhagic tendencies due to decreased synthesis of coagulation factors, edema due to decreased synthesis of albumin by liver. Asterixis is a flapping tremor associated with hepatic encephalopathy

Esophageal Varices

In many patients, the first sign of portal hypertension is bleeding esophageal varices.

- **Location of esophageal varices:** Esophageal veins are dilated veins immediately beneath the mucosa in the lower-third of esophagus especially in cirrhosis. Esophageal veins are linked to the portal system through gastroesophageal anastomoses. Left gastric vein is also dilated in these patients. Esophageal varices are associated with atrophy of muscularis mucosae.
- **Rupture of esophageal varices:** Esophageal varices >5 mm in diameter are prone to rupture and life-threatening hematemesis; requiring emergency care to control hemorrhage and prevent hypovolemic shock.
- **Endoscopy:** Endoscopy is the primary diagnostic tool for confirming esophageal varices. These are graded according to severity. Grade 1 esophageal varices can be depressed by pressure exerted by endoscopy. Grade 2 esophageal varices cannot be depressed by endoscopy. Grade 3 esophageal varices are confluent and extend circumferentially around esophageal lumen.
- **Sclerotherapy:** Esophageal varices are treated by sclerotherapy.
- **Imaging techniques:** Imaging techniques demonstrate numerous prominent blue venous channels beneath the mucosa of the everted esophagus, particularly above the gastroesophageal junction.

Caput Medusae Around Umbilicus

The umbilical vein remnants of fetal circulation present in falciparum ligament. It can become anastomotic link between portal vein and epigastric veins of anterior abdominal wall around umbilicus. Caput medusae results from dilation of the periumbilical venous collaterals due to portal hypertension and activation of portocaval anastomoses.

Hemorrhoids in Rectal Submucosa

Superior and middle hemorrhoidal veins form part of the portal venous drainage, whereas the inferior hemorrhoidal vein drains into the inferior vena cava. Anastomoses formed between these two systems lead to development of rectal varices (hemorrhoids).

- Internal hemorrhoids are formed due to dilatation of superior hemorrhoidal veins, which may protrude from the anus.
- External hemorrhoids are formed due to dilatation of inferior hemorrhoidal veins.

Shunting of Blood in Left Renal Vein

Shunting of blood to left renal vein occurs derived directly from splenic vein or pancreatic or gastric veins.

Massive Splenomegaly

Morphologic consequences of portal hypertension are esophageal varices and massive splenomegaly.

Surgical Pathology: Massive Splenomegaly in Portal Hypertension

Gross Morphology

- The spleen is enlarged, as it is unable to drain through portal vein. Due to excess of blood in spleen, the risk for rupture and internal hemorrhage is very high.
- Due to pooling of platelets in enlarged spleen, patient develops thrombocytopenia (Fig. 21.49).

Light Microscopy

- Sinusoids of spleen are dilated and lined by prominent endothelial cells.
- Macrophages are prominent and containing hemosiderin granules.
- Spleen may show small hemorrhages.

Ascites

Ascites is defined as the accumulation of free fluid in the peritoneal cavity. Clinical examination does not detect ascites if fluid is <500 ml.

- In clinical practice, patient with decompensated cirrhosis may accumulate excessive fluid in the peritoneal cavity leading to gross distension of the abdominal wall.
- Protein content of fluid reveals low protein content about 1–2 g/dl indicating presence of transudate.

Fig. 21.49: Massive splenomegaly in portal hypertension. The spleen is enlarged from the normal 300 g or less to between 500 and 1000 g. Another finding here is the irregular pale tan plaques of collagen over the purple capsule known as sugar icing or hyaline perisplenitis which follows the splenomegaly and/or multiple episodes of peritonitis that are a common accompaniment to cirrhosis of liver.

- Higher concentration of protein in the ascitic fluid reflects either superadded infection or cirrhosis progressing to hepatocellular carcinoma. Pathogenesis of ascites and generalized edema in portal hypertension is shown in Fig. 21.50.

Pathogenesis

Patient develops ascites due to sinusoidal hypertension, percolation of hepatic lymph, intestinal capillary fluid leakage and renal retention of Na^+ and water. There is seepage of plasma out of veins and lymphatic channels into the peritoneal space resulting in ascites and abdominal distension.

Normal flora of gut may seep out to produce infection in ascitic fluid, resulting in life-threatening spontaneous bacterial peritonitis. Patient with cirrhosis develops peripheral edema, ascites and hydrothorax by the following mechanisms:

- Increased pressure at the venous end of splanchnic capillaries leads to transudation of fluid from vascular to the extravascular compartment, which occurs in the presence of sinusoidal portal hypertension as a result of deposition of collagen fibers in the space of Disse.
- Lymphatic channels are dilated at the hilum of the liver. Flow of lymph in thoracic duct is also increased. It is likely that escape of lymph from the liver surface occurs only when the capacity of the thoracic duct is exceeded.
- In the setting of cirrhosis, decreased intravascular oncotic pressure due to hypoalbuminemia is also an important factor in the pathogenesis of ascites. Overall, imbalances in Starling forces lead to transudation of fluid into the abdominal cavity.
- Concentration of aldosterone and angiotensin II is increased due to decreased degradation of these metabolites in cirrhotic patients. Increased aldosterone level acts on distal convoluted tubules and enhances excessive absorption of sodium and water. It is worth mentioning that angiotensin II stimulates adrenal cortex to synthesize aldosterone.

COMPLICATIONS

Complications of portal hypertension include hepatic encephalopathy, altered metabolic activity, disruption of hormonal inactivation, bleeding and bruising; skin lesions and hematologic abnormalities (Figs 21.51 and 21.52). Clinical consequences of cirrhosis are shown in Table 21.51.

Hepatic Encephalopathy

Patient with portal hypertension developing neuropsychiatric disturbances is known as hepatic encephalopathy. It may occur in a background of chronic liver disease such as cirrhosis in association with massive hepatocellular necrosis of liver leading to acute hepatocellular failure. The progressive loss of liver function can

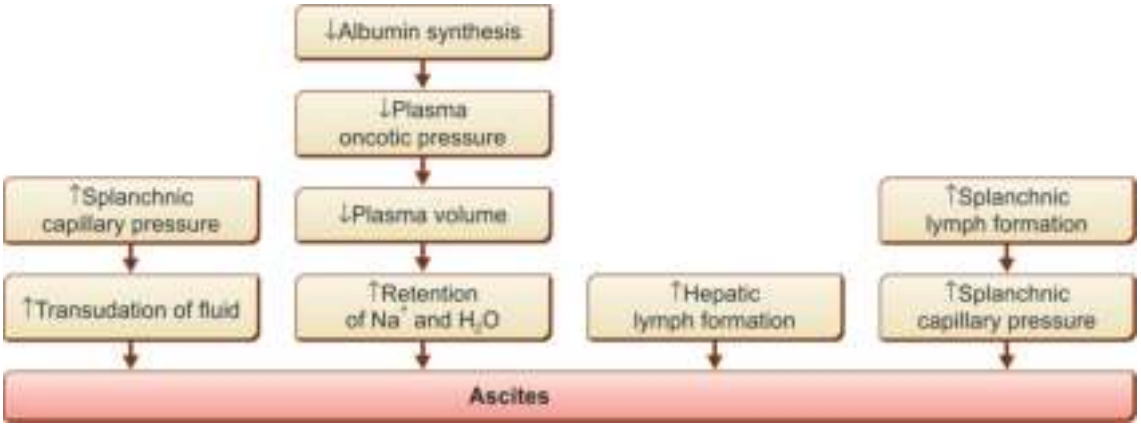

Fig. 21.50: Pathogenesis of ascites and generalized edema in portal hypertension.

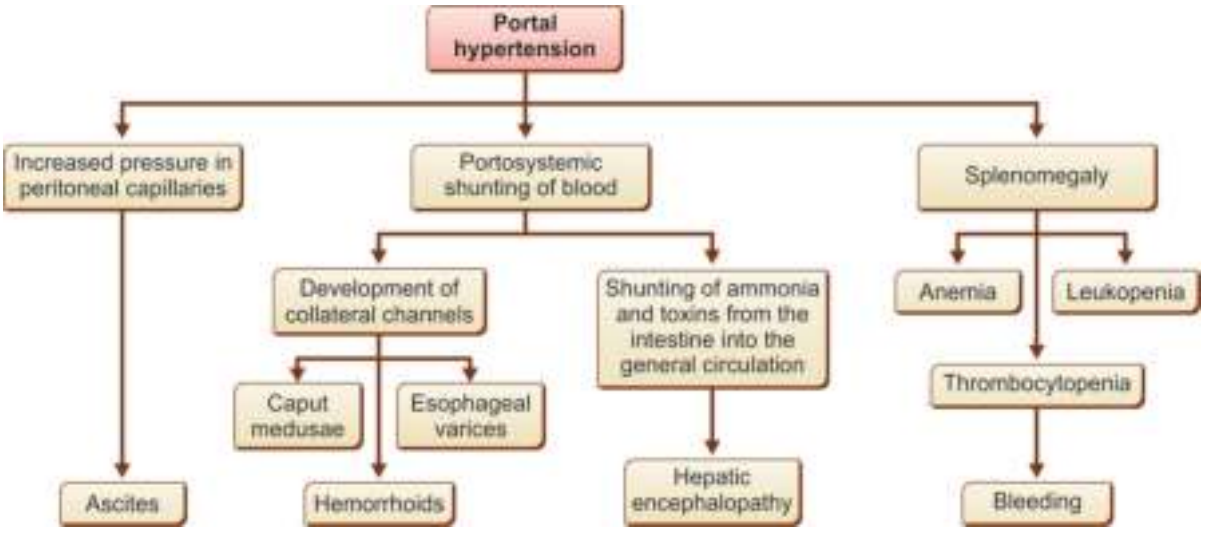

Fig. 21.51: Mechanism of disturbed liver functions related to portal hypertension.

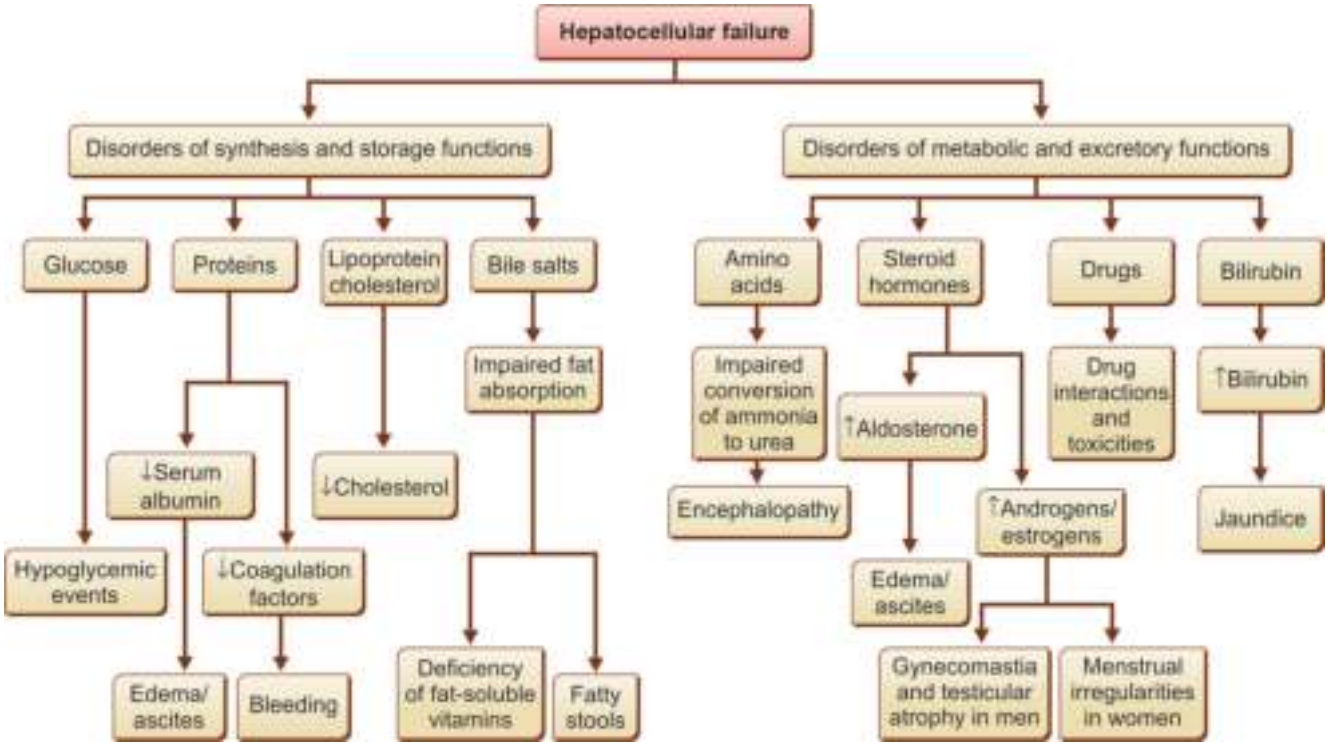

Fig. 21.52: Alterations in liver function and clinical manifestations of hepatocellular failure.

lead to liver failure. A person with end-stage hepatocellular failure needs liver transplantation for survival.

Clinical Course of Hepatic Encephalopathy

- **Acute hepatocellular failure:** Patient with acute hepatocellular failure due to fulminant hepatitis or drug-induced hepatocellular injury develops rapid hepatic encephalopathy associated with poor outcome.
- **Chronic liver disease:** Clinical manifestation is different in patient with chronic liver disease. During clinical course, features of gradual hepatic encephalopathy occur.

Pathogenesis of Hepatic Encephalopathy

Central to the development of hepatic encephalopathy is shunting of portal blood to systemic circulation.

Table 21.51 Clinical consequences of cirrhosis

Parameters of Cirrhosis	Clinical Consequences
Portal hypertension	▪ Ascites ▪ Portosystemic shunts formation • Esophageal varices • Caput medusae around umbilicus • Hemorrhoids ▪ Massive splenomegaly
Hepatocellular dysfunction	▪ Hypoalbuminia ▪ Coagulation defects ▪ Hepatic encephalopathy • Altered metabolic activity • ↑Ammonia in blood • Fetor hepaticus induced by mercaptans • ↑γ-Aminobutyric acid (GABA) in blood • ↑Glutamine in CSF ▪ Hepatorenal syndrome ▪ Hepatopulmonary syndrome ▪ Jaundice ▪ Palmar erythema ▪ Spider nevi
Increased incidence of malignancy	▪ Hepatocellular carcinoma

- **Functional basis:** Massive hepatocellular necrosis resulting from fulminant or toxic damage fails to metabolize the constituents of the portal blood.
- **Anatomical basis:** In patient with cirrhosis, shunting of portal blood to systemic circulation is purely based on disrupted anatomical architecture of liver.

Clinical Features in Hepatic Encephalopathy

Patient with hepatic encephalopathy presents with somnolence, confusion, neck rigidity, flapping tremors of hands (asterixis), hallucinations, and coma with fatal outcome.

Flapping tremors are characteristic of the hepatic encephalopathy but not pathognomonic of portal hypertension, because these may also be seen in patient with uremia, respiratory failure, cardiac failure and hypoglycemia (Fig. 21.53).

Surgical Pathology: Brain Histology in Hepatic Encephalopathy

Gross Morphology

The brain appears normal. Cerebral edema is seen in patient with fulminant hepatitis in 50% of cases, who have been in coma for some days.

Light Microscopy

- **Early histologic changes in brain:** In hepatoencephalopathy, early histologic changes in brain include increase in size and number of protoplasmic astrocytes in the deep cortex, basal ganglion and dentate nucleus in cerebellum. Astrocytes show pale cytoplasm and lobulated nucleus. Such altered astrocytes are also known as Alzheimer type 2 cells.
- **Late histologic changes in brain:** In patients with history of recurrent episodes of hepatic encephalopathy over time, the cerebral cortex is thinned out due to irreversible loss of neurons and fibers. Demyelination is an occasional finding demonstrated in the spinal tracts producing spastic paraplegia.

Biochemical Abnormalities in Hepatic Encephalopathy

- **Altered metabolic activity in hepatic encephalopathy:** Advanced cases of cirrhosis fail to detoxify toxic substances. Further blood–brain barrier in central nervous system becomes less effective in these patients.
  - Altered metabolic activity in hepatic encephalopathy include increased concentration of ammonia, mercaptans, octopamine and γ-aminobutyric acid (GABA).
  - Toxic substances such as ammonia and other enteric degradation products shunting from liver to the systemic circulation deliver neurotoxic substances and cause brain damage (Fig. 21.54). Factors triggering hepatic encephalopathy are given in Table 21.52.
- **Increased blood ammonia concentration:** It is not a reliable indicator of hepatic encephalopathy, because some patients with unequivocal coma may show normal blood ammonia concentration.
- **Mercaptans:** Derivatives of aromatic amino acids such as methionine, phenylalanine, tyrosine and tryptophan are known as mercaptans, which are responsible for the curious odor of breath fetor hepaticus in patient with acute hepatocellular failure.
- **Octopamine false neurotransmitter:** It is derived from colon as a result of bacterial infection.
- **Gamma aminobutyric acid (GABA) neurotransmitter:** Patient with hepatic encephalopathy exhibits increased binding of benzodiazepines and increased blood concentration of GABA.
- **Glutamine concentration in CSF:** Glutamine concentration in CSF is most often increased in hepatic encephalopathy. Its measurement is a reliable diagnostic tool. Glutamine in cerebrospinal fluid is derived from aromatic amino acids such as methionine, phenylalamine, tyrosine and tryptophan.

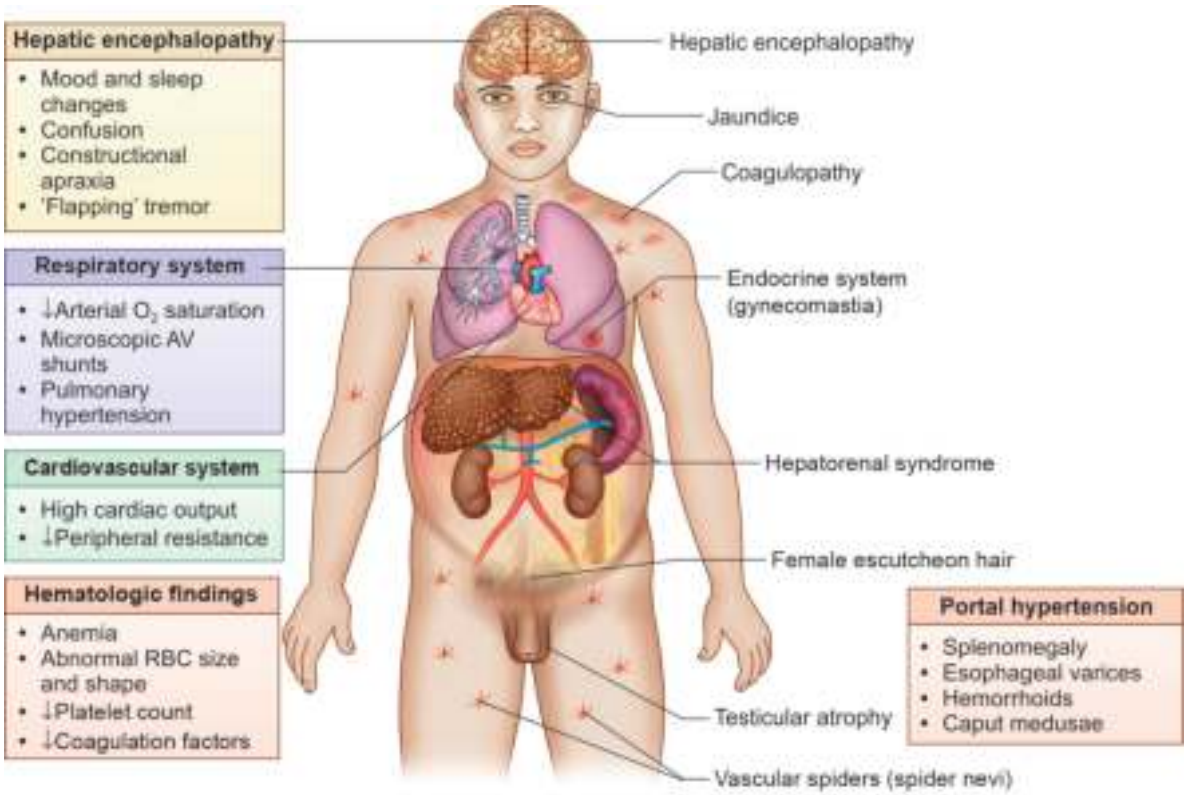

Fig. 21.53: Clinical manifestations and complications of hepatic encephalopathy in a patient of cirrhosis with portal hypertension.

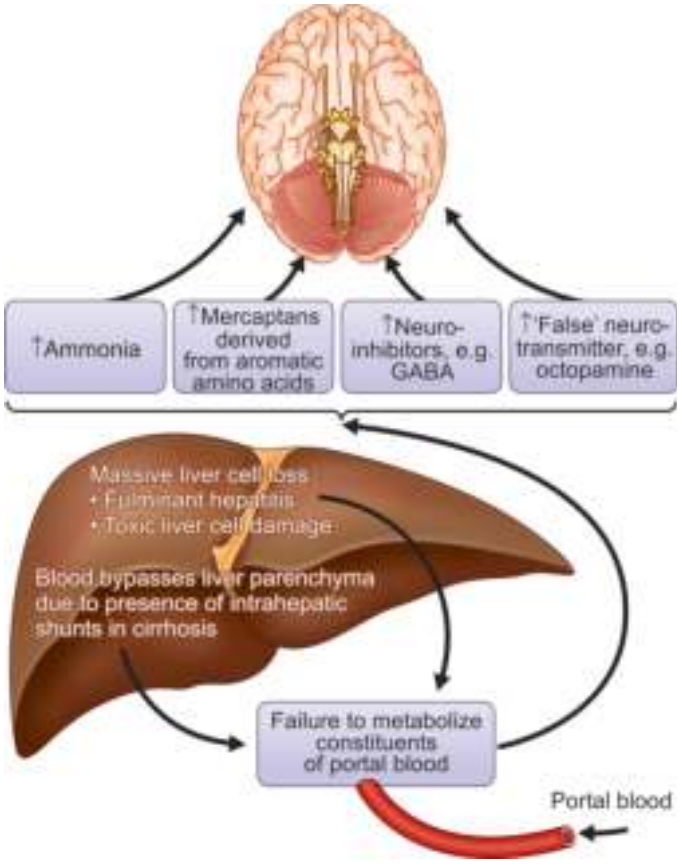

Fig. 21.54: Pathogenesis of hepatic encephalopathy.

Laboratory Findings in Hepatic Encephalopathy

Laboratory findings in hepatoencephalopathy in advanced cirrhosis are elevated conjugated and unconjugated bilirubin, decreased serum albumin, prolonged prothrombin time–INR, anemia, thrombocytopenia, elevated levels of blood creatinine and blood urea nitrogen, and hypoglycemia. Commonly observed laboratory findings in hepatoencephalopathy in advanced cirrhosis are given in Table 21.53.

Hepatorenal Syndrome

Advanced cirrhosis can impair blood flow to the kidneys resulting in hepatorenal syndrome. Renal involvement leads to oliguria, azotemia, and increased levels of serum creatinine.

- Renal failure occurs due to vasoconstriction and hypoperfusion of the kidneys mediated by various hormones and vasoactive substances, some of which may not be cleared by the cirrhotic liver.
- Hepatorenal syndrome is an emergency that requires a liver transplant.

Disruption of Hormones Inactivation

- **Hyperestrinism in men:** Liver normally inactivates estrogen in men. Male patients with cirrhosis no longer inactivate estrogen. Patient presents with gynecomastia, loss of chest and pubic hair; impotence, testicular atrophy and palmar erythema, spider nevi

Table 21.52 Factors triggering hepatic encephalopathy in advanced cirrhosis

Factors	Examples
Infections	Bacterial peritonitis, chest infections, urinary tract infections
Hemorrhage	Esophageal varices, peptic ulcer, Mallory-Weiss syndrome (vomiting induced bleeding)
Electrolytes imbalance	Diuretics
Drugs and toxic substances	Morphea, benzodiazepines, barbiturates, and alcohol

Table 21.53 Commonly observed laboratory findings in hepatoencephalopathy in advanced cirrhosis

Characteristics	Comment(s)
Elevated conjugated and unconjugated bilirubin	Defects in conjugation and excretion in bilirubin
Hypoalbuminemia	Decreased synthesis of albumin
Elevated ALT (alanine transferase) and AST (aspartate transaminase)	Elevation of ALT and AST to 100-fold with acute hepatocellular failure, rapid decline to normal can indicate permanent loss of hepatocytes. ALT and AST can be normal in chronic liver disease
Hyperammonemia	Impaired urea cycle
Hypoglycemia	Impaired gluconeogenesis in the fasting state after glycogenolysis has exhausted liver glycogen stores
Prolonged prothrombin time–INR	Decreased synthesis of coagulation factors, malabsorption of vitamin K, and decreased clearance fibrin-split products
Thrombocytopenia	As a result of disseminated intravascular coagulation or thrombopoietin deficiency
Anemia	Bone marrow suppression leads to chronic anemia, blood loss from esophageal varices
Elevated creatinine and blood urea nitrogen	Decreased urine output, the hepatorenal syndrome may be present; elevated BUN and a normal creatinine can indicate a gastrointestinal bleeding

(capillary telangiectasis) of the face, upper arms, and chest. These findings are attributed to reduced hepatic catabolism of estrogens (i.e. hyperestrogenism).

- **Hyperestrinism in women:** Women patients present with cessation of menstrual periods, infertility and growth of body hair. Both men and women with cirrhosis can expect a decreased sex drive.

