Senior Clinical Research Fellow, Nuffield Department of Orthopaedics, Rheumatology, and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom  
*Psoriatic Arthritis*

**August Colenbrander, MD**

Affiliate Senior Scientist, RERC, Smith-Kettlewell Eye Research Institute, San Francisco, California  
*Vision Rehabilitation*

**Ryan Commins, MD**

Fellow, Department of Medicine, Thomas Jefferson University Hospital, Philadelphia, Pennsylvania  
*High Altitude Illness*

**Christine Conageski, MD**

Associate Professor, Obstetrics and Gynecology, University of Colorado School of Medicine, Aurora, Colorado  
*Vulvar Neoplasia*

**John Conly, MD**

Medical Officer, Infection Prevention and Control, Foothills Medical Centre; Professor, Department of Medicine, Medical Director, Ward of the 21st Century, Cummings School of Medicine; Co-Director, Snyder Institute for Chronic Diseases, University of Calgary, Calgary, Alberta, Canada  
*Methicillin-Resistant Staphylococcus aureus (MRSA)*

**Carlo Contini, MD**

Full Professor of Infectious Diseases, Director of Infectious Diseases Unit, Department of Medical Sciences, University of Ferrara, Ferrara, Italy  
*Toxoplasmosis*

**Ashley Cooper, MD**

Associate Professor, Pediatrics, Children's Mercy Kansas City/University of Missouri-Kansas City, Kansas City, Missouri  
*Juvenile Idiopathic Arthritis*

**Stacy Cooper, MD**

Assistant Professor, Department of Oncology, The Johns Hopkins University School of Medicine, Baltimore, Maryland  
*Acute Leukemia in Children*

**Allison Cormier, MD**

Assistant Professor, Department of Infectious Disease, Tulane School of Medicine, New Orleans, Louisiana  
*Human Immunodeficiency Virus: Treatment and Prevention*

**Burke A. Cunha, MD**

Physician, Division Infectious Disease, NYU Winthrop Hospital, Mineola, New York  
*Babesiosis; Viral and Mycoplasma Pneumonias*

**Cheston B. Cunha, MD**

Medical Director, Antimicrobial Stewardship, Division of Infectious Disease, The Warren Alpert Medical School of Brown University, Providence, Rhode Island  
*Babesiosis; Viral and Mycoplasma Pneumonias*

**Thomas Curran, MD, MPH**

Assistant Professor, Department of Surgery, Medical University of South Carolina, Charleston, South Carolina  
*Tumors of the Colon and Rectum*

**Amy Curry, MD**

Clinical Associate Professor, Department of Family and Community Medicine, Via Christi Family Medicine Residency, University of Kansas School of Medicine-Wichita, Wichita, Kansas  
*Pelvic Inflammatory Disease*

**Cori L. Daines, MD**

Professor and Division Chief of Pediatric Pulmonary and Sleep Medicine, Department of Pediatrics, University of Arizona College of Medicine, Tucson, Arizona  
*Histoplasmosis*

**Oriana M. Damas, MD**

Assistant Professor, Director of Translational Studies for the Crohn's and Colitis Center, Division of Gastroenterology, University of Miami Miller School of Medicine, Miami, Florida  
*Inflammatory Bowel Disease*

**Beth A. Damitz, MD**

Associate Professor, Family and Community Medicine; Associate Program Director, All Saints Family Medicine Residency Program, Medical College of Wisconsin, Milwaukee, Wisconsin  
*Immunization Practices*

**Nandini Datta, PhD**

Postdoctoral Scholar, Child and Adolescent Psychiatry, Stanford University School of Medicine, Stanford, California  
*Eating Disorders*

**Natalie C. Dattilo, PhD**

Director of Psychology, Department of Psychiatry, Brigham and Women's Hospital, Boston, Massachusetts  
*Generalized Anxiety Disorders; Posttraumatic Stress Disorder*

**Raul Davaro, MD**

Associate Professor, Clinical Medicine, University of Massachusetts Medical School, Worcester, Massachusetts  
*Smallpox; Whooping Cough (Pertussis)*

**Kevin A. David, MD**

Hematologist/Oncologist, Director, Lymphoma Program, Rutgers Cancer Institute of New Jersey, Division of Blood Disorders, Rutgers University, New Brunswick, New Jersey  
*Non-Hodgkin Lymphoma*

**André de Leon, MD**

Family Medicine and Sports Medicine, OhioHealth Primary Care & Pediatric Physicians, Delaware, Ohio; Assistant Clinical Professor, Department of Family Medicine, Loma Linda University School of Medicine, Loma Linda, California  
*Chronic Diarrhea*

**Tate de Leon, MD**

Faculty, Family Medicine, Eisenhower Health, Rancho Mirage, California  
*Chronic Diarrhea*

**Alexei O. DeCastro, MD**

Associate Professor, Department of Family Medicine, Medical University of South Carolina, Charleston, South Carolina  
*Osteoporosis*

**Katharine C. DeGeorge, MD, MS**

Associate Professor, Department of Family Medicine, University of Virginia School of Medicine, Charlottesville, Virginia  
*Bacterial Pneumonia; Asthma in Children*

**Thomas G. DeLoughery, MD**

Professor of Medicine, Divisions of Hematology/Oncology and Laboratory Medicine, Oregon Health & Science University, Portland, Oregon  
*Hemolytic Anemia*

**Atul Deodhar, MD, MRCP**

Professor of Medicine, Division of Arthritis and Rheumatic Diseases, Oregon Health & Science University, Portland, Oregon  
*Axial Spondyloarthritis*

**Urmi Desai, MD, MS**

Assistant Professor of Medicine, Center for Family and Community Medicine; Director, Foundations of Clinical Medicine Clerkships, Columbia University Irving Medical Center, New York, New York  
*Vulvovaginitis*

**Clio Dessinioti, MD, MSc, PhD**

Dermatologist, Department of Dermatology, Andreas Syngros Hospital, Athens, Greece  
*Parasitic Diseases of the Skin*

**Michael P. Diamond, MD**

Senior Vice President for Research, Department of Obstetrics and Gynecology, Augusta University, Augusta, Georgia  
*Infertility*

**Christopher Dion, DO**

Medical Toxicology Fellow, Department of Medical Toxicology, Banner - University Medical Center Phoenix, Phoenix, Arizona  
*Venomous Snakebite*

**Catherine Do, MD**

Assistant Professor, Internal Medicine, University of New Mexico School of Medicine; Staff Nephrologist, Medicine Service, New Mexico Veterans Health Care System, Albuquerque, New Mexico  
*Chronic Kidney Disease*

**Thomas Dobbs, MD**

Dean, School of Population Health, University of Mississippi Medical Center; Communicable Diseases, Mississippi State Department of Health, Jackson, Mississippi  
*COVID-19*

**Colleen A. Donahue, MD**

Assistant Professor, Department of Surgery, Medical University of South Carolina, Charleston, South Carolina  
*Tumors of the Colon and Rectum*

**Geoffrey A. Donnan, MD**

Director, The Florey Institute of Neuroscience and Mental Health, Florey Department of Neuroscience and Mental Health, The University of Melbourne, Melbourne, Victoria, Australia  
*Ischemic Cerebrovascular Disease*

**John N. Dorsch, MD**

Professor Emeritus, Department of Family and Community Medicine, University of Kansas School of Medicine-Wichita, Wichita, Kansas  
*Red Eye*

**Michael Dougan, MD, PhD**

Assistant Professor, Medicine/Gastroenterology, Massachusetts General Hospital, Boston, Massachusetts  
*Monoclonal Antibodies*

**Chad Douglas, MD, PharmD**

Assistant Professor, Department of Family and Preventive Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma  
*Erythema Multiforme*

**Dar Dowlatshahi, MD, PhD**

Professor, Department of Medicine, University of Ottawa, Ottawa, Ontario, Canada  
*Intracerebral Hemorrhage*

**Shannon Dowler, MD**

Adjunct Associate Professor, Family Medicine, University of North Carolina, Asheville, North Carolina  
*Nongonococcal Urethritis*

**Douglas Drevets, MD**

Regents' Professor and Chief, Section of Infectious Diseases,  
University of Oklahoma Health Sciences Center, Oklahoma  
City, Oklahoma  
*Plague*

**Samuel C. Dudley Jr., MD, PhD**

Professor of Medicine, Cardiovascular Division, University of  
Minnesota, Minneapolis, Minnesota  
*Atrial Fibrillation*

**Peter R. Duggan, MD**

Clinical Associate Professor, Department of Medicine, Cummings  
School of Medicine, University of Calgary, Calgary, Alberta,  
Canada  
*Polycythemia Vera*

**Kim A. Eagle, MD**

Albion Walter Hewlett Professor of Internal Medicine,  
Cardiovascular Disease, University of Michigan, Ann Arbor,  
Michigan  
*Angina Pectoris*

**Leigh M. Eck, MD**

Professor, Department of Internal Medicine, University of Kansas  
School of Medicine, Kansas City, Kansas  
*Thyroiditis*

**Wissam El Atrouni, MD, MSc**

Associate Professor, Department of Medicine, University of  
Kansas School of Medicine, Kansas City, Kansas  
*Osteomyelitis*

**Dirk M. Elston, MD**

Professor and Chair, Department of Dermatology, Medical  
University of South Carolina, Charleston, South Carolina  
*Diseases of the Hair*

**John M. Embil, MD**

Professor, Department of Medicine, University of Manitoba,  
Winnipeg, Manitoba, Canada  
*Blastomycosis*

**Scott K. Epstein, MD**

Professor, Department of Medicine, Tufts University School of  
Medicine, Boston, Massachusetts  
*Acute Respiratory Failure*

**Susan Evans, MD**

Assistant Professor, Department of Family Medicine, University  
of Nebraska Medical Center, Omaha, Nebraska  
*Iron Deficiency Anemia*

**Andrew M. Evens, DO, MSc**

Professor of Medicine and Chief, Division of Hematology/  
Oncology, Rutgers Cancer Institute of New Jersey, New  
Brunswick, New Jersey  
*Non-Hodgkin Lymphoma*

**J. Barry Fagan, MD**

Service Chief, Specialty Medicine, Chalmers P. Wylie VA  
Ambulatory Care Center, Columbus, Ohio  
*Chronic Obstructive Pulmonary Disease*

**Mark Fairweather, MD, PhD**

Associate Surgeon, Surgery, Brigham and Women's Hospital;  
Assistant Professor, Surgery, Harvard Medical School, Boston,  
Massachusetts  
*Tumors of the Stomach*

**Marni J. Falk, MD**

Executive Director, Mitochondrial Medicine Frontier Program,  
Division of Human Genetics, Department of Pediatrics, The  
Children's Hospital of Philadelphia; Associate Professor,  
Department of Pediatrics, University of Pennsylvania Perelman  
School of Medicine, Philadelphia, Pennsylvania  
*Mitochondrial Disease*

**Anna Faris, MD**

Resident Physician, Department of Urology, University of  
Michigan, Ann Arbor, Michigan  
*Trauma to the Genitourinary Tract*

**Anthony J. Faugno III, MD**

Assistant Professor, Pulmonary, Critical Care, and Sleep, Tufts  
Medical Center, Boston, Massachusetts  
*Acute Respiratory Failure*

**Hilary Faust, MD, MS**

Assistant Professor, Department of Medicine, University of  
Wisconsin School of Medicine and Public Health, Madison,  
Wisconsin  
*Sepsis*

**Kinder Fayssoux, MD**

Faculty, Center for Family Medicine, Eisenhower Medical  
Associates, La Quinta, California  
*Bacterial Infections of the Urinary Tract in Women*

**Dorianne Feldman, MD, MSPT**

Assistant Professor, Department of Physical Medicine and  
Rehabilitation, The Johns Hopkins University School of  
Medicine, Baltimore, Maryland  
*Rehabilitation of the Stroke Patient*

**Ian Ferguson, MD**

Associate Professor, Pediatrics, Yale University School of  
Medicine, New Haven, Connecticut  
*Multisystem Inflammatory Syndrome in Children Associated  
With Severe Acute Respiratory Syndrome Coronavirus 2  
Infection*

**Terry. D. Fife, MD**

Director, Otoneurology and Balance Disorders, Neurology,  
Barrow Neurological Institute; Professor, Department of  
Neurology, University of Arizona College of Medicine,  
Phoenix, Arizona  
*Ménière's Disease*

**David J. Finley, MD**

Chief, Thoracic Surgery, Dartmouth-Hitchcock Medical Center,  
Lebanon, New Hampshire; Associate Professor of Surgery,  
Geisel School of Medicine at Dartmouth, Hanover, New  
Hampshire  
*Pleural Effusion and Empyema*

**Jonathon Firnhaber, MD, MAEd, MBA**

Residency Program Director, Department of Family Medicine,  
East Carolina University, Greenville, North Carolina  
*Diseases of the Nail*

**Lynn Fisher, MD**

Assistant Professor, Department of Family and Community  
Medicine, University of Kansas School of Medicine-Wichita,  
Wichita, Kansas  
*Red Eye*

**William E. Fisher, MD**

Professor, Michael E. DeBakey Department of Surgery, Baylor College of Medicine, Houston, Texas  
*Acute and Chronic Pancreatitis*

**Maria Fleseriu, MD**

Professor of Medicine and Neurological Surgery, Director of the Pituitary Center, Division of Endocrinology, Diabetes, and Clinical Nutrition, Oregon Health & Science University, Portland, Oregon  
*Adrenocortical Insufficiency; Hypopituitarism; Hypopituitarism*

**Donald Fletcher, MD**

Adjunct Associate Professor, Department of Ophthalmology, University of Kansas School of Medicine, Kansas City, Kansas; Medical Director, Low Vision Rehabilitation, Envision, Wichita, Kansas; Senior Scientist, Smith-Kettlewell Eye Research Institute, San Francisco, California; Medical Director, Frank Stein and Paul S May Center for Low Vision Rehabilitation, Department of Ophthalmology, California Pacific Medical Center, San Francisco, California  
*Vision Rehabilitation*

**Jeffrey Michael Foster, DO**

Clinical Assistant Professor of Anesthesiology, University of Missouri at Kansas City; Anesthesiology and Interventional Pain Medicine, Saint Luke's Hospital of Kansas City, Kansas City, Missouri  
*Fibromyalgia*

**Jennifer Frank, MD**

Chief Medical Officer, Clinically Integrated Network, Theda Care Physicians, Neenah, Wisconsin  
*Syphilis*

**Ellen W. Freeman, PhD**

Research Professor, Obstetrics/Gynecology and Psychiatry (retired), University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania  
*Premenstrual Syndrome*

**David A. Frenz, MD**

Adjunct Clinical Assistant Professor, Department of Family Medicine and Community Health, University of Minnesota, Minneapolis, Minnesota  
*Alcohol Use Disorder*

**Ruchi Gaba, MD**

Associate Professor, Endocrinology, Diabetes, and Metabolism, Baylor College of Medicine, Houston, Texas  
*Hyperaldosteronism*

**Melissa Gaines, MD**

Physician, Cox Senior Health, Cox Health, Springfield, Missouri  
*Constipation*

**Mark Garcia, MD**

Assistant Professor, Internal Medicine/Cardiology, University of New Mexico School of Medicine, Albuquerque, New Mexico  
*Congestive Heart Failure*

**Marc G. Ghany, MD**

Staff Clinician, Liver Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, Maryland  
*Hepatitis A, B, D, and E*

**Virgilio V. George, MD**

Director, Division of Colorectal Surgery, Medical University of South Carolina, Charleston, South Carolina  
*Tumors of the Colon and Rectum*

**Muhammad Ahmad Ghazi, MD**

Physician, Family Medicine, Primary Care, Raleigh, North Carolina  
*Pruritus Ani and Vulvae*

**Geoffrey Gibney, MD**

Co-Leader, Melanoma Program, Lombardi Comprehensive Cancer Center, Medstar Georgetown University Hospital, Washington, District of Columbia  
*Melanoma*

**Donald L. Gilbert, MD**

Professor, Department of Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, Ohio  
*Gilles de la Tourette Syndrome*

**Karissa Gilchrist, MD**

Assistant Professor, Department of Family and Community Medicine, University of Kansas School of Medicine—Wichita, Wichita, Kansas  
*Bacterial Diseases of the Skin*

**Erin A. Gillaspie, MD, MPH**

Assistant Professor, Thoracic Surgery, Head of Thoracic Surgery Robotics, Vanderbilt University Medical Center, Nashville, Tennessee  
*Lung Cancer*

**Tarvinder Gilotra, MD**

Fellow, Infectious Disease, Kenmore Specialty Center, Kenmore, New York  
*Intestinal Parasites*

**Mark T. Gladwin, MD**

Jack D. Myers Professor and Chair, Department of Medicine, Division of Pulmonary, Allergy, and Critical Care Medicine, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania  
*Sickle Cell Disease*

**Stephen J. Gluckman, MD**

Professor, Department of Medicine, University of Pennsylvania Perelman School of Medicine; Clinical Director, Penn Global Medicine; Medical Director, Travel Medicine Clinic, Philadelphia, Pennsylvania  
*Myalgic Encephalomyelitis/Chronic Fatigue Syndrome*

**Andrew W. Goddard, MD**

Professor, Department of Psychiatry, University of California San Francisco—Fresno, Fresno, California  
*Generalized Anxiety Disorders*

**Kyle Goerl, MD**

Medical Director, Lafene Health Center; Team Physician, Kansas State Athletics, Kansas State University, Manhattan, Kansas; Clinical Associate Professor, Department of Family and Community Medicine, University of Kansas School of Medicine—Wichita, Wichita, Kansas  
*Bursitis and Tendinopathy*

**Mark S. Gold, MD**

Professor, Department of Psychiatry, Washington University, St. Louis, Missouri  
*Drug Use Disorders*

**Amy Goldstein, MD**

Associate Professor, Department of Pediatrics, University of Pennsylvania Perelman School of Medicine; Clinical Director, Mitochondrial Medicine Frontier Program, Division of Human Genetics, Department of Pediatrics, Children's Hospital of Philadelphia, Philadelphia, Pennsylvania  
*Mitochondrial Disease*

**Marlis González-Fernández, MD, PhD**

Associate Professor, Managing Director Outpatient Rehabilitation Services, Vice-Chair for Clinical Operations, Department of Physical Medicine and Rehabilitation, The Johns Hopkins University School of Medicine, Baltimore, Maryland  
*Rehabilitation of the Stroke Patient*

**Gregory Goodwin, MD**

Assistant Professor of Pediatrics, Senior Associate Physician in Pediatrics, Boston Children's Hospital, Boston, Massachusetts  
*Diabetes Mellitus in Children*

**Aidar R. Gosmanov, MD, PhD, DMSc**

Section Chief, Endocrinology, Stratton VA Medical Center; Professor of Medicine, Endocrinology, Albany Medical College, Albany, New York  
*Diabetic Ketoacidosis*

**Luigi Gradoni, BSc, PhD**

Former Research Director, Vector-Borne Diseases, Istituto Superiore di Sanità, Rome, Italy  
*Leishmaniasis*

**Timothy P. Graham, MD**

Chief Medical Officer, Mount Carmel St. Ann's, Westerville, Ohio  
*Hypertension*

**Jane M. Grant-Kels, MD**

Professor, Founding Chair Emeritus and Vice Chair, Dermatology; Founding Director, Cutaneous Oncology Center and Melanoma Program, Dermatology, University of Connecticut Health Center, Farmington, Connecticut; Adjunct Professor, Department of Dermatology, University of Florida College of Medicine, Gainesville, Florida  
*Nevi*

**Kristine Grdinovac, MD**

Assistant Professor, Section of Endocrinology, Metabolism, and Genetics; Director, Cray Diabetes Self-Management Center, University of Kansas Medical Center, Kansas City, Kansas  
*Diabetes Mellitus in Adults*

**Leslie Greenberg, MD**

Associate Clinical Professor, Department of Family and Community Medicine; Family Medicine, Residency Assistant Program Director, University of Nevada Reno School of Medicine, Reno, Nevada  
*Keloids*

**William Greene, MD**

Associate Professor, Department of Psychiatry, University of Florida College of Medicine, Gainesville, Florida  
*Drug Use Disorders*

**Joseph Greensher, MD**

Professor of Pediatrics, Renaissance School of Medicine at Stony Brook University, Stony Brook, New York; Medical Director and Associate Chair, Department of Pediatrics, Long Island Regional Poison and Drug Information Center, Winthrop-University Hospital, Mineola, New York  
*Medical Toxicology*

**David Gregory, MD**

Associate Professor, Family and Community Medicine, Virginia Tech Carilion School of Medicine, Roanoke, Virginia  
*Resuscitation of the Newborn*

**Justin Greiwe, MD**

Partner, Bernstein Allergy Group, Inc.; Clinical Assistant Professor, Division of Immunology, Allergy, and Rheumatology, University of Cincinnati College of Medicine, Cincinnati, Ohio  
*Anaphylaxis*

**Melissa Hague, MD**

Clinical Associate Professor, Department of Obstetrics and Gynecology, University of Kansas School of Medicine-Wichita, Wichita, Kansas  
*Female Sexual Dysfunction*

**Rebat Halder, MD**

Professor Emeritus and Chairman Emeritus, Dermatology, Howard University College of Medicine, Washington, District of Columbia  
*Pigmentary Disorders*

**Alan M. Hall, MD**

Associate Professor, Internal Medicine and Pediatrics, University of Kentucky College of Medicine, Lexington, Kentucky  
*Parenteral Fluid Therapy for Infants and Children*

**Kari R. Harris, MD**

Associate Professor, Department of Pediatrics, University of Kansas School of Medicine-Wichita, Wichita, Kansas  
*Adolescent Health*

**Taylor B. Harrison, MD**

Associate Professor, Department of Neurology, Emory University, Atlanta, Georgia  
*Myasthenia Gravis*

**Adam L. Hartman, MD**

Program Director, Division of Clinical Research, National Institute of Neurological Disorders and Stroke, Rockville, Maryland  
*Epilepsy in Infants and Children*

**Erin Hayes, MD**

Associate Clinical Professor, Department of Child and Adolescent Psychiatry, Medical University of South Carolina, Charleston, South Carolina  
*Attention-Deficit/Hyperactivity Disorder*

**James W. Haynes, MD**

Professor and Chair, Department of Family Medicine, The University of Tennessee Health Sciences Center College of Medicine-Chattanooga; Family Medicine, Erlanger Health System, Chattanooga, Tennessee  
*Uterine Leiomyoma*

**Joel J. Heidelbaugh, MD**

Clinical Professor, Department of Family Medicine, University of Michigan Medical School, Ann Arbor, Michigan  
*Erectile Dysfunction*

**Molly A. Hinshaw, MD**

Associate Professor and Chief of Dermatopathology, Department of Dermatology, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin  
*Connective Tissue Disorders; Cutaneous Vasculitis*