Bleeding and Bruising

Patient with chronic liver disease (cirrhosis) presents with bleeding and bruise for prolonged periods. Affected person may show several functional bleeding defects. Bleeding and bruise occur by the following mechanisms.

- **Decreased synthesis of coagulant and anticoagulant proteins:** Liver synthesizes inadequate vitamin K-dependent coagulation factors and substrates (II, VII, IX, and X); natural occurring anticoagulants such as protein C, protein S and antithrombin III; and antifibrinolytic protein (plasminogen).
- **Synthesis of abnormal forms of coagulant proteins:** Liver synthesizes abnormal forms of vitamin K-dependent clotting factors, fibrinogen, and factor VIII except von Willebrand factor.
- **Decreased clearance of coagulant proteins:** There is impaired clearance of activated coagulation factors, thrombin–antithrombin III complex and plasminogen activators synthesized by vascular endothelium.

Skin Lesions

- **Jaundice:** Bilirubin, a product of dead red blood cells is produced in the spleen and then recycled in the liver as a component of bile. Cirrhosis interferes with this process; conjugated and unconjugated bilirubin is accumulated in the bloodstream. Bilirubin has affinity for sclera giving yellow discoloration.
- **Spider nevi:** Patient with chronic liver disease (cirrhosis) may develop spider nevi. These lesions consist of a centrally dilated arteriole from which numerous small vessels radiate. Pressure exerted on the central arteriole causes blanching of the lesions. Number of spider nevi increases in patient with worsening chronic liver disease and the converse is true if liver pathology improves.
- **Palmar erythema:** Patient with chronic liver disease (cirrhosis) most often develops warm red palms with eminent thenar and hypothenar regions.

Hematologic Abnormalities

Patient with chronic liver disease (cirrhosis) may show hematologic abnormalities. Patient develops anemia as a result of hypersplenism induced hemolysis, increased plasma volume (sodium and water absorption), recurrent bleeding associated with esophageal varices and bone marrow depression.

- **RBC abnormalities:** Patient may develop macrocytic anemia due to disturbance of vitamin B_{12} and folic acid metabolism. Microcytic anemia occurs as a result of recurrent bleeding. Presence of target cells is associated with increased amount of cholesterol and phospholipid in the cell membrane. Echinocytes are associated with binding of an abnormal high density lipoprotein to the red blood cell surface. Acanthocytes are bizarre cells with many projections on their surfaces. Mechanism of presence of acanthocytes is not known.
- **WBC abnormalities:** Leukocytosis is associated with fulminant hepatitis, hepatic malignancy, ascending cholangitis and alcoholic liver disease. Leukopenia is associated with alcoholic cirrhosis as a result of hypersplenism and toxic effects of alcohol on bone marrow.
- **Platelet abnormalities:** Thrombocytopenia occurs due to increased pooling of platelets in the spleen, shortening of platelet's life span and inability of the bone marrow to compensate fully for platelet abnormalities. There may be abnormality of aggregation defects of platelets.

METABOLIC LIVER DISORDERS

ALCOHOLIC LIVER DISEASE

Alcohol toxicity is the most common cause of morbidity and mortality worldwide. Alcohol is the most common cause of cirrhosis, but disorders related to other systems also occur such as pancreatitis, cardiomyopathy, fetal alcohol syndrome, GIT bleeding, Wernicke-Korsakoff psychosis, polyneuropathy and spontaneous abortion.

- Daily intake of 80–160 g alcohol increases the risk for alcoholic liver disease.
- Chronic alcoholics develop fatty liver (60%), steatohepatitis (20–30%), and micronodular cirrhosis over a span of 10–15 years (10–15%).
- Only 10% of chronic alcoholic cases of micronodular cirrhosis may develop hepatocellular carcinoma. Alcoholic liver disease is shown in Fig. 21.55A to C. Alcohol oxidative pathways and their role in pathogenesis of alcoholic liver disease are given in Table 21.54.

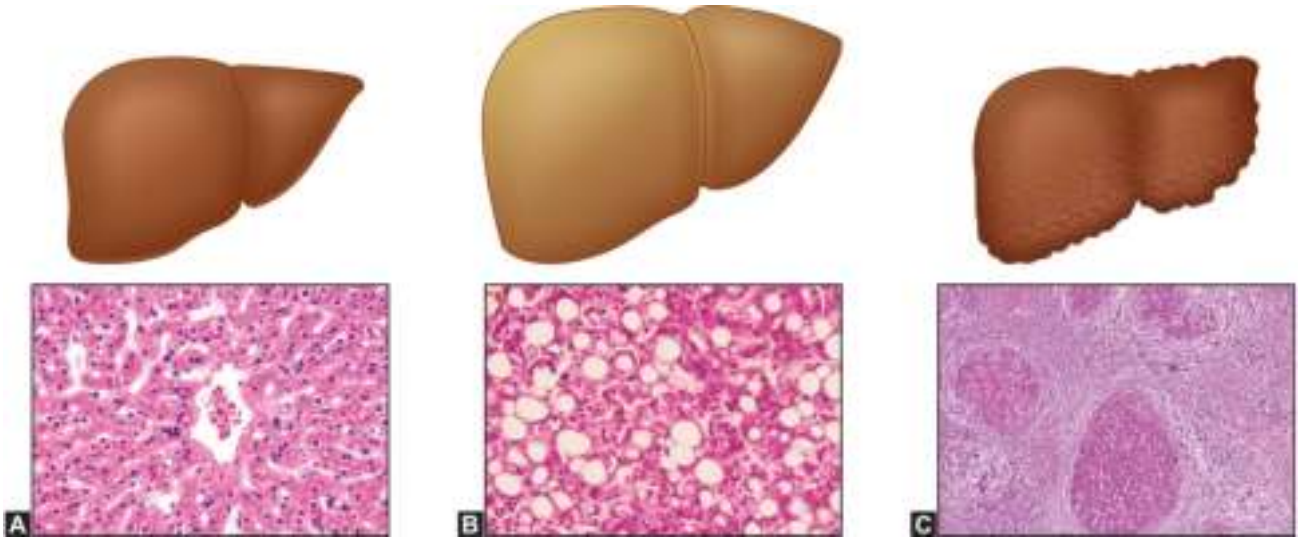

Fig. 21.55: Alcoholic liver disease (ALD). Approximately 60% of chronic alcoholics develop fatty liver. Around 40% develop steatohepatitis, showing inflammation and early fibrosis on histologic examination. Approximately 10–15% may develop micronodular cirrhosis. Only 10% of persons with cirrhosis develop hepatocellular carcinoma. (A) Normal liver, (B) fatty liver, (C) cirrhosis of liver.

Table 21.54 Alcohol oxidative pathways and their role in pathogenesis of alcoholic liver disease

Alcohol Oxidative Pathways	Adverse Effects on Liver
Direct toxic effects of alcohol	
Lipid peroxidation	Synthesis of fatty acid ethyl esters, phosphatidyl-ethanol resulting in alteration in membrane fluid
Alcohol toxic effect	▪ Decreased synthesis of vitamin A, vitamin E, mitochondrial GSH, SAMe ▪ Induces CYP2E1, and hydroxyethyl radicals ▪ Iron deposition
Endotoxemia	Kupffer cell dysfunction
Perivenular hypoxia	Sinusoidal dysfunction
Toll-like receptors, heat shock proteins	Inflammatory cytokines
Acetaldehyde metabolic product	
Acetaldehyde toxic effect	▪ DNA oxidation ▪ Protein oxidation ▪ Lipid peroxidation ▪ Oxidative stress
Acetaldehyde adducts	▪ Enzyme inhibition, malondialdehyde adducts ▪ Adverse immune response ▪ Impaired cytoskeleton function ▪ Mitochondrial injury, decreased ATP, decreased GSH and cysteine, increased collagen synthesis, activation of NF-κB and AP-1 leading to dysfunction of hepatocyte, Kupffer cells, and stellate cell.

AP-1; activator protein 1, ATP; adenosine triphosphate, CYP2E1; cytochrome p-450 system, GSH; glutathione; SAMe; S-adenosyl methionine, NF-κB; nuclear factor κB.

Pathology Pearls: Pathogenesis of Alcoholic Liver Disease

Ethanol absorbed by gastrointestinal tract is metabolized in liver by three pathways: alcohol dehydrogenase (most important), microsomal ethanol oxidizing P450 system and catalase. Alcohol mobilizes fatty acids from peripheral adipose tissue.

Ethanol alters mitochondrial and smooth endoplasmic reticulum thus inhibits fatty acid oxidation to ketone bodies and CO_2. Alcohol also decreases synthesis of lipoproteins resulting in accumulation of fat in liver cells.

- **Mobilization and biosynthesis of fatty acids:** Ethanol participates in mobilization of fatty acids to liver from peripheral stored fat. Alcohol dehydrogenase generates excessive NADH resulting in biosynthesis of lipid.
- **Mitochondrial dysfunction:** Normally, mitochondria participates in metabolism of ethanol to acetaldehyde. Ethanol disrupts normal functions of mitochondria and microtubules resulting in decreased fatty acid metabolism.

  Fatty acids accumulate in smooth endoplasmic reticulum of hepatocytes. There is decreased synthesis of lipoproteins, hence, liver is unable to release fatty acids to peripheral tissues.
- **Lipid peroxidation by acetaldehyde:** Acetaldehyde, metabolic product of ethanol induces lipid peroxidation with formation of malondialdehyde-acetaldehyde adduct. Autoantibody formed against this adduct results in hepatocellular injury.
- **Role of cytokines in cirrhotic nodules formation:** Ethanol stimulates Kupffer cells to synthesize cytokines such as TNF-α, IL-1, IL-6 and TNF-β, responsible for inflammation in liver. These cytokines stimulate stellate cells to synthesize malondialdehyde-acetaldehyde adduct responsible for cirrhotic nodules formation by laying down of collagen fibers.
- **Oxygen-derived free radicals induced hepatocellular injury:** Microsomal ethanol oxidizing system (P450) participates in oxidation of ethanol and generation of oxygen-derived free radicals leading to hepatocellular injury. Clinical consequences of chronic alcohol consumption are given in Table 21.55.

FATTY CHANGE (STEATOSIS) IN LIVER

Fatty change in liver is most frequent morphologic abnormality caused by alcohol intake and characterized by the accumulation of triglycerides within parenchymal cells. Fatty change in liver results from an imbalance between the uptake, utilization, and mobilization of fat from liver cells.

The amount of fat deposited varies with the amount of alcohol consumed, as well as the patient's hormonal status, diet, and other factors. Accumulation of triglyceride by itself is not ordinarily damaging liver, and the condition is fully reversible upon discontinuation of alcohol abuse.

Etiology

Alcohol abuse and diabetes mellitus associated with obesity are the most common causes of fatty change in liver. Alcoholic fatty liver may be reversible with complete abstinence from alcohol. Nonalcoholic fatty liver disease (NAFLD) is a related condition unrelated to alcohol consumption. Normal liver metabolism of free fatty acids (FFAs) is shown in Fig. 21.56.

- Alcohol intake alters mitochondrial and smooth endoplasmic reticulum function and thus inhibits

Table 21.55 Clinical consequences of chronic alcohol consumption

Organs	Disorders
Liver	▪ Steatosis ▪ Steatohepatitis ▪ Cirrhosis ▪ Hepatocellular carcinoma
Gastrointestinal tract	Gastritis
Pancreas	Pancreas
Central nervous system	Wernicke-Korsakoff pshycosis
Pregnancy	Fetal alcohol syndrome
Heart	Congestive/dilated cardiomyopathy due to thiamine deficiency
Other manifestations	▪ Malnutrition ▪ Vitamins deficiency ▪ Anemia

Pathogenesis of hepatic steatosis

- **Dietary factors and obesity:** Excessive consumption of saturated fatty acids leads to hepatic steatosis.
- **Chronic alcohol consumption:** It causes hepatic steatosis progressing to cirrhosis due to various mechanisms: (a) ethanol is oxidized, first to acetaldehyde and then to acetate and finally to enter citric acid cycle virtually in all tissues. This process is irreversible and unregulated, which decreases both cytoplasmic and intramitochondrial NAD, which causes imbalance of NADP: NADPH ratio and thus inhibits free fatty acids oxidation to make energy in tissues, (b) increased mobilization of free fatty acids from peripheral tissue to liver, (c) altering functions of mitochondria and smooth endoplasmic reticulum, inhibit oxidation of free fatty acids, and (d) inhibiting lipoprotein synthesis.
- **Insulin-resistant type 2 diabetes mellitus:** It causes hepatic steatosis progressing to cirrhosis and hepatocellular carcinoma due to various mechanisms: (a) increased mobilization of free fatty acids to liver, (b) imbalance of adipocytokines (i.e. decreased adiponectin and/or increased proinflammatory cytokines), (c) both free fatty acids and adipocytokines activate inflammatory pathways that include protein kinase C, transcription factor NF-κB and c-Jun N-terminal kinases consist of 10 isoforms derived from three genes: JNK1 (4 isoforms), JNK2 (4 isoforms) and JNK3 (2 isoforms) and can accelerate the progression of hepatic steatosis to nonalcoholic steatohepatitis and cirrhosis.

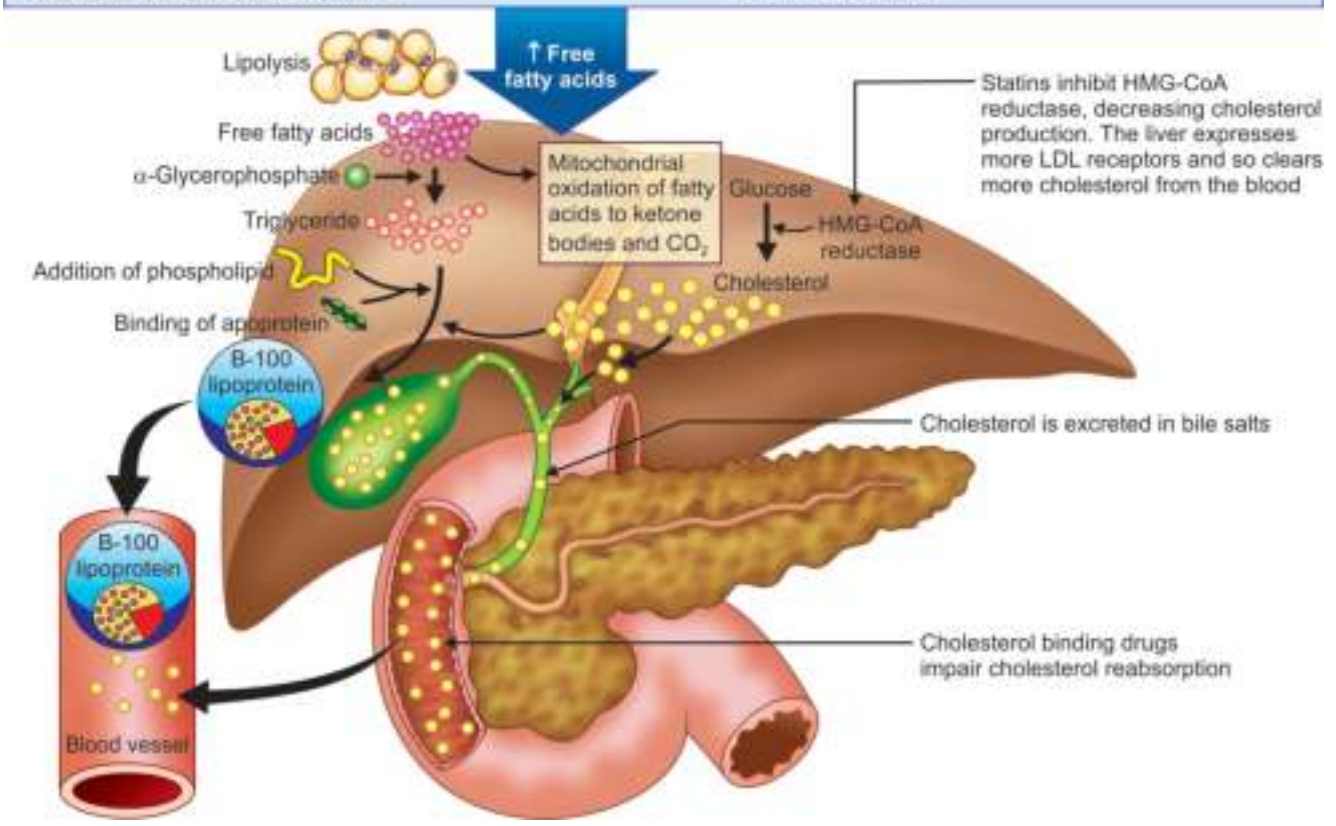

Fig. 21.56: Normal liver metabolism of free fatty acids (FFA). The cholesterol pathway is also shown. Cholesterol is also brought to the liver by high-density lipoproteins (HDL). The point at which alcohol interacts are shown. The effects of drug statin treatment are shown.

Table 21.56 Patterns and etiology of fatty change in liver (hepatic steatosis)

Hepatic Steatosis Pattern	Disorder	
Macrovesicular hepatic steatosis (large droplets)	▪ Alcoholic steatosis/steatohepatitis ▪ Nonalcoholic steatosis/steatohepatitis ▪ Bypass surgery for morbid obesity ▪ Drug- and toxin-induced (e.g. methotrexate, corticosteroids, amiodarone, mushrooms) ▪ Pancreatic insufficiency ▪ Inflammatory bowel disease (Crohn's disease and ulcerative colitis)	▪ Kwashiorkor (late stage) ▪ Metabolic disorders (e.g. abetalipoproteinemia, galactosemia, glycogen liver disease Ia, II,VI) ▪ Septicemia ▪ Viral hepatitis, chronic hepatitis, secondary to hepatitis C virus ▪ Wilson disease
Microvesicular hepatic steatosis (small droplets)	▪ Acute fatty liver of pregnancy* ▪ Alcoholic foamy degeneration ▪ Drug- and toxin-induced (e.g. tetracycline, cocaine, valproic acid, phosphorus) ▪ Kwashiorkor (early disease)	▪ Viral hepatitis, chronic hepatitis, secondary to HDV ▪ Metabolic disorders (e.g. Wolman disease, Alpers disease, cholesterol ester storage) ▪ Reye syndrome

**Acute fatty liver of pregnancy in the third trimester can develop hepatocellular failure with fatal outcome.*

fatty acid oxidation resulting in accumulation of lipids in hepatocytes.
- Protein malnutrition causes decreased synthesis of lipoproteins. Anoxia inhibits fatty acid oxidation.
- Starvation leads to mobilization of fatty acids. Diabetes mellitus and obesity may also cause fatty change.

Patterns of Fatty Change in Liver

Patterns and etiology of fatty change in liver (hepatic steatosis) are given in Table 21.56.

- **Microvesicular steatosis:** Minute multiple droplets of fats are present in hepatocytes not displacing nuclei to periphery.
- **Macrovesicular steatosis:** Single large lipid droplet is present in hepatocytes displacing nuclei to periphery.

Pathophysiology of Fatty Change in Liver

- **Physiologic state:** Free fatty acids from adipose tissue or ingested are normally transported into hepatocytes, where these are esterified to triglycerides, converted into cholesterol or phospholipids, or oxidized to ketone bodies. Some of the fatty acids are synthesized from acetate within hepatocytes as well. Egress of the triglyceride requires the formation of complexes with apoproteins to form lipoproteins, which are able to enter the circulation.
- **Pathologic state:** Defects in any of the steps of uptake, catabolism, or secretion can lead to accumulation of triglycerides in hepatocytes. Hepatotoxins (e.g. alcohol) alter mitochondrial and smooth endoplasmic reticulum function and thus inhibit fatty acid oxidation. Carbon tetrachloride and protein malnutrition decrease the synthesis of apoproteins. Anoxia inhibits fatty acid oxidation. Starvation increases fatty acid mobilization to liver from peripheral stores.

Clinical Significance

Mild fatty change in liver has no effect on cellular functions. Severe fatty change in liver may transiently impair cellular functions. But in carbon tetrachloride poisoning, fatty change in liver is irreversible.

Clinical Features

Patient with fatty change in liver shows hepatomegaly and mild elevation of serum bilirubin and alkaline phosphatase.

Surgical Pathology: Fatty Change in Liver

Gross Morphology

- Fatty change in liver starts at centrilobular area and progresses to involve whole lobule.
- Mild fatty change in liver may not affect the gross appearance.
- Severe fatty change in liver results in enlargement of liver, which becomes progressively yellow on cut surface until it may weigh 3–6 kg. This uniform change is consistent with fatty metamorphosis (fatty change). Gross morphology of fatty liver is shown in Fig. 21.57.

Light Microscopy

- **Fatty change in liver:** Initially, hepatocytes show small fat vacuoles around nucleus (mild fatty change or microvesicular) in hematoxylin and eosin stained sections. Progressive accumulation of fat vacuoles in the cytoplasm coalesces to create spaces that displace the nucleus toward periphery indicating severe fatty change.
- **Fatty cysts in liver:** Occasionally contiguous cells rupture, and the enclosed fat globules unite to produce so-called fatty cysts.
- **Distribution of lipid in liver:** Distribution of lipid vacuoles may be diffuse, focal or zonal, midzonal or peripheral region of liver depending on severity and etiology (Fig. 21.58).

Fig. 21.57: Fatty change in liver. This is a larger liver with more pronounced fatty change in liver. Such fatty change is most often nutritional in etiology when diet is poor in protein and/or when fatty acid metabolism is deranged and/or when liver cell function is impaired.

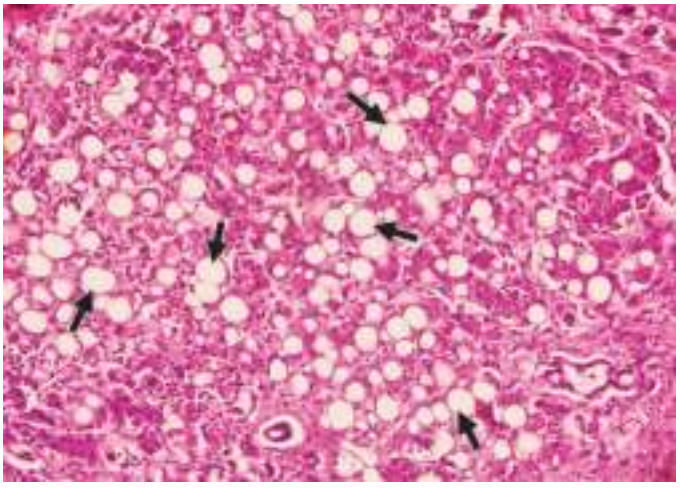

Fig. 21.58: Fatty change in liver. The lipid accumulates in the hepatocytes as vacuoles. These lipid vacuoles have a clear appearance with H&E staining. Alcohol, the most common cause, is a hepatotoxin that interferes with mitochondrial and microsomal function in hepatocytes, leading to an accumulation of lipid. In developing countries, fatty change in liver is seen in kwashiorkor, diabetes mellitus, obesity, and severe gastrointestinal tract malabsorption (arrows) (400X).

Fat Demonstration in Fatty Change in Liver

In paraffin-embedded sections, fat is dissolved during processing of tissue. Fat can be demonstrated by frozen section technique with the fat stains such as Sudan III, Sudan IV, Sudan black, Oil red O and osmic acid.

ACUTE ALCOHOLIC STEATOHEPATITIS

Acute alcoholic steatohepatitis is characterized by hepatic steatosis and hydropic swelling of hepatocytes, focal hepatocellular necrosis, infiltration by neutrophils, and cytoplasmic hyaline inclusions within the hepatocytes (Mallory bodies), which represent precipitated intermediate filament proteins (cytokeratin 8 and 18). Development of irreversible perivenular and perisinusoidal fibrosis in acute alcoholic steatohepatitis may progress to cirrhosis.

Clinical Features

Patient with acute alcoholic steatohepatitis typically presents with malaise and anorexia, fever, loss of weight, pain in right upper quadrant due to hepatomegaly, and jaundice. Serum bilirubin and alkaline phosphatase levels are raised with peripheral neutrophilic leukocytosis.

Surgical Pathology: Acute Alcoholic Steatohepatitis

Light Microscopy

Liver biopsy examined under light microscope shows hepatic steatosis and hydropic swelling of hepatocytes, focal hepatocellular necrosis, infiltration by neutrophils, and cytoplasmic Mallory's hyaline inclusions within the hepatocytes (Fig. 21.59).

- **Mallory-Denk hyaline bodies:** These are demonstrated in hepatocytes.
- **Necroinflammatory change:** Sclerosing hyaline necrosis, lobular focal necrosis and neutrophilic infiltrate may be demonstrated. Hepatocyte ballooning may also be seen.

Electron Microscopy

Giant mitochondria (megamitochondria) are ultrastructural feature of alcoholic liver disease.

Pathology Pearls: Mallory-Denk Hyaline Inclusions

- In histopathology, Mallory-Denk hyaline inclusions are demonstrated in the cytoplasm of hepatocytes.
- These are damaged intermediate filaments within hepatocytes.
- Mallory's hyaline inclusions are also known as **Mallory-Denk hyaline**. These are present in primary biliary cirrhosis but absent in secondary biliary cirrhosis. Liver disorders associated with Mallory-Denk bodies are given in Table 21.57.

ALCOHOLIC CIRRHOSIS

Development of irreversible perivenular and perisinusoidal fibrosis in acute alcoholic steatohepatitis may progress to cirrhosis. Chronic alcoholism is the most frequent cause of cirrhosis.

Initially, patient develops micronodular cirrhosis and later progresses to typical hobnail liver with large, irregular parenchymal regenerative nodules (macronodular cirrhosis). Laennec cirrhosis shows replacement of entire liver lobule by tough pale fibrous scar tissue.

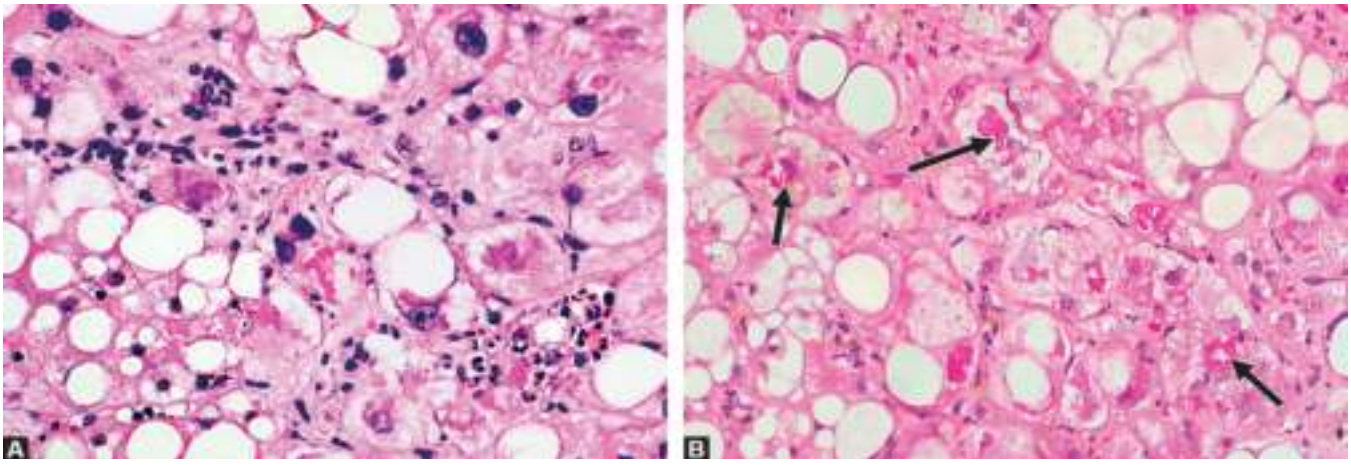

Fig. 21.59: Acute alcoholic steatohepatitis. (A) Hepatocytes show an accumulation of fat and Mallory's hyaline. It is infiltrated by neutrophils, (B) Mallory's hyaline. At high magnification can be seen globular red hyaline material. This is Mallory's hyaline, also known as alcoholic hyaline because it is most often seen in conjunction with chronic alcoholism. The globules are aggregates of intermediate filaments in the cytoplasm resulting from hepatocyte injury (arrows) (400X).

Table 21.57 Liver disorders associated with Mallory-Denk bodies

Category	Disorder
Excessive alcohol consumption	Alcoholic liver disease
Biliary tract disease	▪ Biliary atresia ▪ Extrahepatic bile duct obstruction ▪ Primary biliary cirrhosis ▪ Primary sclerosing cholangitis
Inherited disorders	▪ α_1-Antitrypsin deficiency ▪ Abetalipoproteinemia ▪ Glycogen storage disease 1α ▪ Wilson disease
Drug-induced disorders	▪ Ethanol ▪ Amiodarone
Cirrhosis of unknown etiology	▪ Indian childhood cirrhosis ▪ Nonalcoholic steatohepatitis
Hepatocellular tumors	▪ Hepatic adenoma ▪ Hepatocellular carcinoma
Other cause	Focal nodular hyperplasia

Surgical Pathology: Alcoholic Cirrhosis

Gross Morphology

- The liver may be enlarged or small and shrunken. The pattern is most often micronodular.
- In late stages, the regenerating nodules tend to become larger and irregular; this pattern results in a scarred, shrunken liver termed the hobnail liver (Fig. 21.60).

Light Microscopy

- Hepatic architecture is obscured by fibrous bands surrounding regenerating nodules of distorted liver cell plates.
- The fibrous bands show proliferating bile ducts, lymphocytes and plasma cells (Fig. 21.61).

Fig. 21.60: Alcoholic cirrhosis. Cut surface of liver shows parenchymal regenerative nodules of variable size.

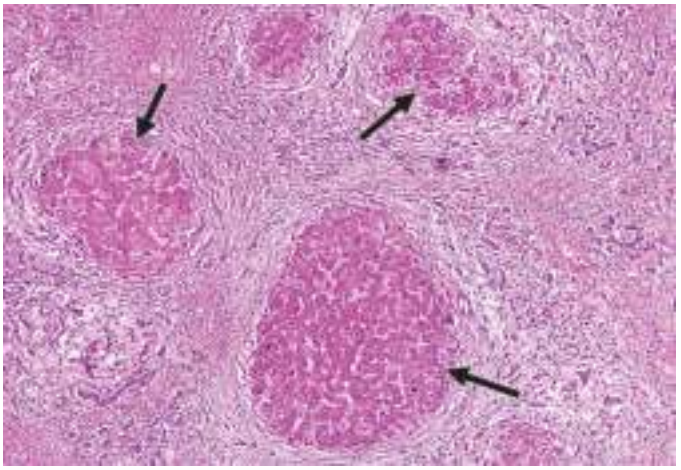

Fig. 21.61: Alcoholic liver cirrhosis. It shows parenchymal regenerative nodules surrounded by fibrous connective tissue that bridges between portal tracts. Within this collagenous tissue is scattered lymphocytes as well as a proliferation of bile ducts (arrows) (100X).

Table 21.58 Differences between alcoholic and post-necrotic cirrhosis

Parameters	Alcoholic Cirrhosis	Post-necrotic Cirrhosis
Nodules in liver		
Size of nodules in liver	Initially micronodular cirrhosis later mixed micronodules and macronodules giving hobnail appearance	Macronodules
Gross morphology		
External surface	Initially, liver yellow-tan in color, later brown colored	Liver small, shrunken and distorted. It shows irregular coarse scars and nodules
Cut surface	Cut surface showing multiple nodules of variable sizes	Cut surface revealing macronodules of variable sizes
Light microscopy		
Fibrous septa	Initially delicate and later thick fibrous septa	Generally thick fibrous septa
Inflammatory cells	Sparse infiltration of fibrous septa by macrophages, lymphocytes and plasma cells	Heavy infiltration of fibrous septa by macrophages, lymphocytes and plasma cells resulting in formation of lymphoid follicles
Mallory body	May be present but rare	Absent
Proliferation of bile ducts	Minimal proliferation	Extensive proliferation
Fatty change in liver	May show fatty change in liver	Absent

Consequences of Cirrhosis

Consequences of intrahepatic scarring with increased portal venous pressure lead to esophageal varices often resulting in upper gastrointestinal tract hemorrhage, rectal hemorrhoids, periumbilical venous collaterals (caput medusae) and splenomegaly.

Differences between alcoholic and post-necrotic cirrhosis are given in Table 21.58.

Clinical Features

Patient with alcoholic cirrhosis presents with jaundice, distended abdomen, esophageal varices, caput medusae, massive splenomegaly with elevated serum transaminase (AST and ALT) levels and serum alkaline phosphatase. Serum protein levels are decreased. Clinical manifestations associated with hepatocellular damage and hepatocellular failure are described as under.

- **Jaundice:** It is most often mixed conjugated and unconjugated.
- **Hypoalbuminemia:** It is caused by decreased albumin synthesis in damaged hepatocytes.
- **Decreased synthesis of coagulation factors:** Liver synthesizes less amount of coagulation factors with the exception of von Willebrand factor.
- **Hyperestrinism:** Patient presents with palmar erythema; spider nevi (capillary telangiectasia) of the face, upper arms, and chest; loss of body and pubic hair; testicular atrophy; and gynecomastia.
- **Peripheral edema, ascites or hydrothorax:** These manifestations occur by various mechanisms. Liver fails to synthesize albumin leading to decreased plasma oncotic pressure. Increased portal venous pressure leads to increased production of hepatic lymph, retention of sodium and water as a result of decreased hepatic degradation of aldosterone, activation of the renin-angiotensin system, or both.
- **Hepatic encephalopathy (portal-systemic encephalopathy):** It is facilitated by shunting from the portal to the systemic circulation, with delivery of neurotoxic substances, such as ammonia and other enteric degradation products, directly into the systemic circulation. Neurological manifestations varying from slight confusion to deep coma along with asterixis (flapping tremor of hands) are characteristic features.

NONALCOHOLIC FATTY LIVER DISEASE

Nonalcoholic fatty liver disease (NAFLD) is so named because it closely resembles alcoholic fatty liver disease. This condition represents a spectrum of hepatocellular injuries that initially display steatosis, with or without hepatitis. NAFLD may progress to bridging fibrosis and cirrhosis of liver. It is consistently associated with metabolic syndromes characterized by central obesity, type 2 diabetes mellitus, dyslipidemia, and microalbuminuria.

- Nonalcoholic fatty liver disease occurs in the settings of insulin resistant diabetes mellitus, lack of exercise

and genetic/epigenetic alteration mechanisms. Hepatocellular injury is caused by oxidants and inflammatory cells induced by chemical mediators such as TNF-α and IL-1. Activation of stellate cells by TNF-α, TNF-β and NK cell results in fibrosis in liver.

Surgical Pathology: Nonalcoholic Fatty Liver Disease

Light Microscopy

- Steatosis is defined as the involvement of >5% of hepatocytes.
- Essential features of nonalcoholic fatty liver disease (NAFLD) include macrovesicular hepatocytes in the zone 3, mild mixed acinar inflammation and hepatocellular injury in the form of hepatocellular degeneration in zone 3 and/or pericellular fibrosis.
- In comparison to acute alcoholic steatohepatitis, Mallory-Denk hyaline bodies are less prominent, but mild mixed acinar inflammation is more prominent. Nonalcoholic fatty liver disease may lead to cirrhosis over years (Fig. 21.62A and B). Comparison between acute alcoholic steatohepatitis and nonalcoholic fatty liver disease is given in Table 21.59.
- Other histologic features may be present, but not essential for diagnosis include Mallory-Denk hyaline bodies in zone 3, mild iron deposition in hepatocytes or sinusoidal cells and megamitochondria; and glycogenated nuclei in zone 1, lipogranulomas in the lobular parenchyma or portal tracts and occasional eosinophilic bodies.

- Grading and staging of nonalcoholic fatty liver disease (NAFLD) is given in Tables 21.60 and 21.61.

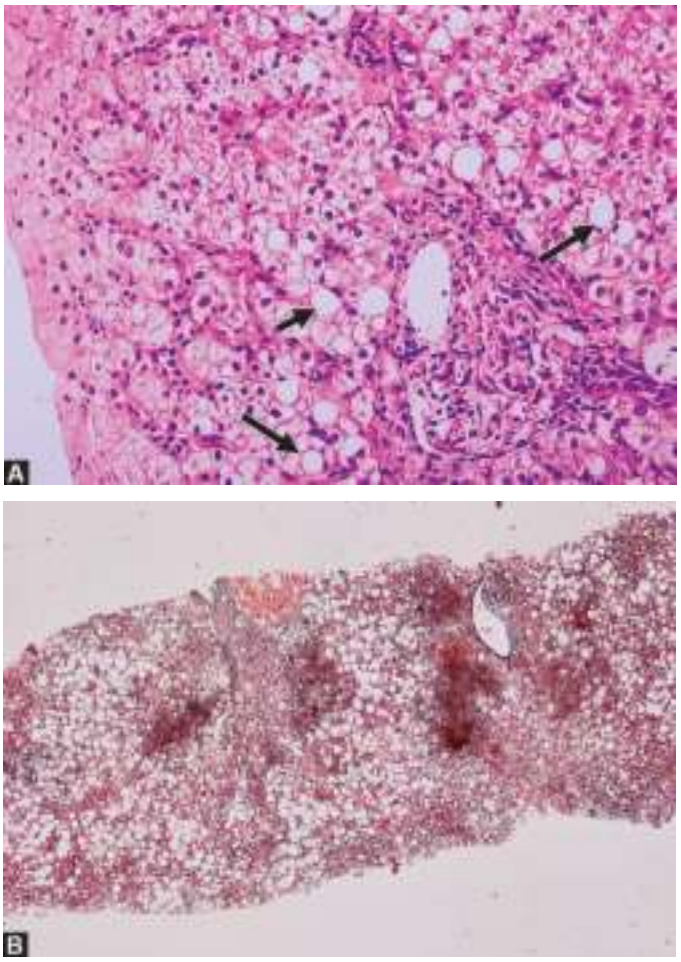

Fig. 21.62A and B: Nonalcoholic fatty liver disease (NAFLD). (A) Histologic examination of liver reveals steatosis involving more than 5% of hepatocytes in zone 3, lobular inflammation (polymorphonuclear cells, lymphocytes, plasma cells), and macrophages, hepatocellular ballooning in zone 3 and perisinusoidal fibrosis in zone 3. Small lipogranulomas or acidophil PAS stained Kupffer cells can be demonstrated in the lobular parenchyma (arrows) (400X). (B) Reticulin staining is done to demonstrate fibrosis in nonalcoholic fatty liver disease. The characteristic pattern of fibrosis in nonalcoholic steatohepatitis is sinusoidal/pericellular (chicken wire) fibrosis, which usually begins in zone 3 and demonstrated by reticulin staining technique.

HEMOCHROMATOSIS

Hemochromatosis is characterized by excessive deposition of iron deposition in the parenchymal cells of liver, pancreas, heart, skin, joints and other organs resulting in organ damage. Disease manifests when body storage iron exceeds 20 g.

- Clinical manifestations occur due to excessive hemosiderin deposition in various organs. Iron in tissues

Table 21.59 Comparison between acute alcoholic steatohepatitis and nonalcoholic steatohepatitis

Parameters	Acute Alcoholic Steatohepatitis	Nonalcoholic Steatohepatitis
History	Alcohol intake	▪ Diabetes mellitus ▪ Hyperlipidemia ▪ Metabolic diseases ▪ Bypass surgery
AST/ALT ratio	AST/ALT >2	AST/ALT <1
Steatosis features	▪ Macrovesicular steatosis ▪ Central venular distribution of steatosis ▪ Fibrosis around central venules	▪ Microvesicular steatosis ▪ Diffuse distribution of steatosis ▪ Portal fibrosis
Mallory-Denk hyaline bodies	Frequent	Less frequent

Table 21.60 Component scores for grading nonalcoholic fatty liver disease (NAFLD)

Stage	Steatosis	Lobular Inflammation	Hepatocellular Ballooning
Stage 0	<5%	None	None
Stage 1	5–33%	<2/20 × per field	Mild (few)
Stage 2	34–66%	2–4/20 × per field	Moderate to marked
Stage 3	>66–100%	>4/20 × per field	Moderate to marked

NAFLD activity score: NAS 0–8 (steatosis + lobular inflammation + ballooning)

Table 21.61 Fibrosis scoring: Based on Masson trichrome stain for nonalcoholic fatty liver disease (NAFLD)

Stage	Masson Trichrome
Stage 0	None
Stage 1a	Delicate zone 3 perisinusoidal fibrosis and requires trichrome stain
Stage 1b	Dense zone 3 perisinusoidal fibrosis, visible on hematoxylin and eosin
Stage 1c	Portal/periportal fibrosis
Stage 2	Zone 3 perisinusoidal and portal fibrosis
Stage 3	Bridging fibrosis
Stage 4	Cirrhosis

is demonstrated by Perls Prussian blue staining technique.

- Patient may present with triad of hepatomegaly, diabetes mellitus and skin pigmentation is known as bronze diabetes.
- Patients are at great risk of developing congestive heart failure secondary to iron deposition in the heart; cirrhosis and hepatocellular carcinoma.
- Serum iron, transferrin saturation and serum ferritin levels are increased. Hemochromatosis is treated by repeated phlebotomy and deferoxamine. Distribution of normal iron in adults is given in Table 21.62. Causes of primary and secondary hemochromatosis are given in Table 21.63.

Table 21.62 Distribution of normal iron in adults

Iron	Examples of Iron in Body	Values of Total Body Iron (3.0–5.0 g)
Functional iron	▪ Hemoglobin ▪ Essential/functional/nonavailable iron	▪ 1.5–3.0 g ▪ Myoglobin: 0.3 g ▪ Enzymes of cellular respiration: 0.05 g
Storage/available tissue iron	▪ Ferritin ▪ Hemosiderin	1.2–2.0 g
Plasma iron	Transferrin bound iron for transport	3–4 mg

Genetic hemochromatosis refers to >50 g of total body iron. Normal liver contains 0.5 g in 98% of hepatocytes.

Table 21.63 Causes of primary and secondary hemochromatosis

Causes	Disorders	
Primary hemochromatosis		
Genetic hemochromatosis	Mutation of HFE gene on chromosome 6	
Secondary hemochromatosis		
Parenteral iron overload due to frequent blood transfusions and iron dextran injections	▪ Aplastic anemia ▪ Leukemias ▪ Sickle cell anemia	▪ Myelodysplastic syndrome ▪ Long-term hemodialysis
Ineffective erythropoiesis with increased erythroid activity	▪ β-Thalassemia ▪ Sideroblastic anemia	▪ Pyruvate kinase deficiency
Increased oral intake of iron	Bantu siderosis also called African iron overload	
Chronic liver disease	▪ Chronic alcohol disease	▪ Porphyria cutanea tarda
Congenital atransferrinemia	Hereditary disorder	
Neonatal hemochromatosis	Abnormal accumulation of iron in the tissues	

- Primary hemochromatosis is caused by a mutation in the type 1 HH, an autosomal recessive disorder (HFE gene), type 2 HH is more severe, an autosomal recessive disorder (hemojuvelin and hepcidin), type 3 HH, an autosomal recessive disorder (transferrin receptor type 2) and type 4 HH, an autosomal dominant disorder (ferroportin 1). Hepcidin is the main regulator of iron absorption. It is also known as liver expressed antimicrobial peptide (LEAP) encoded by HAMP gene located on the short arm of chromosome 6p21.3 in close linkage with HLA locus.
- Secondary hemochromatosis is associated with chronic blood transfusion therapy, ineffective erythropoiesis, or increased oral intake of iron.

PRIMARY/HEREDITARY HEMOCHROMATOSIS

Primary/hereditary hemochromatosis (HH) is caused by a mutation in the type 1 HH is an autosomal recessive disorder (HFE gene), type 2 HH more severe, an autosomal recessive disorder (hemojuvelin and hepcidin), type 3 HH, an autosomal recessive disorder (transferrin receptor type 2) and type 4 HH, an autosomal dominant disorder (ferroportin 1). Unrestricted intestinal iron absorption and mobilization of iron from storage sites result in excessive deposition of iron in parenchymal organs (liver, pancreas, myocardium, endocrine glands, joints, testes and skin) and cause organs damage. Iron stimulates hepatic stellate cells, which promote fibrosis in liver.

Molecular Pathogenesis: Hereditary Hemochromatosis

Four types of primary/hereditary hemochromatosis are given in Table 21.64.

Hereditary Hemochromatosis Type 1

- Hepcidin is the main regulator of iron absorption. It is also known as LEAP (liver expressed antimicrobial peptide) encoded by HAMP gene located on the short arm of chromosome 6p21.3 in close linkage with HLA locus.
- HH type 1 is an autosomal recessive disorder due to hepcidin mutation. Hepcidin mutation leads to low hepcidin level and consequent excess iron absorption and increased mobilization of iron from macrophages.
- HH type 1 is the most common type of hemochromatosis. Two most commonly described mutations are C282Y (substitution of cytosine to tyrosine to aspartate an amino acid at position 282) and H63D (substitution of histidine to aspartate an amino acid at position 63).
- Excessive iron deposition in hepatocytes is more prominent in the periportal region. Patients can be autosomal recessive C282Y, homozygous C282Y and double heterozygous.
- Patient presents in third and fourth decades due to excessive deposition of iron in the liver, pancreas, heart, skin and joints.
- Evidence of excessive iron overload can be assessed by serum ferritin, MRI and liver biopsy.
- Serum ferritin is a highly sensitive index of elevated iron.
- Normal serum ferritin excludes iron overload. Serum ferritin more than 1000 ng/L, elevated ALT, hepatomegaly are risk factors of fibrosis resulting in cirrhosis and hepatocellular failure. Liver biopsy can be considered in these patients.

Hereditary Hemochromatosis Type 2 (Juvenile Type 2 HH)

- HH type 2 occurs in two forms: autosomal recessive mutations involving hemojuvelin located on chromosome 1 (2A) or hepcidin located on chromosome 19 (2B). Hemojuvelin (HJV) mutation leads to low hepcidin level resulting in increased iron mobilization from intestine and macrophages.
- Most cases equally affecting males and females occur due to hemojuvelin gene mutation.
- Excessive iron deposition occurs in the hepatocytes associated with cardiomyopathy and hypogonadism. Patient presents in first three decades with more severe disease compared to HFE associated type 1 (HH).

Hereditary Hemochromatosis Type 3

- HH type 3 is an autosomal recessive disorder. It occurs due to mutation involving transferrin receptor type 2 gene located on chromosome 7.
- It tends to similar to type 1 HFE-HH. Excessive iron deposition occurs in hepatocytes.
- Patient presents in third and fourth decades due to excessive deposition of iron in the liver, pancreas, heart, skin and joints.

Hereditary Hemochromatosis (Ferroportin Disease) Type 4

- HH type 4 is an autosomal disorder caused by mutation involving ferroportin 1 located on chromosome 2.
- Patient presents in fourth decade; severity varies with type of mutation.

Organs Involved and Resulting Complications

Many organs are involved in primary hemochromatosis (Fig. 21.63).

- **Liver:** It shows features of micronodular cirrhosis. Hepatocytes as well as Kupffer cells show excessive deposition of brown granules of hemosiderin. Liver iron concentration is >400 mg/100 g of wet liver in primary hemochromatosis. Normal wet liver contains iron concentration <30 mg/100 g of wet liver Perls Prussian blue iron stain demonstrates the blue granules of hemosiderin in hepatocytes and Kupffer cells (mononuclear phagocyte system). Most common causes of death are **cirrhosis** and **hepatocellular carcinoma**.
- **Pancreas:** Excessive deposition of iron in islets of Langerhans of pancreas causes diffuse interstitial fibrosis resulting in diabetes mellitus.
- **Myocardium:** Excessive deposition of iron in myocardium may cause restrictive myocarditis, cardiac arrhythmias and congestive heart failure.

Table 21.64 Types of primary/hereditary hemochromatosis (HH)

Type	Genetics	Liver Biopsy	Clinical Features
Type 1 (HFE-associated HH)	Autosomal recessive disorder involving HFE gene located on chromosome 6 (C282Y, homozygous C282Y and double heterozygous)	Excessive iron deposition in hepatocytes, more prominent in the periportal region	Patient presents in third and fourth decades due to excessive deposition of iron in the liver, pancreas, heart, skin and joints
Type 2 (juvenile HH)	Autosomal recessive disorder with mutations involving hemojuvelin on chromosome 1 (2A) or hepcidin on chromosome 19 (2B)	Excessive iron deposition in hepatocytes	Patient presents in first three decades with more severe disease compared to HFE associated HH
Type 3 (HH)	Autosomal recessive disorder with mutation involving transferrin receptor type 2 gene located on chromosome 7	Excessive iron deposition in hepatocytes	Patient presents in third and fourth decades similar to HFE-associated HH but intermediate between type 1 and type 2 due to excessive deposition of iron in the liver, pancreas, heart, skin and joints
Type 4 (HH)/ ferroportin disease	Autosomal dominant with mutation involving ferroportin 1 located on chromosome 2	First subtype excessive iron deposition in hepatocytes, second subtype excessive iron deposition in Kupffer cells	Patient presents in fourth decade; severity varies with type of mutation

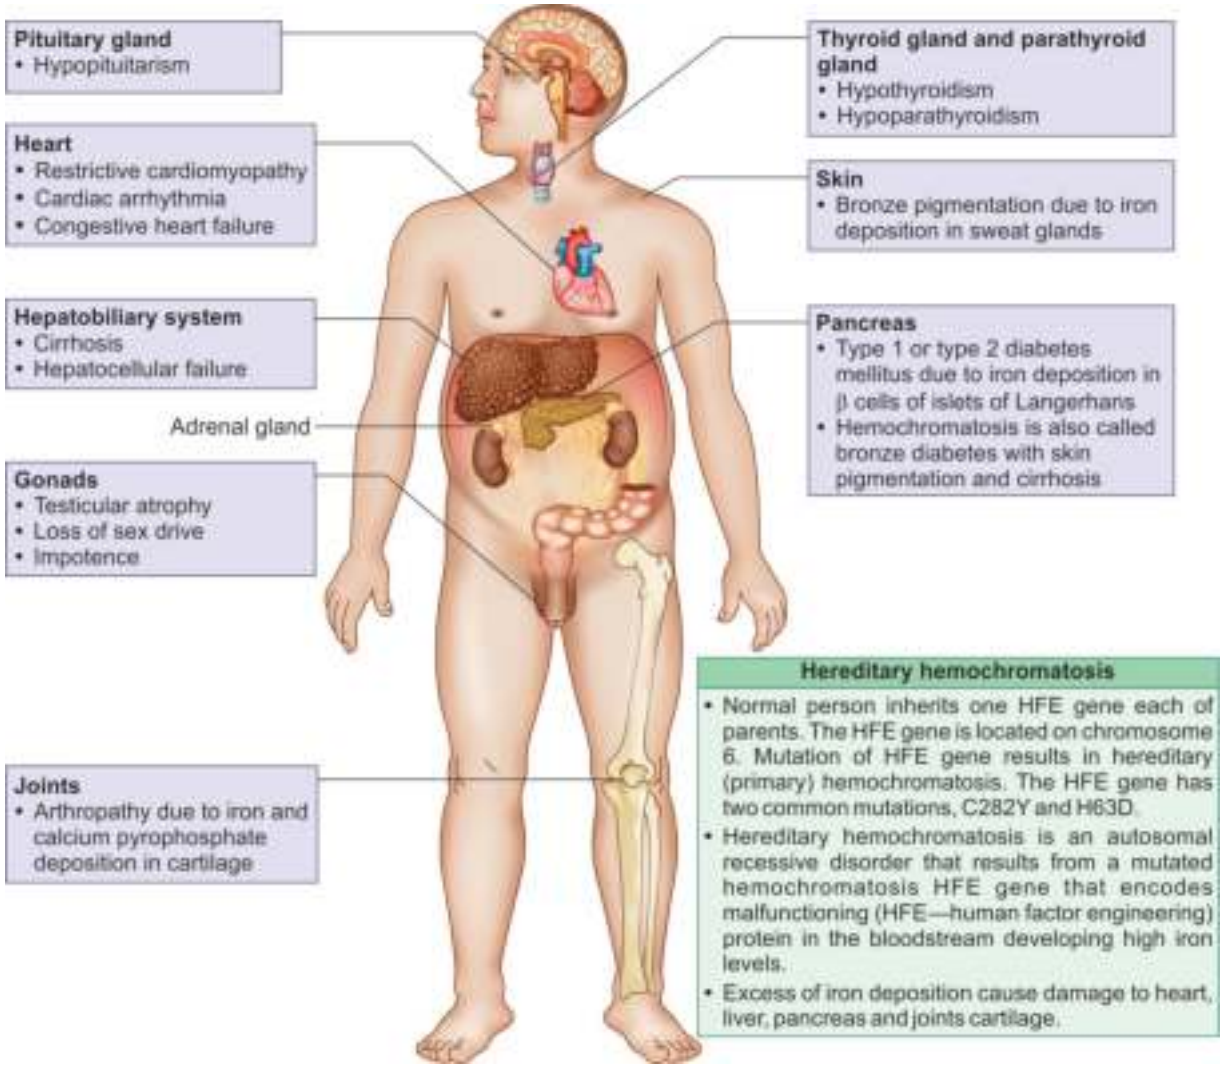

Fig. 21.63: Primary hemochromatosis. It shows involvement of multiple organs due to deposition of iron.