**Brandon Hockenberry, MD**

Family Medicine and Sports Medicine, Renown Health, Reno, Nevada  
*Sports-Related Head Injuries*

**Raymond J. Hohl, MD, PhD**

Director, Cancer Institute, Penn State Cancer Institute; Professor of Medicine and Pharmacology, Milton S. Hershey Medical Center; University Professorship in Medicine, Penn State University College of Medicine, Hershey, Pennsylvania  
*Thalassemia*

**Therese Holguin, MD**

Assistant Professor, Dermatology, University of New Mexico School of Medicine, Albuquerque, New Mexico  
*Fungal Infections of the Skin*

**Sarah A. Holstein, MD, PhD**

Associate Professor, Department of Internal Medicine, University of Nebraska Medical Center, Omaha, Nebraska  
*Thalassemia*

**Michael Holyoak, DO**

Idaho Endocrinology, Meridian, Idaho  
*Thyroid Cancer*

**Gretchen Homan, MD**

Associate Professor, Department of Pediatrics, University of Kansas School of Medicine–Wichita, Wichita, Kansas  
*Pediatric Failure to Thrive*

**Kevin Hommema, BSME**

Principal Research Scientist, Battelle, Columbus, Ohio  
*Biologic Agents Reference Chart; Toxic Chemical Agents Reference Chart*

**Laurie A.M. Hommema, MD**

Associate Program Director, Family Medicine Residency, Riverside Methodist Hospital; Medical Director, Provider and Associate Well-Being, Quality and Patient Safety, OhioHealth, Columbus, Ohio  
*Biologic Agents Reference Chart; Toxic Chemical Agents Reference Chart*

**Leora Horn, MD, MSc**

Ingram Associate Professor of Cancer Research, Associate Professor of Medicine, Vanderbilt Ingram Cancer Center, Vanderbilt University Medical Center, Nashville, Tennessee  
*Lung Cancer*

**Ahmad Reza Hossani-Madani, MD, MS**

Dermatologist, Department of Dermatology, Kaiser Permanente, Upper Marlboro, Maryland  
*Pigmentary Disorders*

**Steven A. House, MD**

Professor, Family and Geriatric Medicine, University of Louisville/ Glasgow Family Medicine Residency Program, Glasgow, Kentucky  
*Pain; Palliative and End-of-Life Care*

**Sarah Houssayni, MD**

Clinical Assistant Professor, Department of Family and Community Medicine, University of Kansas School of Medicine–Wichita, Wichita, Kansas  
*Encopresis*

**William J. Hueston, MD**

Associate Provost for Education and Senior Associate Dean for Medical Education (retired), Family and Community Medicine, Medical College of Wisconsin, Waukesha, Wisconsin  
*Hyperthyroidism; Hypothyroidism*

**Richard Huettemann, MD**

Chairman, Department of Pediatrics, Children’s Medical Group Providence Hospital, Mobile, Alabama  
*Tumors of the Colon and Rectum*

**Alison Huffstetler, MD**

Assistant Professor, Department of Family Medicine and Population Health, Virginia Commonwealth University, Richmond, Virginia; Assistant Professor, Department of Family Medicine, Georgetown University, Washington, District of Columbia  
*Bacterial Pneumonia*

**Anthony Hunter, MD**

Assistant Professor, Hematology and Medical Oncology, Winship Cancer Institute of Emory University, Atlanta, Georgia  
*Acute Leukemia in Adults*

**Oyetokunbo Ibidapo-Obe, MD**

Assistant Professor, Director of Women’s Health, Department of Family Medicine, UTMB Health, Galveston, Texas  
*Infective Endocarditis*

**Alice M. Ing, MD, MA**

Resident Physician, Department of Psychiatry, University of California Irvine School of Medicine, Irvine, California  
*Depressive, Bipolar, and Related-Mood Disorders*

**Gretchen Irwin, MD, MBA**

Associate Dean of Graduate Medical Education, Associate Professor, Department of Family and Community Medicine, University of Kansas School of Medicine–Wichita, Wichita, Kansas  
*Otitis Media*

**Daniel Isaac, DO**

Assistant Professor, Division of Hematology and Oncology, Department of Medicine, Michigan State University, East Lansing, Michigan  
*Chronic Leukemias*

**Alan C. Jackson, MD**

Neurologist, Department of Medicine, Thompson General Hospital, Thompson, Manitoba; Neurologist, Department of Medicine, Lake of the Woods District Hospital, Kenora, Ontario, Canada  
*Rabies*

**Caitlin Jackson-Tarlton, MD**

Assistant Professor, Department of Medicine, Dalhousie University, Halifax, Nova Scotia, Canada  
*Multiple Sclerosis*

**Kurt M. Jacobson, MD**

Associate Professor, Department of Cardiovascular Medicine, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin  
*Mitral Valve Prolapse*

**Jose A. Jaller, MD**

Resident Physician, Department of Dermatology, Albert Einstein College of Medicine, Bronx, New York  
*Venous Ulcers*

**W. Ennis James, MD**

Assistant Professor, Department of Medicine, Medical University of South Carolina, Charleston, South Carolina  
*Sarcoidosis*

**Lauren Jeang, MD**

Assistant Professor, Department of Ophthalmology, University of Florida College of Medicine, Gainesville, Florida  
*Dry Eye Syndrome*

**Abhishek Jha, MBBS**

Visiting Postdoctoral Fellow, Section on Medical Neuroendocrinology, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Maryland  
*Pheochromocytoma*

**Xiaoming Jia, MD**

Instructor, Department of Medicine, Baylor College of Medicine, Houston, Texas  
*Hyperlipidemia*

**Casey R. Johnson, MD, MS**

Pediatric GI Fellow, Boston Children's Hospital, Boston, Massachusetts  
*Obesity in Children*

**Lisa M. Johnson, MD**

Associate Professor, Department of Family Medicine; Assistant Dean, Office of Diversity, Equity, and Inclusion, University of Cincinnati College of Medicine, Cincinnati, Ohio  
*Acne Vulgaris; Rosacea*

**Joshua S. Jolissaint, MD**

Research Fellow, Surgery, Memorial Sloan Kettering Cancer Center, New York, New York; Surgery Resident, Brigham and Women's Hospital; Clinical Fellow, Surgery, Harvard Medical School, Boston, Massachusetts  
*Pancreatic Cancer; Atelectasis*

**Marc A. Judson, MD**

Chief, Division of Pulmonary and Critical Care Medicine, Albany Medical Center, Albany, New York  
*Sarcoidosis*

**Tamilarasu Kadiravan, MD**

Professor, Department of Medicine, Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India  
*Typhoid Fever*

**Rachna Kalia, MD**

Clinical Assistant Professor, Department of Psychiatry and Behavioral Sciences, University of Kansas School of Medicine—Wichita, Wichita, Kansas  
*Obsessive-Compulsive Disorder*

**Sagar Kamprath, MD, MBA**

Associate Professor, Department of Family Medicine, UTMB Health, Galveston, Texas  
*Post-Acute COVID Syndrome*

**Jessica Rachel Kanter, MD**

Shady Grove Fertility, Atlanta, Georgia  
*Infertility*

**Dilip R. Karnad, MD**

Consultant in Critical Care, Jupiter Hospital, Thane, Maharashtra, India  
*Tetanus*

**Rudrudee Karnchanasorn, MD**

Associate Professor, Department of Internal Medicine, University of Kansas School of Medicine, Kansas City, Kansas  
*Thyroid Cancer*

**Andreas Katsambas, MD, PhD**

Professor of Dermatology–Venereology, University of Athens School of Medicine, Hygeia Hospital, Athens, Greece  
*Parasitic Diseases of the Skin*

**Ben Katz, MD**

Professor of Pediatrics, Northwestern University Feinberg School of Medicine; Attending Physician, Division of Infectious Diseases, Ann & Robert H Lurie Children's Hospital of Chicago, Chicago, Illinois  
*Infectious Mononucleosis*

**Rebecca Katzman, MD**

Clinical Assistant Professor, Family Medicine, University of Washington School of Medicine, Seattle, Washington  
*Palpitations*

**Andrew M. Kaunitz, MD**

Professor and Associate Chairman, Department of Obstetrics and Gynecology, University of Florida College of Medicine—Jacksonville, Jacksonville, Florida  
*Menopause*

**B. Mark Keegan, MD**

Professor, Neurology, Mayo Clinic, Rochester, Minnesota  
*Multiple Sclerosis*

**Rick D. Kellerman, MD**

Professor and Chair, Department of Family and Community Medicine, University of Kansas School of Medicine—Wichita, Wichita, Kansas  
*Chikungunya; Zika Virus; Monkeypox*

**Scott Kellermann, MD, MPH**

Adjunct Professor, Tulane School of Public Health and Tropical Medicine, New Orleans, Louisiana; Clinical Professor, Clinical Sciences, California Northstate College of Medicine, Elk Grove, California; Adjunct Professor, School of Nursing and Health Professions, University of San Francisco, San Francisco, California  
*Chikungunya; Zika Virus; Monkeypox*

**Christina M. Kelly, MD**

Assistant Professor, Family Medicine, Uniformed Services University of the Health Sciences, Bethesda, Maryland  
*Ectopic Pregnancy*

**Sheevaun Khaki, MD**

Associate Professor of Pediatrics, Division of General Pediatrics, Oregon Health & Science University, Portland, Oregon  
*Infant Hyperbilirubinemia*

**Arthur Y. Kim, MD**

Associate Professor, Medicine, Harvard Medical School, Boston, Massachusetts  
*Hepatitis C*

**Haejin Kim, MD**

Senior Staff Allergist, Department of Allergy and Clinical Immunology, Henry Ford Health System; Clinical Assistant Professor, School of Medicine, Wayne State University, Detroit, Michigan  
*Hypersensitivity Pneumonitis*

**Robert S. Kirsner, MD, PhD**

Chair and Harvey Blank Professor, Dr. Phillip Frost Department of Dermatology and Cutaneous Surgery, University of Miami Miller School of Medicine, Miami, Florida  
*Venous Ulcers*

**Sonam Kiwalkar, MD**

Assistant Professor, Rheumatology, The Vancouver Clinic, Vancouver, Washington  
*Axial Spondyloarthritis*

**Janice Knoefel, MD, MPH**

Professor, Neurology and Internal Medicine (Geriatrics), University of New Mexico School of Medicine, Albuquerque, New Mexico  
*Alzheimer's Disease*

**Amanda Kolb, MD**

Assistant Professor, Family Medicine, University of Vermont Medical Center, Burlington, Vermont  
*Asthma in Children*

**Bhanu Prakash Kolla, MD, MRCPsych**

Sleep Medicine, Mayo Clinic, Rochester, Minnesota  
*Sleep Disorders*

**Frederick Korley, MD**

Robert E. Meyerhoff Assistant Professor of Emergency Medicine, The Johns Hopkins University School of Medicine; Staff, Johns Hopkins Medicine, Baltimore, Maryland  
*Disturbances Due to Cold*

**Adrienne N. Kovalsky, DO, MPH**

Assistant Professor of Medicine, Hospital Medicine, Georgetown University Hospital, Washington, District of Columbia; Hospitalist, Internal Medicine, Sts. Mary and Elizabeth Medical Center, Chicago, Illinois  
*High Altitude Illness*

**Megan Krause, MD**

Assistant Professor, Department of Internal Medicine, Division of Allergy, Clinical Immunology, and Rheumatology, University of Kansas School of Medicine, Kansas City, Kansas  
*Rheumatoid Arthritis*

**Eric H. Kraut, MD**

Professor of Medicine, Director, Benign Hematology, The Ohio State University Wexner Medical Center, Columbus, Ohio  
*Platelet-Mediated Bleeding Disorders*

**Lakshmanan Krishnamurti, MD**

Chief of Pediatric Hematology, Oncology, and Bone Marrow Transplant, Yale School of Medicine, New Haven, Connecticut  
*Sickle Cell Disease*

**Kumar Krishnan, MD**

Assistant Professor, Internal Medicine, Harvard Medical School, Boston, Massachusetts  
*Dysphagia and Esophageal Obstruction*

**Zachary Kuhlmann, DO**

Program Director, Clinical Professor, Department of Obstetrics and Gynecology, University of Kansas School of Medicine–Wichita, Wichita, Kansas  
*Endometriosis*

**Roshni Kulkarni, MD**

Professor and Director Emerita, MSU Center for Bleeding and Clotting Disorders, Department of Pediatrics and Human Development, Michigan State University, East Lansing, Michigan  
*Hemophilia and Related Conditions*

**Seema Kumar, MD**

Professor, Pediatric and Adolescent Medicine, Mayo Clinic, Rochester, Minnesota  
*Obesity in Children*

**Mary R. Kwaan, MD, MPH**

Health Sciences Clinical Associate Professor, Surgery, David Geffen School of Medicine at UCLA, Los Angeles, California  
*Hemorrhoids, Anal Fissure, and Anorectal Abscess and Fistula*

**Robert A. Kyle, MD**

Hematologist, Hematology, Mayo Clinic, Rochester, Minnesota  
*Multiple Myeloma*

**Lucius M. Lampton, MD**

Clinical Associate Professor, Department of Family and Community Medicine, Tulane University School of Medicine, New Orleans, Louisiana; Clinical Professor, Department of Family Medicine, William Carey University College of Osteopathic Medicine, Hattiesburg, Mississippi; Mississippi State Board of Health, Jackson, Mississippi  
*COVID-19; Yellow Fever*

**Richard A. Lange, MD, MBA**

President of Department of Medicine, Dean of Paul L. Foster School of Medicine, Texas Tech University Health Sciences Center El Paso, El Paso, Texas  
*Congenital Heart Disease*

**Fabienne Langlois, MD**

Medicine and Endocrinology, Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, Quebec, Canada  
*Adrenocortical Insufficiency; Hypopituitarism; Hypopituitarism*

**Christine Lau, MD**

George Minor Professor of Surgery, Department of Surgery, University of Virginia Health System, Charlottesville, Virginia  
*Atelectasis*

**Susan Lawrence-Hylland, MD**

Clinical Assistant Professor, Rheumatology Section, University of Wisconsin Hospital and Clinics, Madison, Wisconsin  
*Connective Tissue Disorders; Cutaneous Vasculitis*

**Jake Lazaroff, MD**

Resident Physician, Section of Dermatology, University of Chicago Pritzker School of Medicine, Chicago, Illinois  
*Nonmelanoma Cancer of the Skin*

**Lydia U. Lee, MD**

Clinical Lecturer, Department of Family Medicine, University of Michigan, Ann Arbor, Michigan  
*Postpartum Depression*

**Jerrold B. Leikin, MD**

Consultant, Illinois Hospital Association, Illinois Poison Center, Chicago, Illinois; Professor, Department of Medicine, Rosalind Franklin University/Chicago Medical School, North Chicago, Illinois  
*Disturbances Due to Cold*

**Scott Leikin, DO**

Attending Physician, Critical Care Medicine, Northwestern Medicine Regional Medical Group, Winfield, Illinois  
*Targeted Temperature Management (Therapeutic Hypothermia); Disturbances Due to Cold*

**Alexander K.C. Leung, MBBS**

Clinical Professor, Department of Pediatrics, Cummings School of Medicine, University of Calgary; Pediatric Consultant, Department of Pediatrics, Alberta Children's Hospital, Calgary, Alberta, Canada  
*Nocturnal Enuresis*

**Grace Levy-Clarke, MD**

Associate Professor, Department of Ophthalmology, West Virginia University, Morgantown, West Virginia  
*Uveitis*

**Martin M. LeWinter, MD**

Professor of Medicine and Molecular Physiology & Biophysics, University of Vermont Larner College of Medicine; Attending Cardiologist, University of Vermont Medical Center, Burlington, Vermont  
*Pericarditis*

**Jennifer Lewis, MD, MPH**

Assistant Professor of Medicine, Vanderbilt Ingram Cancer Center, Vanderbilt University Medical Center; VA Quality Scholars Fellow, Geriatric Research Education and Clinical Center, VA Tennessee Valley Healthcare System, Nashville, Tennessee  
*Lung Cancer*

**Ming Li, MD, PhD**

Clinical Assistant Professor, Department of Medicine, University of Arizona College of Medicine; Staff Physician, Medicine, Carl T. Hayden Veterans' Administration Medical Center, Phoenix, Arizona  
*Hyperprolactinemia*

**Tyler Liebenstein, PharmD**

Clinical Pharmacist, William S. Middleton Memorial Veterans Hospital, Madison, Wisconsin  
*Human Immunodeficiency Virus: Treatment and Prevention*

**Albert P. Lin, MD**

Assistant Professor, Department of Ophthalmology, Baylor College of Medicine; Staff Physician, Eye Care Line, Michael E. DeBakey VA Medical Center, Houston, Texas  
*Glaucoma*

**Jeffrey A. Linder, MD, MPH**

Professor and Chief, Division of General Internal Medicine, Northwestern University Feinberg School of Medicine, Chicago, Illinois  
*Influenza*

**James Lock, MD, PhD**

Professor, Psychiatry, Stanford University School of Medicine, Stanford, California  
*Eating Disorders*

**M. Chantel Long, MD**

Clinical Assistant Professor, Department of Family and Community Medicine, University of Kansas School of Medicine–Wichita; Staff Physician, Concierge Primary Care Clinic, Ascension Via Christi, Wichita, Kansas  
*Condylomata Acuminata; Warts (Verrucae)*

**Colleen Loo-Gross, MD, MPH**

Assistant Professor, Department of Family and Community Medicine, University of Kansas School of Medicine–Wichita, Wichita, Kansas  
*Amenorrhea*

**Julia R. Lubsen, MD**

Assistant Professor, Department of Family Medicine and Community Health, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin  
*Pyelonephritis*

**Ronda Lun, MD**

Resident Physician, Department of Medicine, Division of Neurology, The Ottawa Hospital, Ottawa, Ontario, Canada  
*Intracerebral Hemorrhage*

**David (Sasha) Mahvi, MD**

Surgical Resident, Department of Surgery, Brigham and Women's Hospital, Boston, Massachusetts  
*Tumors of the Stomach*

**RosaMarie Maiorella, MD**

Assistant Professor, Department of Pediatrics, University of Cincinnati College of Medicine, Cincinnati, Ohio  
*Viral Meningitis*

**Uma Malhotra, MD**

Clinical Professor, Infectious Diseases, University of Washington School of Medicine, Seattle, Washington  
*Ebola Virus Disease*

**Emily Manlove, MD**

Adjunct Clinical Assistant Professor, Department of Family Medicine, Indiana University School of Medicine, Bloomington, Indiana  
*Cough*

**JoAnn E. Manson, MD, DrPH**

Chief, Division of Preventive Medicine, Department of Medicine, Brigham and Women's Hospital; Professor, Medicine, Michael and Lee Bell Professor of Women's Health, Harvard Medical School, Boston, Massachusetts  
*Menopause*

**Meghna Mansukhani, MD**

Associate Professor, Sleep Medicine, Mayo Clinic, Rochester, Minnesota  
*Sleep Disorders*

**Claudio Marcocci, MD**

Professor of Endocrinology, Clinical and Experimental Medicine, University of Pisa, Pisa, Italy  
*Hyperparathyroidism and Hypoparathyroidism*

**Curtis E. Margo, MD, MPH**

Clinical Professor, Departments of Pathology & Cell Biology and Ophthalmology, University of South Florida Morsani College of Medicine, Tampa, Florida  
*Uveitis*

**Jason E. Marker, MD, MPA**

Associate Director, Memorial Family Medicine Residency, Memorial Hospital, South Bend, Indiana  
*Neurofibromatosis (Type 1)*

**Paul Martin, MD**

Chief, Division of Hepatology, Department of Medicine, University of Miami Miller School of Medicine, Miami, Florida  
*Cirrhosis*

**Samuel E. Mathis, MD**

Assistant Professor, Department of Family Medicine, UTMB Health, Galveston, Texas  
*Infective Endocarditis*

**Kristine Matson, MD**

Clinical Professor, Department of Medicine, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin  
*Travel Medicine*

**Mark A. Matza, MD, MBA**

Rheumatologist, Massachusetts General Hospital; Instructor, Medicine, Harvard Medical School, Boston, Massachusetts  
*Polymyalgia Rheumatica and Giant Cell Arteritis*

**Pinckney J. Maxwell IV, MD**

Associate Professor, Division of Colon and Rectal Surgery, Medical University of South Carolina, Charleston, South Carolina  
*Tumors of the Colon and Rectum*

**Danica May, MD**

Urologic Oncologist, Department of Urology, University of Kansas Medical Center, Kansas City, Kansas  
*Malignant Tumors of the Urogenital Tract*

**Gregory Marshall Mazepa, MD**

Assistant Professor, Department of Medicine, Division of Hematology, Oncology, and Transplantation, University of Minnesota, Minneapolis, Minnesota  
*Porphyrias*

**Molly McClain, MD, MPH, MS**

Assistant Professor, Program Director, Family and Community Medicine, University of New Mexico School of Medicine, Albuquerque, New Mexico  
*Gender Affirming Care*

**Christopher McGrew, MD**

Professor, Family & Community Medicine and Orthopedics & Rehabilitation, Sports Medicine Division, University of New Mexico Health Sciences Center, Albuquerque, New Mexico  
*Sports-Related Head Injuries*

**Christopher Charles McGuigan, MBChB, MPH**

Honorary Senior Lecturer, Public Health Medicine, University of Aberdeen, Aberdeen, Scotland, United Kingdom  
*Psittacosis*

**Meetal Mehta, MD**

Nutrition Support Service Attending, Department of Surgery; Obesity Medicine Physician, Department of Endocrinology, Diabetes, and Hypertension, Brigham and Women's Hospital, Boston, Massachusetts  
*Parenteral Nutrition in Adults*

**Mick S. Meiselman, MD**

Director of Advanced Therapeutic Endoscopy, Dignity Health Central Coast, San Luis Obispo, California  
*Cirrhosis*

**Moises Mercado, MD**

Director, Endocrine Research Unit, Hospital de Especialidades, Centro Medico Nacional Siglo XXI – Instituto Mexicano del Seguro Social; Professor of Medicine, Faculty of Medicine, Universidad Nacional Autónoma de Mexico, Mexico City, Mexico  
*Acromegaly*

**Ryan Merrell, MD**

Clinical Assistant Professor, Department of Neurology, NorthShore University HealthSystem, Evanston, Illinois  
*Brain Tumors*

**Steven L. Meyers, MD**

Vice Chair, Quality and Informatics, Department of Neurology, NorthShore University Health System, Evanston, Illinois  
*Acute Facial Paralysis*

**William Michael, MD**

Assistant Professor, Department of Family Medicine and Community Health, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin  
*Peripheral Artery Disease*

**Brian J. Miller, MD, PhD, MPH**

Professor, Department of Psychiatry and Health Behavior, Augusta University, Augusta, Georgia  
*Schizophrenia*

**Timothy M. Millington, MD**

Assistant Professor, Surgery, Dartmouth-Hitchcock Medical Center, Lebanon, New Hampshire  
*Pleural Effusion and Empyema*

**Moben Mirza, MD**

Associate Professor, Department of Urology, University of Kansas School of Medicine, Kansas City, Kansas  
*Hematuria; Malignant Tumors of the Urogenital Tract*

**Howard C. Mofenson, MD**

Professor of Pharmacology and Toxicology, New York College of Osteopathic Medicine, Old Westbury, New York; Professor of Pediatrics and Emergency Medicine, Renaissance School of Medicine at Stony Brook University, Stony Brook, New York  
*Medical Toxicology*

**Kris M. Mogensen, MS**

Team Leader Dietitian Specialist, Department of Nutrition, Brigham and Women's Hospital, Boston, Massachusetts  
*Parenteral Nutrition in Adults*

**Michael L. Moritz, MD**

Professor, Pediatrics, UPMC Children's Hospital of Pittsburgh, Pittsburgh, Pennsylvania  
*Parenteral Fluid Therapy for Infants and Children*

**Rami Mortada, MD**

Endocrine Center of Kansas, Wichita, Kansas  
*Diabetes Insipidus*

**Parisa Mortaji, MD**

Instructor, Department of Medicine, University of Colorado School of Medicine, Aurora, Colorado  
*Tuberculosis and Other Mycobacterial Diseases*

**Heather E. Moss, MD, PhD**

Assistant Professor, Ophthalmology & Neurology and Neurological Sciences, Stanford University School of Medicine, Stanford, California  
*Optic Neuritis*

**Judd W. Moul, MD**

James H. Semans, MD Professor of Surgery, Urologic Surgery, Duke University School of Medicine, Durham, North Carolina  
*Benign Prostatic Hyperplasia*

**Martha Muller, MD**

Professor, Pediatrics, University of New Mexico School of Medicine, Albuquerque, New Mexico  
*Bacterial Meningitis*

**Natalia E. Murinova, MD**

Clinical Assistant Professor, Neurology, University of Washington School of Medicine, Seattle, Washington  
*Migraine*

**Michael Murphy, MD**

Dermatopathologist, Dermatology, UConn Health, Farmington, Connecticut  
*Nevi*

**Arjun Muthusubramanian, MD, MPH**

Attending Physician, MedExpress Urgent Care, Optum, Richmond, Virginia  
*Bacterial Pneumonia*

**Alykhan S. Nagji, MD**

Resident, Department of Surgery, University of Virginia School of Medicine, Charlottesville, Virginia  
*Atelectasis*

**Laura Naranjo, MD**

Senior Medical Affairs Manager, Vaccines CARICAM, GlaxoSmithKline Biologicals; Investigator, National Research System, National Secretariat of Science, Technology and Innovation, Panama City, Panama  
*Malaria*

**Rabab Nasim, MD**

Fellow, Division of Pulmonary and Critical Care Medicine, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin  
*Sepsis*

**Matthew A. Nazari, MD**

Physician, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Maryland  
*Pheochromocytoma*

**Moniba Nazeef, MD**

Assistant Professor, Division of Hematology, Medical Oncology, and Palliative Care, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin  
*Venous Thromboembolism*

**Viswanathan K. Neelakantan, MD**

Senior Professor of Medicine and Consultant in Tropical Medicine, Faculty of Medicine, Sri Manakula Vinayagar Medical College Hospital, Pondicherry, India  
*Foodborne Illnesses*

**Don Neff, MD**

Assistant Professor, Department of Urology, University of Kansas School of Medicine, Kansas City, Kansas  
*Urinary Tract Infections in the Male*

**Tara Neil, MD**

Senior Associate Program Director, University of Kansas School of Medicine–Wichita, Family Medicine Residency Program at Via Christi Hospital; Associate Professor, Department of Family and Community Medicine, University of Kansas School of Medicine–Wichita, Wichita, Kansas  
*Postpartum Care*

**William G. Nelson, MD, PhD**

Professor and Director, Sidney Kimmel Comprehensive Cancer Center, The Johns Hopkins University School of Medicine, Baltimore, Maryland  
*Prostate Cancer*

**David G. Neschis, MD**

Clinical Associate Professor of Surgery, The Maryland Vascular Center, University of Maryland Baltimore Washington Medical Center, Glen Burnie, Maryland  
*Aortic Disease: Aneurysm and Dissection*

**Theresa Nester, MD**

Professor, Laboratory Medicine and Pathology, University of Washington Medical Center; Medical Director of Integrated Transfusion Services, Bloodworks Northwest, Seattle, Washington  
*Blood Component Therapy and Transfusion Reactions*

**Tam T. Nguyen, MD**

Clinician and Instructor, Family Medicine, Washington Township Medical Group, Fremont, California  
*Papulosquamous Eruptions*

**Andrea L. Nicol, MD, MSc**

Associate Professor, Department of Anesthesiology, University of Kansas School of Medicine, Kansas City, Kansas  
*Fibromyalgia*

**Lucybeth Nieves-Arriba, MD**

Assistant Professor, Gynecology and Oncology, Zimmer Cancer Center, Wilmington, North Carolina  
*Cancer of the Uterine Cervix*

**Crystal North, MD, MPH**

Physician, Pulmonary and Critical Care Medicine, Massachusetts General Hospital; Instructor, Medicine, Harvard Medical School, Boston, Massachusetts  
*Monoclonal Antibodies*

**Andrei Novac, MD**

Clinical Professor, Director of Traumatic Stress Program, Department of Psychiatry, University of California Irvine School of Medicine, Irvine, California  
*Depressive, Bipolar, and Related-Mood Disorders*

**Enrico M. Novelli, MD**

Associate Professor of Medicine, Division of Hematology/Oncology, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania  
*Sickle Cell Disease*

**Lauren Nye, MD**

Assistant Professor, Internal Medicine, Division of Medical Oncology, University of Kansas School of Medicine, Kansas City, Kansas  
*Benign Breast Disease; Breast Cancer*

**Andrea T. Obi, MD**

Assistant Professor, Department of Surgery, University of Michigan, Ann Arbor, Michigan  
*Venous Thrombosis*

**Jeffrey P. Okeson, DMD**

Professor and Dean, Oral Health Science, University of Kentucky College of Medicine, Lexington, Kentucky  
*Temporomandibular Disorders*

**Carlos R. Oliveira, MD, PhD**

Assistant Professor, Pediatrics, Yale University School of Medicine, New Haven, Connecticut  
*Lyme Disease and Post-Treatment Lyme Disease Syndrome; Multisystem Inflammatory Syndrome in Children Associated With Severe Acute Respiratory Syndrome Coronavirus 2 Infection*

**Peck Y. Ong, MD**

Associate Professor, Department of Pediatrics, USC/Children's Hospital Los Angeles, Los Angeles, California  
*Atopic Dermatitis*

**Daniel S. Oram, MD**

Adjunct Assistant Professor, Department of Family Medicine, University of Michigan, Ann Arbor, Michigan  
*Postpartum Depression*

**David D. Ortiz, MD**

Director, Medical Residency Programs, National Health Institute, Asunción, Paraguay  
*Leg Edema and Venous Stasis*

**Bulent Ozgonenel, MD**

Physician, Pediatric Hematology and Oncology, Children's Hospital of Michigan, Detroit, Michigan  
*Hemophilia and Related Conditions*

**Karel Pacak, MD, PhD, DSc**

Chief, Section on Medical Neuroendocrinology, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Maryland  
*Pheochromocytoma*

**Jose A. Padin-Rosado, MD**

Associate Professor, Neurology, University of New Mexico School of Medicine; Medical Director, Neurodiagnostic Laboratory, University of New Mexico, Albuquerque, New Mexico  
*Seizures and Epilepsy in Adolescents and Adults*

**Tanyatuth Padungkiatsagul, MD**

Associate Professor, Department of Ophthalmology, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand  
*Optic Neuritis*

**Heather L. Paladine, MD, MEd**

Assistant Professor of Medicine at Columbia University Medical Center, Center for Family and Community Medicine, Columbia College of Physicians and Surgeons, New York, New York  
*Vulvovaginitis*

**John E. Pandolfino, MD**

Hans Popper Professor of Medicine, Northwestern University Feinberg School of Medicine, Chicago, Illinois  
*Dysphagia and Esophageal Obstruction*

**Deval Patel, MD**

Pediatric Hospitalist, Division of Hospital Pediatrics, Nemours Children's Specialty Care; Associate Program Director, Department of Pediatrics, University of Florida College of Medicine—Jacksonville, Jacksonville, Florida  
*Parenteral Fluid Therapy for Infants and Children*

**Simon Patton, MD**

Division of Female Pelvic Medicine and Reconstructive Surgery, Ascension Via Christi, Wichita, Kansas  
*Urinary Incontinence*

**Gerson O. Penna, MD, PhD**

Institute of Collective Health, Federal University of Bahia, Salvador, Brazil  
*Leprosy*

**Maria Lucia Penna, MD, PhD**

Professor, Epidemiologia e Bioestatística, Universidade Federal Fluminense, Niteroi, Rio de Janeiro, Brazil  
*Leprosy*

**Allen Perkins, MD, MPH**

Professor and Chair, Family Medicine, USA Health, University of South Alabama, Mobile, Alabama  
*Marine Poisonings, Envenomations, and Trauma*

**Leah Peterson, MD**

Clinical Assistant Professor, University of Kansas School of Medicine—Wichita Family Medicine Residency Program at Smokey Hill, Salina, Kansas  
*Hypertension in Pregnancy*

**Georg A. Petroianu, MD, PhD**

Professor and Chair, Department of Pharmacology and Therapeutics, College of Medicine—Khalifa University, Abu Dhabi, United Arab Emirates  
*Hiccups*

**Vesna M. Petronic-Rosic, MD, MSc, MBA**

Physician, Dermatology, Cook County Health, Chicago, Illinois  
*Melanoma*

**Hanna Phan, PharmD**

Clinical Associate Professor, Department of Clinical Pharmacy, College of Pharmacy, University of Michigan; Clinical Pharmacist Specialist, Pediatric Pulmonary; Pharmacy Innovations & Partnerships, C.S. Mott Children's Hospital, Michigan Medicine, Ann Arbor, Michigan  
*Cystic Fibrosis*

**Mark Pietroni, MD, MBA**

Medical Director, Gloucestershire Hospitals NHS Foundation Trust, Gloucester, United Kingdom  
*Cholera*

**Gregory A. Plotnikoff, MD, MTS**

Medical Director, Internal Medicine and Pediatrics, Minnesota Personalized Medicine, Minneapolis, Minnesota  
*Genetic Testing*

**Susan M. Pollart, MD, MS**

Ruth E. Murdaugh Professor, Family Medicine; Senior Associate Dean for Faculty Affairs and Faculty Development, Office of the Dean, University of Virginia School of Medicine, Charlottesville, Virginia  
*Asthma in Children*

**Jennifer Poon, MD**

Associate Professor, Department of Pediatrics, Medical University of South Carolina, Charleston, South Carolina  
*Attention-Deficit/Hyperactivity Disorder*

**Andrew S.T. Porter, DO**

Director of Sports Medicine Fellowship, Clinical Associate Professor, Department of Family and Community Medicine, University of Kansas School of Medicine–Wichita, Wichita, Kansas  
*Common Sports Injuries*

**Charles Powell, MD**

Associate Professor, Department of Urology, Indiana University School of Medicine, Indianapolis, Indiana  
*Prostatitis*

**Margaret Pusateri, MD**

Fellow, Emergency Medicine, University of New Mexico School of Medicine, Albuquerque, New Mexico  
*Sports-Related Head Injuries*

**James M. Quinn, MD**

Associate Program Director, Allergy/Immunology, San Antonio Uniformed Service Health Education Consortium, San Antonio, Texas; Associate Professor of Medicine, Department of Medicine, Uniformed Services University of the Health Sciences, Bethesda, Maryland  
*Allergic Reactions to Insect Stings*

**Peter S. Rahko, MD**

Professor, Department of Medicine, University of Wisconsin School of Medicine and Public Health; Director, Adult Echocardiography Laboratory, University of Wisconsin Hospital, Madison, Wisconsin  
*Mitral Valve Prolapse*

**S. Vincent Rajkumar, MD**

Edward W. and Betty Knight Scripps Professor of Medicine, Hematology, Mayo Clinic, Rochester, Minnesota  
*Multiple Myeloma*

**Anand Rajpara, MD**

Associate Professor and Founding Chair, Department of Dermatology, University Health/University of Missouri School of Medicine, Kansas City, Missouri  
*Autoimmune Bullous Diseases; Pyoderma Gangrenosum*

**Kalyanakrishnan Ramakrishnan, MD**

Professor, Department of Family and Preventive Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma  
*Necrotizing Skin and Soft-Tissue Infections*

**Julio A. Ramirez, MD**

Professor of Medicine, University of Louisville School of Medicine; Chief, Division of Infectious Diseases, Robley Rex Veterans Affairs Medical Center, Louisville, Kentucky  
*Legionellosis (Legionnaires' Disease and Pontiac Fever)*

**Jatin Rana, MD**

Assistant Professor, Division of Hematology and Oncology, Department of Medicine, Michigan State University, East Lansing, Michigan  
*Chronic Leukemias*

**Matthew A. Rank, MD**

Professor, Allergy, Asthma, and Clinical Immunology, Mayo Clinic, Scottsdale, Arizona  
*Asthma in Adolescents and Adults*

**Didier Raoult, MD, PhD**

Unite de Recherche Sur les Maladies Infectieuses Tropicales, Aix-Marseille Universite, Marseille, France  
*Q Fever*

**Alwyn Rapose, MD**

Consultant, Infectious Diseases, Reliant Medical Group; Assistant Professor, Medicine, University of Massachusetts Medical School, Worcester, Massachusetts  
*Toxic Shock Syndrome*

**Rachel E. Rau, MD**

Assistant Professor, Department of Pediatrics, Baylor College of Medicine, Houston, Texas  
*Acute Leukemia in Children*

**Anita Ravindran, MD**

Physician, Department of Microbiology, Manipal University College Melaka, Jalan Padang Jambu, Bukit Baru, Melaka, Malaysia  
*Foodborne Illnesses*

**Jared Regehr, MD**

Assistant Professor, Department of Family and Community Medicine, University of Kansas School of Medicine–Wichita, Wichita, Kansas  
*Fatigue*

**Ian R. Reid, MD**

Distinguished Professor, Department of Medicine, University of Auckland, Auckland, New Zealand  
*Paget's Disease of Bone*

**Elissa Rennert-May, MD, MSc**

Infectious Diseases Physician, Department of Medicine, Cummings School of Medicine, University of Calgary, Calgary, Canada  
*Methicillin-Resistant Staphylococcus aureus (MRSA)*

**Karl Rew, MD**

Associate Professor, Departments of Family Medicine and Urology, University of Michigan, Ann Arbor, Michigan  
*Erectile Dysfunction*

**Mona Rezapour, MD, MHS**

Assistant Clinical Professor, Gastroenterology, David Geffen School of Medicine at UCLA, Los Angeles, California  
*Inflammatory Bowel Disease*

**Amanda Rhyne, MD**

Clinical Assistant Professor, Department of Family and Community Medicine, University of Kansas School of Medicine, Wichita Family Medicine Residency Program at Smokey Hill, Salina, Kansas  
*Serum Sickness*

**Martha Riese, MD**

Clinical Assistant Professor, Department of Family and Community Medicine, University of Kansas School of Medicine–Wichita; Family Medicine Residency at Smokey Hill, Salina, Kansas  
*Varicella (Chicken Pox)*

**David C. Robbins, MD, MPH**

Professor, Director, University of Kansas Diabetes Institute, Department of Medicine, University of Kansas School of Medicine, Kansas City, Kansas  
*Diabetes Mellitus in Adults*

**Sophie Robert, PharmD**

Assistant Professor, Department of Psychiatry and Behavioral Sciences, Medical University of South Carolina, Charleston, South Carolina  
*Attention-Deficit/Hyperactivity Disorder*

Assistant Professor, College of Pharmacy, University of Arkansas for Medical Sciences Northwest Regional Campus, Fayetteville, Arkansas  
*Serum Sickness*

**Malcolm Robinson, MD**

Assistant Professor, Surgery, Harvard Medical School; Attending Physician, Metabolic Support Service, Brigham and Women's Hospital, Boston, Massachusetts  
*Parenteral Nutrition in Adults*

**William P. Roche, MD**

Neuromuscular Division, Emory University, Atlanta, Georgia  
*Myasthenia Gravis*

**Tessa Rohrberg, MD**

Assistant Professor, Department of Family and Community Medicine, University of Kansas School of Medicine–Wichita, Wichita, Kansas  
*Delirium*

**Candice Rose, MD, MS**

Assistant Professor, Section of Endocrinology, University of Kansas School of Medicine, Kansas City, Kansas  
*Diabetes Mellitus in Adults*

**Peter G. Rose, MD**

Staff Physician, Gynecological Oncology, Cleveland Clinic, Cleveland, Ohio  
*Cancer of the Uterine Cervix*

**Stephen Ross, MD**

Professor and Vice Chair, Department of Neurology, Penn State University College of Medicine, Hershey, Pennsylvania  
*Nonmigraine Headache*

**Alan R. Roth, DO**

Chairman, Family Medicine, Jamaica Hospital Medical Center, Jamaica, New York; Assistant Professor, Family and Social Medicine, Albert Einstein College of Medicine, Bronx, New York; Professor, Family Medicine, NYITCOM, Old Westbury, New York; Chief, Integrative Pain and Palliative Care, Medisys Health Network, Jamaica, New York  
*Fever*

**Anne-Michelle Ruha, MD**

Chair, Medical Toxicology, Banner - University Medical Center Phoenix; Professor, Internal Medicine and Emergency Medicine, University of Arizona College of Medicine, Phoenix, Arizona  
*Spider Bites and Scorpion Stings; Venomous Snakebite*

**Kristen Rundell, MD, MS**

Professor and Chair, Department of Family and Community Medicine, University of Arizona College of Medicine, Tucson, Arizona  
*Drug Hypersensitivity Reactions; Mumps*

**Adnan Said, MD, MS**

Professor, Division of Gastroenterology and Hepatology, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin  
*Nonalcoholic Fatty Liver Disease*

**Tomoko Sairenji, MD, MS**

Associate Professor, Family Medicine, University of Washington School of Medicine, Seattle, Washington  
*Acute Bronchitis and Other Viral Respiratory Infections*

**Susan L. Samson, MD, PhD**

Senior Associate Consultant, Medicine/Endocrinology, Mayo Clinic, Jacksonville, Florida  
*Hyponatremia*

**Carlos E. Sanchez, MD**

Faculty, Interventional Cardiology and Advanced Structural Heart Disease, Internal Medicine, Riverside Methodist Hospital, Columbus, Ohio  
*Valvular Heart Disease*

**Sandeep Sangodkar, DO**

Cardiologist, Cardiology Specialists Medical Group, Riverside, California; Assistant Clinical Professor, Internal Medicine/Cardiology, University of California Riverside, Riverside, California; Clinical Assistant Professor, Internal Medicine/Cardiology, Western University, Pomona, California  
*Hypertrophic Cardiomyopathy*

**Arelis Santana, MD, MPH**

Assistant Professor, Infectious Diseases, University of New Mexico School of Medicine, Albuquerque, New Mexico  
*Salmonellosis*

**Ravindra Sarode, MD**

Director, Division of Transfusion and Hemostasis, Department of Pathology, UT Southwestern Medical Center, Dallas, Texas  
*Thrombotic Thrombocytopenic Purpura*

**Michael Schatz, MD, MS**

Staff Physician, Department of Allergy, Kaiser Permanente; Clinical Professor, Medicine, University of California San Diego School of Medicine, San Diego, California  
*Asthma in Adolescents and Adults*

**Alex Schevchuck, MD, MS**

Associate Professor, Internal Medicine/Cardiology, University of New Mexico School of Medicine, Albuquerque, New Mexico  
*Congestive Heart Failure; Tachycardias*

**Lawrence R. Schiller, MD**

Attending Physician, Gastroenterology Division, Baylor University Medical Center, Dallas, Texas  
*Malabsorption*

**Sarina Schrage, MD, MS**

Professor, Department of Family and Community Medicine, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin  
*Abnormal Uterine Bleeding*

**Dan Schuller, MD**

Professor, Department of Medicine, Texas Tech University Health Science Center; Chair, Department of Medicine—Transmountain, Texas Tech University Health Sciences Center, Paul L Foster School of Medicine, El Paso, Texas  
*Lung Abscess; Pulmonary Hypertension*

**Justin Seashore, MD**

Assistant Professor, Department of Pulmonary and Critical Care Medicine, UTMB Health, Galveston, Texas  
*Post-Acute COVID Syndrome*

**Amy Seery, MD**

Pediatrics, Ascension Via Christi Hospitals; Assistant Professor, Department of Family and Community Medicine, University of Kansas School of Medicine—Wichita, Wichita, Kansas  
*Normal Infant Feeding*

**†Steven A. Seifert, MD**

Professor, Emergency Medicine, University of New Mexico School of Medicine; Medical Director, New Mexico Poison and Drug Information Center, University of New Mexico Health Sciences Center, Albuquerque, New Mexico, Editor in Chief, *Clinical Toxicology (Taylor & Francis)*, London, United Kingdom  
*Venomous Snakebite*

**Jeffery D. Semel, MD**

Section of Infectious Diseases, Department of Medicine, NorthShore University Healthsystem, Evanston, Illinois; Associate Professor of Clinical Medicine, University of Chicago Pritzker School of Medicine, Chicago, Illinois  
*Clostridium difficile Colitis*

**Saeed Kamran Shaffi, MD**

Associate Professor, Internal Medicine/Nephrology, University of New Mexico School of Medicine, Albuquerque, New Mexico  
*Primary Glomerular Disease*

**Beejal Shah, MD**

Endocrinologist, Endocrinology, Diabetes, and Metabolism, Bay Pines Veterans Affairs Healthcare System, Tampa, Florida  
*Hyponatremia*

**Meera Shah, MBChB**

Consultant, Endocrinology, Diabetes, and Nutrition, Mayo Clinic, Rochester, Minnesota  
*Obesity in Adults*

**Prediman Krishan Shah, MD**

Professor of Medicine, University of California Los Angeles Cedars-Sinai Medical Center; Shapell and Webb Chair in Clinical Cardiology, Director of Oppenheimer Atherosclerosis Research Center and Atherosclerosis Prevention and Treatment Center, Smidt Heart Institute, Cedars-Sinai Medical Center, Los Angeles, California  
*Acute Myocardial Infarction*

**Shenil Shah, MD**

Cardiology, Franciscan Physician Network, Indianapolis, Indiana

# Preface

An axiom in clinical medicine says that from year to year the practice of medicine changes little but over 5 years there is a revolution. The 2023 edition of *Conn's Current Therapy* may prove the first half of this principle to be wrong.