- **Endocrine glands:** Excessive deposition of iron in thyroid, parathyroid, pituitary and adrenal glands may lead to endocrinal gland dysfunction.
- **Joints:** Excessive iron is deposited in synovial linings of joints in 30 to 50% of cases. Cartilage damage leads to disabling polyarthritis.
- **Skin pigmentation:** Skin pigmentation on face, neck and extensor surface of forearms occurs due to deposition of melanin and hemosiderin in 70 to 90% of patients. It is component of bronze diabetes mellitus.
- **Testes:** Small atrophic testes (hypogonadism) in primary hemochromatosis occur due to impairment of hypothalamopituitary function due to iron deposition and not due to excessive deposition of iron in testes.

Clinical Features

Patient with primary hemochromatosis presents with hepatomegaly, abdominal pain, skin pigmentation, diabetes mellitus or deranged glucose metabolism, cardiac dysfunction, amenorrhea in females, decreased libido and impotence in males. Cause of death is due to development of hepatocellular carcinoma, cardiac dysfunction and hepatocellular failure. Chelating agent **desferrioxamine** is administered in these patients with severe anemia and hypoproteinemia.

Surgical Pathology: Primary Hemochromatosis in Liver

Light Microscopy

Hepatocytes as well as Kupffer cells show excessive deposition of brown granules of hemosiderin (Fig. 21.64).

Screening Tests

The recommended screening test for primary hemochromatosis is increased serum transferrin saturation. In selected cases, molecular testing is done to demonstrate mutations in the HFE gene in tissues. Early detection and occasional phlebotomy can prevent multiorgan failure attributed to iron accumulation in tissues.

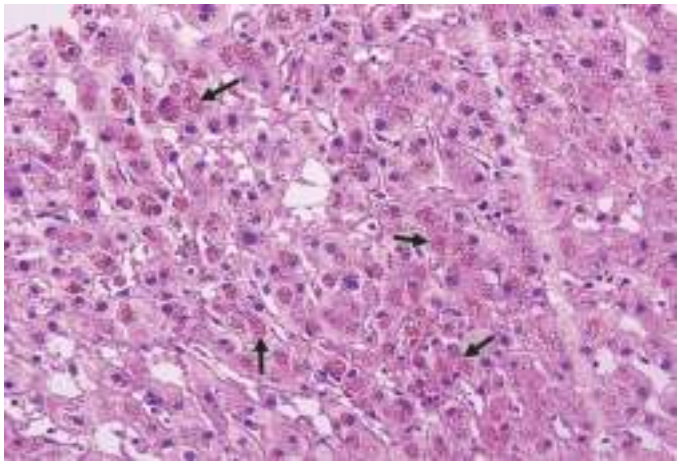

Fig. 21.64: Primary hemochromatosis involving liver. Hepatocytes as well as Kupffer cells show excessive deposition of brown granules of hemosiderin (arrows) (400X).

Laboratory Diagnosis

- There is marked increase in serum iron and modest reduction in total iron-binding capacity (TIBC, transferrin). This combination results in increased transferrin iron saturation (100%).
- Serum ferritin levels are increased >500 ng/ml (normal value is <150 ng/ml) in these patients.
- Blood biochemistry such as blood sugar and urine analysis should be done in patients with bronze diabetes. Iron is demonstrated by Perls Prussian blue reaction in the tissues. Scheuer system of grading of liver iron is given in Table 21.65.

Pathology Pearls: Liver Biopsy for Iron Analysis in Primary Hemochromatosis

- Liver biopsy specimen should be sent in two cores. One core fixed in 10% formalin is submitted for histopathologic examination. Other core wrapped in lens paper submitted for measurement of drug weight iron on molecular testing.
- Hepatic iron index is calculated by hepatic iron in micromole/gram dry weight and age. Hepatic iron <1 is normal.
- Hepatic iron >2 g is diagnostic of primary hemochromatosis.

Prognosis

Common causes of death from primary hemochromatosis are liver cirrhosis, cardiac failure and hepatocellular carcinoma.

SECONDARY HEMOCHROMATOSIS

Secondary hemochromatosis is most often associated with a combination of ineffective erythropoiesis and multiple blood transfusions in β-thalassemia major, high intake of iron and '**Bantus siderosis**' due to consumption of traditional beer home-brewed in steel drums.

Excessive iron is deposited largely in mononuclear phagocytic system, which in some instances, may spill over into parenchymal cells, producing a hybrid condition.

Table 21.65 Scheuer system of grading of liver iron

Iron Grade	Interpretation of Results
Grade 0	Hemosiderin granules absent or barely discernible at 400X
Grade 1	Hemosiderin granules barely discernible at 250X, easily demonstrated
Grade 2	Discrete hemosiderin granules demonstrated at 100X
Grade 3	Discrete hemosiderin granules demonstrated at 25X
Grade 4	Masses of hemosiderin granules demonstrated at 10X

WILSON DISEASE

Wilson disease is an autosomal recessive disorder of copper metabolism in which excess copper can be deposited in the liver and brain due to impaired transport of copper across lysosomal membrane or bile canaliculi. Ceruloplasmin levels are decreased in Wilson disease secondary to copper deposition in liver, basal ganglion and corneal limbus.

- **Normal copper metabolism:** Copper absorbed from proximal small intestine is bound to apoceruloplasmin in liver to form ceruloplasmin, that is secreted into the blood, which is then taken up by liver and broken down in lysosomes. Released copper is then excreted through the bile.
- **Pathogenesis:** In Wilson disease, mutation of ATP7B gene located on chromosome 13 leads to deficiency of a copper transporting ATPase resulting in decrease in copper transport into bile and impairing its incorporation into ceruloplasmin. Accumulated copper causes toxic injury to organs by oxygen-derived free radical mediated injury and displacing of metals from metalloenzymes (Table 21.66).

Table 21.66 Organs involved in Wilson disease and consequences

Organs Involved	Wilson Disease
Liver	▪ Steatosis ▪ Acute/chronic hepatitis ▪ Micronodular/macronodular cirrhosis
Eye	Kayser-Fleischer rings due to brown deposits of copper in Descemet membrane in the limbus of cornea demonstrated by slit-lamp eye examination
Kidney tubules	▪ Aminoaciduria ▪ Glycosuria
Brain	Basal ganglia especially putamen involvement impairing extrapyramidal functions, e.g. psychosis and tremors

- **Pathology:** Accumulation of copper in various organs results in liver (e.g. chronic hepatitis to micronodular or macronodular cirrhosis), brain (e.g. basal ganglia especially the putamen of the lenticular nucleus impairing extrapyramidal motor functions), kidney tubular cells (e.g. aminoaciduria and glycosuria), and eye (e.g. Descemet membrane known as '**Kayser-Fleischer ring**').
- **Clinical features:** Patient presents with neuropsychiatric symptoms and movement disorders, rigid dystonia as a result of basal ganglia involvement. Patient may also present with symptoms of acute or chronic liver disease and ocular Kayser-Fleischer ring.

Surgical Pathology: Cirrhosis in Wilson Disease

Light Microscopy

- Liver biopsy shows chronic hepatitis and fatty change.
- Liver cell nuclei are vacuolated.
- Mallory bodies in periportal hepatocytes and piecemeal necrosis are present in the cytoplasm.
- Stainable copper is present in liver cells.
- Cirrhosis occurs following chronic hepatitis.

Histochemistry

Excessive copper in tissues can be demonstrated by **rhodamine stain** or reddish orange orcein for copper and orcein stain for copper associated protein.

Biochemical Investigations

Decreased serum ceruloplasmin, increased hepatic copper level (>250 μg/1 g dry weight of liver) and increased urinary copper are consistently seen in Table 21.67).

α_1-ANTITRYPSIN DEFICIENCY

The α_1-antitrypsin deficiency is the most common autosomal recessive disorder of liver disease in infants and children in which liver transplantation is indicated.

Table 21.67 Laboratory diagnosis of Wilson's disease

Test	Results
Ocular findings	Kayser-Fleischer rings
Hepatic copper content (confirmatory test)	250 g copper per 10 g of dried liver tissue
Serum ceruloplasmin level (most specific screening)	Decreased
Urinary excretion of copper	Increased
Rhodamine stain	Used to stain copper
Reddish orange orcein stain	Used to stain copper associated protein

Table 21.68 Liver diseases associated with α_1-antitrypsin deficiency in age groups

Liver Disorder	Clinical Features	Light Microscopy
Neonatal hepatitis	Cholestasis jaundice	▪ Cholestasis (marked) ▪ Liver cell necrosis ▪ Lymphocytes, plasma cells and macrophages infiltration ▪ Globules of α_1-antitrypsin demonstrated after attaining 6 months of age ▪ Recovery is common
Childhood cirrhosis	Persistence of jaundice >6 months	Cirrhosis
Adult macronodular cirrhosis (60–70 years)	Only liver involved and lungs spared	▪ Cirrhosis (globules of α_1-antitrypsin demonstrated) ▪ Hepatocellular carcinoma

Liver may be involved with or without lung disease in the form of emphysema. There is increased risk of development of hepatocellular carcinoma.

- The disorder may affect infants, children and adults. Liver diseases associated with α_1-antitrypsin deficiency in these age groups are given in Table 21.68.
- Normally α_1-antitrypsin (AAT) is a protein encoded by SERPINA-1 gene on the proteinase inhibitor locus (Pi) on chromosome 14. It is synthesized by liver in normal genotype persons (PiMM phenotype). This protein prevents elastases to degrade normal host tissue. It accounts for 90% of antiproteinase activity in the blood.
- The α_1-antitrypsin (AAT) deficiency is an autosomal dominant disorder equally affecting men and women. Most patients with clinically-diagnosed emphysema <40 years of age have α_1-antitrypsin (PiZZ phenotype) deficiency.

Pathology Pearls: Clinical Consequences in α_1-Antitrypsin Deficiency

- Homozygous PiZZ genotype patients deficient in α_1-antitrypsin (AAT) (<11 μm/L) are prone to develop panacinar emphysema, cirrhosis, cutaneous panniculitis, neonatal hepatitis, bronchiectasis and Wegener's granulomatosis. Serum electrophoresis reveals absence of α_1-globulin peak.
- Tobacco smoking appears to be the most important risk factor for the development of panacinar emphysema among AAT deficient persons. Among smokers, even mild to moderate reduction in AAT levels may be associated with panacinar emphysema resulting in more rapid decline in lung function.
- Destruction of lung parenchyma and consequent emphysema results from an imbalance between the major natural antiprotease, AAT and inflammatory proteases (especially leukocyte elastase). Intravenous purified pooled human plasma is recommended to enhance ATT levels in these patients.

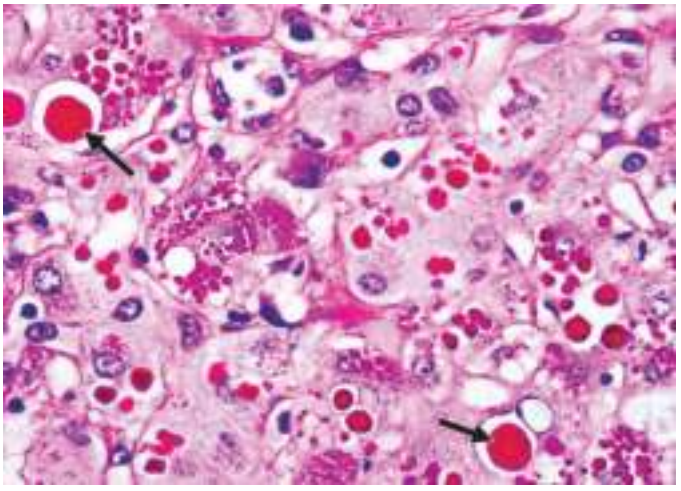

Fig. 21.65: The α_1-antitrypsin (AAT) deficiency. The periportal red hyaline globules seen here with periodic acid–Schiff (PAS) stain are characteristic for α_1-antitrypsin deficiency (a person with homozygous PiZZ genotype). The globules are intrahepatic collections of α_1-antitrypsin that is not being excreted from the hepatocytes. This may eventually lead to a macronodular cirrhosis. These patients are also prone to develop panacinar emphysema of lungs (arrows) (400X).

Surgical Pathology: Liver in α_1-Antitrypsin Deficiency

Light Microscopy

- Histologic examination of liver biopsy shows round-to-oval cytoplasmic globular inclusions of misfolded α_1-antitrypsin PAS positive diastase resistant proteins in hepatocytes.
- These globules stain red with PAS after removing glycogen with diastase (Fig. 21.65).

GLYCOGEN STORAGE DISEASE TYPE 4

Andersen disease, also known as glycogen storage disease type 4, is an autosomal recessive disorder caused by deficiency of a glycogen-branching enzyme. This enzyme deficiency results in the accumulation of abnormal glycogen (amylopectin) in the liver, muscle, and other tissues.

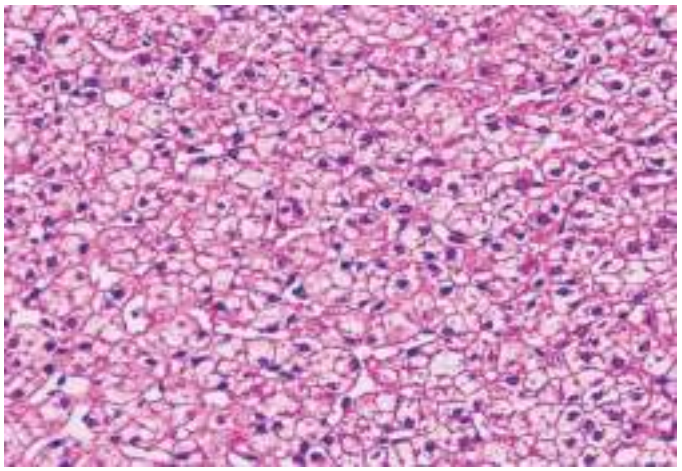

Fig. 21.66: Glyocogen storage disease in liver. It shows deposition of glycogen in hepatocytes giving mosaic appearance (400X).

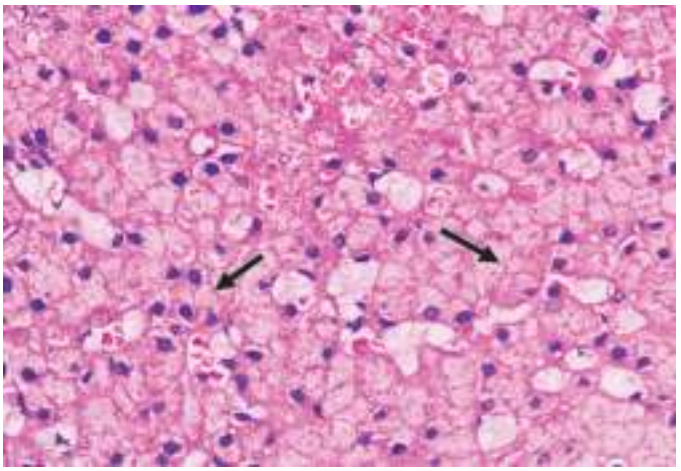

Fig. 21.67: Niemann-Pick disease. Liver Kupffer cells show foamy histiocytes containing sphingomyelin (arrows) (400X).

- In most affected persons, the disorder becomes evident in the first month of life. Patient presents with failure to thrive and hepatomegaly. Disease progresses to hepatic fibrosis leading to cirrhosis and hepatocellular failure.
- Histologic examination of liver biopsy shows pale distended hepatocytes giving mosaic appearance.
- PAS diastase histochemical staining and electron microscopy may help in confirming diagnosis (Fig. 21.66).

NIEMANN-PICK DISEASE

Niemann-Pick disease is a hereditary lysosomal storage disease due to deficiency of sphingomyelinase resulting in accumulation of sphingomyelin in phagocytes (types A and B Niemann-Pick disease). Type C Niemann-Pick disease is caused by defect in a gene involved in cholesterol transport with cholesterol accumulation within phagocytes.

- Diagnostic hallmark of Niemann-Pick disease is presence of foamy histiocytes containing sphingomyelin in liver, spleen, lymph nodes, and skin.
- Child presents with hepatosplenomegaly, anemia, fever and neurologic manifestations. Approximately 50% of the patients develop cherry red spot in the macula similar to that of Tay-Sachs disease. Death occurs by 3 years of age.

Surgical Pathology: Liver in Niemann-Pick Disease

Light Microscopy

Histologic examination of liver biopsy shows foamy histiocytes containing sphingomyelin in Kupffer cells (Fig. 21.67).

GAUCHER'S DISEASE

Gaucher's disease is an autosomal recessive disorder most often seen in persons of European Ashkenazi Jewish lineage. Disease is characterized by accumulation of glucosylceramide (membrane glycosphingolipids) derived from the catabolism of senescent leukocytes, primarily in the lysosomes of macrophages.

The membranes of macrophages are rich in the cerebrosides. Their degradation is blocked by the deficiency of glucocerebrosidase (lysosomal acid β-glucosidase), an intermediate metabolite such as glucosylceramide accumulates.

- **Adult Gaucher's disease (type 1):** It accounts for 80% of cases. Patient presents with hepatosplenomegaly, bone pain and fracture due to erosion of femoral head and other long bones.
- **Infantile Gaucher's disease (type 2):** Infant develops severe CNS involvement associated with fatal outcome before 1 year of age.
- **Juvenile Gaucher's disease (type 3):** Its onset usually occurs in early childhood. There is involvement of brain and visceras. It is less severe than Gaucher's disease (type 2).

Surgical Pathology: Liver in Gaucher's Disease

Light Microscopy

- Histologic examination of liver biopsy shows Gaucher's cells with a distinctive cigarette paper-like cytoplasmic appearance and eccentric nuclei, which are lipid-laden macrophages present along liver sinusoids (Kupffer cells).
- Diagnosis is confirmed by presence of Gaucher's cells, and assay of specific enzymes (chitotriosidase and angiotensin-converting enzyme markers of macrophage proliferation) (Fig. 21.68).

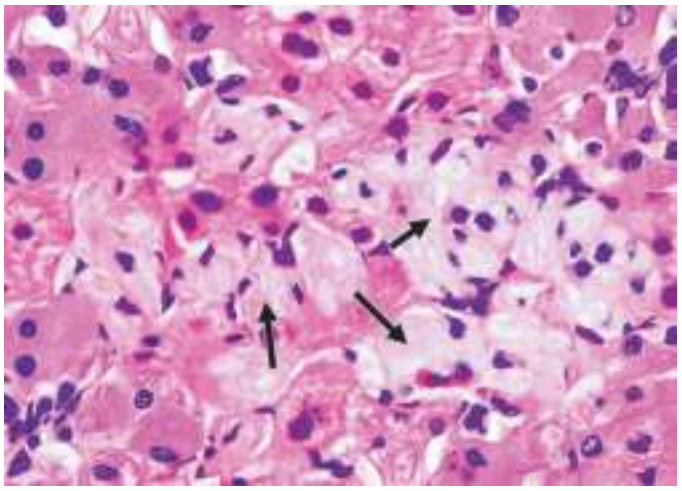

Fig. 21.68: Gaucher's disease. It shows cell containing cigarette paper-like cytoplasmic appearance and eccentric nuclei, which are lipid-laden macrophages (arrows) (400X).

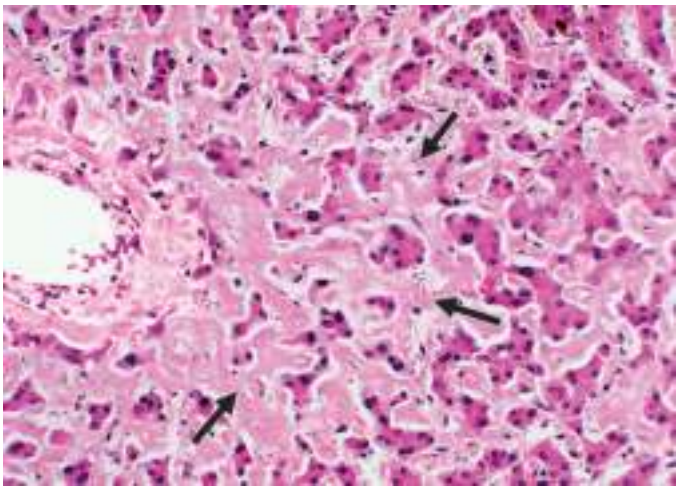

Fig. 21.69A: Amyloid deposit of liver. It shows deposition of amyloid material in the space of Disse between the hepatocytes and vascular sinusoids leading to compression of hepatic cords (arrows) (400X).

AMYLOIDOSIS OF LIVER

Amyloidosis is a well-known complication of chronic inflammatory disorders, i.e. tuberculosis, bronchiectasis, rheumatoid arthritis, or osteomyelitis. It stimulates the production of amyloid from the serum amyloid A (SAA) protein, an acute phase reactant secreted by the liver. The kidneys in 80% of cases, liver, spleen, and adrenals are the most common organs involved.

Surgical Pathology: Amyloidosis of Liver
Gross Morphology
Amyloid liver is usually grossly enlarged (as much as 900 g), pale, and smooth surface, firm in consistency. When sectioned, it shows sharp rigid edges.
Light Microscopy
▪ Amyloid material is initially deposited in the space of Disse between the hepatocytes and vascular sinusoids. As more amyloid accumulates, it compresses the hepatic cords and sinusoids. ▪ The hepatic cords undergo nutritional and pressure atrophy and become displaced or replaced by bands and nodules of amyloid (Fig. 21.69A and B).

Amyloid Stains

Amyloid material is demonstrated by Congo red staining under light microscopy. Pretreatment of tissue with potassium permanganate and stained by Congo red demonstrates amyloid. AL amyloid only but not AA amyloid. Various stains used to demonstrate amyloid material are given in Table 21.69.

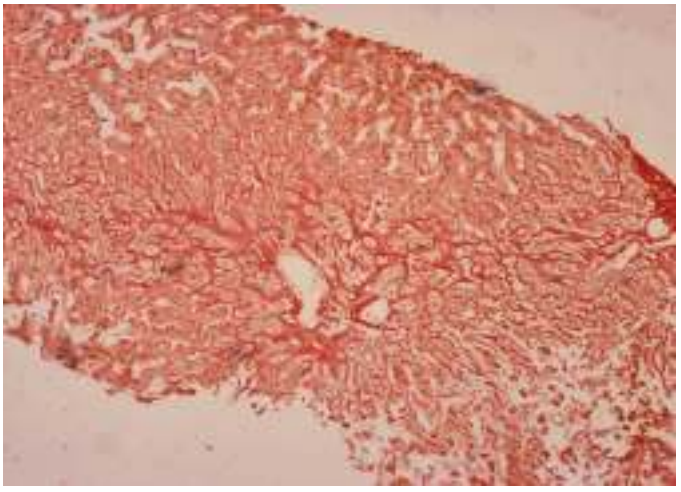

Fig. 21.69B: Congo red stain demonstrates amyloid in liver.

INDIAN CHILDHOOD CIRRHOSIS

Indian childhood cirrhosis most often affects children between 6 months to 5 years in Indian population. Exact etiology is unknown. It is most often seen in Aggarwal, Brahmin, Kayastha and Sikhs. Serum copper and copper binding protein levels are increased in these patients. Child presents with hepatosplenomegaly and jaundice. Child develops portal hypertension with fatal outcome.

Surgical Pathology: Indian Childhood Cirrhosis
Light Microscopy
Liver biopsy shows micronodular cirrhosis, Mallory's hyaline body, and diffuse fibrosis around individual hepatocytes (known as creeping fibrosis), chronic inflammatory cells, bile stasis and ductular proliferation.

Table 21.69 Stains used to demonstrate amyloid material

Amyloid Stain	Color Imparted
Congo red with light microscopy	Pink color
Congo red with polarizing microscopy	Apple green birefringence (color of a Granny Smith apple)
Methyl violet (metachromatic stain)	Bright pink color
Crystal violet (metachromatic stain)	Pink color
Fluorescent stains: Thioflavin T, thioflavin S	Greenish color (immunofluorescence study)
Van Gieson stain	Khaki color
PAS stain	Magenta color

ACUTE FATTY LIVER OF PREGNANCY

Acute fatty liver of pregnancy (AFLP) is a rare life-threatening complication of pregnancy associated with fatal outcome. It usually occurs in late third trimester. Acute hepatocellular failure is associated with microvesicular fatty liver.

- Patient develops severe liver dysfunction with hypoalbuminemia, hypofibrinogenemia, prolonged clotting times and hypocholesterolemia.
- The most critical component of caring for a woman with AFLP is the delivery of her fetus. While the natural history of the disease is improvement within 24–48 hours of delivery.

REYE SYNDROME

Reye syndrome is a potentially fatal pediatric disorder defined as acute non-inflammatory encephalopathy with fatty microvesicular hepatocellular failure. Child presents with vomiting and confusion, rapid progression to coma and fatal outcome. Reye syndrome is associated with aspirin administration in children associated with fatal outcome.

BILE DUCT DISORDERS

BILE DUCT DISORDERS: OVERVIEW

Biliary cirrhosis occurs as primary or secondary disorder. Primary biliary cirrhosis (PBC) is an autoimmune chronic progressive disorder and more frequent than secondary biliary cirrhosis due to extrahepatic biliary obstruction. Ductular proliferation is the single most important histologic feature on liver biopsy for establishing diagnosis of extrahepatic biliary atresia in a neonate. Causes of biliary tract disease are given in Table 21.70.

Table 21.70 Causes of biliary tract disease

Failure of Formation of the Bile Ducts
Biliary atresia
Obstruction or Obliteration of the Bile Ducts
▪ Cholelithiasis ▪ Cholangitis ▪ Primary biliary cirrhosis ▪ Primary sclerosing cholangitis ▪ Post-surgical strictures ▪ Parasitic infection
Compression of the Bile Ducts Outside the Liver
▪ Pancreatic cancer ▪ Pancreatitis ▪ Hepatic cancers

In biliary tract disease, the relative elevation in ALP exceeds the relative elevation in ALT and AST.

PRIMARY BILIARY CIRRHOSIS

Primary biliary cirrhosis, a nonsuppurative destructive cholangitis, occurs due to chronic destruction of intrahepatic bile ducts in the portal tracts. It evolves through ductal lesions, scarring, and eventually cirrhosis.

- The hallmark of PBC is the presence of antimitochondrial antibodies in serum. These autoantibodies recognize epitopes associated with the mitochondrial pyruvate dehydrogenase complex.
- Primary biliary cirrhosis occurs more often in women than men (10:1 female predominance) between 40 and 50 years of age.

Predisposing Factors

Majority of patients are associated with autoimmune disorder such as thyroiditis, rheumatoid arthritis, scleroderma, Sjögren syndrome, or systemic lupus erythematosus.

Pathogenesis

Intrahepatic bile duct destruction is caused by circulating antimitochondrial antibodies in >95% of patients. These antimitochondrial antibodies play no role in the pathogenesis of the disease. The complement system is chronically activated.

Clinical Features

Patient presents with itching of skin, jaundice, hepatosplenomegaly, passage of clay-colored stool and dark-colored urine. Serum cholesterol level is raised secondary to severe obstructive jaundice. Hypercholesterolemia leads to cutaneous xanthomas formation.

Surgical Pathology: Primary Biliary Cirrhosis

Light Microscopy

- Histologic examination of liver biopsy shows nonsuppurative inflammation of interlobular ducts (florid duct lesions). The cells surrounding bile duct destruction site include predominant suppressor/cytotoxic CD8+ T cells, macrophages, B cells and plasma cells in some portal tracts.
- Bile duct destruction is mediated by these suppressor/cytotoxic CD8+ T cells.
- There may be presence of epithelioid cell granulomas. Proliferation of bile ductules within portal tracts is common and may be florid.
- It is worth mentioning that macrophages and B cells cause periductal inflammation but do not mediate epithelial cytotoxicity (Fig. 21.70).

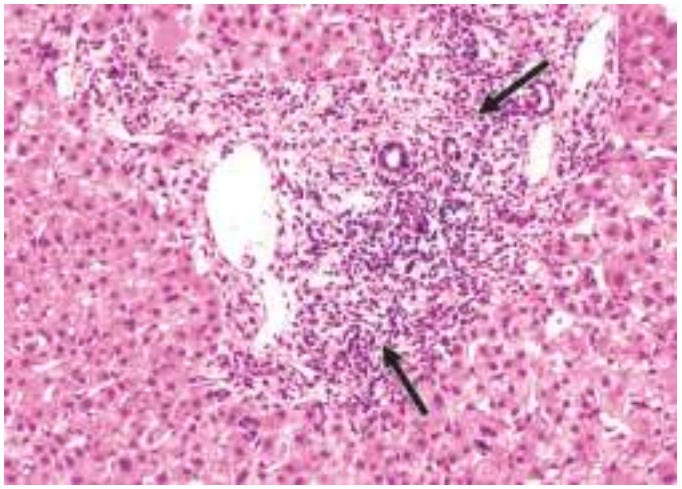

Fig. 21.70: Primary biliary cirrhosis. This is a case of primary biliary cirrhosis, a rare autoimmune disease (mostly of middle-aged women) that is characterized by destruction of bile ductules within the triads of the liver. Antimitochondrial antibody can be detected in serum. Seen here in a portal tract is an intense chronic inflammatory infiltrate with loss of bile ductules. Micronodular cirrhosis ensues (arrows) (400X).

Table 21.71 Grading and staging of primary biliary cirrhosis

Stages	Scheuer System	Ludwig System
Stage 1	▪ Florid duct lesion ▪ Bile duct damage ▪ Portal inflammation	*Portal stage:* Portal inflammation
Stage 2	▪ Ductular proliferation (reaction) ▪ Expanded portal tracts ▪ Proliferated ductules ▪ Piecemeal necrosis	*Periportal stage:* Periportal inflammation ± and piecemeal necrosis
Stage 3	▪ Scarring ▪ Bridging fibrosis ▪ Loss of ducts	*Septal stage:* Fibrous septa and bridging necrosis
Stage 4	Nodular cirrhosis	Cirrhosis

Laboratory Findings

Serum conjugated bilirubin, alkaline phosphatase and cholesterol levels are increased.

Diagnostic Tool

Serum antimitochondrial antibodies (IgM especially M2) are analyzed in the diagnosis of primary biliary cirrhosis.

Prognosis

Patient with primary biliary cirrhosis may develop micronodular cirrhosis. Hepatocellular carcinoma does not develop. Most common causes of death include liver failure and variceal bleeding.

Grading and Staging

Grading and staging of primary biliary cirrhosis is given in Table 21.71.

SECONDARY BILIARY CIRRHOSIS

Secondary biliary cirrhosis is caused by extrahepatic biliary obstruction due to passage of stone in common bile duct or carcinoma head of pancreas.

- Persistent extrahepatic obstruction increases the pressure within intrahepatic bile ducts and cholangioles resulting in ductal injury.
- Lodgment of stones in the common bile duct leads to obstructive jaundice, cholangitis, and acute pancreatitis. Men and women are equally affected.

Clinical Features

Patient presents with pruritus, jaundice, malaise, diarrhea, steatorrhea, weight loss, dark urine, clay-colored stool and hepatosplenomegaly.

Laboratory Findings

Serum conjugated bilirubin, cholesterol and alkaline phosphatase levels are raised. Urine shows bile salts and bile pigments.

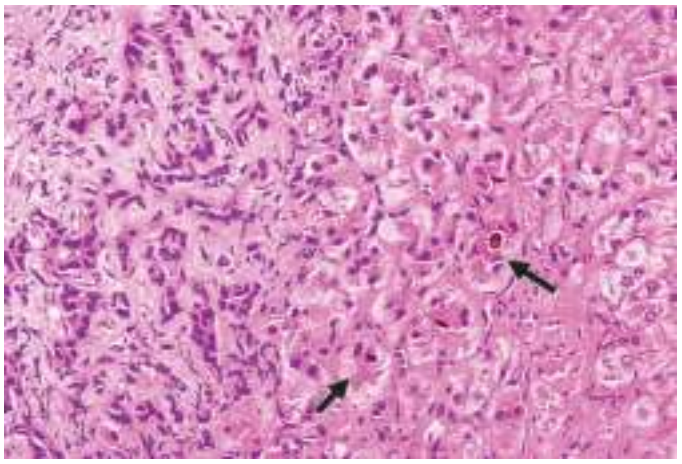

Fig. 21.71: Extrahepatic biliary obstruction. It shows bile stasis forming bile lakes as a result of accumulation of bile within hepatic parenchyma. Mononuclear inflammation is seen in ducts and around ducts (arrows) (400X).

Surgical Pathology: Secondary Biliary Cirrhosis

Light Microscopy

- Histologic examination of liver biopsy shows bile stasis and bile lakes, accumulations of bile within hepatic parenchyma.
- Inflammation is seen in ducts and periductal region. Healing occurs by formation of fibrous tissue (Fig. 21.71).

Complications

Complications of secondary biliary cirrhosis include ascending cholangitis and bacterial inflammation of the intrahepatic bile ducts. Differences between intrahepatic and extrahepatic biliary obstruction are given in Table 21.72.

PRIMARY SCLEROSING CHOLANGITIS

Primary sclerosing cholangitis (PSC) is rare pathologic progressive fibro-obliterative disorder of unknown etiology. It primarily affects young men between 30 and 50 years of age group.

Men are more affected than women in 2:1 ratio. Approximately 70% of patients with PSC have long-standing ulcerative colitis indicating autoimmune disorder. It is associated with HLAB-8, DR-3 and DQ-2.

Pathology

Primary sclerosing cholangitis is characterized by inflammation, onion skin fibrosis and obliteration of intrahepatic and extrahepatic bile ducts, with dilation of preserved segments, which eventually develops into biliary cirrhosis. Cholangiocarcinoma is a late complication in these patients.

Imaging Techniques

Definite diagnosis of primary sclerosing cholangitis rests on imaging by MRCP and ERCP. Radiograph shows beaded biliary tree, representing sporadic strictures.

Clinical Features

Patient presents with pruritus, jaundice, malaise, hepatosplenomegaly, passage of clay-colored stool and dark-colored urine. Complications of primary sclerosing cholangitis are secondary biliary cirrhosis, chronic pancreatitis, hepatocellular carcinoma and cholangiocarcinoma in 10% of cases.

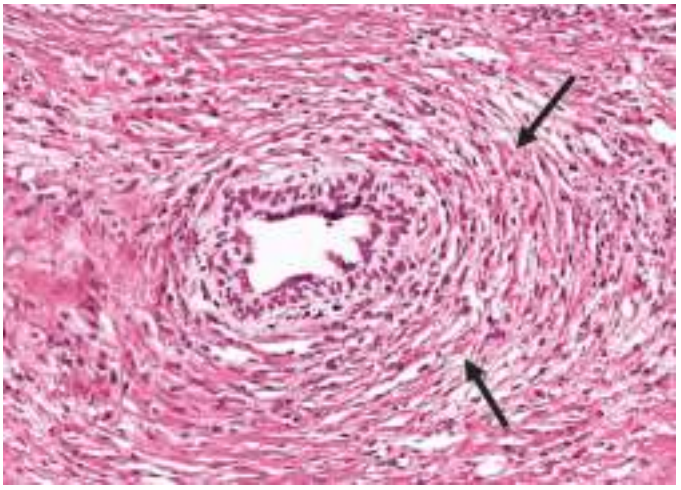

Fig. 21.72: Primary sclerosing cholangitis. Microscopically, this bile duct in a case of sclerosing cholangitis is surrounded by marked collagenous connective tissue deposition (arrows) (100X).

Table 21.72 Differences between intrahepatic and extrahepatic biliary obstruction

Characteristics	Intrahepatic Biliary Obstruction	Extrahepatic Biliary Obstruction
Bile pigment	Bile pigment is present in hepatocytes and Kupffer cells	Bile plugs present in bile ducts and ductules result in rupture of bile canaliculi
Cholestasis severity	Mild degree	Bile lakes present
PMN cells infiltration around bile ducts and canaliculi	Absent	Present
Feathery degeneration of hepatocytes	Marked	Not much marked

Laboratory Findings

Serum conjugated bilirubin, cholesterol, and alkaline phosphatase, IgM levels are raised.

Surgical Pathology: Primary Sclerosing Cholangitis

Light Microscopy

- Extrahepatic duct biopsy in primary sclerosing cholangitis is performed to rule out malignancy. Histologic examination reveals inflammation, onion skin fibrosis and obliteration of bile ducts.
- Liver biopsy exaination shows concentric fibrosis around ducts in onion skin appearance, segmental stenosis of extrahepatic and intrahepatic bile ducts.
- Chronic cholestasis is typical finding (Fig. 21.72).
- Distinction between primary biliary cirrhosis and primary sclerosing cholangitis is given in Table 21.73.

Grading and Staging

Grading and staging of primary sclerosing cholangitis is given in Table 21.74.

Table 21.73 Distinction between primary biliary cirrhosis and primary sclerosing cholangitis

Feature	Primary Biliary Cirrhosis	Primary Sclerosing Cholangitis
Epidemiology	Female predominance, age 40–50 years	Male predominance, age 30–50 years
Associated antibody	Anti-mitochondrial antibody (IgM)	p-ANCA
Histologic features	Chronic destruction and scarring of intrahepatic bile ducts	Concentric fibrosis around ducts within portal tracts resulting in chronic cholestasis
Clinical features	Jaundice, pruritus, hepatomegaly, clay-colored stool	Jaundice, pruritus, fever and chills; and 70% of cases have ulcerative colitis
Complication	Micronodular cirrhosis	Secondary biliary cirrhosis, chronic pancreatitis, hepatocellular carcinoma, cholangiocarcinoma (10%)

Table 21.74 Grading and staging of primary sclerosing cholangitis

Stages	Scheuer System	Ludwig System
Stage 1	Portal stage	Portal inflammation or bile duct abnormalities
Stage 2	Periportal stage	Periportal fibrosis or enlargement of portal tract
Stage 3	Septal stage	Fibrous septal or bridging necrosis
Stage 4	Cirrhotic stage	Cirrhosis

VASCULAR DISORDERS OF LIVER

Vascular disorders of liver occur due to impairment of hepatic venous drainage, arterial underperfusion and miscellaneous intrahepatic vascular conditions.

IMPAIRMENT OF HEPATIC VENOUS DRAINAGE (CHRONIC VENOUS CONGESTION OF LIVER)

In long-standing right-sided heart failure, increased venous pressure leads to chronic venous congestion of liver due to impairment of hepatic veins drainage into inferior vena cava. Pitting edema is seen in lower extremities.

Chronic venous congestion of the liver occurs due to right-sided heart failure, chronic obstructive pulmonary disease (COPD) and thrombosis in hepatic vein or inferior vena cava.

Surgical Pathology: Chronic Venous Congestion of Liver

Gross Morphology

- Liver is enlarged, tense, and cyanotic with rounded edges.
- Cut surface of the liver can assume a variegated red and yellow appearance referred to as nutmeg liver, with dark red congested centrilobular areas alternating with pale unaffected peripheral portions of the lobules.
- Cut surface resembles a cross section of a nutmeg, and so-called as nutmeg liver.

Light Microscopy

Macrophages contain iron pigment. Bile stasis within canaliculi may also be seen. Acinar pattern of liver becomes exaggerated due to these changes. Post-congestion fibrosis may produce finely nodular liver known as cardiac cirrhosis (Fig. 21.73).

- **Dark areas of the nutmeg appearance:** These are represented by the congested and dilated venous radicles and sinusoids of zone 3 region. These changes cause pressure atrophy of the centrilobular liver cords. In severe cases, the hepatocytes show necrosis.
- **Pale hypoxic areas of the liver:** These are represented by the hypoxic fatty change in hepatocytes. Hepatocytes in mid-zone show fatty change. Hepatocytes are normal in the peripheral zones. Left heart failure leads to decreased perfusion resulting in centrilobular ischemic necrosis of hepatocytes.
- **Centrilobular hemorrhagic necrosis:** Combination of decreased perfusion and congestion causes centrilobular hemorrhagic necrosis. Liver shows variegated mottled appearance. There is sharp demarcation of viable periportal necrotic centrilobular hepatocytes.
- **Cardiac cirrhosis of liver:** Long-standing chronic passive congestion of liver leads to bridging fibrosis in extreme cases resulting in cardiac cirrhosis of liver. With the progression of fibrosis around portal region with bridging between adjacent hepatic portal region (Figs 21.74 and 21.75).

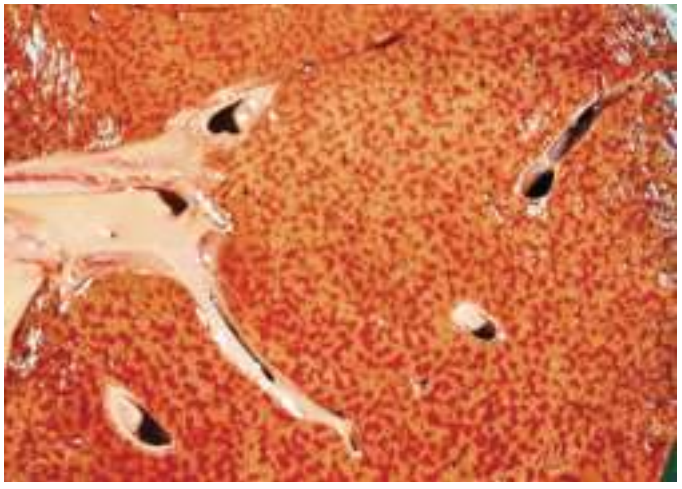

Fig. 21.73: Chronic venous congestion of liver. Here is an example of a nutmeg liver seen with chronic passive congestion of the liver. Note the dark red congested regions that represent accumulation of RBCs in centrilobular regions.

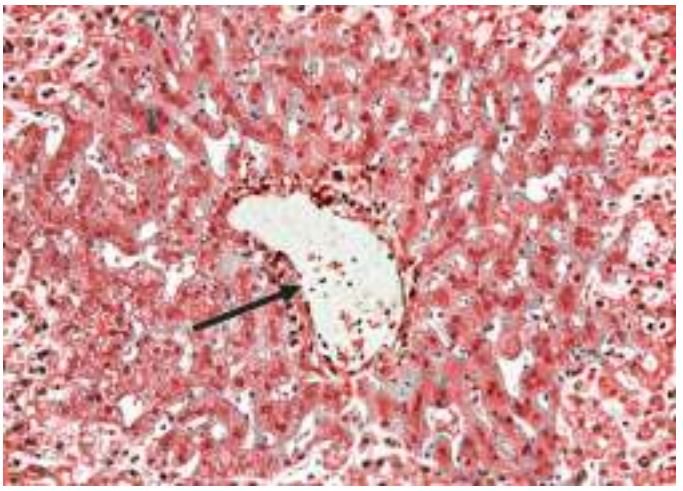

Fig. 21.74: Chronic venous congestion of liver. Microscopically, the nutmeg pattern results from congestion around the central veins, as seen here. This is usually due to a right-sided heart failure (arrow).

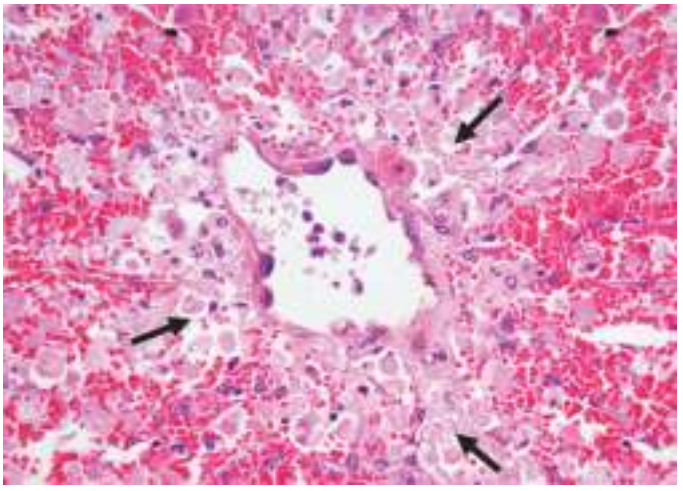

Fig. 21.75: Cardiac cirrhosis. Chronic venous congestion of liver continues for a long time, a condition is called cardiac cirrhosis may develop in which there fibrosis is bridging between central zonal regions, as shown below, so that the portal tracts appear to be in the center of the reorganized lobule. This process is best termed cardiac sclerosis because, unlike a true cirrhosis, there is minimal nodular regeneration (arrows) (400X).

BUDD-CHIARI SYNDROME

Budd-Chiari syndrome occurs due to thrombotic occlusion in major hepatic veins at their origin or inferior vena cava distal to its junction with the hepatic veins and is characterized by classic triad: hepato-megaly, abdominal pain and ascites. It most often occurs due to thrombosis or invasion of the hepatic veins. Etiology of large hepatic vein thrombosis is given in Table 21.75.

- Classic clinical manifestations in a case of Budd-Chiari syndrome are marked hepatomegaly in caudate lobe of liver demonstrated by imaging techniques. Lumbar veins in posterior region show visible dilatation. Patient improves after mesocaval shunt.
- Patient presents with abdominal pain, mild jaundice, ascites, and eventual acute hepatocellular failure and death. Clinical features and their frequency in Budd-Chiari syndrome are given in Table 21.76.

Surgical Pathology: Budd-Chiari Syndrome
Gross Morphology
Thrombus in the hepatic veins causes obstruction to blood flow to liver leading to venous congestion of the liver (Fig. 21.76).

Light Microscopy

- Histologic examination of liver biopsy shows severe centrilobular necrosis and hemorrhage.
- The sinusoids of the central zone are dilated and packed with erythrocytes showing chronic passive congestion as a result of localized obstruction to venous drainage.
- Rim of hepatocytes in zone 1 shows survival.

SINUSOIDAL OBSTRUCTION SYNDROME (VENO-OCCLUSIVE DISORDER)

Veno-occlusive disorder, also known as sinusoidal obstruction syndrome, is characterized by non-thrombotic luminal narrowing affecting hepatic vein radicles and sublobular veins. Narrowing of these blood vessels occurs due to growth of a new layer of subendothelial connective tissue. Patient presents with abdominal pain, ascites and hepatosplenomegaly similar to Budd-Chiari syndrome. Predisposing factors for veno-occlusive disorder are described as under:

- Poisoning with pyrrolizidine alkaloids occurs either due to contamination of flour or ingestion of products derived from alkaloid-containing plants such as *Crotalaria* and *Senecio* species.
- Irradiation of liver
- Treatment with anticancer drugs
- Bone marrow transplantation within 4 weeks in 20% of cases due to high doses of chemotherapeutic agents (cyclophosphamide) and total body irradiation
- Graft-versus-host reaction

Table 21.75 Etiology of large hepatic vein thrombosis

Primary myeloproliferative disorders (polycythemia vera)
Paroxysmal nocturnal hemoglobinuria
Acute promyelocytic leukemia
Protein C deficiency
Protein S deficiency
Antithrombin III deficiency
Antiphospholipid autoantibodies (lupus anticoagulant)
Hepatocellular carcinoma
Behçet's disease
Allergic vasculitis
Oral contraceptives
Pregnancy and postpartum state
Certain solid tumors
Idiopathic (10% cases)

Table 21.76 Budd-Chiari syndrome, clinical features and their frequency

Clinical Manifestations	Frequency
Ascites	96%
Hepatomegaly	90%
Abdominal pain	80%
Splenomegaly	64%
Edema	46%
Jaundice	44%
Fever	40%
Hepatic encephalopathy	22%
Gastrointestinal bleeding	14%

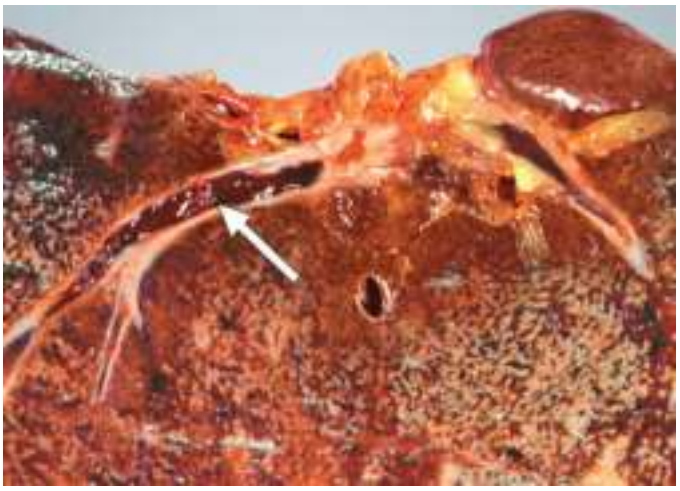

Fig. 21.76: Budd-Chiari syndrome. The liver has been sliced coronally, with the caudate lobe in the middle. Thrombus can be seen in the hepatic veins. This caused obstruction, which resulted in venous congestion of the liver, most marked in the caudate lobe (arrow).