The pace of change and imperative to adapt in health care has been breathtaking during each of the last 3 years. As one pundit put it, “the winds of change are blowing so hard, one must have nerves of steel . . . just to maintain balance.” Perhaps no other condition has forced us to alter our traditional ways of practice more than COVID-19. Over 6.5 million people have died worldwide from COVID-19, with more than 1 million dead in the United States since the onset of the pandemic 3 years ago. The long-term complications associated with COVID-19 are uncertain. Novel vaccinations and treatment options are now available, though we remain challenged by the emergence of new variants and a significant number (one out of six) of US citizens who have not received a single COVID-19 vaccination.

Who could have predicted the downstream effects of COVID-19? The virus has stimulated the use of telemedicine, insurance coverage for telemedicine services, sales of medical masks and other personal protective equipment, virtual meetings, and care of patients in medical office parking lots. Downstream effects of the pandemic have led to supply chain shortages of a variety of medications used in everyday practice and a shortage of health care workers. Physicians report increased levels of burnout and job dissatisfaction, which were already at epidemic rates prior to COVID-19. Physicians and other health care professionals have not been immune to The Great Retirement.

The pandemic has laid bare the depth of systemic health inequalities that have been just below the surface of the U.S. health care system. The pandemic has made it clear that primary care and public health are under-resourced, undervalued, and underappreciated, though both are foundational to a health care system that functions effectively, efficiently, and equitably.

Now, monkeypox and a possible resurgence of polio are at the doorstep.

That's not all. The rate of chronic disease remains inordinately high and continues to increase. The prevalence of obesity in the United States is now more than 40%, resulting in an increase in heart disease, stroke, type 2 diabetes and certain types of cancer. All are among the leading causes of preventable, premature death. Rates of hypertension, lipid disorders, obstructive sleep apnea, fatty liver disease, degenerative joint disease, and depression are downstream effects of the obesity epidemic.

Let's not forget that the opioid epidemic is worse now than before the worldwide COVID-19 outbreak. It has been pushed off the front page of the newspaper and news media websites by the pandemic. In 2021, there were more than 100,000 drug overdose deaths in the United States.

In 2020, the average life expectancy in the United States declined by well over a year, the first time it has decreased in modern times. Some say that today's children will have shorter average life spans than their parents. Others say that due to new medications and technological advances, today's children will live longer than their parents and spend their senior years in poor health burdened by multiple chronic conditions.

The authors of *Conn's Current Therapy 2023* have responded to the challenge of change in clinical care by reviewing each chapter of the textbook and updating and rewriting whenever necessary. For example, the book has chapters on COVID-19, long-COVID, and multisystem inflammatory syndrome in children (MIS-C), which detail the most current thinking in the management of these conditions. New information about the genetics of pheochromocytoma, hemochromatosis, and many cancers are examples of how the Human Genome Project is affecting our management of disease and our thinking about who is at risk. A detailed chapter on the care of adult patients with type 2 diabetes outlines the management of a too-common disease that is, in general, poorly controlled despite an abundance of drug treatment options.

A new section of the book titled “Emerging Therapies” has been added to this edition of *Conn's Current Therapy*. Our goal is to help practicing physicians better organize their thinking about an amazing array of new therapies that were only figments of the imagination in the not-too-distant past. Monoclonal antibody, genetic, and stem cell therapies are included in this section. We recognize that the title of this section is a little bit of a misnomer because many of these therapies have already emerged. When appropriate, authors have updated their individual chapters to include the use of these therapies in their area of expertise.

This is the 75th year in a row that *Conn's Current Therapy* has been published. It is one of the longest-running continuously published textbooks in world history. Until now, there have only been five editors: Howard Conn, MD; Bob Rakel, MD; Ed Bope, MD; Rick Kellerman, MD; and David Rakel MD. This year, we welcome two additional editors: Joel Heidelbaugh, MD, and Ernestine Lee, MD, MPH. Dr. Heidelbaugh and Dr. Lee have already put their stamp on the history of *Conn's Current Therapy*.

Miriam Chan, PharmD, is an indispensable member of the editorial team. Dr. Chan reviews each and every drug mentioned in the textbook for FDA approval status and dosing instructions. Dr. Chan is also a direct contributor to the text as a co-author of the chapter on drug hypersensitivity reactions and the appendix on popular herbs and nutritional supplements.

Two individuals who help us “keep the trains running on time” are Katie DeFrancesco, Senior Content Development Manager, and Kevin Travers, Content Development Specialist. Kevin joined us this year and immediately fit into the “Conn's culture.” You might ask, What does a Content Development Specialist do? Imagine organizing a textbook that is totally updated each year with 335 chapters, 1500+ pages, and more than 500 authors during an annual 8-month publication window. The job was particularly difficult this year as a supply-chain shortage of paper (another downstream effect of COVID-19) forced us to move the final deadline to have all chapters ready for publication up by 2 months. The medical editors communicate with either Katie or Kevin almost every day and they are dedicated, organized, skilled, and fun to work with.

The leader of the team is Charlotta “Lotta” Kryhl, Senior Content Specialist. Lotta offers sage advice and counsel about the direction of the book. She listens well during editorial team discussions and updates us about the larger concerns in the

publication industry. She helps us monitor data on electronic chapter utilization. She manages all the higher-level aspects of the publication, ensuring that all contracts are finalized.

Doug Turner, Senior Project Manager, goes to work during the final stages of production when the book is ready for hard-copy and electronic publication. He works with Renee Duenow, Senior Book Designer, on all aspects of the layout, front cover, and back cover design.

There are multiple copyeditors around the world who help us with *Conn's Current Therapy*. We respect and appreciate their mastery of language, spelling, phrasing, grammar, and punctuation, especially because of the technical nature of medical writing.

Thank you to each and every one who contributes to the production of this amazing publication.

We dedicate *Conn's Current Therapy 2023* to the doctors, nurses, and other health care professionals on the frontlines of the COVID-19 pandemic. They have literally put their own lives and health on the line, focused their work on the care of patients and families, and sacrificed their own family and personal time and energy to care for others.

*Rick D. Kellerman, MD*  
*David P. Rakel, MD*  
*Joel J. Heidelbaugh, MD*  
*Ernestine M. Lee, MD, MPH*

# Symptomatic Care Pending Diagnosis

## CHEST PAIN

Method of

William E. Cayley Jr., MD, MDiv

### CURRENT DIAGNOSIS

- Initial evaluation of chest pain should include evaluation of clinical stability, a concise history and physical examination, and a chest x-ray and electrocardiogram (ECG) unless the cause is clearly not life threatening.
- Chest pain described as exertional, radiating to one or both arms, similar to or worse than prior cardiac chest pain, or associated with nausea, vomiting, or diaphoresis indicates high risk for acute coronary syndrome (ACS). ECG identifies ST-elevation myocardial infarction (STEMI); cardiac biomarkers are essential for further evaluation of suspected chest pain in the absence of STEMI.
- The Wells, Geneva, and Pisa clinical prediction rules as well as the Pulmonary Embolism Rule-out Criteria (PERC) can help stratify a patient's risk of pulmonary embolism (PE).
- Aortic dissection is an uncommon cause of chest pain, but patients with abrupt or instantaneous chest pain that is ripping, tearing, or stabbing should be evaluated for dissection with chest x-ray, computed tomography (CT), or magnetic resonance imaging (MRI).
- Chest pain associated with dyspnea or painful inspiration and tachycardia or friction rub on auscultation may indicate pericarditis or myocarditis.
- Esophageal rupture may be suspected in patients with pain, dyspnea, and shock following a forceful emesis, and prompt imaging with CT or esophagography is essential.
- Patients who have suspected tension pneumothorax and who are clinically stable should have a chest x-ray for confirmation before needle decompression is attempted.

### CURRENT THERAPY

- Patients with STEMI require urgent reperfusion, and those with unstable angina or non-ST-elevation myocardial infarction (NSTEMI) require admission for further monitoring and evaluation.
- Most patients with PE require admission for monitoring and anticoagulation, although outpatient treatment may be possible for low-risk patients after initial evaluation and anticoagulation.
- Prompt surgical consultation is required for patients with confirmed or suspected aortic dissection or esophageal rupture.
- Clinically unstable patients with suspected tension pneumothorax need immediate needle decompression.

### Epidemiology

Chest pain is the chief complaint in 1% to 2% of all outpatient primary care visits. More than 50% of emergency department (ED) visits for chest pain are for serious cardiovascular conditions such as acute coronary syndrome (ACS) or pulmonary embolism (PE), but these account for less than 15% of outpatient primary care encounters for chest pain, and up to 15% of chest pain episodes never reach a definitive diagnosis. Other potentially life-threatening etiologies for chest pain include PE, dissecting aortic aneurysm (AA), esophageal rupture, and tension pneumothorax. In outpatient primary care, the most common causes of chest pain are musculoskeletal, gastrointestinal, angina caused by stable coronary artery disease (CAD), anxiety or other psychiatric conditions, and pulmonary disease.

### Initial Assessment

In the initial evaluation of chest pain, it is important to obtain a clear history of the onset and evolution of the pain, especially details such as location, quality, duration, and aggravating or alleviating factors. Initial physical examination should include vital signs, assessment of the patient's overall general condition, and examination of the heart and lungs. If there are any clinical signs of instability (altered mental status, hypotension, marked dyspnea, or other signs of shock), initial stabilization and diagnosis must be addressed simultaneously, consistent with current guidelines for emergency cardiovascular care. Unless the history and physical examination suggest an obviously nonthreatening cause of chest discomfort, most adults with chest pain should at least have basic diagnostic testing with an ECG and a chest x-ray. Several clinical prediction rules are available to help confirm or exclude some common causes of chest pain ([Box 1](#)).

### Diagnosis and Treatment

#### Acute Coronary Syndrome

ACS includes acute myocardial infarction (MI) (ST-segment elevation and depression, and Q wave and non-Q wave) and unstable angina. Findings on the history and physical examination that increase the likelihood of ACS include radiation of pain to the right arm or shoulder, to both arms or shoulders, or to the left arm; pain associated with exertion, diaphoresis, nausea, or vomiting; pain described as pressure or as "worse than previous angina or similar to a previous MI"; or the presence of hypotension or an S3 on cardiac auscultation. Elements of the history and examination that decrease the likelihood of ACS are pleuritic, positional, or sharp chest pain; pain in an inframammary location; pain not associated with exertion; pain lasting just seconds or lasting more than 24 hours; or chest pain reproducible with palpation. A low-risk score on the Marburg Heart Score (MHS) or the Interchest Clinical Prediction Rule can help exclude CAD in primary care patients with chest pain, and use of the MHS when evaluating primary care patients with chest pain has been shown to improve clinical diagnostic accuracy ([Table 1](#)). Recent studies have demonstrated that the presence or absence of typical cardiac risk factors (e.g., gender, diabetes, hypertension, smoking, high cholesterol, or family history) have little diagnostic value for determining the likelihood of ACS in patients older than 40 years of age, and the absence of risk factors should not preclude further cardiac evaluation in patients with concerning symptoms.

**TABLE 2** Simplified Wells Scoring System for Pulmonary Embolism

CLINICAL FINDING	SCORE
Symptoms of DVT	3.0
No alternative diagnosis more likely than PE	3.0
Heart rate >100 beats/min	1.5
Immobilization greater than 3 days or surgery in past 4 weeks	1.5
Previous objectively diagnosed DVT or PE	1.5
Hemoptysis	1.0
Malignancy	1.0
Probability of PE: <2 points = low, 2–6 points = moderate, >6 points = high	

DVT, Deep vein thrombosis; PE, pulmonary embolism. Modified from Miniati M, Bottai M, Monti S: Comparison of 3 clinical models for predicting the probability of pulmonary embolism, *Medicine (Baltimore)* 84(2):107–114, 2005; Torbicki A, Perrier A, Konstantinides S, et al: Guidelines on the diagnosis and management of acute pulmonary embolism: the Task Force for the Diagnosis and Management of Acute Pulmonary Embolism of the European Society of Cardiology (ESC), *Eur Heart J* 29(18):2276–2315, 2008.

depression of more than 0.5 mm in leads V2 to V3 or more than 1 mm in all other leads, dynamic T-wave inversion with chest discomfort, or transient ST-segment elevation of 0.5 mm or more is classified as unstable angina or NSTEMI. However, none of these findings is sensitive enough that its absence can exclude MI, and patients whose chest pain is not low risk still require further assessment for ACS.

In patients with high-risk chest pain but without STEMI, elevated cardiac troponin (cTn) I or T levels distinguish NSTEMI from unstable angina. High-sensitivity cardiac troponin assays (hs-cTn I or hs-cTn T) have higher sensitivity and better negative predictive values than standard troponin measurements. Because studies have demonstrated the superiority of cardiac troponins over both CK-MB and myoglobin for the diagnosis of MI, the addition of these assays to troponin measurement is no longer considered beneficial.

Initial management of NSTEMI includes hospital admission for antiplatelet, antithrombin, and antianginal therapy. Patients with unstable angina should also be hospitalized for observation, and those with either NSTEMI or unstable angina require risk stratification using the Thrombolysis in Myocardial Infarction Study Group (TIMI) or Global Registry of Acute Coronary Events (GRACE) risk scores (see Box 1). Patients with chest pain suspicious for CAD but no definite initial diagnosis of STEMI or NSTEMI on initial presentation are often admitted to the hospital for overnight observation and serial cardiac biomarker measurements to “rule out MI.” However, numerous accelerated diagnostic protocols have been developed integrating history, ECG findings, and cardiac biomarkers to determine who is at sufficiently low risk of major adverse cardiac events (MACE) to allow discharge for close follow-up. Recent evidence suggests that the HEART score may outperform TIMI and GRACE in determining which patients are at low risk (see Box 1), and the combination of a low-risk HEART score plus a single normal troponin value may predict sufficiently low risk of ACS to allow discharge from emergency care with short-term outpatient follow-up.

Patients at low risk for ACS or MI can usually defer further testing unless there are other risk factors in their family or past medical history markedly increasing the likelihood of CAD. Current recommendations are that all other patients with chest pain suggestive of CAD should have further noninvasive testing within 7 days. However, a study of 4181 patients in an emergency department chest pain unit found that a reasonable alternative may be to test troponin levels twice over a 6-hour interval, with no stress testing if both values are normal, and a retrospective analysis of

**TABLE 1** Marburg Heart Score\*

FINDING	POINTS
Women >64 years, men >54 years	1
Known CAD, cerebrovascular disease, or peripheral vascular disease	1
Pain worse with exercise	1
Pain not reproducible with palpation	1
Patient assumes pain is cardiac	1

\*Approximately 23% of patients with an MHS score of 3 or more will have CAD. Approximately 97% of patients with an MHS score of 2 or less will not have CAD. CAD, Coronary artery disease. Modified from Haasenritter J, Bösner S, Vaucher P, et al: Ruling out coronary heart disease in primary care: External validation of a clinical prediction rule, *Br J Gen Pract* 62(599):e415–e421, 2021.

An ECG should be obtained promptly for any patient with suspected ACS. ST-segment elevation in two or more contiguous leads or a presumed new left bundle branch block is diagnostic of STEMI and requires urgent revascularization with thrombolysis or angioplasty at an appropriate facility. Ischemic ST-segment

**TABLE 3** Pulmonary Embolism Rule-out Criteria

Criteria (Excludes PE if all criteria are met and pretest probability is estimated at less than 15%)

Age <50 years

Heart rate <100 beats/min

Pulse oximetry on room air >95%

No unilateral leg swelling

No hemoptysis

No surgery or trauma in the last 4 weeks

No prior DVT or PE

No hormone use

DVT, Deep vein thrombosis; PE, pulmonary embolism.

Modified from Kline JA, Mitchell AM, Kabrhel C, et al: Clinical criteria to prevent unnecessary diagnostic testing in emergency department patients with suspected pulmonary embolism, *J Thromb Haemost* 2(8):1247–1255, 2004.

7988 ED patients with chest pain who were discharged to complete diagnostic testing found no difference in MACE between those who had testing within 3 days and those who had testing between 4 and 30 days from discharge.

Patients who can exercise and have no left bundle branch block, preexcitation, or significant resting ST-segment depression on an ECG can be evaluated with an exercise stress ECG, and the Duke Treadmill Score can then be used to further quantify cardiac risk (see [Box 1](#)). Patients with baseline ECG abnormalities should have perfusion imaging performed along with a stress ECG, and those who cannot exercise may be evaluated with a pharmacologic stress or vasodilator test (e.g., dobutamine [Dobutrex]<sup>1</sup> or adenosine [Adenocard]<sup>1</sup>). Patients at high risk for CAD or those with NSTEMI should generally proceed directly to angiography, which enables definitive assessment of the coronary artery anatomy.

### Pulmonary Embolism

There are no individual symptoms or physical examination findings that reliably diagnose or exclude PE, but four clinical prediction rules have all been validated for use in determining the likelihood of PE and therefore whether further testing is needed (see [Box 1](#)). The Pisa rule may be the most accurate, but it is also the most mathematically complicated and depends on clinical, ECG, and x-ray findings. The Geneva rule requires blood gas and chest x-ray findings. The Wells rule ([Table 2](#)) is based on the simplest combination of history and examination findings, and a comparison between the Wells and Geneva rules found that the Wells rule has a lower failure rate. With the Wells and Geneva prediction rules, the likelihood of PE is approximately 10% in the low-probability category, 30% in the moderate-probability category, and 65% in the high-probability category. If a patient is clinically suspected to be at low risk for PE (<15% pretest probability) and meets all of the PERC ([Table 3](#)), the risk of PE is less than 2%, and no further testing is needed.

Routine tests done for patients with chest pain are not particularly helpful in diagnosing or excluding PE. The chest x-ray may be abnormal, but findings that typically occur with PE (atelectasis, effusion, or elevation of a hemidiaphragm) are nonspecific. ECG signs of right ventricular strain (S wave in lead I, Q wave and inverted T wave in lead III) may be helpful if present, but their absence does not exclude PE. Hypoxia may be present, but up to 20% of patients with PE have a normal alveolar-arterial oxygen gradient.

Additional tests recommended for evaluating patients with suspected PE include D-dimer testing, compression ultrasonography,

and pulmonary imaging with ventilation-perfusion (VQ) scintigraphy or computed tomography (CT) angiography. Although CT may be more sensitive than VQ scanning, CT is also associated with higher radiation doses; for younger patients with suspected PE and a normal chest x-ray, VQ scanning may be preferable to limit overall radiation exposure. The use of adjusted D-dimer levels based on age or clinical setting has been studied, but none of these approaches have been standardized. Patients with suspected high-risk PE (i.e., those with shock or hypotension) should have immediate imaging and treatment for PE if the imaging is positive, although an echocardiographic finding of right ventricular overload may be used to justify treatment for PE in the unstable patient with high clinical suspicion for PE when imaging is not available. Patients who have suspected PE and are not at high risk (i.e., no shock or hypotension) and have a high clinical probability (based on Wells, Geneva, or Pisa scoring) should also proceed directly to imaging, with appropriate treatment if the scan is positive. Patients with a low clinical probability of PE (based on one of the validated clinical prediction rules) do not need further D-dimer testing or imaging. Patients with intermediate clinical probability should initially have D-dimer testing; further testing or treatment for PE is unnecessary if the D-dimer is negative, and imaging should be performed if the D-dimer is positive.

Anticoagulation, with thrombolysis in high-risk patients, is the foundation of treatment for PE. Patients with shock or hypotension are at high risk and require hemodynamic and respiratory support, thrombolysis, or embolectomy, followed by appropriate attention to anticoagulation. Normotensive patients with echocardiographic evidence of right ventricular dysfunction or serologic evidence of myocardial injury (elevated cTn I or T) have intermediate risk and should be admitted for anticoagulation. Normotensive patients who have normal results on echocardiography and testing for myocardial injury are at low risk and often may be discharged early for management at home after initiation of anticoagulation. Anticoagulation for PE should be started at the time of diagnosis. Apixaban (Eliquis) or rivaroxaban (Xarelto) may be used without prior oral anticoagulation; alternatively, unfractionated heparin, low-molecular-weight heparin, or fondaparinux (Arixtra) may be started and continued for 5 to 10 days with simultaneous initiation of dabigatran (Pradaxa), edoxaban (Savaysa or Lixiana), or warfarin (Coumadin) titrated to maintain an international normalized ratio (INR) between 2.0 and 3.0.

### Thoracic Aortic Dissection

Thoracic aortic dissection is a much less common cause of chest pain; prevalence estimates are 2 to 3.5 cases per 100,000 person-years. Up to 40% of patients die immediately, and 5% to 20% die during or shortly after surgery. Risk factors for acute thoracic aortic dissection include hypertension, presence of a pheochromocytoma, cocaine use, weightlifting, trauma or a rapid deceleration event, coarctation of the aorta, and certain genetic abnormalities. Pain caused by acute aortic dissection is perceived as abrupt and severe in 84% to 90% of cases, and more than 50% of patients describe the pain as sharp or stabbing. No physical findings are sensitive or specific for detecting aortic dissection because approximately equal percentages of patients are hypertensive or normotensive or have hypotension or shock. The most common physical findings (a murmur of aortic insufficiency or a pulse deficit) occur in less than one-half of patients.

In any patient with severe chest pain that is abrupt or instantaneous in onset or has a ripping, tearing, or stabbing quality, acute thoracic aortic dissection should be suspected. Physical examination should assess for a pulse deficit, a systolic pressure differential between limbs of greater than 20 mm Hg, a focal neurologic deficit, or a new aortic regurgitation murmur. It is also important to ask about a family history of connective tissue disease (including Marfan syndrome), about any family or personal history of aortic dissection or thoracic aneurysm, and about any known aortic valve disease or recent aortic interventions. D-dimer testing has been proposed as a way to screen for aortic dissection, but it

<sup>1</sup>Not FDA approved for this indication.

is more important to obtain prompt imaging and surgical intervention for those in whom dissection is confirmed. A low-risk Aortic Dissection Detection Risk Score (ADD-RS) (see [Box 1](#)) can help exclude the diagnosis of aortic dissection, whereas patients with a high-risk score require further evaluation.