NONCIRRHOTIC PORTAL HYPERTENSION

Noncirrhotic portal hypertension is also known as idiopathic portal hypertension, which usually occurs as a result of presinusoidal causes. It may also occur due to hepatic causes such as sarcoidosis, schistosomiasis or congenital hepatic fibrosis. Clinically liver functions are maintained. Noncirrhotic portal hypertension can occur in the settings of following:

- Nodular regenerative hyperplasia of liver occurs due to aberrant blood flow hepatic lobules. Liver parenchyma is diffusely nodular without fibrosis. Reticulin stain highlights regenerative hepatocytes outlined by atrophic cords.
- Hepatoportal sclerosis due to intrahepatic portal vein injury occurs due to intrahepatic portal vein injury and scarring. Portal vein remains initially patent, that later on shows marked thickening with luminal narrowing.

- Hemorrhagic (red) infarcts in liver are rare due to its dual blood supply, e.g. portal vein and hepatic arteries. Liver receives blood from hepatic arteries and portal vein. Interruption of blood supply to liver due to blockage in hepatic artery or portal vein results in hemorrhagic (red) infarct in liver. Hemorrhagic (red) infarct region receives constant blood supply from normal spared vessel of liver, allows RBCs to diffuse through necrotic tissue.
- Hemorrhagic (red) infarct in liver occurs due to embolism, sepsis, polyarteritis nodosa, disseminated intravascular coagulation and Budd-Chiari syndrome (portal vein thrombosis).

MISCELLANEOUS INTRAHEPATIC VASCULAR CONDITIONS

PELIOSIS HEPATITIS

Peliosis hepatitis is reversible sinusoidal dilatation of liver and of unknown etiology and characterized by blood-filled cystic spaces partly lined by endothelial cells.

- Peliosis hepatitis is associated with tuberculosis, cancers, AIDS, post-transplantation immunodeficiency, therapeutic use of anabolic hormones, oral contraceptives and danazol.
- Peliosis hepatitis has also been observed in patients to control renal transplant rejection with azathioprine.
- Patient presents with hepatomegaly and jaundice.

Surgical Pathology: Peliosis Hepatitis
Light Microscopy
Histologic examination of liver shows numerous blood-filled spaces partly lined by endothelial cells.

RENDU-OSLER-WEBER DISEASE

Rendu-Osler-Weber disease is an autosomal dominant hemorrhagic telangiectasia characterized by the presence of numerous blood-filled spaces affecting many tissues.

Liver lesions in hereditary hemorrhagic telangiectasia type 2 occur due to mutation of ALK gene located on chromosome 12. Patient presents with noise bleed.

Surgical Pathology: Rendu-Osler-Weber Disease
Gross Morphology
Liver contains subcapsular enlarged blood vessels.
Light Microscopy
Hepatic lesions are composed of thick-walled veins, scattered dilated sinusoids and abnormal-sized portal tracts.

NEOPLASTIC DISORDERS OF LIVER

Current 2019 WHO classification of primary hepatic neoplasms and non-neoplastic lesions are given in Table 21.77. Most common type of metastases from various organs in noncirrhotic liver. Metastases most often present as multiple nodules in contrast to the single nodules of primary tumors. Metastases to a cirrhotic liver are very uncommon.

Immunohistochemistry technique plays an important role in differential diagnosis of primary liver tumors and tumor-like lesions; and metastases in

Table 21.77 Current 2019 WHO classification of primary hepatic neoplasms and non-neoplastic lesions

Cell Origin	Benign Tumors	Malignant Tumors
Epithelial origin tumors		
Hepatocellular origin	▪ Hepatocellular adenoma ▪ Focal nodular hyperplasia ▪ Nodular regenerative hyperplasia ▪ Macrogenerative nodule ▪ Dysplastic nodule ▪ Compensatory lobar hyperplasia ▪ Accessory lobe	▪ Hepatocellular carcinoma ▪ Fibrolamellar hepatocellular carcinoma ▪ Combined hepatocellular carcinoma and cholangiocarcinoma ▪ Hepatoblastoma epithelial type
Biliary epithelial origin	▪ Bile duct hamartoma (von Meyenburg complex) ▪ Bile duct adenoma	▪ Cholangiocarcinoma ▪ Intraductal papillary biliary neoplasia

Contd...

Table 21.77 Current 2019 WHO classification of primary hepatic neoplasms and non-neoplastic lesions (*Contd...*)

Cell Origin	Benign Tumors	Malignant Tumors
	▪ Biliary cysts (non-neoplastic) • Solitary cyst • Polycystic disease • Caroli disease • Multiple hilar cysts ▪ Biliary cystadenoma • Mucinous biliary cystadenoma (+/– mesenchymal stroma) • Serous biliary cystadenoma	▪ Adenosquamous carcinoma ▪ Mucoepidermoid carcinoma ▪ Squamous cell carcinoma ▪ Combined cholangiocarcinoma and neuroendocrine tumor ▪ Biliary cystadenocarcinoma
Mesenchymal origin tumors		
Vascular tumors	▪ Hemangioma ▪ Infantile hemangioma ▪ Hemangiomatosis ▪ Lymphangioma ▪ Hereditary hemorrhagic telangiectasia ▪ Peliosis hepatic	▪ Angiosarcoma ▪ Epithelioid hemangioendothelioma ▪ Kaposi sarcoma
Adipocytic tumors	▪ Angiolipoma (and related tumors) ▪ Pseudolipoma ▪ Focal hepatocellular fatty change	Liposarcoma
Other mesenchymal tumors	▪ Solitary fibrous tumor ▪ Inflammatory myofibroblastic tumor (pseudotumor) ▪ Leiomyoma	▪ Embryonal sarcoma (undifferentiated) ▪ Rhabdomyosarcoma ▪ Fibrosarcoma ▪ Undifferentiated pleomorphic sarcoma (malignant fibrous histiocytoma) ▪ Leiomyosarcoma ▪ Osteosarcoma
Mixed tumors with epithelial and mesenchymal components		
Mixed tumors with epithelial and mesenchymal components	▪ Necrotic/fibrous nodule ▪ Heterotopia (adrenal, pancreas, spleen) ▪ Endometrial cyst (endometrioma) ▪ Benign nerve sheath tumors ▪ Sarcoid pseudotumor (sarcoidoma) ▪ Abscesses ▪ Ciliated foregut cyst ▪ Alimentary duplication cyst ▪ Pseudocysts (pancreatic, traumatic)	▪ Malignant schwannoma ▪ Germ cell tumors (teratoma, yolk sac tumor) ▪ Malignant rhabdoid tumor ▪ Primary lymphoma ▪ Primary neuroendocrine tumor ▪ Pheochromocytoma ▪ Solid and cystic tumor
Other tumors and tumor-like masses		
Other tumors and tumor-like masses	▪ Necrotic/fibrous nodule ▪ Heterotopia (adrenal, pancreas, spleen) ▪ Endometrial cyst (endometrioma) ▪ Benign nerve sheath tumors ▪ Sarcoid pseudotumor (sarcoidoma)* ▪ Abscesses ▪ Parasitic cysts ▪ Ciliated foregut cyst ▪ Alimentary duplication cyst ▪ Pseudocysts (pancreatic, traumatic)	▪ Malignant schwannoma ▪ Germ cell tumors (teratoma, yolk sac tumor) ▪ Malignant rhabdoid tumor ▪ Primary lymphoma ▪ Primary neuroendocrine tumor ▪ Pheochromocytoma ▪ Solid and cystic tumor

***** *Sarcoid pseudotumor (sarcoidoma) is borderline tumor, however placed in benign category.*
Liver metastases occur from epithelial origin carcinomas (breast, lung, stomach, colon, rectum, pancreas, prostate, endometrium, thyroid and kidney) and mesenchymal origin sarcomas (angiosarcomas. rhabdomyosarcoma) and round cell tumors (Wilm's tumors, Ewing sarcoma, neuroblastoma and bronchopulmonary neuroendocrine tumors).

liver arising from epithelial and mesenchymal tumors. Panel of immunohistochemical markers applied in conventional and fibrolamellar variants of hepatocellular carcinoma, hepatoblastoma and cholangiocarcinoma is given in Table 21.78.

PRIMARY BENIGN TUMORS

HEPATOCELLULAR ADENOMA

Hepatocellular adenoma is a rare tumor in young women taking oral contraceptives. It usually occurs as a solitary, sharply demarcated encapsulated mass up to 40 cm in diameter and 3 kg in weight which is located anywhere in liver beneath capsule. Subtypes of hepatocellular adenoma are given in Table 21.79.

Complications

Subcapsular hepatocellular adenoma has a tendency to rupture resulting in severe bleeding in peritoneal cavity especially during pregnancy which induces hypovolemic shock that requires emergency treatment.

Pathogenesis

Hepatocellular adenoma has three variants. Each has risk of development of malignant transformation.

Table 21.78 Panel of immunohistochemical markers applied in conventional and fibrolamellar variants of hepatocellular carcinoma, hepatoblastoma and cholangiocarcinoma

Immunohistochemical Markers	Expression
Hepatocellular origin	
Conventional hepatocellular carcinoma	
Hepatocyte paraffin 1 (Hep Par 1)	Positive (95%)
p-CEA	Positive (80%), highly specific canalicular marker
AFP (α-fetoproteins)	Positive (30–60%)
CD10	Positive (canalicular)
Villin	Positive (canalicular)
CK20	Positive (up to 20%)
CK AE1/AE3 (pan-CK)	Positive
CAM 15.2 (LMWCK) pan-CK	Positive (5–20%)
CK903 (HMWCK)	Positive
Glypican 3	Positive (promising new marker of hepatocellular differentiation)
Arginase 1	Positive (new marker of hepatocellular differentiation)
α_1-Antitrypsin	Positive (up to 50%)
TTF-1 (thyroid transcription factor 1)	Positive (cytoplasmic staining)
Cytokeratin 7 (CK7)	Negative
EMA (epithelial membrane antigen)	Negative
MOC-31	Negative
Mucicarmine	Negative
Fibrolamellar hepatocellular carcinoma	
Neurotensin	Positive
AFP (α-fetoproteins)	Negative
Hepatoblastoma	
AFP (α-fetoproteins)	Positive
Hep Par 1 (hepatocyte paraffin 1)	Positive
DLK (delta-like protein)	Positive
hCG (human chorionic gonadotropin)	Positive
Cytokeratins (CKs)	Positive
CEA (carcinoembryonic antigen)	Positive
Glypican 3	Positive
EMA (epithelial membrane antigen)	Positive
Vimentin	Positive
Hepatic small ducts or large extrahepatic bile ducts	
Cholangiocarcinoma	
CK19 (cytokeratin 19)	Positive (70–100%)
m-CEA (carcinoembryonic antigen monoclonal)	Positive
p-CEA	Positive (cytoplasmic staining)
CK7 (cytokeratin 7)	Positive
CK20 (cytokeratin 20)	Positive
CK AE1/AE3 (pan-CK)	Positive
CAM 15.2 (LMWCK) pan-CK	Positive
CK903 (HMWCK)	Positive
Hep Par 1 (hepatocyte paraffin 1)	Negative
AFP (α-fetoproteins)	Negative/positive
CD10	Negative
Villin	Negative
Glypican 3	Negative
Arginase 1	Negative

Contd...

Table 21.79 Subtypes of hepatocellular adenoma

Subtype	Molecular Genetics	Histologic Features
HNF1α (hepatic nuclear factor 1α) inactivated subtype	Biallelic inactivation of HNF1α	Liver demonstrates marked fatty change
β-Catenin activated subtype	CTNNB1 mutation	Hepatocytes demonstrate nuclear atypia
Inflammatory subtype	In-frame deletions of gpl 190 (60%) and JAK/STAT pathway activation	Sinusoidal dilatation; patchy inflammation; and variable number of ductules
Unclassified subtype	No specific genetic abnormality	No specific histologic features

- **HNF-α inactivated mutation-linked hepatocellular adenoma:** HNF-α encodes for transcriptional factor. Approximately 80% of these tumors show somatic mutations of HNF-α. Heterozygous germline mutations of HNF-α are responsible for autosomal dominant maturity-onset diabetes of the young type 3 (MODY-3).
- **β-Catenin activated mutation-linked hepatocellular adenoma:** Mutation of β-catenin is associated with hepatocellular adenoma undergoing malignant transformation.
- **Inflammatory hepatocellular adenoma:** It is associated with small risk of development of malignant transformation. It is associated with gp130 a co-receptor for IL-6, that leads to consecutive JAK-STAT signaling and overexpression of acute phase reactant.

Surgical Pathology: Hepatocellular Adenoma

Gross Morphology

- Hepatocellular adenoma is well circumscribed tumor. The cut surface demonstrates greenish bile staining, indicating that it is of hepatocyte origin.
- Occasionally, tumor has pseudopods projecting into liver substance mimicking hepatocellular carcinoma (Fig. 21.77).

Light Microscopy

- Tumor is composed of uniform population of hepatocytes with a normal nucleus to cytoplasm ratio.
- Tumor cells are arranged in one- to three-cell-thick plates with intact reticulin framework similar to that in normal liver. The limiting plates are usually more irregular and nonlinear than in the normal liver. Portal tracts are absent.
- The presence of arterioles without accompanying bile ducts and surrounded by scant connective tissue is a characteristic feature of hepatocellular adenoma with naked arterioles (Fig. 21.78).

HEPATIC HEMANGIOMA

Hepatic hemangioma is the most common benign tumor of liver. Occasionally, spontaneous bleeding and rupture and thrombocytopenia due to sequestration of platelets.

Fig. 21.77: Hepatocellular adenoma. The cut surface of the hepatic adenoma demonstrates greenish bile staining, indicating that it is of hepatocyte origin (no other neoplasm could accumulate bile pigment). Such neoplasms are rare. One setting for its occurrence is young women taking oral contraceptives (arrow).

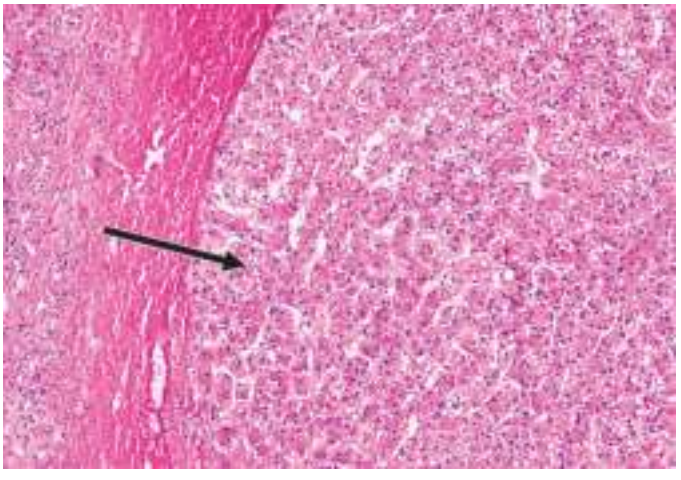

Fig. 21.78: Hepatocellular adenoma. Normal liver tissue with a portal tract is seen on the left. The hepatic adenoma is on the right and is composed of tumor cells that closely resemble normal hepatocytes, but the neoplastic liver tissue is disorganized hepatocyte cords and does not contain normal lobular architecture (arrow).

Surgical Pathology: Hepatic Hemangioma
Gross Morphology
Tumor is most often <1 cm located just beneath liver capsule. Cut surface is brown (Fig. 21.79).
Light Microscopy
Hepatic hemangioma is composed of vascular channels lined by endothelial cells (Fig. 21.80).

HEPATIC LYMPHANGIOMA

Hepatic lymphangioma occurs in infants and children. Liver involvement occurs as a part of multicentric process affecting other organs.

Fig. 21.79: Hepatic hemangioma. This is benign hemangioma of the liver just beneath the capsule. Perhaps one person in 50 has such a neoplasm, which is typically just an incidental finding, since most are 1 cm or less. They can sometimes be multiple (arrow).

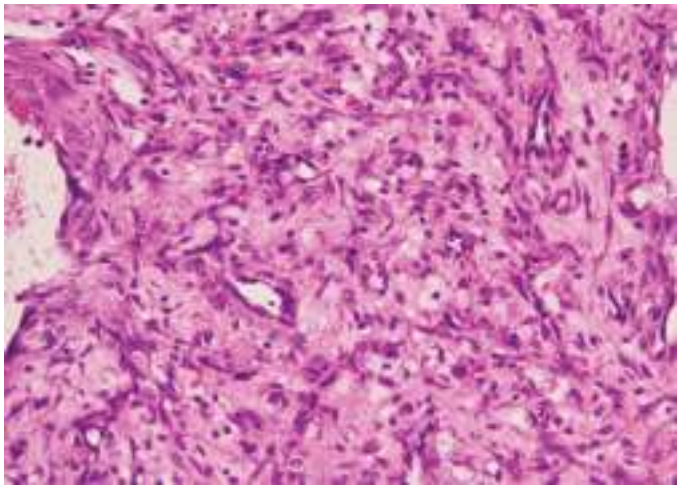

Fig. 21.80: Hepatic hemangioma. It shows vascular channels lined by endothelial cells (100X).

MULTIPLE BILIARY HAMARTOMAS (VON MEYENBURG COMPLEX)

Multiple biliary hamartomas are asymptomatic lesions also known as von Meyenburg complex, which show irregularly dilated bile ducts. This disorder is characterized by multiple bile duct hamartomas and biliary microhamartomas <5 mm.

It is important to distinguish multiple biliary hamartomas from multiple hepatic metastases. Women are more affected than men.

Predisposing Factors

Multiple biliary hamartomas are attributed to ischemia, inflammation or genetic abnormalities. These are known to be associated with polycystic liver disease and autosomal polycystic disease of kidney. Several reports suggest that these patients may develop hepatocellular carcinoma and cholangiocarcinoma.

Surgical Pathology: Multiple Biliary Hamartomas
Gross Morphology
▪ Liver surface shows creamy nodules in multiple biliary hamartomas mimicking secondary deposits from colon carcinoma. ▪ Histologic examination of the nodule shows proliferation of bile ducts (Fig. 21.81).
Light Microscopy
Multiple biliary hamartomas are composed of small disorganized clusters of dilated cystic bile ducts lined by columnar cells enclosed within fibrocollagenous stroma (Fig. 21.82).

Fig. 21.81: Multiple bile duct hamartomas. Liver surface shows creamy nodules consisting of proliferation of bile ducts. During surgery for bowel cancer, surgeon may consider metastatic deposits in liver. Histologic examination of one or two nodules confirms diagnosis that these are not secondary deposits (arrows).

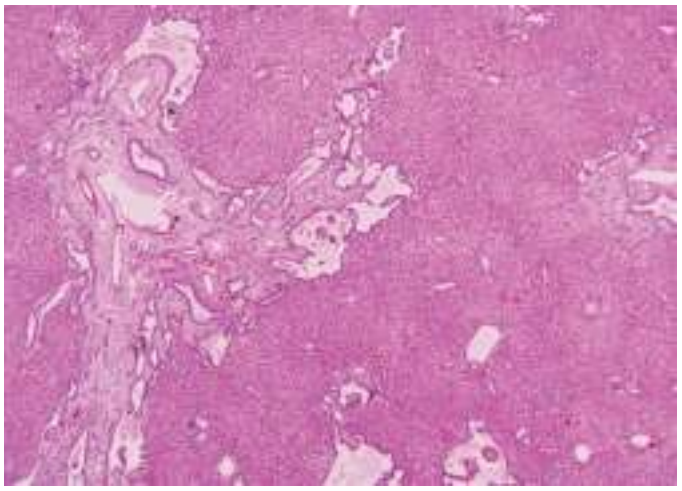

Fig. 21.82: Multiple bile duct hamartomas are also known as von Meyenburg complex. Hamartoma is composed of small disorganized clusters of dilated cystic bile ducts lined by columnar cells enclosed within fibrocollagenous stroma (100X).

HEPATOCELLULAR NODULES

Liver cirrhosis is characterized by irreversible remodeling of the hepatic architecture with advanced bridging fibrosis and a spectrum of hepatocellular nodules observed under light microscopy.

- The hepatocellular nodules are classified into various categories: (a) regenerative lesions (e.g. regenerative nodules, lobar hyperplasia, segmental hyperplasia, focal nodular hyperplasia), and (b) dysplastic or neoplastic lesions (e.g. dysplastic foci, dysplastic nodules, hepatocellular carcinoma).
- Cirrhosis-associated hepatocellular nodules are formed due to proliferation of hepatocytes and their supporting stroma in response to hepatocellular injury. Majority are benign regenerative nodules; however, regenerative nodules may progress along a well-described carcinogenic pathway to become dysplastic nodules or hepatocellular carcinomas.
- The differentiation of these hepatocellular lesions is important because regenerative nodules are benign in nature. On the other hand, dysplastic nodules are premalignant and neoplastic nodules are malignant in nature, respectively. However, their accurate characterization may be difficult even at histopathologic examination.
- Differential diagnosis of cirrhosis associated hepatocellular nodules may be facilitated by comparing the clinical, gross morphologic and histologic findings with radiologic imaging features; in particular, size of nodules, vascularity, hepatocellular function, Kupffer cell densities assessed at magnetic resonance imaging (MRI) using various contrast media, which provides better soft-tissue contrast and a more nuanced depiction of different tissue properties. Therefore, MRI is for optimal diagnosis and management of cirrhotic disease.

HEPATOCELLULAR NODULES: CLASSIFICATION

There are four classes of hepatocellular nodular lesions that characteristically are found in the cirrhotic liver: regenerative nodules, dysplastic foci, dysplastic nodules, and hepatocellular carcinomas. These lesions are referred to collectively as cirrhosis associated hepatocellular nodules.

Regenerative Nodules in Liver

Regenerative nodules typically occur in the cirrhotic liver in response to injury and altered circulation and/or other stimuli, hence referred as cirrhotic nodules. In this setting, regenerative nodules are surrounded by fibrous septa. Less characteristically, regenerative nodules may also arise in an otherwise normal liver; in this setting, the regenerative nodules are surrounded by normal liver parenchyma instead of fibrotic septa.

- **Large regenerative nodules in liver:** Large regenerative nodules measuring >1.00 to <1.00 cm in the setting of cirrhosis. On histologic examination, regenerative nodules in the liver resemble cirrhotic nodules with an intact reticulin framework similar to that of normal liver. Liver cell limiting plates are one to two cells thick. Portal tracts are usually present within the nodule, and bile ductular reaction may be prominent. Large regenerative nodules have been associated with an increased incidence of hepatocellular carcinoma.
- **Diffuse hepatocellular hyperplasia:** Diffuse hepatocellular hyperplasia occurs without fibrosis. It is associated with rheumatoid arthritis (most common), myeloproliferative disorders, hyperviscosity syndromes, transplantation of liver and kidney, HIV infection, vasculitis and drugs (anabolic drugs, cytotoxic drugs).
- **Focal nodular hyperplasia in liver:** Focal nodular hyperplasia in liver is a benign non-neoplastic lesion often diagnosed as an incidental finding during radiological investigations done for other causes. It is commonly seen in young women in 3rd to 4th decades. It is associated with use of anabolic steroid or oral contraceptives. Liver shows central stellate fibrous scar with arterial blood vessels. Liver functions are normal. AFP levels are not raised. It rarely grows or bleeds. It does not undergo malignant transformation. Patient presents with upper abdominal mass. Risk of hemorrhage and rupture is less as compared to hepatocellular adenoma. It is treated by local resection.

Surgical Pathology: Focal Nodular Hyperplasia in Liver

Gross Morphology

- Focal nodular hyperplasia in liver is most often a solitary well circumscribed lesion measuring <5 mm in diameter. It is usually located near the capsule of liver in 80% of cases.
- Multifocal lesions can also be seen in 20% of cases, which may be focal or diffuse. Focal lesion appears nodular, well demarcated, unencapsulated with lighter color when compared to surrounding liver. Focal nodular hyperplasia in liver has a characteristic central scar on gross examination and is shown in Fig. 21.83A.

Light Microscopy

- Focal nodular hyperplasia has normal-appearing hepatocytes arranged in nodules and separated by fibrous tissue.
- The limiting plate layer is of 2–3 cells in thickness and the reticulin framework intact similar to normal liver.
- Rarely foci of mild nuclear atypia and conspicuous nucleoli can be seen. Histology of focal nodular hyperplasia is shown in Fig. 21.83B.
- Comparison of benign hepatocellular nodules (adenoma, focal nodular hyperplasia, regenerative nodule in cirrhosis and conventional hepatocellular carcinoma is given in Table 21.80.

Immunohistochemistry Technique

Hepatocyte markers such as Hep Par 1, CAM 5.2, and polyclonal CEA are positive. Glutamine synthetase has a characteristic map-like pattern in FNH. AFP is negative.

Markers	Expression
▪ Hep Par 1	▪ Positive
▪ CAM 5.2	▪ Positive
▪ Carcinoembryonic antigen (CEA) polyclonal	▪ Positive
▪ Glutamine synthetase	▪ Positive
▪ α-Fetoprotein (AFP)	▪ Negative

Dysplastic Nodules in Liver

Cirrhosis-associated dysplastic and neoplastic nodules are composed of hepatocytes that exhibit histologic features of abnormal growth caused by a presumed or proved genetic alteration.