An ECG should be obtained in all patients with suspected aortic dissection to exclude STEMI (which can manifest with similar symptoms). In all low- and intermediate-risk patients, a prompt chest x-ray can help by either confirming an alternative diagnosis or confirming the presence of thoracic aortic disease. High-risk patients should have prompt imaging with CT or MRI, and those who are in shock or clinically unstable may be evaluated by bedside transesophageal echocardiography. If thoracic aortic dissection is confirmed on imaging, urgent surgical consultation is required. Medical therapy should be started with intravenous  $\beta$  blockers. Patients with dissection of the ascending aorta require urgent surgery, whereas those with descending thoracic aortic dissection may be managed medically unless hypotension or other complications develop.

### Pericarditis and Myocarditis

Acute pericarditis is an inflammatory syndrome of the pericardium (with or without effusion), and myocarditis is an inflammation of the myocardium. Some patients may have an inflammatory myopericarditis. Viral infections are the most common identified cause of pericarditis (although most cases are idiopathic). Myocarditis may also be caused by a viral infection (including COVID-19) or secondary to systemic disease (e.g., rheumatoid arthritis or sarcoidosis) or toxin exposure (e.g., alcohol). Pericarditis or myocarditis should be suspected in patients with acute substernal chest pain that is associated with dyspnea or painful inspiration and tachycardia or friction rub on auscultation; myocarditis should also be suspected in any patient with heart failure and no clear underlying cause. Diagnostic testing should include ECG, cNt, and echocardiography. Supportive care and electrocardiographic monitoring are important for any patient with hemodynamic compromise. Pericarditis is typically treated with nonsteroidal antiinflammatory drugs (NSAIDs) plus colchicine,<sup>1</sup> while treatment of myocarditis generally involves addressing treatment of any identified causes.

### Esophageal Rupture

Esophageal rupture, or Boerhaave syndrome, has a high mortality rate. Esophageal rupture is rare; the most common cause is endoscopically induced injury, but it can happen in other settings as well. Common misdiagnoses include perforated ulcer, MI, PE, dissecting aneurysm, and pancreatitis. The “classic” presentation has been described as pain, dyspnea, and shock followed by forceful emesis, but the history and physical examination are commonly nonspecific. Diagnosis most commonly is made by contrast esophagography or CT of the chest.

Patients whose rupture is diagnosed less than 48 hours after symptom onset should be treated surgically (especially if sepsis is present) or endoscopically. Those who present more than 48 hours after symptom onset may be considered for conservative treatment with hyperalimentation, antibiotics, and nasogastric suction.

### Tension Pneumothorax

Tension pneumothorax is relatively rare among patients presenting with chest pain, but it is potentially life threatening if not treated properly. Common symptoms and physical findings include chest pain, respiratory distress, decreased ipsilateral air entry, and tachycardia; hypoxia, tracheal deviation, and hypotension are less common.

Emergency needle decompression is usually recommended if tension pneumothorax is suspected, but this is ineffective in some cases and is associated with risks to the patient of pain, bleeding,

infection, and cardiac tamponade. However, waiting for radiographic confirmation of the diagnosis is associated with up to a fourfold increase in mortality because of delay in decompression of the pneumothorax. Patients most likely to benefit from an immediate attempt at needle decompression are those with an oxygen saturation below 92% while on oxygen, a decreased level of consciousness while on oxygen, a systolic blood pressure less than 90 mm Hg, or a respiratory rate below 10 breaths/min. Patients without signs of instability may be better managed by waiting for chest imaging to confirm or exclude the presence of a pneumothorax. Although plain chest x-rays have typically been used for diagnosing a pneumothorax, pleural ultrasonography may have higher sensitivity. A meta-analysis of 8 trials with 1342 patients found that for spontaneous pneumothorax there may be no difference in clinical success rates between conservative and interventional treatment.

### Other Causes of Chest Pain

A patient with chest pain and cough, fever, egophony, or dullness to percussion might have pneumonia, but none of these individual findings is specific enough to confirm the diagnosis. However, adults with an acute respiratory infection who have normal vital signs and a normal pulmonary examination are very unlikely to have community-acquired pneumonia. A large study in 1984 developed a decision rule ([Table 4](#)) using seven clinical findings to predict the likelihood of pneumonia. There is ongoing debate over the reliability of pneumonia diagnosis based solely on history and physical examination; chest x-ray is usually considered the reference standard. However, a recent Cochrane review found two trials suggesting that routine chest radiography does not affect the clinical outcomes in adults and children whose presentations are suggestive of a lower respiratory tract infection. Thus at least for clinically stable outpatients, treatment for pneumonia based on appropriate clinical findings alone may be reasonable.

Heart failure alone is an uncommon cause of chest pain, but it may accompany ACS or cardiac valve disease. A displaced apical impulse and a prior history of CAD support this diagnosis, and because virtually all patients with heart failure have exertional dyspnea, its absence is very helpful in excluding this diagnosis. An abnormal ECG and cardiomegaly on chest x-ray can increase the likelihood of heart failure among patients with chest pain, and

<sup>1</sup>Not FDA approved for this indication.

<sup>2</sup>Not available in the United States.

B-natriuretic peptide (BNP) or N-terminal pro-B-type natriuretic peptide (NT-proBNP) are now commonly used for detecting heart failure in patients presenting with acute dyspnea. Point-of-care ultrasonography (POCUS) may have high sensitivity and specificity for diagnosing acute cardiogenic pulmonary edema.

Panic and anxiety are a common cause of chest pain in those at low risk for heart disease. There is good evidence that psychological interventions such as cognitive behavioral therapy (CBT) and breathing exercises can improve chest pain symptoms for patients with nonspecific chest pain who do not have CAD. However, even in patients with possible panic disorder, further cardiac testing should be done if there are significant cardiac risk factors.

Gastrointestinal disease can cause chest pain, but the history and physical examination are relatively inaccurate for diagnosing or excluding serious gastrointestinal pathology. However, if life-threatening cardiovascular or pulmonary causes of chest pain have been excluded, it is appropriate to try a short course of a high-dose proton pump inhibitor (omeprazole [Prilosec] 40 mg daily,<sup>3</sup> lansoprazole [Prevacid] 30 mg daily, or esomeprazole [Nexium] 40 mg daily<sup>3</sup>) to evaluate for undiagnosed gastroesophageal reflux disease (GERD) as the cause of chest pain (even for patients without typical GERD symptoms).

Chest wall pain can usually be diagnosed by history and examination if other etiologies have been excluded, and such pain is more likely if the patient's pain is reproducible by palpation. Measurement of the sedimentation rate is not generally helpful in making the diagnosis, although in unusual situations radiography may be helpful. Typical management options include heat, NSAIDs, topical lidocaine, physical therapy, or acupuncture.

<sup>3</sup>Exceeds dosage recommended by the manufacturer.

## CONSTIPATION

Method of

Melissa Gaines, MD

### CURRENT DIAGNOSIS

- Although constipation is a benign process, it is important to recognize signs of a serious condition.
- Classification of normal transit constipation, slow transit constipation, or pelvic floor dysfunction guides therapy.
- Clinical testing has low benefit, but colonoscopy or imaging can assess organic causes.

### CURRENT THERAPY

- Initial therapy includes soluble dietary fiber to improve symptoms in chronic constipation.
- Osmotic laxatives are preferred while using stimulant laxatives as rescue agents.
- Surgery is reserved for pelvic floor dysfunction after optimal therapies have failed.

### Epidemiology

Constipation is common, with a prevalence of 1.9% to 27.2%, but the description of symptoms is variable. A thorough history and focused physical examination aids diagnosis. Treatment is directed toward relief of symptoms, alleviation of precipitating factors, and prevention of recurrence. Although constipation is a benign process, it is important to recognize concerning signs for a more serious medical condition such as malignancy.

### Risk Factors

Vulnerable populations include female, elderly, neurodegenerative disease, low-fiber diet, painful rectal disorders, hypothyroidism, and diabetes mellitus.

### Pathophysiology

With aging, there is decreased rectal compliance, diminished rectal sensation, and decreased resting anal pressures, while colonic transit time is preserved. Normal transit constipation is a component of irritable bowel syndrome with normal transit time and stool frequency. Slow transit constipation is a condition with colonic dysmotility resulting from altered enteric nervous system. Defecatory disorders include structural disturbances of the pelvic floor. Pelvic floor dysfunction is the paradoxical contraction of the external anal sphincter and puborectalis muscles during defecation. Secondary causes of constipation are listed in [Table 1](#).

**TABLE 1** Causes of Constipation

Dietary	Low-fiber diet, dementia, depression, anorexia, dehydration
Metabolic	Diabetes mellitus, hypercalcemia, hypokalemia, hypothyroidism, systemic sclerosis
Neurologic	Parkinson disease, spinal cord disorder, multiple sclerosis, cerebrovascular disease (stroke)
Iatrogenic	Antacids, iron, anticholinergics, antidepressants, antipsychotics, opiates, antiepileptics
Painful anorectal condition	Anal fissure, hemorrhoids, abscess, fistula, pelvic floor dysfunction, malignancy

**Prevention**

Provide an environment of privacy and comfort to allow for natural defecation. Prescribe an adequate fluid and fiber intake with specific amounts that vary depending on the patient’s condition. Encourage physical activity, with a low to moderate level of exercise depending on the patient’s functional status. Develop a routine for defecation with a prompt response to a call to defecate urgently. Recurrent fecal impaction can be prevented with polyethylene glycol (PEG, MiraLAX).

**Clinical Manifestations**

Patients will complain using qualitative terms of hard stools, a feeling of incomplete voiding, straining, prolonged time for laxation, the need for additional maneuvers, abdominal bloating, and abdominal pain (Table 2). A change in bowel habit differentiates the current complaint from a serious medical condition. Red flags include acute onset, weight loss, abdominal pain or cramping, rectal bleeding, nausea or vomiting, rectal pain, fever, or a change in stool caliber. Infants with abdominal distension and failure to pass meconium within 24 hours indicate Hirschsprung disease. Patients should be asked if they have had loose stools or bowel incontinence to assess for fecal impaction. A medication review is required (see Table 1). Classification of patients with normal transit constipation, slow transit constipation, or pelvic floor dysfunction/defecatory disorders guides therapy.

**Diagnosis**

Diagnostic criteria have been established because the symptoms can vary (see Table 2). Conduct a physical examination that includes an assessment of vital signs, weight, volume status, auscultation of bowel sounds, abdominal percussion for tympani, and abdominal palpation for tenderness or mass. A rectal examination can detect resting rectal tone, fecal impaction, anorectal disorders, or rectal mass. Defecatory disorders show an increased resistance to the insertion of the examiner’s finger with an impaired relaxation of the sphincter complex and reduced perineal descent during a Valsalva maneuver. Conduct laboratory testing on electrolytes, hemoglobin, thyroid-stimulating hormone, and fecal occult after initial measures fail. Red flag symptoms require imaging with computed tomography (CT) of the abdomen and pelvis or an endoscopy to diagnose malignancy or fecal impaction. Anorectal testing with manometry and a rectal balloon expulsion test is appropriate for pelvic floor dysfunction or defecatory disorders. Hirschsprung disease is diagnosed with barium enema, rectal manometry, or a rectal suction biopsy. Colonic transit rates with radiopaque markers (Sitz) on serial abdominal radiographs over 4 to 7 days diagnose slow transit constipation disorders.

**TABLE 2** Rome III Criteria

More than two present:
1. Straining in more than 25% of defecations
2. Hard or lumpy stool in more than 25% of defecations
3. Sensation of incomplete evacuation
4. Sensation of anorectal blockage
5. Manual maneuvers
6. Fewer than three defecations per week
Loose stools are rare without laxative use
Insufficient criteria for irritable bowel syndrome
Symptoms for 3 months with onset 6 months before diagnosis

**Treatment**

Nonpharmacologic therapies have limited benefit. Unless there are signs of dehydration, increasing fluid intake is not indicated. Moderate-intensity exercise improves symptoms of irritable bowel syndrome. Probiotics are not beneficial.

There is moderate evidence for pharmacologic agents (Table 3). Normal transit constipation responds to soluble dietary fiber supplements (e.g., psyllium [Metamucil]); however, these should not be used in the case of slow transit constipation or drug-induced constipation. Osmotic agents with PEG (MiraLAX) or lactulose (Chronulac) can be dose increased for soft stools. Stimulant laxatives are used as rescue therapy if patients do not have a bowel movement for 2 days.

New classes of drugs to manage constipation include intestinal secretagogues, serotonin 5-HT<sub>4</sub> receptor antagonists, and opiate antagonists. Lubiprostone (Amitiza) requires a negative pregnancy test with contraception. Linaclotide (Linzess) is a 14-amino acid peptide similar to heat-stable enterotoxins that cause diarrhea. Lubiprostone and linaclotide are US Food and Drug Administration (FDA)-approved for chronic idiopathic constipation (CIC) and irritable bowel syndrome with constipation (IBS-C). Lubiprostone is also indicated for treatment of opioid-induced constipation (OIC). Plecanatide (Trulance) is an approved drug for treatment of CIC and IBS-C in adults. It is a guanylate cyclase-C agonist that increases fluid secretion into the upper intestine. Methylnaltrexone (Relistor) and naloxegol (Movantik) are opiate receptor antagonists that can cause laxation in patients on chronic opiate therapy with number needed to treat (NNT) of 5.

Pelvic floor dysfunction or defecatory disorders respond to biofeedback therapy by using manometry and visual or auditory feedback. Patients practice expelling a balloon and improve pelvic floor muscle coordination with Kegel exercises. Surgical intervention with subtotal colectomy with ileorectal anastomosis is indicated for slow transit constipation or defecatory disorders after failure of optimal medical management.

**Complications**

Fecal impaction is a complication and a large bowel obstruction with colonic perforation has high mortality. Pediatric and geriatric patients are most susceptible with signs and symptoms of fecal incontinence, abdominal pain, abdominal distention, anorexia, weight loss, and delirium. Treatments for adults include a large-volume tap-water enema (500 to 1000 mL), local anesthetics administered topically with abdominal massage, a colonoscopy, or surgery. The prevention of recurrence requires maintenance bowel regimen with osmotic agents such as PEG (MiraLAX).

**TABLE 3** Drug Dosing and Adverse Effects

CLASS	DRUG NAME (BRAND)	ADULT DOSING	MECHANISM OF ACTION	TIME TO ONSET (H)	ADVERSE EFFECT
Fiber	Bran Psyllium (Metamucil) Methylcellulose (Citrucel) Calcium polycarbophil (FiberCon)	1 cup/day 1 tsp 1 tbsp or 1 tab twice daily 2–4 tabs/day	Increase water content and bulk of stool decreasing transit time	Unknown	Bloating excessive gas
Hyperosmolar agent	Sorbitol 70% Lactulose (Chronulac)	15–30 mL twice daily	Disaccharide metabolized by colonic bacteria into acetic acid and short-chain fatty acids	24–48	Sweet tasting, transient abdominal cramps, flatulence
Hyperosmolar agent	PEG-ES (GoLyteLy, <sup>1</sup> CoLyte <sup>1</sup> ) PEG (MiraLAX)	8–32 oz daily 17 g (1 tbsp) qd	Osmotic effect increasing intraluminal fluids	0.5–1	Incontinence
Guanylate cyclase-C agonist	Plecanatide (Trulance) Linaclotide (Linzess)	CIC and IBS-C: 3 mg once daily CIC: 72–145 mcg once daily IBS-C: 290 mcg once daily	Osmotic effect increasing intraluminal fluids, increase transit time	Cannot be calculated	Diarrhea Abdominal pain, diarrhea
Chloride channel activator	Lubiprostone (Amitiza)	CIC and OIC: 24 mcg twice daily IBS-C in women ≥18 y: 8 mcg twice daily	Increase intestinal fluid secretion and improve fecal transit	Unknown	Headache, nausea, diarrhea
Stimulant	Glycerin suppository Bisacodyl (Dulcolax) Senna (Senokot, Perdiem) Senna/docusate (Peri-Colace)	1 daily 10 mg suppository or 5–10 mg PO 3 times a week 2–4 tabs twice daily	Local rectal stimulation, secretory and prokinetic effect	8–12	Degeneration of Meissner and Auerbach plexus
Enemas	Mineral oil retention enema Tap water enema Sodium phosphate enema (Fleet)	199–250 mL daily PR 500–1000 mL PR 1 unit PR	Evacuation induced by distended colon and mechanical lavage	6–8 for a mineral oil enema 5–15 min for all other enemas	Mechanical trauma, incontinence, rectal damage
Opioid antagonist	Methylnaltrexone (Relistor)	8–12 mg 1 dose SC every other day as needed for OIC with advanced illness. 450 mg PO once daily or 12 mg SC once daily for OIC with chronic noncancer pain.	Opioid mu receptor antagonist in gut decreasing transit time	4	Diarrhea, intestinal perforation
Opioid antagonist	Naloxegol (Movantik)	12.5–25 mg PO daily	Same as Relistor	6–36	Abdominal pain, opioid withdrawal reported

<sup>1</sup>Not US Food and Drug Administration (FDA) approved for this indication.

CIC, Chronic idiopathic constipation; IBS-C, irritable bowel syndrome with constipation; OIC, opioid-induced constipation; PEG-ES, polyethylene glycol and electrolyte solution; PO, by mouth; PR, per rectum; SC, subcutaneously.

## COUGH

Method of  
Emily Manlove, MD

### CURRENT DIAGNOSIS

- Acute cough
  - Noninfectious
    - Chronic obstructive pulmonary disease exacerbation
    - Asthma exacerbation
    - Congestive heart failure exacerbation
    - Pulmonary embolism
  - Infectious
    - Viral rhinosinusitis (the common cold)
    - Acute bacterial sinusitis
    - Acute bronchitis (chest cold)
    - Pneumonia
    - Pertussis (whooping cough)
    - Bronchiolitis (infants)
- Chronic cough
  - First, evaluate/rule out
    - Tobacco smoking and risk for lung cancer
    - Angiotensin-converting enzyme (ACE) inhibitor–associated cough
  - Next, evaluate for the three most common etiologies
    - Chronic upper airway cough syndrome
    - Cough variant asthma/nonasthmatic eosinophilic bronchitis
    - Gastroesophageal reflux disease
  - Last, consider other causes and more advanced testing (bronchoscopy, high-resolution computed tomography [CT], referral), and consider earlier if history, physical examination, or chest x-ray suggests an alternative diagnosis
    - Oral pharyngeal dysphagia
    - Lung tumors
    - Interstitial pulmonary diseases
    - Bronchiectasis
    - Occupational and environmental exposures
    - Sarcoidosis
    - Tuberculosis
    - Somatic cough syndrome
    - Tic cough

### CURRENT THERAPY

- Acute cough caused by viral rhinosinusitis
  - Dextromethorphan (Delsym) 30 mg PO every 6 to 8 hours × 1 week
  - Diphenhydramine (Benadryl) 25 mg PO every 4 hours × 1 week
  - Nasal saline irrigation twice daily × 1 week
- Acute or subacute cough caused by *Bordetella pertussis*
  - Azithromycin (Z-Pak)<sup>1</sup> 500 mg PO on day 1 followed by 250 mg PO daily on days 2 to 5
- Treatment of unexplained chronic cough
  - Multimodality speech pathology therapy
  - Gabapentin (Neurontin) 300 mg PO daily, can be titrated up to a maximum daily dose of 1800 mg a day in two divided doses (off-label use)

<sup>1</sup>Not FDA approved for this indication.

## Acute Cough

Acute cough is a cough that lasts fewer than 3 weeks. It is a common presenting complaint in the primary care physician's office and also in the emergency department. The key goal is to differentiate between patients whose cough has a benign cause and those who may be at risk for more serious illness. Infectious causes of cough are most common, but noninfectious causes should also be considered. Exacerbations of preexisting pulmonary conditions such as asthma and chronic obstructive pulmonary disease (COPD) can be associated with cough, therefore a thorough medical history should be obtained. Cough can also be associated with decompensated heart failure; in fact, cough is present in 70% of congestive heart failure (CHF) exacerbations. Also, 30% to 40% of patients with acute pulmonary embolism (PE) have a new cough at presentation of symptoms, and the classic signs and symptoms of chest pain, dyspnea, and hypoxia may not always accompany the cough.

Upper respiratory tract infections are a common cause of benign acute cough. The common cold, also known as *viral rhinosinusitis*, is probably the most common cause of acute cough. The lung examination is normal. If fever is present, it is low grade and is only present on the first or second day of illness. Most symptoms begin to resolve by 7 to 10 days, but cigarette smokers may be ill for twice as long. Symptomatic treatment is the mainstay of therapy. First-generation antihistamines combined with a decongestant and naproxen have been proven to reduce the length of cough. Second-generation antihistamines are not effective in the treatment of cough associated with viral rhinosinusitis; it is likely that first-generation antihistamines are effective because of their anticholinergic properties. Other treatments that may be helpful include nasal saline irrigation, nasal glucocorticoids, and nasal decongestants. It is necessary to distinguish viral rhinosinusitis from acute bacterial rhinosinusitis, which may also be associated with cough. Less than 2% of all rhinosinusitis has a bacterial cause. Acute bacterial rhinosinusitis should not be diagnosed in the first week of symptoms unless the patient displays severe symptoms such as high fever. Sinus imaging studies are unlikely to be helpful, as both viral and bacterial sinusitis will have radiologic evidence of inflammation.

It is also necessary to distinguish an acute cough caused by an upper respiratory tract infection from that caused by a lower respiratory tract infection. Furthermore, it is necessary to distinguish between acute bronchitis, which almost always has a viral cause, versus pneumonia, which has a bacterial cause. Both illnesses often have a presenting symptom of cough, which may be productive. If there is any derangement in vital signs or evidence of pulmonary consolidation on the lung examination, a chest x-ray should be performed. Infectious Diseases Society of America (IDSA) guidelines require the presence of consolidation on chest x-ray to diagnose pneumonia. Influenza and COVID-19 should also be considered for patients who have fever and cough. An elevated procalcitonin level may help guide the physician in his or her decision to prescribe antibiotics. Inhaled beta agonists should not be routinely used to alleviate cough in acute viral bronchitis, but they may be helpful to alleviate wheezing and are more likely to benefit patients with airflow obstruction at baseline.

In pediatric patients, bronchiolitis should be considered as a cause of cough and fever. It is the most common cause of hospitalization in those younger than 1 year of age. The most recent guidelines recommend abstaining from laboratory testing (including viral swabs), radiographic imaging, and treatment with beta agonists, epinephrine, or glucocorticoids as these interventions do not change the course of illness. Exclusive breastfeeding for the first 6 months of infancy can decrease the morbidity of respiratory infections. *Bordetella pertussis* can cause severe illness with cough and apnea in infants. However, adults have subtle symptoms and lack the classic "whooping cough" and posttussive emesis seen in children. The physician should have suspicion for pertussis in patients who have a cough lasting longer than 2

weeks and paroxysms of coughing; the cough can last up to 2 months. The diagnosis can be confirmed with polymerase chain reaction (PCR). Antibiotics do not alter the course of illness but reduce the spread of infection; azithromycin (Zithromax)<sup>1</sup> should be given for 3 to 5 days. Vaccination rates remain low. Pregnant women should be vaccinated with each pregnancy, and other adults should replace 1 dose of Td at the earliest convenience.

### Chronic Cough

A chronic cough is a cough lasting more than 8 weeks. Patients may have a presenting symptom of a cough that has been present for more than 3 weeks but fewer than 8 weeks; this is considered a subacute cough. In this case, the physician should illicit a history of respiratory infection; the patient is likely suffering from a postinfectious cough, which is related to inflammation of the airway epithelium, mucus hypersecretion, and/or increased cough reflex sensitivity. Inhaled corticosteroids may provide some benefit. If there is no history of recent infection, then the cough should be managed as a chronic cough. Chest x-ray can be considered during this time frame, but if no red flags are present (fever, unintended weight loss, night sweats, dysphagia, odynophagia, hemoptysis), the physician and patient together can decide to wait on radiography.

Chronic cough must be approached in a systematic manner, which is more likely to identify the causative agent of the cough and provide alleviation of symptoms. All of the common causes of chronic cough (see later) must be considered as the associated symptoms and the patient's description of the cough do not alter the diagnostic algorithm. It is important to confirm compliance throughout the treatment course and identify barriers to compliance with the patient. Failure to respond to empiric treatment does not necessarily rule out a diagnosis as the patient may have two diagnoses. Therefore it is prudent to continue any partially effective treatment for chronic cough.

First, it must be determined if the patient smokes. If so, the differential diagnosis is altered. The physician must determine if the smoke is a simple smoker's cough, chronic bronchitis, or possibly lung cancer; cough is the most common presenting symptom of lung cancer. Smokers are less likely to seek help for a cough and may not see a physician until a more serious problem has advanced. It is possible for a cough to worsen initially after smoking cessation, but a cough persisting more than 1 month after cessation should be investigated. Any change in a smoker's cough, a new cough, and cough with hemoptysis should be investigated. Physicians should consider low-dose CT scanning as screening for lung cancer in qualifying smokers. The second factor to rule out in all chronic cough cases is cough induced by an angiotensin-converting enzyme (ACE) inhibitor. All patients with chronic cough should stop taking an ACE inhibitor. The medication is more likely to cause a cough if it was started in the prior year, and the cough should resolve within 1 month after cessation of the ACE inhibitor. The next step to determining the cause of a chronic cough is to rule out the three most common causes of cough. Last, all patients with a cough lasting more than 8 weeks should be evaluated with chest radiography to identify any obvious causative factors.

### Upper Airway Cough Syndrome

Upper airway cough syndrome (UACS), previously called *post-nasal drip syndrome*, is likely caused by activation of cough receptors in the hypopharynx or larynx and increased sensitivity of these receptors. It is likely the most common cause of chronic cough. UACS is almost always associated with rhinosinusitis, which can be caused by a number of factors (allergic rhinitis, postinfectious rhinitis, perennial nonallergic rhinitis, rhinitis resulting from chemical irritants, rhinitis medicamentosa, pregnancy-associated rhinitis, bacterial sinusitis, allergic fungal sinusitis). The patient may complain of frequently needing to

clear the throat or a sensation of "dripping" in the back of the throat; however, absence of these symptoms does not rule out UACS, nor does a history of wheezing. The physical examination may reveal mucus in the posterior oropharynx and cobblestoning of the mucosa. If the cause of rhinitis is obvious, it should be specifically treated. Otherwise, a trial of a first-generation antihistamine should be started; improvement should be seen in 2 weeks. If the side effects of this therapy are intolerable, a nasal antihistamine, nasal anticholinergic, or nasal corticosteroid can be used. If the diagnosis of UACS is highly suspected but the patient does not respond to empiric therapy, sinus CT imaging may be necessary to guide diagnosis and treatment.

### Cough Variant Asthma and Nonasthmatic Eosinophilic Bronchitis

Cough-variant asthma and nonasthmatic eosinophilic bronchitis (NAEB) both primarily present with a cough, and the patient may have few other symptoms. Patients with cough-variant asthma will have abnormal spirometry, whereas those with NAEB will not. When spirometry is performed, bronchoprovocation testing with methacholine should be performed as it increases the negative predictive value of the test. If spirometry is negative, the sputum should be evaluated for eosinophils, which are present in both diseases. Both diseases are treated as asthma; an inhaled corticosteroid should be started and long-acting beta agonists and leukotriene receptor antagonists can be considered as adjunctive therapy. A positive response should be expected within 2 weeks.

### Gastroesophageal Reflux Disease

Gastroesophageal reflux disease (GERD) is common, but not all patients with GERD have an associated cough; therefore, the presence of GERD does not ensure that it is the source of the patient's cough. However, patients whose cough is clearly not caused by UACS, cough-variant asthma, or NAEB are very likely to have a GERD-induced cough. Cough can be caused by acidic and non-acidic reflux, so a proton pump inhibitor (PPI) may not always be of benefit. A pH probe can be performed in cases when it is unclear whether reflux is occurring. All patients should utilize lifestyle changes to attenuate reflux, such as smoking cessation, avoidance of alcohol and acidic foods, weight loss, and treatment of sleep apnea. It may take 3 to 6 months of treatment to see improvement in cough. If the patient does not improve and GERD is highly suspected, referral to a surgeon may be necessary for fundoplication.

### Other Causes of Chronic Cough

In patients who still suffer from chronic cough and the above causes have been ruled out, further investigation should be sought. Referral to a pulmonologist may be necessary in addition to high-resolution CT scanning and bronchoscopy. Causative factors may include oral pharyngeal dysphagia, lung tumors, interstitial pulmonary diseases, bronchiectasis, occupational and environmental exposures, sarcoidosis, and tuberculosis. Somatic cough syndrome (previously referred to as *psychogenic cough*) and tic cough (previously referred to as *habit cough*) may be considered in some patients. Treatment options include speech language pathology intervention, empiric gabapentin, and/or referral to a cough clinic.

## DIZZINESS AND VERTIGO

Method of

Jennifer Wiperman, MD, MPH

### CURRENT DIAGNOSIS

- Benign paroxysmal positional vertigo
  - Repeated, brief episodes lasting less than 1 minute
  - Triggered by changes in head position
  - Positive Dix-Hallpike or Supine Roll Test
- Vestibular neuritis
  - Single, severe, constant episode lasting days
  - Subacute onset
  - Positive head impulse test
  - Nystagmus is unidirectional and horizontal
- Vestibular migraine
  - Recurrent episodes lasting hours to days
  - Includes features of migraine headache
  - Responds to traditional migraine treatment
- Ménière's disease
  - Recurrent episodes of vertigo lasting hours
  - May have hearing loss, tinnitus, or ear fullness
- Red flags for stroke include:
  - Sudden onset
  - Risk factors for stroke
  - Bidirectional or purely vertical nystagmus
  - Abnormal HINTS exam
  - Focal neurologic signs
  - Inability to walk

### CURRENT THERAPY

- Benign paroxysmal positional vertigo
  - The canalith repositioning procedure (Epley maneuver) is the most effective treatment.
  - Avoid vestibular suppressant medications
  - Observation with close follow-up is optional if a patient will not tolerate the canalith repositioning procedure and if symptoms are mild
- Vestibular neuritis
  - Brief symptomatic care with benzodiazepines, antiemetics, and antihistamines
  - Early vestibular rehabilitation speeds recovery.
  - Use of corticosteroids is controversial.

The “dizzy” patient is often a frustrating phenomenon in clinical medicine. However, after a careful history and physical examination, most patients can be diagnosed and serious causes excluded. Peripheral causes of vertigo are usually benign and include vestibular neuritis and benign paroxysmal positional vertigo (BPPV). Life-threatening central causes include stroke, demyelinating disease, and an intracranial mass. The first step in evaluating vertigo is differentiating among the four types of dizziness: near syncope or lightheadedness, disequilibrium, psychogenic dizziness, and true vertigo. True vertigo is a false sense of motion, and patients often report that “the room is spinning.” This chapter will focus on the two most common causes of episodic vertigo: BPPV and vestibular neuritis.

### Epidemiology

Vertigo is a common office complaint. Every year, millions of Americans are evaluated for dizziness in ambulatory care settings, and approximately 50% of these cases are vertigo. BPPV and vestibular neuritis are two of the most common causes of vertigo seen in the office setting.

### Risk Factors

BPPV is seven times more likely in individuals over age 60, and it is also more common in women. A history of prior head trauma and other vestibular disorders increases risk of BPPV. There are no identified risk factors for vestibular neuritis.

### Pathophysiology

BPPV is thought to occur when calcium carbonate debris (otoconia) are dislodged and float freely in the semicircular canals of the inner ear. The posterior canal is most often involved. During head movement, loose otoconia move in the canal and cause a continued sense of motion for a few seconds until they settle. The pathophysiology of vestibular neuritis is uncertain. Limited evidence supports a viral infection, most likely HSV-1, which causes inflammation of the eighth cranial nerve. When hearing loss accompanies vertigo, the condition is called *acute labyrinthitis*.

### Clinical Manifestations

The history and physical examination are fundamental in the evaluation of vertigo. Key questions include the frequency and duration of attacks, triggers such as positional or pressure changes, prior head trauma, associated neurologic symptoms, hearing loss, and headache. A personal history of diabetes, hypertension, and hyperlipidemia are risk factors for stroke. BPPV, stroke, and migraine can have a familial preponderance. Many medications, including anticonvulsants and antihypertensives, cause dizziness.

BPPV causes brief, recurrent episodes that last less than 1 minute and are brought on by changes in head movement or position. Nausea and vomiting may be associated. Vestibular neuritis usually has a subacute onset over several hours, peaks in intensity for 1 to 2 days, and then gradually subsides over the next few weeks. Symptoms of vertigo are constant, and nausea and vomiting can be severe during the first few days. Patients with vestibular neuritis may have difficulty standing and veer toward the affected side. Although changes in position worsen the vertigo in vestibular neuritis, vertigo is always present at baseline. In BPPV, patients have no vertigo between attacks.

General physical examination should include a thorough cardiovascular, ear, nose, throat, and neurologic examination. The neurologic examination can differentiate between benign (peripheral) and life-threatening (central) causes based on the ability to walk, type of nystagmus, results of the head impulse test, and presence of associated neurologic signs (Table 1).

Patients with vestibular neuritis may have difficulty walking, but the inability to walk is a red flag for a central lesion. Nystagmus is unidirectional (always beats in the same direction) and horizontal in vestibular neuritis, and is suppressed by visual fixation. Having a patient focus on an object in the room will stop the nystagmus, which reappears if a blank sheet of paper is placed a few inches in front of the patient's face. Nystagmus in central causes is not suppressed by visual fixation and may be direction-changing (nystagmus beats to the right when the patient looks right, and beats to the left when the patient looks left) or purely vertical. The head impulse test (Figure 1) is positive in peripheral causes like vestibular neuritis. The examiner holds the patient's head while the patient fixes her eyes on the examiner's nose, and then the examiner quickly moves the patient's head 10 degrees to the right and left. If a saccade (the eyes look away and then re-fixate on the examiner's nose) is found, this indicates a peripheral lesion on the side that the head is turned toward. Central lesions will not cause saccades, and the head impulse test will be negative. HINTS (Head Impulse test, Nystagmus, Test of Skew), which combines three physical examination findings, has been found to have a 97% sensitivity and 99% specificity for a central cause of vertigo in the acute setting and to be more accurate than MRI in the initial 24 hours after symptom onset. If one or more of the tests indicate a central cause, (e.g., a negative head impulse test, direction-changing horizontal nystagmus, or vertical eye misalignment grossly observed or detected on cover-uncover test), then the HINTS test is considered positive for a central cause and imaging should be obtained. A negative HINTS exam is an excellent rule-out test for stroke, with a negative likelihood ratio of 0.02.

**TABLE 1** Differentiating Peripheral and Central Causes of Vertigo

	PERIPHERAL CAUSES		
	BPPV	VESTIBULAR NEURITIS	CENTRAL CAUSES
History	Brief, recurrent attacks of vertigo lasting less than 1 minute Triggered by positional changes No vertigo between attacks	Subacute onset Constant and severe vertigo lasting days Nausea and vomiting may be severe	Sudden onset Risk factors for stroke May have severe headache
Nystagmus	Up-beating and torsional	Horizontal and unidirectional	Bidirectional Pure vertical Pure torsional
Gait	Unaffected between episodes	May veer towards affected side	Unable to walk
Specialized physical examination tests	Positive Dix-Hallpike or Positive supine roll test	Positive head impulse test Visual fixation stops nystagmus	HINTS exam abnormal Visual fixation does not stop nystagmus
Additional neurologic signs	Rare	Rare	Common (e.g., dysarthria, aphasia, incoordination, weakness, or numbness)

Abbreviation: BPPV = benign paroxysmal positional vertigo.

**Figure 1** Head impulse test. Top panel shows a positive head impulse test. The examiner moves the patient's head quickly 10 degrees to the side, in this case to the patient's left. A catch-up saccade is observed when the patient looks away and then reflexes on the visual target, indicating a peripheral lesion on the left. Lower figure shows a normal head impulse test. The patient maintains visual fixation during head movement. Adapted from Seemungal BM, Bronstein AM. A practical approach to acute vertigo. *Pract Neurol* 2008; 8:211–21.

The Dix-Hallpike maneuver is diagnostic of posterior canal BPPV (Figure 2). The patient should be warned that nausea and vomiting may occur. After the patient is placed in the head-hanging position, there is a 5- to 20-second latency period before the nystagmus and symptoms appear. Both the nystagmus and vertigo will increase in severity and then resolve within 60 seconds. The nystagmus observed is up-beating and torsional. If nystagmus is constant for as long as the head is in the hanging position, the patient should be evaluated for a central cause. The maneuver should be repeated with the head held to the opposite side. The side that elicits the symptoms and nystagmus diagnoses BPPV in the ipsilateral ear. If both sides elicit symptoms, the patient may have bilateral BPPV. If the test is negative and BPPV is strongly suspected, the patient should lie supine and the examiner can turn the head to each side (supine roll test; Figure 3). This maneuver will cause vertigo and nystagmus in patients with horizontal canal BPPV.

**Figure 2** Treatment maneuver for posterior canal benign paroxysmal positional vertigo affecting the right ear. To treat the left ear, the procedure is reversed. The drawing of the labyrinth in the center shows the position of the particle as it moves around the posterior semicircular canal (PSC) and into the utricle (UT). The patient is seated upright, with head facing the examiner, who is standing on the right. A, The patient is rapidly moved to head-hanging right position (Dix-Hallpike test). This position is maintained until the nystagmus ceases. B, The examiner moves to the head of the table, repositioning hands as shown. C, The head is rotated quickly to the left with right ear upward. This position is maintained for 30 seconds. D, The patient rolls onto the left side while the examiner rapidly rotates the head leftward until the nose is directed toward the floor. This position is then held for 30 seconds. E, The patient is rapidly lifted into the sitting position, now facing left. The entire sequence should be repeated until no nystagmus can be elicited. After the maneuver, the patient is instructed to avoid head-hanging positions to prevent the particles from reentering the posterior canal. Reprinted with permission from Rakel RE. *Conn's Current Therapy* 1995. Philadelphia, WB Saunders, 1995, p 839.

### Diagnosis

BPPV and vestibular neuritis are diagnosed clinically. Further diagnostic testing is indicated if the diagnosis is uncertain or a central cause is suspected. Audiometry may be abnormal in Ménière's disease. MRI is the best imaging test for central lesions because it includes the posterior fossa and is most sensitive for

**Figure 3** Supine roll test. Patient begins lying supine facing upward. The patient's head is rotated to one side laterally 90 degrees and the examiner observes for nystagmus and vertigo. Once symptoms resolve, the patient's head is rotated back to midline. Next, the patient's head is rotated 90 degrees laterally to the opposite side and the examiner observes for nystagmus and vertigo. The side with the worst symptoms indicates the involved ear. (From Kerber KA, et al: Benign paroxysmal positional vertigo in the acute care setting. NCL, Elsevier, 2015.)

stroke. Vestibular function testing is useful if the diagnosis is unclear or in cases of refractory vertigo. Vestibular function testing evaluates the ocular and vestibular response to position changes and caloric stimulation. Video-oculographic recordings of nystagmus can magnify the eye and allow for repeated viewings for further study. Some patients with BPPV may have additional vestibular disorders causing vertigo that vestibular function testing can elucidate.

### Differential Diagnosis

Ménière's disease is suspected in patients with the triad of tinnitus, fluctuating hearing loss, and vertigo. Episodes usually last hours, are disabling, and are recurrent over years, over time leading to permanent dysfunction. Migrainous vertigo features episodes lasting hours to days in patients with other migraine symptoms such as headache, photophobia, phonophobia, or aura. Central lesions such as stroke or intracranial mass are most concerning. Red flags for stroke include sudden onset, risk factors for stroke, associated neurologic signs, inability to walk, abnormal HINTS exam, severe associated headache, and characteristic nystagmus. Posttraumatic vertigo may occur in patients after head trauma who present with vertigo, tinnitus, and headache. A perilymphatic fistula is rare, but may be suspected in a patient with episodic vertigo after head trauma, heavy lifting, or barotrauma. Pressure changes with sneezing or coughing trigger vertigo attacks. Postural hypotension should be ruled out in all patients. An acoustic neuroma presents with slowly progressive, unilateral sensorineural hearing loss and tinnitus. Many patients may have an unsteady gait, but true vertigo is rare.

### Treatment

Posterior canal BPPV is best treated with the *canalith repositioning procedure (CRP)*, such as the Epley maneuver (Figure 2). Studies have shown the procedure is safe and effective with an odds ratio of 4.2 (95% CI. 2.3-11.4) for symptom resolution. Patients should be warned that nausea or vomiting may occur during the procedure, and may be pretreated with an antiemetic medication. The procedure can be repeated immediately if unsuccessful, and the majority of patients will

respond after three attempts. Posttreatment activity restrictions are unnecessary. Horizontal canal BPPV can be treated with the barbeque roll maneuver (Figure 4). Vestibular rehabilitation (VR) is a treatment option for BPPV but is significantly less effective than the canalith repositioning procedure. VR is helpful in patients with chronic, nonspecific dizziness after successful treatment with CRP and for improving gait stability in those with increased fall risk, such as the elderly. Observation is an option if symptoms are mild and if a patient will not tolerate the canalith repositioning procedure. However, time to resolution with observation is 1–3 months, and recurrence rates are higher compared to treatment with CRP. Vestibular-suppressant medications such as antihistamines and benzodiazepines are discouraged because they increase fall risk and treatment with CRP is effective. Surgery is rarely needed for BPPV, but may be helpful in refractory cases.

Vestibular neuritis is primarily treated with rest, vestibular suppressant medications, and vestibular rehabilitation. Patients may initially be hospitalized if symptoms, such as nausea and vomiting, are severe or if stroke is suspected. Treatment with antihistamines (dimenhydrinate [Dramamine]<sup>1</sup> 50 mg every 6 hours), antiemetics (promethazine [Phenergan]<sup>1</sup> 25 mg every 6 hours), or benzodiazepines (lorazepam [Ativan]<sup>1</sup> 1 to 2 mg every 4 hours) may be used to treat severe symptoms. However, these should not be continued for more than 2 to 3 days because they inhibit central compensation. In vestibular neuritis, patients' vertigo improves not due to return of vestibular nerve function, but due to central compensation for the peripheral deficit. Using vestibular suppressants blocks central compensation and lengthens the course of the disease. The use of corticosteroids is controversial; a 2011 Cochrane review concluded that there is insufficient evidence to recommend corticosteroids for the treatment of vestibular neuritis. Finally, antiviral medications have not been proven effective for vestibular neuritis.

For patients with vestibular neuritis, vestibular rehabilitation should be started as soon as symptoms improve and a patient can tolerate the exercises. Exercises include balance and gait training as well as coordination of head and eye movements. Vestibular rehabilitation hastens recovery and improves balance, gait, and

<sup>1</sup>Not FDA approved for this indication.

**Figure 4** Barbecue roll (Lempert maneuver). Patient begins lying supine facing upward (A). Head is rotated laterally 90 degrees toward the affected ear (B). Next, the head is rotated another 90 degrees laterally back to midline (B). Next, the head is rotated laterally 90 degrees toward the opposite side (C). Next, the head is rotated laterally 90 degrees in the same direction (D). Finally, with the patient's head in the same position, the patient is brought into a seated position (E). Each position is held 30 to 60 seconds, long enough for symptoms to occur and then resolve. Once resolved, the patient is moved into the next position. (From Moseley L, Cucco RT: *Essential guide to the cervical spine - Volume 2: Clinical Syndromes and Manipulative Treatment*. Elsevier, 2016.)

vision by increasing central compensation for vestibular dysfunction. Exercises may be home-based for compliant patients with mild symptoms, whereas formal referral may be more beneficial for patients with severe symptoms, or for the elderly.

### Monitoring

Patients diagnosed with BPPV should be reassessed in 1 month regardless of treatment. Failure to improve warrants further evaluation for other etiologies, including central causes. Similarly, patients with vestibular neuritis should slowly improve over several weeks, and failure to do so suggests alternative diagnoses.

### Complications

Patients with BPPV are at increased risk for falls. Thirty percent of elderly patients with BPPV have multiple falls in a year. Thus patients should be assessed for fall risk, functional mobility, and balance. Home safety evaluation and home supervision should be considered. BPPV often recurs, with an estimated rate of 15% per year. Counseling patients about recurrence can lead to earlier recognition, earlier treatment, and avoidance of falls. Patients with vestibular neuritis are at increased risk for BPPV and Ménière's disease. Vestibular neuritis rarely recurs.

## FATIGUE

Method of  
Jared Regehr, MD

### CURRENT DIAGNOSIS

- It is important to evaluate for potential causes of fatigue with a thorough history and physical exam. Basic lab work is also important to evaluate for organic etiologies of fatigue.
- Most cases of fatigue do not have an identifiable underlying etiology.
- A broad differential is important as clinicians evaluate patients with fatigue.

### CURRENT THERAPY

- Identifying the underlying cause of fatigue is the most important step in treatment, and any discovered cause should be treated promptly.
- Good sleep hygiene, physical activity, regularly scheduled follow-up visits, and cognitive behavioral therapy have all been shown to improve symptoms of fatigue.
- Short naps are proven performance enhancers.

## Epidemiology

Fatigue is a common concern for patients and is the primary complaint for 5% to 10% of patient encounters in the primary care setting. Certain risk factors predispose patients to fatigue. Female sex (1.5 times more likely to report fatigue than males), increased age, and coexisting depression are all associated with higher rates of fatigue. While fatigue can be a normal physiologic response to prolonged activity or stressors, pathologic fatigue has a significant negative impact on patients each year. Individuals with fatigue report decreased quality of life, along with social and emotional dysfunction. Furthermore, it is estimated that fatigue costs US employers \$126 billion each year due to decreased production and lost work days.