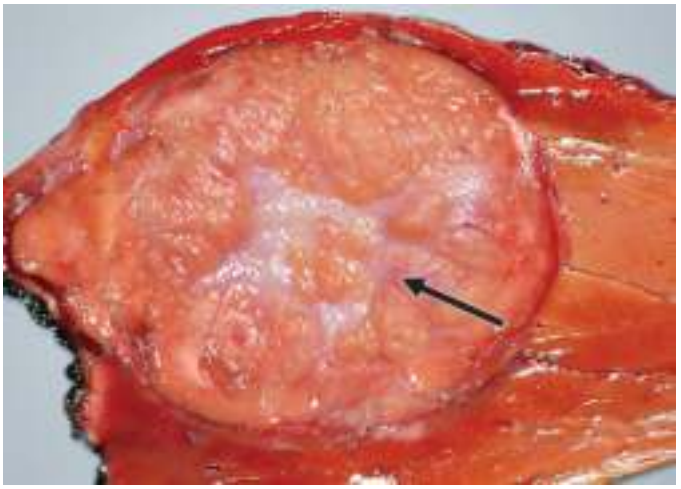

Fig. 21.83A: Gross morphology of focal nodular hyperplasia in liver. This well circumscribed mass in the liver is a benign lesion. It is regarded as being a hamartoma and is distinguished from a true adenoma by the presence of the central stellate scar, which contains bile ductules. This is a large example of FNH. The abnormal areas are usually multiple and smaller than this one (arrow).

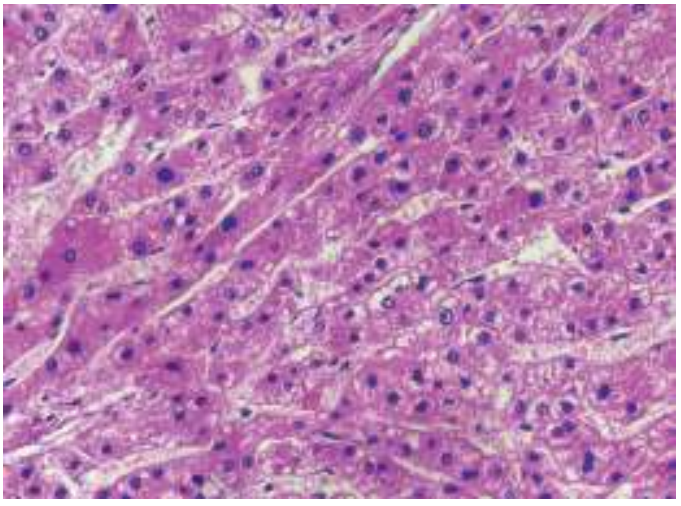

Fig. 21.83B: Histology of focal nodular hyperplasia in liver. Focal nodular hyperplasia has normal-appearing hepatocytes arranged in nodules and separated by fibrous tissue. The limiting plate layer is of 2–3 cells in thickness and the reticulin framework intact similar to normal liver.

Table 21.80 Comparison of benign hepatocellular nodules (adenoma, focal nodular hyperplasia, regenerative nodule in cirrhosis) and conventional hepatocellular carcinoma

Histochemical Stain and Immunohistochemical Marker	Benign Hepatocellular Nodules (Adenoma, Focal Nodular Hyperplasia, Regenerative Nodule in Cirrhosis)	Conventional Hepatocellular Carcinoma
Reticulin stain	Hepatic platelets are of normal thickness (1–2 cells in thickness)	Hepatic platelets are thickened (>3 cells in thickness)
Glypican 3	Negative	Positive
CD34	Negative	Positive (sinusoidal capillarization)
Factor VIII	Negative	Positive (sinusoidal capillarization)

- Dysplastic nodules do not satisfy the histologic criteria for malignancy or invasion, which may be either dysplastic foci (<1 mm in diameter) or dysplastic nodules (≥1 mm in diameter).
- A dysplastic focus is a cluster of dysplastic hepatocytes and recognized microscopically measuring <1 mm in diameter. Dysplastic nodule is a large lesion measuring ≥1 mm in diameter, that is grossly or radiologically apparent.
- Small cell dysplastic nodule is characterized by smaller than the normal hepatocytes, higher than normal nucleus to cytoplasm ratio, and hyperchromatic nuclei. Small expansive foci of small cell dysplastic nodules are closely associated with hepatocellular carcinoma than large cell dysplastic nodules.
- Large cell dysplastic nodule is characterized by nuclear enlargement, hyperchromasia, prominent nucleoli, but with abundant cytoplasm and hence, a normal nucleus to cytoplasm ratio. It may represent a regenerative phenomenon or a response to prolonged cholestasis. Large cell dysplastic nodules usually arise in cirrhosis and may be classified as low-grade or high-grade according to the degree of dysplasia. It is difficult to differentiate dysplastic nodules from other cirrhosis-associated hepatocellular nodules on histologic examination, hence molecular genetic techniques may be essential in this context.

Pathology Pearls: Dysplastic Nodules in Liver

- Dysplastic focus measures <1 mm
- Dysplastic nodules ≥1 mm in diameter
- Early hepatocellular carcinoma's cut of size is 2 cm

Neoplastic Nodules in Liver

Dysplastic nodules and neoplastic nodules in liver may transform into hepatocellular carcinoma slowly overtime. Therefore, understanding histologic and magnetic resonance imaging features of dysplastic nodules is essential for diagnosis and management of the patients.

- Hepatocellular carcinomas are malignant neoplasms composed of dedifferentiated hepatocytes. Neoplastic nodules are categorized either small (<2 cm in diameter) or large (≥2 cm in diameter). Based on gross morphologic features, hepatocellular carcinoma is classified into three major types: nodular, massive and diffuse. Hepatocellular carcinomas are scored by using World Health Organization grading system.
- Nodular hepatocellular carcinomas are small lesions with distinct margins. Massive hepatocellular carcinomas are larger than nodular types and characterized by multiple infiltrating tumors.
- Diffuse hepatocellular carcinomas are characterized by multiple infiltrating tumors.

Pathology Pearls: Hepatocarcinogenesis in Cirrhotic Liver

Cirrhosis is the most common predisposing factor for hepatocellular carcinoma in 80–90% of patients. Other predisposing factors for hepatocellular carcinoma in cirrhotic nodules include nonalcoholic steatohepatitis, hemochromatosis, Wilson disease, α_1-antitrypsin deficiency and aflatoxin B from contaminated food.

- Recent studies have elucidated the molecular mechanisms and morphologic features of hepatocellular carcinoma in cirrhosis-associated hepatocellular nodules.
- Oxidative stress induced by chronic injury, inflammation, and continuous liver cellular regeneration predispose hepatocytes to mutation in the TP53 tumor suppressor gene that results in abnormal cellular proliferation. The dysplastic foci initially congregate in dysplastic foci or dysplastic nodules then followed by further cumulative mutations.
- Cellular architecture becomes disorganized that results in increased nodule size and vascularity, nodule cellular density; and change in hepatocellular function and Kupffer cells. This pathway involves processes, such as capillarization and neoangiogenesis that result in gradual change in blood supply from portal to arterial pattern, and thus uncontrolled cellular growth and overtime to produce hepatocellular carcinoma via a dysplasia-carcinoma sequence.
- An oncoprotein produced by hepatitis B virus can directly bind to and inactivate T53 tumor suppressor gene thereby inducing hepatocellular carcinoma without cirrhosis. Cirrhosis is more prevalent in hepatitis C virus infection.

PRIMARY MALIGNANT TUMORS

CONVENTIONAL HEPATOCELLULAR CARCINOMA

Conventional hepatocellular carcinoma (HCC) is the most common primary malignant tumor with hepatic differentiation. It constitutes 85% of hepatic malignancies, which usually affects adults of more than 50 years of age without cirrhosis. However, it may affect children in 30% of cases. HCC is marked by increased serum concentration of α-fetoprotein. There is propensity for invasion of vascular channels with hematogenous dissemination. HCC may obstruct the biliary ducts and results in increased serum alkaline phosphatase. HCC is prone to hemorrhage and necrosis resulting in hemoperitoneum. Adenomatous hyperplasia and liver dysplasia are thought to be precursor of hepatocellular carcinoma.

Epidemiology

Conventional hepatocellular carcinoma is the fifth most common malignancy worldwide. Highest rates

of conventional HCC is observed in Korea, Taiwan, Southeast China, Japan and sub-Sahara Africa. Rate of incidence varies due to difference in the risk factors such as infection with HBV, HCV; aflatoxin β_1 exposure and cirrhosis. Other less common risk factors are thorotrast exposure, androgenic steroids and tyrosinemia.

Risk Factors

- **Aflatoxin β_1:** It is produced by *Aspergillus flavus* (aflatoxin β_1) and *Aspergillus parasiticus*, which contaminate grain particularly peanuts stored in warm and humid conditions in tropical and subtropical regions. Aflatoxin β_1 is a potent carcinogen can bind covalently to DNA of hepatocytes resulting in formation of mutagenic adducts with guanosine, which are thought to cause specific mutation in the TP53 tumor suppressor gene and resulting in hepatocellular carcinoma. Normally, enzymes in hepatocytes can detoxify aflatoxin β_1. People in Africa and China have mutations in hepatic enzymes, that normally detoxify aflatoxin β_1.
- **Cirrhosis:** Major risk factors for hepatocellular carcinoma include alcoholism, α_1-antitrypsin deficiency, HCV, nonalcoholic fatty liver disease (NAFLD), hereditary tyrosinemia, primary biliary cirrhosis and primary hemochromatosis. Hepatocellular carcinoma occurs without chronic liver disease in elderly persons or associated with hepatocellular adenoma with β-catenin gene mutations.
- **Hepatitis B virus:** HBV DNA is integrated into the host genome and inducing genomic instability. HBV contains four open reading frames. HBV-X protein disrupts normal growth control by transcriptional activation of insulin-like growth factor II (IGF-II) and receptors for insulin-like growth factor I. HBV-X protein binds to TP53 tumor suppressor gene resulting in its inactivation. HBV-X protein also disrupts β-catenin gene.
- **Hepatitis C:** Conventional hepatocellular carcinoma is rare in the absence of cirrhosis, because HCV lacks direct carcinogenic role. HCC first induces post-necrotic cirrhosis, that results in development of conventional hepatocellular carcinoma.
- **Drugs:** Therapeutic administration of thorotrast radiocontrast dye, androgens, anabolic steroids and oral contraceptives increases risk for hepatocellular carcinoma.
- **Chemical agents:** Azo dyes derivatives of aromatic amines such as dimethylaminobenzene is used in imparting yellow color to butter increase risk for hepatocellular carcinoma (Tables 21.81 and 21.82).
- **Pathogens:** Pathogens inducing hepatocellular carcinoma include viruses (HBV, HCV), fungus (*Aspergillus flavus*) and parasites (*Clonorchis sinensis*) increase risk for hepatocellular carcinoma.

Clinical Features

Clinical symptoms of conventional hepatocellular carcinoma may be masked in the background of chronic viral hepatitis or cirrhosis.

- Patient presents with abdominal fullness, upper abdominal pain, weight loss and generalized weakness.

Table 21.81 Pathogens induced liver cell cancers

Organisms	Pathogens	Associated Tumors
Viruses	▪ HCV (RNA) ▪ HBV (DNA)	Hepatocellular carcinoma
Fungus	*Aspergillus flavus* (aflatoxin β_1 product)	Hepatocellular carcinoma
Parasites	▪ *Clonorchis sinensis* (liver fluke) ▪ *Opisthorchis viverrini* ▪ *Fasciola hepatica*	▪ Hepatocellular carcinoma ▪ Cholangiocarcinoma (bile duct carcinoma) ▪ Pancreatic carcinoma ▪ Cholangiocarcinoma (bile duct carcinoma)
Steatohepatitis	▪ Alcoholic etiology ▪ Nonalcoholic etiology	Hepatocellular carcinoma
Metabolic disorders	▪ Hemochromatosis ▪ α_1-Antitrypsin deficiency ▪ Tyrosinemia ▪ Porphyria cutanea tarda	Hepatocellular carcinoma
Drugs	▪ Thorostat ▪ Androgens ▪ Anabolic steroids ▪ Oral contraceptives	Hepatocellular carcinoma

Table 21.82 Indirect acting chemical carcinogens induced liver cancers

Chemical Carcinogen	Examples	Associated Cancers
Azo dyes derivatives of aromatic amines	Dimethylaminoazobenzene, known as butter yellow imparts an appetizing yellow color to margarine	Hepatocellular carcinoma
Natural carcinogens	Aflatoxin β_1 synthesized by fungus *Aspergillus flavus* in growing stored grains, nuts and peanut	Hepatocellular carcinoma
Organohalogen compounds	Polyvinyl chloride, carbon tetrachloride, chloroform, hexachlorobenzene, trichloroethylene	Liver angiosarcoma
Occupational carcinogens	Arsenic used in alloys, medication, preparation of fungicides and herbicides	Liver angiosarcoma, skin squamous cell carcinoma and basal cell carcinoma, lung carcinoma

- Other clinical features are due to hypoglycemia, polycythemia, increased serum calcium level, hypercholesterolemia and porphyria.
- Patient reaches into terminal stage characterized by cachexia, gastrointestinal or esophageal variceal bleeding, and hepatocellular failure with hepatic coma or rupture of tumor with fatal hemorrhage.
- On clinical examination, liver is enlarged with irregular nodularity surface.

Surgical Pathology: Conventional Hepatocellular Carcinoma

Gross Morphology

- Conventional hepatocellular carcinoma (HCC) can be unifocal or multifocal or diffusely infiltrative soft tumor, paler than surrounding normal liver. Color of the HCC may be green due to presence of bile. Extensive intrahepatic metastases are common. Tumor may be partially or completely encapsulated.
- Snake-like masses of tumor may involve the portal vein (35–80%), hepatic vein (20%) or inferior vena cava (similar to renal cell carcinoma).
- Cut surface of tumor has greenish yellow hue with necrosis and hemorrhage.
- Occasional tumor may be pedunculated arising from posterior and inferior surfaces of right lobe or accessory lobe in <1% of cases.
- Tumor <2 cm in diameter is referred to as small hepatocellular carcinoma lacking gross vascular invasion necrosis or hemorrhage. Gross morphology of conventional hepatocellular carcinoma is shown in Fig. 21.84.

Light Microscopy

Histology of conventional hepatocellular carcinoma is shown in Fig. 21.85. Histologic grading of conventional hepatocellular carcinoma (HCC) is given in Table 21.83.

Well-differentiated conventional hepatocellular carcinoma:

- Tumor is composed of large polyhedral cells with hyperchromatic round nuclei, thick nuclear membrane, prominent nuclei, intracytoplasmic globular hyaline inclusions and atypical mitoses.
- Tumor cells are arranged in trabecular (sinusoidal, plate-like) pattern with ≥3 cells much wider than normal liver plate thickness of 2 cells thick.
- Tumor cells may also be arranged in solid (compact), tubular, pseudoglandular or sarcomatoid patterns.
- Tumor cells are surrounded by layer of flattened endothelial cells. Presence of sinusoidal vessels surrounding tumor cells is an important diagnostic factor.
- The reticulin framework is generally reduced or absent.
- Common features in conventional HCC are portal vein thrombosis, vascular invasion and mitotic figure.
- Variable amount of fat, bile within bile canaliculi and Mallory-Denk hyaline bodies may be demonstrated.

Moderately-differentiated conventional hepatocellular carcinoma:

- Tumor is composed of large polyhedral cells with hyperchromatic round nuclei, thick nuclear membrane, prominent nuclei, more eosinophilic cytoplasm and atypical mitoses.
- Tumor cells are arranged in trabecular pattern with ≥3 cells much wider than normal liver plate thickness of 2 cells thick.

Poorly-differentiated conventional hepatocellular carcinoma:

- Tumor shows marked pleomorphism, scant cytoplasm, bizarre mitotic figures, tumor giant cells, prominent nuclei with nucleoli.
- Confluent growth or compression of adjacent trabeculae results in compact (solid) growth pattern with conspicuous or obliterated sinusoids.
- Cytoplasmic inclusions such as Mallory-Denk bodies, globular eosinophilic bodies composed of proteins including albumin, fibrinogen, α_1-antitrypsin, or ferritin, may be present.
- Pale bodies in large cytoplasmic inclusions containing fibrinogen are seen in fibrolamellar hepatocellular carcinoma.

Other Histologic Variants of Hepatocellular Carcinoma

Pleomorphic (giant cell) HCC

- Tumor cells demonstrate marked pleomorphic bizarre tumor giant cells with marked loss of cell cohesion.
- Distinct trabecular pattern is difficult to demonstrate in this HCC variant.

Clear cell HCC

- Tumor is composed of clear cytoplasm resulting from accumulation of cytoplasmic glycogen and/or fat that is lost in the paraffin embedding process.
- It is difficult to differentiate from metastatic renal, adrenal, or ovarian carcinoma.
- Immunohistochemical analysis is essential to establish diagnosis by highlighting bile canliculi (polyclonal CEA, pCEA) or hepatocellular differentiation (Hep Par 1 or glypican 3).
- Elevated serum AFP level, presence of chronic liver disease, and the absence of an extrahepatic mass indicate a hepatic primary neoplasm.

Sarcomatoid (spindle cell, pseudosarcomatous) HCC

- Tumor is composed of spindle-shaped cells. Sometimes, the tumor has been reported as carcinosarcoma when foci of more differentiated sarcoma such as osteosarcoma, chondrosarcoma, leiomyosarcoma and rhabdomyosarcoma are demonstrated.
- Epithelial component shows positivity for CAM 5.2 in 60% of cases.
- Spindle cell component demonstrates positivity for vimentin, smooth muscle actin and desmin. S-100 positivity is demonstrated in small number of cases. Serum AFP level is increased in 50% of cases.

Combined HCC and cholangiocarcinoma

- Combined HCC and cholangiocarcinoma constitutes <1% of primary hepatocellular carcinomas.

Diffuse cirrhosis-like HCC

- Diffuse and extensive liver involvement by small cirrhosis-like nodules evade clinical and radiographic detection of hepatocellular carcinoma.

Steatohepatitis HCC

- Tumor has been recently described associated with non-alcoholic fatty liver.
- Tumor has firmer consistency due to fibrosis.
- Histologic examination of tumor shows steatosis, hepatic ballooning degeneration, inflammation, and pericellular fibrosis with neoplastic element.

Immunohistochemistry Technique

Conventional hepatocellular carcinoma shows positivity for α_1-antitrypsin, α-fetoproteins, CEA, arginase 1, glypican 3, CAM 5.2 (CD8/CD18), Hep Par 1, Des-gamma carboxyprothrombin (DCP), TTF-1, vitamin B_{12} binding protein and human hepatocyte growth factor and copper.

- Recommended panel of markers is performed to differentiate conventional hepatocellular carcinoma from metastatic carcinoma are arginase 1 + Hep Par 2 + glycpican 3.
- Recommended panel of markers is performed to differentiate hepatocellular carcinoma from nonmalignant lesions are 2 of 3: glypican 3/GPC3 (cytoplasmic and canalicular), HSP70 and glutamine synthetase; adding clathrin heavy chain may be helpful.
- Recommended panel of markers is performed to differentiate hepatocellular carcinoma from nonmalignant lesions: GPS3 plus CD34 complete staining pattern.
- Recommended panel of immunohistochemical markers applied in differential diagnosis of hepatocellular carcinoma and cholangiocarcinoma are given in Table 21.84.

Markers	Expression
Hep Par 1 (hepatocyte paraffin 1)	Positive (80–90%)
α_1-Antitrypsin	Positive (75%)
α-Fetoproteins (AFP)	Positive (60–80%)
CEA (carcinoembryonic antigen) polyclonal	Positive (canalicular pattern 50–90%)
Arginase 1*	Positive (sensitive marker)
Glypican 3	Positive
CAM 5.2 (CD8/CD18)	Positive (50%)
Des-gamma carboxyprothrombin (DCP protein induced by vitamin K absence or antagonist II/PIVKA-2)	Positive
TTF-1	Positive (cytoplasmic staining)
Vitamin B_{12} binding protein	Positive
Human hepatocyte growth factor	Positive
Copper	Positive (7–40%)

**Arginase 1 is a binuclear metalloproteinase enzyme that catalyzes by hydrolysis of arginine to ornithine and urea. It is sensitive and specific marker for hepatocellular carcinoma.*

Neurotensin is expressed by fibrolamellar hepatocellular carcinoma.

Fig. 21.84: Gross morphology of conventional hepatocellular carcinoma. The satellite nodules of this hepatocellular carcinoma represent either intrahepatic spread of the tumor or multicentric origin of the tumor. Such masses may also focally obstruct the biliary tract and lead to an elevated alkaline phosphatase (arrow).

Table 21.83 Histologic grading of conventional hepatocellular carcinoma

Histologic Grade	Liver Architecture	Nuclear Features	Cell Size and Cytoplasmic Features	Other Features
Well-differentiated HCC grade I	Liver plates ≥3 cells, pseudoglandular pattern common	Minimal nuclear atypia	Neoplastic cells relatively smaller in size; fatty change	Well differentiated tumor; with presence of sinusoidal vessels surrounding tumor cells an important diagnostic factor
Moderately-differentiated HCC grade II	Liver plates ≥3 cells, trabecular pattern common	Nuclear atypia more marked	Neoplastic cells relatively larger in size with abundant eosinophilic cytoplasm; giant cells and bile may be demonstrated	Differentiation in tumor >2 cm size
Poorly-differentiated HCC grade III	Compact growth pattern with rare or absent trabeculae	Nuclear atypia marked with enlarged hyperchromatic nuclei	Spindle and small cells; and bile absent	Difficult to recognize hepatocellular origin

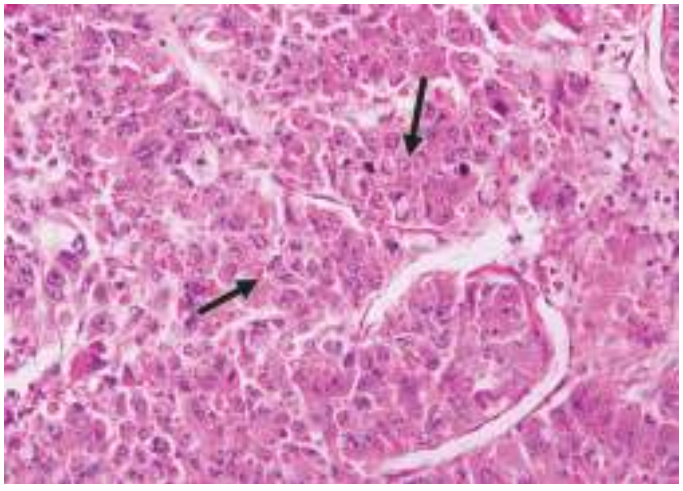

Fig. 21.85: Histology of conventional hepatocellular carcinoma. Tumor is composed of liver cords that are much wider than the normal liver plate that is two cells thick. Tumor cells are arranged in trabeculae. There is no discernible normal lobular architecture, though vascular structures are present. It is associated with elevated α-fetoprotein (arrows) (400X).

Electron Microscopy

Electron microscopy of conventional hepatocellular carcinoma demonstrates numerous mitochondria, microbodies and abundant glycogen. Intracytoplasmic blue products (bile canaliculi, peroxisomes) are present in the tumor cells.

Molecular Genetic Alterations

- **Hepatocyte growth factor increased baseline activity:** Many cancer stem cells acquire the ability to synthesize the same growth factors to which they are responsive, generating an autocrine loop. Increased baseline activity of hepatocyte growth factor (HGF) oncogene product is linked to hepatocellular carcinoma and thyroid carcinoma.
- **Insertional mutagenesis:** It is form of oncogene activation, which occurs due to insertion of viral gene into the mammalian DNA, resulting in genetic dysregulation and development of hepatocellular

Table 21.84 Panel of immunohistochemical markers applied in differential diagnosis of hepatocellular carcinoma and cholangiocarcinoma

Immunohistochemical Markers	Conventional Hepatocellular Carcinoma	Cholangiocarcinoma
Hep Par 1	Positive (95% fairly specific)	Negative
α-Fetoproteins (AFP)	Positive (30–60% not specific)	Negative (positive in rare case)
mCEA	Negative	Positive
p-CEA	Positive (80% canalicular highly specific)	Positive (cytoplasmic)
CD10	Positive (canalicular)	Negative
Villin	Positive (canalicular)	Negative
CK7 (cytokeratin 7)	Negative	Positive
CK19 (cytokeratin 19)	Negative	Positive (70–100%)
CK20 (cytokeratin 20)	Positive (up to 20%)	Positive (usually)

Contd...

Table 21.84 Panel of immunohistochemical markers applied in differential diagnosis of hepatocellular carcinoma and cholangiocarcinoma (*Contd...*)

Immunohistochemical Markers	Conventional Hepatocellular Carcinoma	Cholangiocarcinoma
CK AE1/AE3 (pan-CK)	Positive	Positive
CAM 5.2 (LMWCK) pan-CK	Positive (5–20%)	Positive
CK903 (HMWCK)	Positive	Positive
Glypican 3	Positive (new marker of hepatocellular differentiation)	Negative
Arginase 1 (new marker of hepatocellular differentiation)	Positive	Negative
α_1-Antitrypsin	Positive (up to 50%)	Negative
TTF-1 (thyroid transcription factor 1)	Positive (cytoplasmic staining)	Negative
EMA (epithelial membrane antigen) marker of glandular epithelium	Negative	Negative
MOC-31	Negative (marker of glandular epithelium)	Negative
Mucicarmine	Negative (marker of glandular epithelium)	Negative

Fibrolamellar variant of hepatocellular carcinoma is positive for neurotensin.

carcinoma. The best example of such an event may be found in hepatitis virus-infected hepatocytes.

- **Mutant RAS:** Mutant signal transducing RAS protein has been linked to hepatocellular carcinoma.
- **Translocation and amplification of CCND1/cyclin D1:** It has been demonstrated in conventional hepatocellular carcinoma.
- **Amplification or point mutation of CDK4 (cyclin-dependent kinase):** It has been demonstrated in hepatocellular carcinoma.