## Prevention

Prevention of fatigue is very similar to the treatment of fatigue. Good sleep hygiene, regular physical exercise, and stress reduction all help with preventing fatigue. Additionally, regularly

scheduled follow-up for health maintenance examinations with primary care physicians helps patients avoid comorbidities that may exacerbate fatigue.

## Clinical Manifestations

Patients with fatigue often present with lack of energy, delayed recovery after activity, poor muscle endurance, mental exhaustion, and nonrestorative sleep. There is a wide spectrum of severity of disease from a general nuisance to debilitating symptoms.

## Diagnosis

Fatigue can be classified based on duration: recent (<1 month), prolonged (1–6 months), and chronic (>6 months). Notably, these timeframes are arbitrary based on the continuous nature of fatigue. For most clinicians, having a broad differential is more helpful in identifying a cause than categorizing fatigue based on time. Even so, identifying the underlying etiology of fatigue can be a challenging and frustrating diagnosis for primary care physicians to make because of vague symptoms and the overlap with comorbidities. A thorough history and physical examination along with appropriate laboratory tests can aid in the diagnosis. There is much debate about the extent of initial laboratory workup, but a reasonable approach includes a complete blood count, basic metabolic panel, hepatic function testing, erythrocyte sedimentation rate, thyroid-stimulating hormone, ferritin, pregnancy test in women of childbearing age, and screening for HIV and hepatitis C in at-risk populations. These tests are useful to help identify “can’t miss” diagnoses, but results of laboratory studies only affect management in about 5% of cases. Therefore the importance of a thorough history and physical examination is paramount. It is essential to remember that the information collected from the patient does not need to be limited to the time spent together in the office; a symptom diary with close follow-up can be an extremely beneficial tool as the physician–patient dyad works to find a cause.

The causes of fatigue are extensive and oftentimes coexisting. The most common causes are encompassed in the mnemonic DEAD TIRED (Table 1). Most of these categories have multiple subcategories. As with all chief complaints, it is imperative to allow patients the opportunity to lead the physician to the diagnosis by letting them speak without interruption. Depression is a common cause of fatigue. Medically unexplained symptoms of fatigue are associated with depressive disorders in 50% to 75% of patients, and patients are nearly 11 times more likely to have a lifetime diagnosis of depression than nonfatigued individuals. Importantly, fatigue may be the first presenting symptom for patients who do not yet meet the *Diagnostic and Statistical Manual of Mental Disorders* (DSM) criteria for depression, so close monitoring for other depressive symptoms is vital for prompt recognition and treatment. In most of these cases, there are often other lifestyle factors that contribute to patients’ feelings of fatigue. It is important to ask about sleep hygiene, physical exercise, and home/social stressors, as suboptimal functioning in these areas can exacerbate symptoms of fatigue.

**TABLE 1** Common Causes of Fatigue: DEAD TIRED

D	Depression
E	Endocrine
A	Anemia, apnea
D	Diabetes
T	Thyroid, tumors
I	Infection, insomnia
R	Rheumatologic
E	Endocarditis/cardiovascular
D	Drugs

Other common secondary causes of fatigue include anemia, endocrine abnormalities, sleep apnea, and medication use. If anemia is noted on initial laboratory evaluation, further workup is usually patient-specific. Markers such as mean corpuscular volume (MCV), ferritin, iron profile, B12, folate, lactate dehydrogenase, and haptoglobin can help guide decision making as clinicians consider causes of anemia. Gastrointestinal bleeding secondary to ulcers, colon cancer, inflammatory bowel disease, or diverticulosis are critical to rule out. Lack of sufficient dietary vitamin intake may be a simple reason for anemia. Endocrine abnormalities that can lead to fatigue include thyroid dysfunction, diabetes mellitus, and adrenal insufficiency. If patients describe persistent daytime sleepiness, evaluation for obstructive sleep apnea is useful, especially in the setting of risk factors (obesity, snoring, hypertension). Additionally, medication usage can cause fatigue. An in-depth review of the legion of medications that can cause fatigue is beyond the scope of this article, but prescription, over-the-counter, and illicit drugs should be considered in the evaluation of fatigue.

Infection is a cause of fatigue, and the most frequent infectious etiology associated with fatigue is of viral origin. Any one of several viruses can cause fatigue, including hepatitis A, B, and C; Epstein-Barr virus; human immunodeficiency virus; and as of recently, COVID-19. Certainly not every patient presenting with fatigue necessitates laboratory evaluation for each of these causes, but if the history or examination suggests an infectious cause, further workup is prudent. Even after recovery from COVID-19, 72.8% of patients report persistent fatigue, by far the most common long-term symptom reported by survivors of COVID-19. This is an important consideration even months after patients have otherwise recovered from the disease. Postinfluenza asthenia refers to the prolonged fatigue some patients experience after a bout of influenza.

Finally, rheumatologic, cardiovascular, and neoplastic causes should be considered when appropriate in the evaluation of fatigue. Although there are innumerable reports of fatigue in patients with rheumatologic, cardiovascular, oncologic, and hematologic disorders, isolated fatigue as the presenting complaint is not well documented in current medical literature. Additionally, multiple neurologic and autoimmune disorders can have associated fatigue. If the rest of the history and examination warrants further workup for these causes, then evaluation should be pursued. However, an extensive workup based on an isolated complaint of fatigue is not likely to yield beneficial results.

## Therapy

Treatment for fatigue should be directed at managing the underlying cause of fatigue when an etiology can be identified based on the history, physical, and laboratory evaluation. However, when no organic cause is identified, there are still ways to help patients get relief. Importantly, ordering more tests is not one of them. In a systemic review of patients with fatigue in which there was a low level of clinical concern for serious illness, the degree of patient reassurance was not increased with additional laboratory testing. Instead, the clinician should start with having an honest conversation with the patient regarding ways to move forward. It is imperative to acknowledge the patient's symptoms and the negative effects on the patient's life, discuss consistent follow-up, and discuss assessment of any new symptoms that may develop. Additionally, there is evidence that sleep hygiene, physical activity, and cognitive behavioral therapy may be helpful in these settings of nondiagnostic fatigue. Short naps have also proven to be helpful and may be a possible solution for some patients.

## Monitoring

Monitoring patients with persistent fatigue in the primary care setting can be accomplished by administering a Fatigue Severity Scale (FSS). This method assesses the impact of fatigue on patients' daily lives with a nine-item survey that incorporates a Likert-type rating scale. The FSS has been validated in multiple studies as a reliable tool

to assess fatigue. Although there is no generally agreed upon timing for frequency of monitoring, it is reasonable to start with monthly assessments and utilize shared decision making with each patient to individualize a management plan.

## FEVER

Method of

Alan R. Roth, DO; and Gina M. Basello, DO

## CURRENT DIAGNOSIS

- Numerous endogenous and exogenous factors play a role in determining body temperature. Current standards define fever as an oral temperature of  $\geq 100.4^{\circ}\text{F}$  ( $\geq 38^{\circ}\text{C}$ ).
- Though temperature varies with measurement technique, in clinical practice, most recommendations refer to oral, rectal, and axillary temperature measurements, with rectal temperature being the standard of care in infants and young children.
- Tympanic thermometers should not be used in young children.
- Fever is not an illness. It is the body's physiologic response to a disease process and has beneficial effects in fighting infection.
- All neonates with a fever should be admitted to the hospital for a full sepsis evaluation. For infants between 1 and 3 months of age, evidence-based guidelines, along with clinical evaluation, determine the diagnostic and therapeutic approach.
- With widespread immunization use, the incidence of bacteremia and bacterial meningitis in young infants has significantly decreased, and UTI is now the most prevalent bacterial infection, with the most common etiologic pathogen being *E. coli*.
- The possibility of infection with the SARS-CoV-2 virus must be considered in all patients presenting with fever and tested for appropriately.
- Urine leukocyte esterase has emerged as a highly accurate diagnostic test for UTI in febrile infants with greater than 95% sensitivity.
- FUO requires a systematic, thoughtful, and thorough evaluation based on the age of the patient and the existing clinical evidence, with repeated clinical assessments being essential.
- Hyperthermia is an unregulated, significant elevation of core body temperature above the normal diurnal range due to failure of thermoregulation from a hypothalamic insult, not a pyrogenic source, and is considered a medical emergency. It is not synonymous with fever and often requires immediate intervention to avoid deleterious central nervous system (CNS) effects.

## CURRENT THERAPY

- Treating a fever significantly increases the patient's level of comfort, activity, and oral feeding and fluid intake, in addition to decreasing the body temperature.
- Multiple randomized, controlled trials reveal that treating fever does not shorten or prolong the overall duration of illness or reduce the occurrence of febrile seizures.
- Many clinical recommendations state that a temperature less than 102.2°F (39°C) in healthy children does not require treatment. Antipyretics are known to provide comfort to children and their caregivers.
- Antipyretic treatment for children includes acetaminophen (Tylenol) 10 to 15 mg/kg every 4 to 6 hours or ibuprofen (Advil, Motrin) 10 mg/kg every 6 hours.
- Ibuprofen and acetaminophen have both been shown to reduce fever effectively and safely. Combination therapy has been shown in some studies to have an added benefit in both reduction of temperature and comfort without an increase in side effects, though caution should be taken to avoid dosing errors.
- Antipyretic therapy for adults and adolescents includes acetaminophen 650 to 1000 mg orally (PO) every 6 hours to a maximum of 3 g per day, ibuprofen 200 to 400 mg PO every 6 hours, or aspirin (ASA) 325 to 650 mg every 6 hours as needed (PRN) for fever.
- ASA should not be used in children due to the risk of Reye's syndrome.
- Sponge bathing should be done with tepid water and no alcohol. Recommendation: sponge bathing and other home remedies should not be used as sole treatment.

Fever is one of the most common clinical presentations encountered by primary care physicians and the most common complaint of acute visits for children in the ambulatory or emergency department setting. Fever is a symptom and one of the most reliable signs of illness rather than a disease process itself. Most causes of fever are secondary to acute viral illnesses such as upper respiratory infections (URIs), which account for 50 million visits to primary care providers annually. Less commonly, bacterial infections may cause pharyngitis, otitis, sinusitis, pneumonia, and urinary tract infections (UTIs). A cost-effective, evidence-based approach using clinical protocols, guidelines, and consensus recommendations to the diagnosis and management of febrile illness, including the appropriate use of antibiotic therapy, is the cornerstone of quality medical care for this presentation. Fever produces significant anxiety for patients, parents, and health care providers, which can lead to overtreatment. Typically, fever is transient and only requires treatment to provide patient comfort.

### Definitions

The definition of fever is dependent on numerous endogenous and exogenous factors that play a role in determining body temperature, including age, time of day, site, and measuring device, as well as operator variables. Fever is an elevation of body temperature due to the adjustment of the hypothalamic-pituitary set point. This usually occurs in response to a pathologic stimulus. Fever is a beneficial physiologic mechanism that helps to promote an augmented immunologic response.

Despite individual variability, core body temperature is maintained at about 98.6°F (37°C). Diurnal variation results in lower body temperatures in the early morning and a temperature higher in the late afternoon or early evening, which is consistent with what is encountered in clinical practice.

In adults, a morning oral temperature of 98.9°F (37.2°C) or higher, or an evening temperature of 99.9°F (37.7°C) or higher

defines a fever. Rectal temperatures are generally considered to be 0.7°F (0.4°C) higher than oral readings.

In infants and young children, rectal temperatures are still considered the standard of care and a rectal temperature greater than 100.4°F (38°C) is considered a fever.

Axillary temperatures of greater than 98.6°F (37°C) are regarded as a fever, though this measurement site is generally considered less accurate. An accurate measurement of body temperature is dependent on site, measuring device, and the clinical skills of the operator. Site selection should be determined by the age of the patient.

Young infants and older adults often have a diminished febrile response due to physiologic factors, thereby warranting the use of other clinical factors to guide diagnosis.

Recent technologic advances, including electronic devices, tympanic membrane scanning, and temporal artery scanning, have replaced the older mercury-in-glass thermometers. These devices offer faster results and minimal inconvenience to the patient and are becoming increasingly reliable. Chemical content or liquid crystal thermometers applied to the skin are neither accurate nor cost-effective.

Hyperthermia is an uncontrolled elevation of core body temperature that exceeds the body's ability to lose heat. In hyperthermia, the setting of the hypothalamic thermoregulatory center is unchanged, in contrast to fever. Hyperthermia requires urgent medical intervention because it could be rapidly fatal and does not respond to antipyretics. Common etiologies include heat stroke, neuromalignant syndrome, serotonin syndrome, malignant hyperthermia, endocrinopathy, and CNS damage.

Classic *fever of unknown origin* (FUO) is defined as a disorder with temperatures  $\geq 100.9^\circ\text{F}$  (38.3°C) that have persisted for at least 3 weeks, with no definitive cause elucidated after initial comprehensive inpatient or outpatient workup. The etiologies of FUO generally fall into four diagnostic categories: infectious, autoimmune or inflammatory, neoplastic, and miscellaneous.

### Pathophysiology

Fever occurs as part of an inflammatory response to an inciting stimulus. The response includes the production of various cytokines that ultimately increase the production of prostaglandin E<sub>2</sub> (PGE<sub>2</sub>), which resets the hypothalamic thermoregulatory set point at a higher level. Important pyrogenic cytokines include interleukin-1 (IL-1), interleukin-6 (IL-6), tumor necrosis factor  $\alpha$  (TNF- $\alpha$ ), interferon- $\beta$  (IFN- $\beta$ ), and interferon- $\gamma$  (IFN- $\gamma$ ).

### Risks and Benefits of Fever

Fever is known to enhance the immunologic response while suppressing the growth and replication of bacterial and viral infections. Though often uncomfortable for patients, caregivers, and health care providers, evidence supports the notion that fever is beneficial and ultimately protects against the development of asthma and other allergic disorders. In most instances, fever is not harmful. It does increase cardiac demand and metabolic needs, resulting in the common associated signs and symptoms of tachycardia, tachypnea, shivering, malaise, and diaphoresis.

The use of antipyretic agents has not been shown to either prolong or shorten the duration of illness. Febrile seizures cause significant anxiety for parents. They occur most commonly in children between the ages of 6 months and 6 years. Most febrile seizures are uncomplicated and have not been shown to be associated with significant bacteremia or to lead to the development of seizure disorder in older children. Antipyretic agents have not been shown to decrease the incidence of febrile seizures.

### Diagnostic Evaluation of Fever

In most cases, the etiology of a febrile illness is a self-limiting viral infection. From 5% to 10% of fevers may be associated with a more serious bacterial infection such as pneumonia, UTI,

bacteremia, meningitis, or bone and joint infections. At times, these conditions may be challenging to distinguish, and a thoughtful, systematic, evidence-based approach to the diagnostic evaluation will be most cost-effective while avoiding the inappropriate use of antibiotics.

Although the most common clinical presentation of COVID is fever with respiratory symptoms, a significant proportion of patients will present with fever alone or atypically. Considering this, COVID testing is indicated for all patients presenting with fever.

All infants less than 28 days old with a fever should be admitted to the hospital for a full sepsis workup and empiric intravenous antibiotic therapy.

Young infants, 1 to 3 months of age, with a febrile illness can be especially challenging. Numerous studies addressing this challenging population have led to the development of multiple guidelines and clinical protocols that utilize risk stratification criteria. The use of these age-specific stratification criteria, along with clinical treatment guidelines, helps guide the clinician in the evaluation of febrile illness. Clinical judgment remains the cornerstone of good clinical care.

With the widespread use of *Haemophilus influenzae* type B (Hib) and pneumococcal vaccinations, the incidence of bacteremic illness has decreased significantly. UTI has emerged as the most prevalent bacterial infection. The increased use of rapid viral testing in the office and emergency department settings may alleviate the need for more invasive testing and antibiotic use because the risk of concurrent bacterial infection has been reported to be negligible.

In this age group, an initial workup that reveals a white blood cell (WBC) count of less than 5000 or greater than 15,000 indicates an increased likelihood of a significant bacterial illness (SBI). Blood cultures, urinalysis, urine culture, and cerebrospinal fluid (CSF) evaluation should then be obtained and accompanied by intravenous antibiotic therapy. When considering the use of inflammatory markers diagnostically, procalcitonin has emerged as the most accurate inflammatory marker, followed by (in descending order) C-reactive protein, absolute neutrophil count, and white blood cell count. Incorporating urine concentration when interpreting urine analyses can help in the differentiation of infants at higher risk of UTI.

Children age 3 to 36 months, who appear well and do not have any underlying medical history, require only a comprehensive clinical evaluation and do not warrant antibiotic therapy or diagnostic testing in most instances. Septic or ill-appearing children need a more aggressive evaluation, including complete blood count (CBC), inflammatory markers, urinalysis, urine culture, blood cultures, and a chest x-ray. High-risk children in this age group require empiric antibiotic therapy, and clinical judgment should guide the decision to hospitalize.

*Classic FUO* is defined as a disorder with temperatures greater than 100.9°F (38.3°C) that has persisted for at least 3 weeks with no clear etiology determined after 3 days of hospital evaluation or three outpatient visits. Common etiologic categories include infectious, neoplastic, inflammatory, and miscellaneous causes, of which drug fever has been shown to be the most prevalent.

The initial approach includes a thorough history, physical examination, and appropriate laboratory testing. The initial choice of imaging should be guided by clinical findings and most commonly includes a chest x-ray and a CAT scan of the abdomen and pelvis. If the etiology remains elusive, positron emission tomography (PET) scanning or invasive diagnostic testing should then be considered.

### Differential Diagnosis

Hyperthermia is an unregulated, significant elevation of core body temperature above the normal diurnal range due to failure of thermoregulation from a hypothalamic insult, not a pyogenic source, and is considered a medical emergency. It is not

synonymous with fever and often requires immediate intervention to avoid deleterious CNS effects. Since the hypothalamic set point remains unchanged, antipyretics are ineffective in hyperthermia. The most common etiology is the inability to regulate or dissipate excess body heat. Hyperthermia is a medical emergency that requires immediate treatment to prevent excessive morbidity and mortality.

### Treatment

Though controversy exists regarding the necessity of lowering fever, antipyretics have been shown to effectively and safely reduce temperature and improve symptoms with minimal side effects. Acetaminophen (Tylenol) is available in many formulations. Dosing should be based on body weight and not age of the patient. The dose is 10 to 15 mg/kg every 4 to 6 hours, not to exceed 3 g daily or 2 g in patients with renal or hepatic impairment. Ibuprofen (Advil, Motrin) is a nonsteroidal anti-inflammatory drug (NSAID) that has both antiinflammatory and antipyretic effects. Dosing is 10 mg/kg every 6 to 8 hours in children and 200 to 400 mg every 6 hours in adolescents and adults. Ibuprofen is also available in multiple formulations, including a newer intravenous preparation (ibuprofen [Cal-dolor]) that may be beneficial in oral-intolerant hospitalized patients. Some studies suggest that ibuprofen may be a more effective antipyretic agent than acetaminophen.

In adults, aspirin (ASA) remains a therapeutic alternative for lowering fever at a dose of 325 to 650 mg every 4 to 6 hours. It should not be used in children with a febrile illness due to the risk of Reye's syndrome.

A combination of acetaminophen and ibuprofen in alternating doses has been shown in some studies to have an added benefit in both reduction of temperature and comfort without an increase in side effects, though caution should be taken to avoid dosing errors.

Nonpharmacologic therapies such as sponge bathing with tepid water and other environmental measures to control temperature, including adjusting room temperatures and sipping cool fluids to avoid dehydration, are used commonly and do provide symptom relief and comfort. These measures should never be used as the sole therapy for fever reduction.

## GASEOUSNESS, INDIGESTION, NAUSEA, AND VOMITING

Method of  
Justin Bailey, MD

Nausea is a vague, subjective feeling that vomiting (forceful expulsion of gastric contents) is imminent. Dyspepsia (based on Rome III criteria) can include postprandial fullness, early satiety, epigastric pain, burning, and reflux (return of gastric content to the lower esophagus or mouth, accompanied by a sour taste or “heartburn” sensation). Gaseousness can present with a variety of complaints, including belching, bloating, abdominal pain, or flatulence.

### Epidemiology

Nausea and vomiting (ICD-10 Code R11.2) is one of the top reasons patients see a primary care provider. Infectious diseases causing nausea and vomiting, gastroenteritis, diarrhea, and dehydration are leading causes of death in developing countries, and of sick days and reduction of employee productivity in the United States. Nausea and vomiting postoperatively and during cancer chemotherapy add significant costs, pain, and discomfort to hospital and ambulatory treatment. Dyspepsia occurs in an estimated 25% of the US population every year, many of whom do not seek care. Gaseousness is ubiquitous in the population and is troubling to a small portion.

### Risk Factors

Previous gastrointestinal (GI) surgery, certain medications, chemotherapeutic regimens, substance abuse, pregnancy, infectious diseases, medical conditions, and central nervous system disorders increase the risk for nausea and vomiting symptoms. Dyspepsia risk is increased significantly with ingestion of nonsteroidal anti-inflammatory drugs (NSAIDs), tobacco use, *Helicobacter pylori* infection, obesity, anxiety, somatization, neuroticism, depression, and unemployment. Increased upper GI gaseousness can be seen with air swallowing from gum chewing and eating quickly, as well as consumption of foods that relax the lower esophageal sphincter (e.g., chocolate, fats, mints). Ingestion of lactose, fructose, sorbitol, undigested starches (e.g., bran), and carbonated beverages can all increase the risk of bloating and flatulence.

### Pathophysiology

The pathophysiologic regulation of nausea and vomiting is complex and incompletely understood. Multiple neurotransmitters are involved, including acetylcholine, dopamine, histamine, and serotonin. The therapeutic action of antiemetics is often based on blocking the action of these neurotransmitters. Neurologic regulation of nausea and vomiting involves the chemoreceptor triggers in the fourth ventricle, the nucleus tractus solitarius in the medulla, motor nuclei that control the vomiting reflex, and vagal afferent nerves from the GI tract. The sympathetic and parasympathetic nervous systems are involved in conjunction with the smooth muscle cells and the enteric brain within the wall of the stomach and intestine.

The pathophysiology of dyspepsia is unclear but probably has multiple causes. Delayed gastric motility can occur in up to 30% of patients with dyspepsia. In addition, decreased gastric compliance, alteration in gut microbiome, duodenal inflammation, and psychosocial dysfunction can also be associated with dyspeptic patients.