Pathology Pearls: Molecular Genetic Alterations in HCC

- Hepatocytic growth factor (HGF) increased baseline activity
- Insertional mutagenesis by viruses
- RAS mutation
- Translocation and amplification of CCND1/cyclin D1
- Amplification or point mutation of CDK4 (cyclin-dependent kinase)

Mode of Spread

- **Lymphatic route:** Conventional hepatocellular carcinoma spreads by lymphatic route to peripancreatic and para-aortic lymph nodes.
- **Hematogenous route:** Hematogenous spread of conventional hepatocellular carcinoma is relatively less frequent. It may spread by hematogenous route by invading portal vein reaching to right side of heart resulting in metastases to lungs, bones, adrenal glands and central nervous system.

Prognostic Factors

Patients with hepatocellular carcinoma measuring ≤5 cm in size treated by surgical excision have five-year survival in 10–50% of cases.

- Death occurs from hepatocellular failure, rupture of malignant tumor, cachexia and gastrointestinal bleeding.
- Favorable prognostic factors are low stage, encapsulated tumor size <5 cm, without lymphovascular invasion, negative surgical margin and low nuclear grade.
- Conventional hepatocellular carcinoma is treated by surgical resection, liver transplantation and radiofrequency ablation/transarterial chemoembolization.

Pathology Pearls: Protocol for Reporting Hepatocellular Carcinoma

Protocol for reporting resection of hepatocellular carcinoma recommended by College of American Pathologists are given as under.

Gross Morphology

- Tumor size
- Tumor focality
- Tumor margins
- Tumor extension
- Lymph nodes study

Histologic Examination

- Histologic type
- Histologic grade
- Lymphovascular invasion
- Perineural invasion

Pathologic Findings

- Grading
- Staging

Ancillary Studies

- Immunohistochemistry technique
- Serum tumors

Pathology Pearls: Protocol for Reporting Lymph Node in Hepatocellular Carcinoma

Protocol for reporting lymph node biopsy specimen recommended by College of American Pathologists is given below.

- Most often, three or four lymph nodes are submitted for histologic examination.
- Lymph node biopsy is obtained from hepatic region, i.e. hilar, hepatoduodenal ligament, inferior phrenic and caval regions. Involvement of these lymph nodes is considered as distant metastases.

Pathology Pearls: Increased Serum α-Fetoprotein (AFP) Tumor Marker in Various Disorders

Serum α-fetoprotein level is increased in 60–80% cases of hepatocellular carcinoma. Serum α-fetoprotein is also raised in cirrhosis, chronic viral hepatitis, hepatoblastoma and yolk sac tumor of gonads.

- Hepatocellular carcinoma
- Hepatoblastoma
- Yolk sac tumors of gonads
- Cirrhosis
- Pregnancy
- Massive liver cell necrosis with regeneration
- Chronic viral hepatitis
- Immunohistochemistry technique in hepatocellular and metastatic carcinomas is given in Table 21.85.

Clinical Features

Patient with conventional hepatocellular carcinoma may present with symptoms of paraneoplastic syndrome such as hypoglycemia, increased red blood cell count, increased serum calcium level, hypercholesterolemia and porphyria.

- Clinical symptoms of conventional HCC may be masked in the background of chronic viral hepatitis or cirrhosis. Patients present with abdominal fullness, upper abdominal pain, weight loss and generalized weakness.
- These patients reach terminal stage characterized by cachexia, gastrointestinal tract or esophageal variceal bleeding, and hepatocellular failure with hepatic coma or rupture of tumor with fatal hemorrhage.
- On clinical examination, liver is enlarged with irregular nodularity.

Table 21.85 Immunohistochemistry technique in hepatocellular and metastatic carcinomas

Markers	Hepatocellular Carcinoma	Metastatic Carcinoma
▪ Arginase 1 ▪ Glypican 3 ▪ *Hep Par 1* (hepatocyte paraffin 1)	Positive	Negative

Specific markers are used to confirm origin of tumors metastasizing to liver.

Laboratory Diagnosis

Conventional hepatocellular carcinoma is screened by ultrasonography, hepatic angiography, MRI and serum AFP and des-gamma carboxyprothrombin markers. MRI demonstrates location, invasiveness and presence or absence of multifocality.

- **Serum α-fetoprotein:** It is a glycoprotein synthesized in the fetus by the yolk sac, liver, and gastrointestinal tract. In adults, an elevated serum level of AFP is a useful indicator of hepatocellular carcinoma and germ cell tumors of the testis. Elevated serum AFP is demonstrated in 60–80% cases of conventional HCC. Its sensitivity is reduced in alcohol-related cirrhosis, tumors arising in noncirrhotic liver and tumor size 2 cm or less. Disorders associated with serum AFP are conventional hepatocellular carcinoma, hepatoblastoma, cirrhosis, massive hepatocellular necrosis with regeneration, chronic hepatitis, yolk sac tumor of gonads and pregnancy. Disorders associated with elevated AFP are given in Table 21.86.
- **Serum des-gamma carboxyprothrombin:** Its positivity is demonstrated in 75–90% cases with large tumor. Small tumors do not show its positivity. Serum des-gamma carboxyprothrombin marker (DCP protein induced by vitamin K absence or antagonist II/PIVKA-2) is more specific marker than serum AFP for poor prognosis. Abnormal des-gamma carboxyprothrombin is synthesized by hepatocellular carcinoma associated with early portal vein invasion, intrahepatic metastasis and capsular invasion.
- **Imaging techniques:** Imaging techniques include ultrasonography, hepatic angiography, CT scan and MRI. MRI demonstrates location, invasiveness and presence or absence of multifocality.

Table 21.86 Disorders associated with elevated AFP

Conventional hepatocellular carcinoma
Hepatoblastoma
Cirrhosis
Massive hepatocellular necrosis with regeneration
Chronic viral hepatitis
Yolk sac tumor of gonads
Pregnancy

- **Fine needle aspiration cytology (FNAC):** FNAC is cost effective diagnostic tool for early diagnosis.
- **Histologic examination:** It is performed to confirm the diagnosis of conventional hepatocellular carcinoma, which should be differentiated from hepatocellular adenoma and focal nodular hyperplasia. Gross and histologic features of hepatocellular tumors are given in Table 21.87.
- **Immunohistochemistry:** Panel of markers is used to study the expression of hepatocellular carcinoma and metastases.

Prognosis

Without aggressive surgical resection, abalative therapy or liver transplantation hepatocellular carcinoma results in hepatocellular failure and eventually death.

FIBROLAMELLAR HEPATOCELLULAR CARCINOMA

Fibrolamellar hepatocellular carcinoma, a variant of hepatocellular carcinoma is a rare primary malignant tumor of liver. It affects adolescents with female predominance. It occurs without chronic liver disease (hepatitis B virus infection).

- Tumor is composed of large polygonal neoplastic cells arranged in nests and cords. Collagen fibers are arranged in lamellar fashion around tumor cells. It is diagnosed by imaging techniques and histologic examination. It is associated with better prognosis than conventional hepatocellular carcinoma.
- Tumor appears to be more common in Western countries and accounting for 6% of liver cancers. It usually affects younger patients with slightly female predominance.

Molecular Genetic Alterations

The recent studies revealed the presence of DNAJB-1-PRKACA chimeric transcript resulting from a 400 kb somatic deletion on chromosome 19 in cases of fibrolamellar hepatocellular carcinoma.

Clinical Features

Initially, the patient is asymptomatic. Cases are diagnosed in advanced disease.

Table 21.87 Gross and histologic features of hepatocellular tumors

Parameters	Conventional Hepatocellular Carcinoma	Fibrolamellar Hepatocellular Carcinoma	Hepatocellular Adenoma	Focal Nodular Hyperplasia of Liver
Gross morphology				
Tumor number	Solitary > multiple	Solitary pale brown tumor	Solitary tumor in subcapsular region	Well circumscribed lesion without capsule
Background liver morphology	Fibrotic or cirrhotic background	Normal background features	Normal background features	Normal background features
Histologic features				
Architecture	Tumor cells (cell platelets) arranged in trabecular, acinar, pseudoglandular architecture with mitoses, bile in tumor cells	Neoplastic cells arranged in clusters enmeshed in dense collagen	Neoplastic cells with normal-appearing hepatocytes with thickened plates	Nodules composed of normal hepatocytes
Quality of fibrous stroma of tumor	Absent or minimal stroma, fibrous in fibrolamellar variant	Dense collagenous stroma	Fibrous septa but absence of portal tracts	Radiating septa with ductular proliferation present
Cytomorphological features	Uniform tumor cells resembling hepatocytes; pleomorphism in high-grade tumor	Neoplastic cells with abundant cytoplasm and nucleus with macronucleoli; cytoplasm containing small intracytoplasmic hyaline globules and pale bodies	Neoplastic cells with normal-appearing hepatocytes with thickened plates; and naked blood vessels, cholestasis and bile plugs	Nodules composed of normal hepatocytes with thickened arteries within fibrous stroma
Mitoses	Easily demonstrated	Less common	Absent	Absent

- Patient presents with epigastric mass, vague abdominal pain and fullness, nausea, vomiting, malaise, weight loss. Rare presentation is Budd-Chiari syndrome, hypoglycemia, obstructive jaundice and gynecomastia.
- Later, patient develops jaundice, ascites, fulminant hepatocellular failure, encephalopathy, thrombophlebitis of lower extremities, recurrent deep vein thrombosis and anemia.
- Serum aminotransferases (ALT, AST) and serum AFP may be within normal range or mildly elevated. Serum des-gamma carboxyprothrombin (DCP) level is increased.
- About 70% of cases have lymph node metastasis at presentation, in contrast to conventional HCC, which seldom involves lymph nodes.

Surgical Pathology: Fibrolamellar Hepatocellular Carcinoma

Gross Morphology

- Fibrolamellar hepatocellular carcinoma is single large, hard scirrhous tumor with fibrous bands running through it. Sometimes tumor may show encapsulation.
- Cut surface of tumor reveals multiple nodules.
- Bcakground liver shows no evidence of cirrhosis.
- Bile stain is demonstrated on cut surface of tumor.

Light Microscopy

- Collagen fibers are arranged in lamellar fashion around the large polygonal tumor cells arranged in nests and cords (Fig. 21.86A to C).
- Differences between fibrolamellar hepatocellular carcinoma and conventional hepatocellular carcinoma are given in Table 21.88.

Immunohistochemistry Technique

Neurotensin is tumor marker for fibrolamellar variant of hepatocellular carcinoma.

Mode of Spread

Fibrolamellar hepatocellular carcinoma spreads by lymphatic route to draining lymph nodes.

Prognosis and Treatment

Prognosis of fibrolamellar hepatocellular carcinoma is better than conventional hepatocellular carcinoma.

- Plasma neurotensin and vitamin B_{12} binding globulins are increased in fibrolamellar hepatocellular carcinoma. These parameters are useful in monitoring the disease and detecting recurrence after surgery.

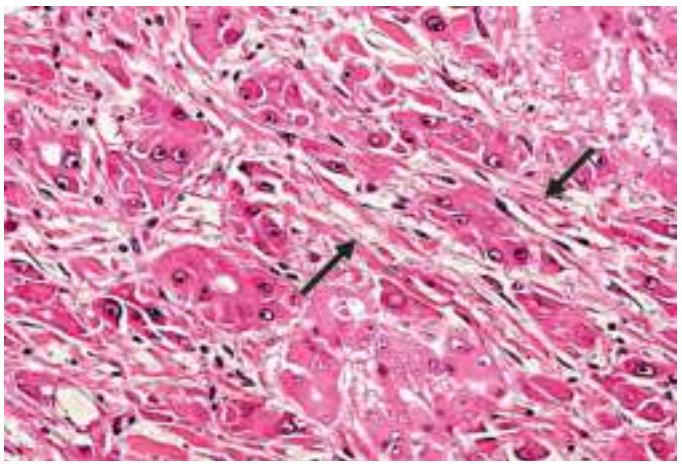

Fig. 21.86A: Fibrolamellar hepatocellular carcinoma shows tumor cells surrounded by fibrocollagenous tissue (arrows) (400X).

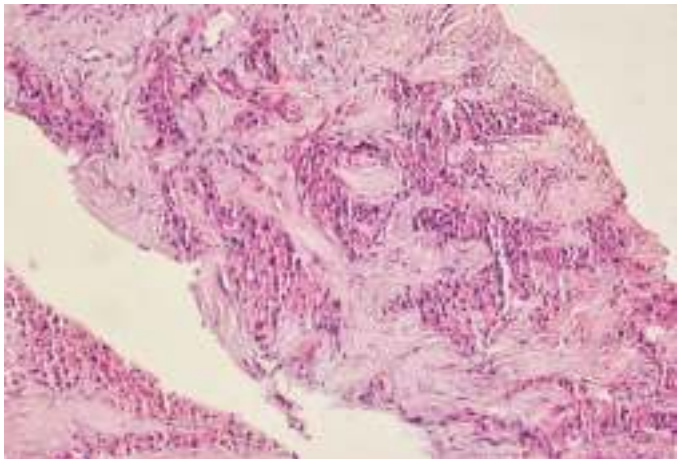

Fig. 21.86B: Fibrolamellar hepatocellular carcinoma on hematoxylin and eosin-stained section. Tumor is composed of large polygonal neoplastic cells with well-defined borders arranged in sheets, cords and trabeculae with abundant granular eosinophilic cytoplasm and nuclei with open chromatin and prominent nucleoli in background of dense collagen bundles. Histologically, fibrous bands coalesce into central scar (400X).

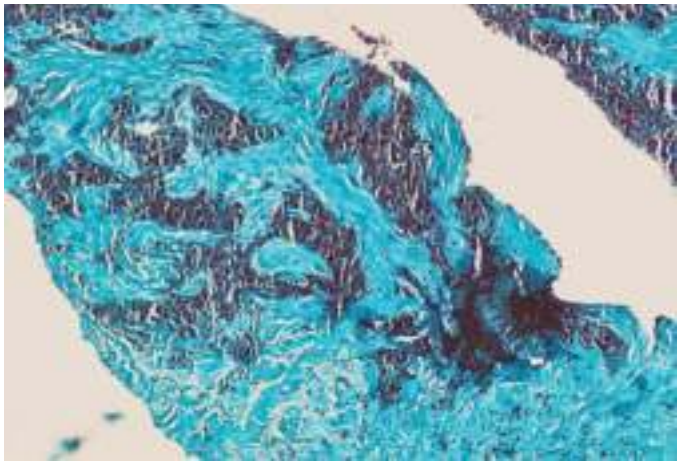

Fig. 21.86C: Masson trichrome stain demonstrates collagen fibers in fibrolamellar hepatocellular carcinoma (400X).

Table 21.88 Differences between fibrolamellar hepatocellular carcinoma and conventional hepatocellular carcinoma

Clinical Manifestations	Fibrolamellar Hepatocellular Carcinoma	Conventional Hepatocellular Carcinoma
Epidemiology		
Incidence	1–5%	95–99%
Age group	Peak incidence in third decade	Peak incidence in sixth to seventh decade
Sex predilection	Women > men	Men > women
Serum des-gamma carboxy-prothrombin (DCP)	100%	60–90%
Serum AFP	10–15%	60–80%
Imaging analysis and tumor resectibility		
Calcification	40–80%	≤5%
Central scarring	50–70%	Rare
Resectability	50–75%	10–80%
Gross morphology		
Solitary or multifocal lesion	Solitary (75%) left lobe > right lobe	Usually multifocal, solitary uncommon
Fibrous septa, scarring	10–60%	Absent
Hemorrhage necrosis	Occasional but may be present in large tumor	Common
Associated cirrhosis in the background	<10%	60–90%
Histologic features		
Cell size, shape	Large	Smaller cell size
Cytoplasm abundance	More	Less
Cytoplasmic granularity	More	Less
Pale bodies in cytoplasm	50%	10%
Hyaline globules	50%	10–50%
Fibrous stroma	Prominent lamellar bands	Scan
Overall histologic features	▪ Collagen fibers are arranged in lamellar fashion around large polygonal tumor cells arranged in nests and cords ▪ Lamellar stromal strands around tumor cells present ▪ Presence of granular cytoplasm in tumor cells common ▪ Hyaline/pale bodies in cytoplasm of tumor cells common	▪ Tumor cells are polyhedral containing hyperchromatic nuclei and prominent nucleoli arranged in solid, tubular and trabecular patterns ▪ Lamellar stromal strands around tumor cells absent ▪ Presence of granular cytoplasm in tumor cells uncommon ▪ Hyaline/pale bodies in cytoplasm of tumor cells uncommon
Electron microscopy		
Mitochondria on electron microscopy	Numerous	Less common
Immunohistochemistry		
Immunomarkers	Neurotensin	▪ Hep Par 1 (hepatocyte paraffin 1), positive (80–90%) ▪ α_1-Antitrypsin, positive (75%) ▪ α-Fetoprotein (AFP), positive (60–80%) ▪ CEA (carcinoembryonic antigen) polyclonal ▪ hCG ▪ Cytokeratin

Contd...

Table 21.88 Differences between fibrolamellar hepatocellular carcinoma and conventional hepatocellular carcinoma (*Contd...*)

Clinical Manifestations	Fibrolamellar Hepatocellular Carcinoma	Conventional Hepatocellular Carcinoma
		▪ Glypican 3 ▪ EMA ▪ Vimentin ▪ Glypican 3, positive ▪ CAM 5.2 (CD8/CD18), positivity (50%) ▪ Des-gamma carboxyprothrombin (DCP protein induced by vitamin K absence or antagonist II/ PIVKA-2), positive
Five-year survival		
Overall survival	25–90%	0–7%
Resected tumor	55–75%	20–50%

- In view of its recurrence nature of fibrolamellar hepatocellular carcinoma, periodic follow-up is essential by use of imaging modality and plasma level of neurotensin and vitamin B_{12} binding globulins.
- Death occurs due to gastrointestinal bleeding and hepatocellular failure.

CHOLANGIOCARCINOMA

Cholangiocarcinoma is most often associated with primary sclerosing cholangitis, which is less common than hepatocellular carcinoma. It is never associated with HBV infection or cirrhosis.

Origin of Tumor

According to WHO convention, the term cholangiocarcinoma is reserved for carcinoma arising in the intrahepatic bile ducts. Cholangiocarcinoma arises from epithelium lining intrahepatic biliary ducts at the porta hepatis to the smallest bile ductules at the periphery of the hepatic lobules.

Locations

- Extrahepatic cholangiocarcinoma is most common type seen in 90% of cases. Perihilar type is most common type seen in 60% of cases and known as Klatskin tumor located at the junction of left and right hepatic ducts. It may be located in distal bile ducts in 20–30% of cases.
- Intrahepatic cholangiocarcinoma is less common type seen in 10% of cases.

Risk Factors

- ***Clonorchis sinensis* (liver fluke):** It is transmitted through consumption of raw or undercooked vegetables. It resides in the biliary tree resulting in cholangiocarcinoma in far East population.
- ***Opisthorchis viverrini*:** It may cause cholangiosarcoma of the bile ducts.
- **Thorotrast contrast medium:** Sometimes, it occurs as a late complication of thorium dioxide (thorotrast) administration.
- **Primary sclerosing cholangitis:** It is associated with ulcerative colitis. There is increased incidence of cholangiocarcinoma.
- **Caroli's disease:** It is also known as choledocal cyst. It is congenital fibropolycystic disease of biliary system, which increases risk for cholangiocarcinoma.
- **Chronic alcoholic disease:** There may be increased risk for development of cholangiocarcinoma.
- **Hepatitis C virus (HCV):** Patient with hepatitis C infection may develop cholangiocarcinoma.

Molecular Genetic Alterations

Upregulation of IL-6 activates AKT results in overexpression of MCL-1 (antiapoptotic protein) leading to cholangiocarcinoma.

K-RAS gene mutation and alteration of p53 tumor suppressor gene play role in development of cholangiocarcinoma.

Clinical Features

Patient presents with painless lump, jaundice, pruritus, weight loss and acholic stools.

Surgical Pathology: Cholangiocarcinoma

Gross Morphology

- Extrahepatic cholangiocarcinoma is either firm gray nodules within bile duct wall or diffusely infiltrative (2%), which often extends into adjacent structures. Tumors may be papillary, multifocal and friable.
- Intrahepatic cholangiocarcinoma is usually large, noncapsulated, well-demarcated, firm (due to desmoplastic reaction), white-tan to gray and nodular mass. It is more frequent in the right lobe. Calcification is common in the tumor.

Light Microscopy
▪ Extrahepatic cholangiocarcinoma is composed of small cuboidal cells with vesicular nuclei and prominent nucleoli arranged in glandular pattern. Mucin is always present within cytoplasm of tumor cells and glandular lumina. ▪ Intrahepatic cholangiocarcinoma consists of infiltrating well-formed glands in abundant fibrous stroma. Malignant glands are lined by cells with varying degrees of atypia and intrapleomorphism (Fig. 21.87A and B).

Immunohistochemistry Technique	
The tumor cells express CK7, CK19 and claudin 4.	
Markers	**Expression**
▪ CK7 ▪ CK19 ▪ Claudin 4	▪ Positive ▪ Positive ▪ Positive

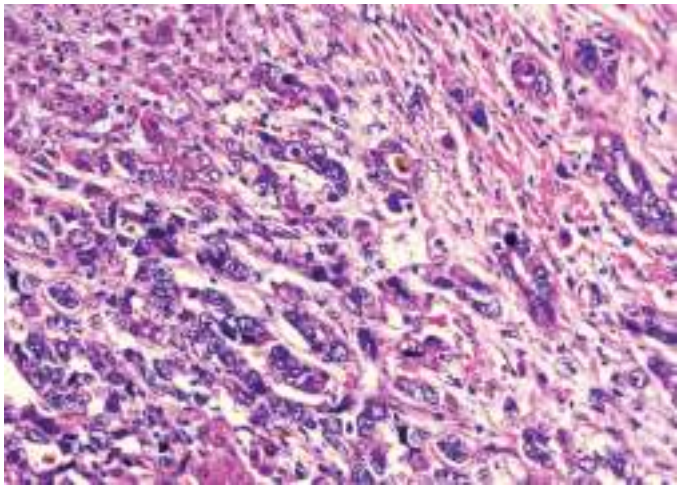

Fig. 21.87A: Cholangiocarcinoma shows glandular appearance. It does not make bile, but the cells do make mucin, and they can be almost impossible to distinguish from metastatic adenocarcinoma on biopsy or fine needle aspirate (400X).

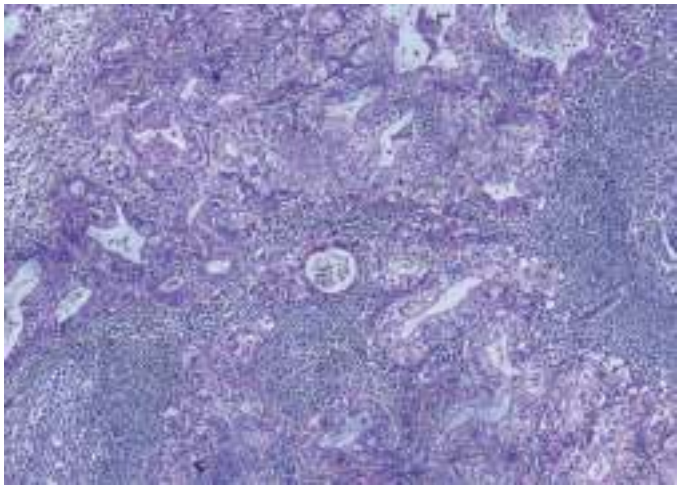

Fig. 21.87B: Cholangiocarcinoma matastasis in lymph node.

Differential Diagnosis

Tumor cells of cholangiocarcinoma are not bile stained, as bile is synthesized by hepatocytes. It is worth mentioning that hepatocellular carcinoma tumor cells show bile. It does not make bile, but the cells do make mucin, and they can be almost impossible to distinguish from metastatic adenocarcinoma on biopsy or fine needle aspirate. Fibrolamellar hepatocellular carcinoma consists of fibrous septa but negative for CK7 and CK19.

Mode of Spread

Like hepatocellular carcinoma, cholangiocarcinoma has a propensity for early invasion of vascular channels.

HEPATOBLASTOMA

Hepatoblastoma is uncommon malignant liver cancer in infants and children <3 years of age. Tumor is composed of tissue resembling fetal liver cells or bile ducts. It is diagnosed during first year of childhood.

Origin of Tumor

Hepatoblastoma originates from immature liver precursor cells. The tumor is usually unifocal affecting right lobe of liver more often than left lobe.

Predisposing Factors

Although the exact etiology of hepatoblastoma is unknown. Genetic disorders associated with an increased risk for developing hepatoblastoma include familial adenomatous polyposis, hemihypertrophy and Beckwith-Wiedemann syndrome.

Molecular Genetic Alterations

β-Catenin has been demonstrated in 70% cases of hepatoblastoma. Activation of Wnt signaling pathway may play an important role in the pathogenesis of hepatoblastoma.

Clinical Features

Patient with hepatoblastoma presents with abdominal mass and failure to thrive. It is usually associated with nephroblastoma, cleft palate, hemihypertrophy, renal or cardiac malformations.

Surgical Pathology: Hepatoblastoma
Gross Morphology
Tumor is solitary with pseudocapsule. It shows no underlying cirrhosis.

Light Microscopy

Histologic pattern of hepatoblastoma includes epithelial type, e.g. fetal, embryonal, macrotrabecular and small cell undifferentiated patterns, and mixed epithelial–mesenchymal type, e.g. teratoid and nonteratoid.

- **Fetal variant of hepatoblastoma:** Tumor is composed of polygonal cells with central round nuclei and prominent nucleoli. The 2–3 cells thick plates are arranged in sheets, trabeculae and solid groups. There may be foci of hematopoiesis.
- **Embryonal variant of hepatoblastoma:** Tumor cells are arranged in sheets, ribbons, acinar and rosettes.