Sensations of lower tract gaseousness result from one of three different mechanisms: excess gas production, abnormal intestinal transit, and increased visceral sensitivity. Gas production caused by carbohydrate maldigestion, (e.g., lactose intolerance, poorly absorbed starches) results in bloating and a sensation of fullness. High-fiber diets, celiac disease, and small intestine bacterial overgrowth can increase gas production. Dysmotility associated with diabetes mellitus, scleroderma, amyloidosis,

and endocrine disease may result in gastroparesis and chronic intestinal pseudo-obstruction. In addition, previous Nissen fundoplication, fat intolerance, and various familial conditions may cause dysmotility. Increased visceral sensitivity is thought to be a main cause of pain and fullness in patients with functional bowel disorders such as irritable bowel syndrome (IBS) and functional dyspepsia.

### Prevention

Once the diagnosis has been established, appropriate treatment of the underlying cause of the symptoms can be instituted. When the cause of nausea and vomiting is related to medication, the dose can be adjusted or the medication changed as appropriate.

Upper GI bloating and fullness is almost exclusively caused by excess air swallow and can be improved with altering behaviors such as gulping food and gum chewing. Lower GI symptoms can be prevented by avoiding problem foods such as milk products in patients with lactose intolerance.

### Clinical Manifestations

Nausea and vomiting are extremely common and are associated with many conditions. Associated symptoms are helpful in sorting out causes. Many common historical associations are listed in Table 1.

The diagnosis of dyspepsia is based mainly on clinical symptoms. The Rome III criteria are listed in the opening paragraph. Alarm symptoms that should raise suspicions for gastric cancer include unintended weight loss, persistent vomiting, progressive

**TABLE 1** Key Symptoms and Differential Vomiting, Dyspepsia, and Bloating

SYMPTOMS	DIFFERENTIAL
Abdominal Pain ± N/V <ul style="list-style-type: none"> <li>• RUQ</li> <li>• Epigastric</li> <li>• RLQ</li> <li>• LLQ</li> <li>• Pelvic</li> </ul>	Organic etiologies <ul style="list-style-type: none"> <li>• Cholelithiasis, cholecystitis</li> <li>• Dyspepsia, pancreatitis, GERD, gastritis, MI</li> <li>• Appendicitis</li> <li>• Diverticulitis</li> <li>• PID, ovarian torsion, ectopic pregnancy</li> </ul>
Abdominal pain + distention + N/V	Bowel obstruction
Abdominal distention associated with foods (lactose, wheat-based products, bran, legumes)	Lactose intolerance Celiac disease Carbohydrate malabsorption, Oligosaccharide fermentation (legumes)
Vomiting several hours after eating + succussion splash + N/V	Gastric obstruction Gastroparesis
Heartburn ± N/V	GERD, dyspepsia
Early morning + N/V	Pregnancy
Feculent vomiting + N/V	Intestinal obstruction Gastrocolic fistula
Vertigo + nystagmus + N/V	Vestibular neuritis
Dental erosions, parotid gland enlargement, lanugo-like hair, callus on dorsal surface of hands	Bulimia
Positional N/V	Neurogenic
N/V relieved with hot shower or bath	Cannabis hyperemesis

GERD, Gastroesophageal reflux disease; LLQ, left lower quadrant; MI, myocardial infarction; N/V, nausea and vomiting; PID, pelvic inflammatory disease; RLQ, right lower quadrant; RUQ, right upper quadrant.

dysphasia, odynophagia, unexplained anemia, iron deficiency, hematemesis, palpable abdominal mass, lymphadenopathy, family history of gastric cancer, previous gastric surgery, or jaundice.

Gaseousness usually presents with abdominal fullness and bloating. Pain associated with the fullness is often relieved with eructation or flatulence (see Table 1).

### Diagnosis

The first step in the assessment of patients with abdominal complaints is complete history of the duration of symptoms, the frequency of episodes, work environment, recent travel, household member illness, association of symptoms with certain foods or beverages (i.e., pain relief or worsening with food), and determination of the success or failure of what the patient has tried to alleviate the symptoms, all of which may offer diagnostic clues. Focused inquiries into surgeries, sexual activity, and other elements of a review of symptoms may be helpful. A complete review of medication usage, with particular attention to GI-irritating medications such as NSAIDs and over-the-counter medications, illicit drugs, and herbal products is important. Physical examination and diagnostic work-up can help isolate the cause (Table 2).

In patients with acute (<24 hours) nausea and vomiting, a laboratory work-up is often unnecessary. Patients with the most commonly identified acute causes, such as acute gastroenteritis, vestibular neuritis, chemotherapy, medication, and alcohol ingestion, and those who are postoperative, can be started on symptomatic therapy. For persistent symptoms of nausea and vomiting, laboratory work-up is guided by the history and physical examination and can include a complete blood count and differential, serum chemistries, renal function, liver function tests, serum protein and albumin, thyroid-stimulating hormone, amylase or lipase, drug screen, and a pregnancy test in women of childbearing age. Imaging should not be routine but should be directed by the history and physical findings as well as pertinent laboratory results. Useful studies may include acute abdominal series (chest x-ray, flat and upright views of the abdomen), abdominal computed tomography (CT), and abdominal ultrasound.

Similarly, in patients with dyspeptic symptoms, laboratory tests should be obtained based on the history and physical examination. Many therapies, such as discontinuing offending medications (e.g., NSAIDs) or acid suppression in patients without alarm symptoms, may be started without a laboratory work-up. Blood count chemistries and *H. pylori* testing can be considered if warranted. Alarm symptoms may warrant further imaging or direct visualization with esophagogastroduodenoscopy (EGD).

In gaseousness and bloating, the most sensitive work-up is the history and physical examination. Further work-up should be directed by initial findings. Patients with alarm symptoms such as weight loss, diarrhea, abdominal pain, distention, and anorexia may benefit from a malabsorption work-up including lactose tolerance test, stool fat, ova and parasites, stool culture, *Clostridium difficile*, acute abdominal series, or EGD. A hydrogen breath test may be beneficial in selected patients to assess the relationship between specific foods and symptoms. Other blood work, tests, and imaging, such as CT, magnetic resonance imaging (MRI), and EGD are guided by availability of testing and the history, examination, and laboratory findings.

### Differential Diagnosis

Tables 3, 4, and 5 summarize the wide differential diagnoses of nausea and vomiting, dyspepsia, and gaseousness.

### Treatment

Antiemetics, hydration, and dietary changes are the first line treatments for acute episodes of nausea and vomiting. Controlling the symptoms is often all that is necessary in acute, self-limited bouts of nausea and vomiting symptoms. If patients are dehydrated,

**TABLE 2** Physical Examination: Nausea, Vomiting, Dyspepsia, and Gaseousness

FINDINGS	POSSIBLE ETIOLOGY
Fever	Infectious
Tachycardia, hypotension	Dehydration, volume depletion, sepsis (infectious), ectopic pregnancy, myocardial infarction, aortic aneurysm
Exophthalmos	Hyperthyroid
Papilledema	Increased intracranial pressure (tumors, subdural hemorrhage)
Bulging tympanic membrane	Otitis media, effusion
Thyromegaly	Hypothyroid
Lymphadenopathy	Infection, malignancy
Dry mucous membranes	Dehydration, volume depletion
Dental erosions	Bulimia
Abdominal distention	Obstruction, ileus, gastroparesis, irritable bowel, hepatic/splenic flexure syndrome, postoperative gas-bloat syndrome
Absent bowel sounds	Ileus, perforation
Sense of abdominal distention without bloating	Irritable bowel syndrome
Abdominal bloating	Irritable bowel syndrome, obstruction
RUQ abdominal pain/guarding	Cholecystitis, cholelithiasis
RLQ/LLQ abdominal pain/guarding	Appendicitis (RLQ), ovarian torsion, diverticulitis, ectopic pregnancy
Cervical motion tenderness	Pelvic inflammatory disease, endometriosis
Bladder tenderness	Urinary tract infection
Testicular pain	Torsion, epididymitis
Abnormal rectal examination	Fecal impaction, prostatitis, appendicitis, ovarian tumor, ectopic pregnancy, endometriosis
Delayed cap refill, poor skin turgor	Dehydration
Jaundice	Gallbladder disease, biliary obstruction

LLQ, Left lower quadrant; RLQ, right lower quadrant; RUQ, right upper quadrant.

oral rehydration can be accomplished by encouraging the patient to take small amounts (6 ounces or less) of cool water or electrolyte solutions on a frequent basis. If patients are unable to accomplish this, parenteral rehydration and antiemetics may be warranted.

Table 6 lists the common antiemetics agent, indications, dosages, side effects, and relative cost of medications.

Location of the cause with directed treatment is most effective for gaseousness. If no cause is found, it can be difficult to treat. Avoiding foods that are contributory, such as those containing lactose, fructose, sorbitol, high fiber, and starches, may be all that is necessary. Symptoms associated with increased sensitivity to normal levels of gas (i.e., IBS) can be difficult to treat. Therapeutic relationships, education, and dietary modification are the

strategy can be effective. In other patients, proton pump inhibitors, H-2 receptor antagonists, prokinetic agents, and peppermint oil are all effective short-term therapies.

**Monitoring**

For patients who have complications related to nausea and vomiting, monitoring serum electrolytes, renal function, nutritional status, and other parameters may be necessary until hydration improves, electrolytes are replaced, and laboratory results and clinical status return to normal.

Further testing is needed in patients with dyspepsia and alarm symptoms; however, in patients without alarm symptoms, no further testing is needed.

**Complications**

The complications of prolonged nausea and vomiting are dehydration, electrolyte disturbances (e.g., hypokalemia, hypophosphatemia, and hypomagnesemia), depletion of vitamins and trace elements, metabolic alkalosis, and malnutrition. Usually these can be corrected with oral or intravenous hydration, correction of electrolyte deficiencies, and treatment of the underlying cause. In patients whose nausea and vomiting are accompanied by gastroenteritis, symptoms and clinical status may not return to baseline unless all electrolytes such as potassium, magnesium, phosphorus, and trace elements such as zinc are replaced.

Dyspeptic patients without alarm symptoms rarely have complications. In patients with chronic bloating, complications are uncommon.

**TABLE 6** Medications for Nausea and Vomiting

DRUG	USE	SIDE EFFECTS	DOSAGE
<b>Anticholinergics</b> Act as antimuscarinic agents			
		Sedation, dry mouth, dizziness, hallucinations, confusion, exacerbate narrow angle glaucoma, blurred vision.	
Scopolamine	Nausea associated with motion sickness		1–1.5 mg patch TD q3d
<b>Antihistamines</b>			
		Sedation, dry mouth, confusion, urinary retention, blurred vision	
Diphenhydramine (Benadryl)	Nausea associated with motion sickness		50 mg PO q6h or 10–50 mg IV or IM
Doxylamine (Unisom) <sup>1</sup>	Nausea associated with pregnancy		5–10 mg PO qd
Hydroxyzine (Vistaril) <sup>1</sup>	Nausea associated with motion sickness		25–100 mg q6h
Meclizine (Antivert)	Nausea associated with motion sickness		25–50 mg q6h
Promethazine (Phenergan)	Nausea associated with motion sickness		12.5–25 mg (PO, IM, IV, PR) q4–6h
<b>Benzamides: Prokinetic agents; work on peripheral and central dopamine, weak hydroxytryptamine type 3 (5-HT<sub>3</sub>)</b>			
		Sedation, hypotension, extrapyramidal effects, diarrhea, neuroleptic syndrome, supraventricular tachycardia, CNS depression	
Metoclopramide (Reglan)	Second line therapy for chemotherapy-induced nausea		10 mg (PO, IM, IV) q6h
Trimethobenzamide (Tigan) <sup>1</sup>	Chemotherapy-induced nausea		300 mg PO q6h
<b>Butyrophenones: Dopamine antagonists</b>			
		Sedation, hypotension, extrapyramidal effects, tachycardia, dizziness, QT prolongation and torsades de pointes, neuroleptic malignant syndrome	
Droperidol (Inapsine)	Postoperative nausea/vomiting		0.625–1.25 mg (IM, IV) q4h
Haloperidol (Haldol) <sup>1</sup>			0.5–5 mg (PO, IM, IV) q8h
<b>Phenothiazines: Dopamine antagonists</b>			
		Sedation, hypotension, extrapyramidal effects, neuroleptic malignant syndrome, cholestatic jaundice	
Chlorpromazine (Thorazine)	Generalized nausea		10–25 mg (PO, IM, PR) q6h
Prochlorperazine (Compazine)	Generalized nausea		10 mg (PO, IM, IV) q6h; 2.5 mg q12h PR
<b>5-HT<sub>3</sub>: Serotonin Antagonists</b>			
		Fever, constipation, diarrhea, dizziness, sedation, nervousness, altered liver function tests, headache, fatigue	
Dolasetron (Anzemet)	Chemotherapy-induced nausea		100 mg (PO, IV) q24h
Granisetron (Kytril)	Chemotherapy-induced nausea		2 mg (PO, IV) q24h
Ondansetron (Zofran)	Chemotherapy-induced nausea		4–8 mg (PO, IV) q8–12h
Palonosetron (Aloxi)	Prevention of chemotherapy-induced nausea		0.5 mg PO or 0.25 mg IV ×1
<b>Neurokinin Receptor Antagonists</b>			
		Headache, site reaction	
Aprepitant capsule (Emend)	Prevention of postoperative nausea and vomiting (POV)		40 mg PO × 1 prior to anesthesia
Fosaprepitant (Emend IV)	Prevention of chemotherapy-induced nausea		115 mg IV × 1, 125 mg PO ×1 <sup>3</sup>

Continued

**TABLE 6** Medications for Nausea and Vomiting—cont'd

DRUG	USE	SIDE EFFECTS	DOSAGE
<b>Steroids</b>			
		GI upset, anxiety, euphoria, flushing, insomnia	
Dexamethasone (Decadron) <sup>1</sup>	Prophylaxis of chemotherapy-related nausea and vomiting		4 mg–10 mg (PO, IM, IV) q6–12h
Methylprednisolone (Medrol) <sup>1</sup>			40–100 mg (PO, IM, IV) q24h
<b>Cannabinoids</b>			
		Vertigo, xerostomia, hypotension, dysphoria	
Dronabinol (Marinol)	Chronic or chemotherapy-induced nausea and vomiting		5 mg/m <sup>2</sup> PO q2–4h; 4–6 doses per day
<b>Miscellaneous</b>			
Erythromycin <sup>1</sup>	Nausea associated with gastroparesis		250 mg PO q8h × 5–7 d
Ginger <sup>7</sup>	Nausea associated with pregnancy		250 mg PO q6h or 1 g qd
Pyridoxine (vitamin B6) <sup>1</sup>	Nausea associated with pregnancy (traditionally combined with doxylamine)		10 mg q6h
Aromatherapy-Isopropyl Alcohol <sup>1</sup>	Nausea	None	Swab held under nose and inhaled.

CNS, central nervous system; IM, intramuscular; IV, intravenous; PO, by mouth; PR, per rectum

<sup>1</sup>Not US Food and Drug Administration (FDA) approved for this indication.

<sup>3</sup>Exceeds dosage recommended by the manufacturer.

<sup>7</sup>Available as dietary supplement.

**TABLE 7** Medications for Treatment of Gaseousness and Bloating

MEDICATION	INDICATION	DOSE
Rifaximin (Xifaxan) <sup>1</sup>	Bloating (flatulence) from suspected bacterial overgrowth	200 mg PO tid × 7 days
Probiotics (multi-component) <sup>7</sup>	Bloating (flatulence)	Varies by preparation
Alpha-galactosidase (Bean-o)	Bloating associated with gas-producing foods	300–1200 mg with meals high in fermentable carbs
Simethicone	Bloating (flatulence) (indicated but not found to be effective)	80–120 mg qid prn
Bismuth subsalicylate	Odor from flatus	525 mg PO qid prn
Odor-neutralizing devices (briefs, pillows)	Odor from flatus	prn

<sup>1</sup>Not US Food and Drug Administration (FDA) approved for this indication.

<sup>7</sup>Available as dietary supplement

## HEMATURIA

Method of

Matthew Banti, MD; and Moben Mirza, MD

### CURRENT DIAGNOSIS

- Hematuria is defined as the presence of red blood cells in the urine.
- Hematuria can be gross (readily visible) or microscopic (detected by dipstick or microscopy).
- In the adult population, any unexplained hematuria should be presumed to be of malignant origin until proven otherwise.
- Urologic evaluation of the upper and lower urinary tract is compulsory for patients with gross hematuria.
- Patients with asymptomatic microscopic hematuria (>3 RBC/HPF) should have a careful history and physical examination performed to rule out benign causes of hematuria as well as to assess overall risk of urologic malignancy.
- Following patient risk stratification, further diagnostic evaluation with repeat urinalysis, cystoscopy, and upper tract imaging (renal ultrasound or multiphasic computed tomography) may be indicated.
- Concurrent nephrologic evaluation should occur in select cases.

### Epidemiology

Hematuria is a common clinical finding in adults. The prevalence of hematuria ranges from 2.4% to 31.1%. Prevalence varies based on age, gender, frequency of testing, threshold used to define hematuria, and study group characteristics. Transient microscopic hematuria may occur in up to 40% of patients; however, persistent microscopic hematuria in greater than three evaluated urine samples is limited to 2% of the population. A wide range of causes can result in hematuria. Transient hematuria may be caused by vigorous exercise, sexual intercourse, mild trauma, menstrual contamination, and instrumentation. Patients with underlying urinary tract disease can have transient or persistent hematuria. The difference between gross and microscopic hematuria is that the chances of finding significant pathology are higher in patients with gross hematuria. For example, approximately 5% of patients with microscopic hematuria in contrast to 40% of patients with gross hematuria are found to have urologic malignancy on evaluation. The most common cause of gross hematuria in adults older than age 50 is bladder cancer.

### Risk Factors

Given the wide range of etiologies for hematuria, the risk factors are dependent on the etiology itself. The most concerning etiology of hematuria is urothelial malignancy. Smoking is the best-established and the most significant risk factor for the development of urothelial malignancies of the kidney, ureter, and bladder.

### Pathophysiology

The presence of blood in the urine can be separated into glomerular and nonglomerular origin. Normal urine contains less than three red blood cells per high-power field. The kidney does not excrete red blood cells under physiologic conditions. Therefore presence of blood in the urine is due to pathology at the glomerulus (glomerular hematuria), allowing excretion of red blood cells into the urine or pathology in the urinary tract distal to the glomerulus (nonglomerular hematuria), which results in blood mixing into the already excreted urine. Nonglomerular hematuria can be further divided into medical and surgical disorders. Except for renal tumors, nonglomerular hematuria of medical/renal origin is due to tubulointerstitial, renovascular, or systemic disorders. Surgical nonglomerular hematuria or essential hematuria includes urologic tumors, stones, and urinary tract infections.

The urine dipstick commonly used for the detection of blood in the urine is dependent on the peroxidase-like activity of hemoglobin, which catalyzes the reaction and causes oxidation of the chromogen indicator. False positives can occur in states of hemoglobinuria and myoglobinuria, and microscopic examination of the urine for red blood cells can distinguish hematuria. Glomerular hematuria is suggested when dysmorphic erythrocytes, red blood cell casts, and proteinuria are present. Nonglomerular hematuria can be distinguished from glomerular hematuria in the presence of circular erythrocytes and the absence of erythrocyte casts. In the surgical and medical subcategories of nonglomerular hematuria, surgical hematuria is suggested by the absence of significant proteinuria.

Anticoagulation at normal therapeutic levels does not predispose patients to hematuria. Therefore patients who have hematuria while receiving anticoagulation therapy should undergo evaluation similarly to patients who are not receiving anticoagulation therapy. In fact, super therapeutic anticoagulation may serve to unmask underlying pathology.

### Prevention

Hematuria can be caused by a spectrum of causes. Prevention can be achieved by the prevention of what results in the pathologic state. For example, smoking is a modifiable risk factor in urothelial malignancy. Patients who have never smoked are at low risk for bladder cancer. Smoking cessation can also reduce the risk of developing bladder cancer. Liberal fluid intake and balanced sodium and protein intake can help prevent urolithiasis. Urinary tract infections can also be prevented by good voiding habits, facilitation of complete bladder emptying, and use of vaginal estrogen cream<sup>1</sup> in postmenopausal women.

### Clinical Manifestations

The presentation of hematuria is often dependent on the cause. Certain characteristics of the presentation can help in the investigation. Is the hematuria gross or microscopic? Is the hematuria associated with pain? Are there any irritative voiding symptoms? Is there a presence of blood clots? Is it related to exercise? Is there any family history? Is there a presence of rash, arthritis, hemoptysis, upper respiratory infection, or skin infection? Is there a history of radiation, diabetes, or analgesic abuse? Is there a history of smoking or occupational exposures? [Table 1](#) highlights findings in etiologies of hematuria. Patients with bladder cancer generally present with gross painless hematuria.

### Diagnosis

The diagnosis and evaluation of hematuria starts with a careful history, physical examination, and microscopic urinalysis. The cause in an adult patient is urologic malignancy until proven otherwise. Some important questions are outlined in the section Clinical Manifestation. The physical examination should focus on blood pressure, a cardiovascular examination, an abdominal examination, a palpable mass, costovertebral angle tenderness, and a complete genitourinary examination inclusive of a prostate examination in the male and vaginal examination in the female patient. The assessment should help rule out causes such as infection, menstruation, vigorous exercise, medical renal disease, viral illness, trauma, or recent urologic procedures.

The urine should be collected as a midstream sample, and patients should be instructed to discard the initial 10 mL. The sample should be collected in a sterile cup after gently cleaning the urethral meatus with a sterilization towelette. Uncircumcised men should retract the foreskin before collection. Female patients should be asked to spread the labia adequately to allow cleansing of the urethral meatus and avoid introital contamination.

The following patients may require catheterization for collection: menstruating women, obese patients, patient with a nonintact urinary tract, and patients who do intermittent

<sup>1</sup>Not FDA approved for this indication

**TABLE 1** Differential Diagnosis and Findings in Etiologies of Hematuria

DIAGNOSIS	FINDINGS	OTHER
<b>Glomerular</b>		
Familial hematuria	Abnormal urinalysis	Family history
Systemic lupus erythematosus	Elevated C3, C4, ANA	Rash, arthritis
Goodpasture syndrome	Microcytic anemia	Hemoptysis, bleeding tendency
Poststreptococcal glomerulonephritis	Elevated ASO titer, C3	Recent upper respiratory infection, rash
IgA nephropathy	Normal ASO and C3, renal biopsy positive for IgA, IgG	Related to exercise
<b>Nonglomerular Medical</b>		
Exercise-induced hematuria	Abnormal urine analysis	After strenuous exercise
Papillary necrosis	Gross hematuria, absence of urolithiasis on CT	Flank pain, African American, analgesic abuse, diabetes
Medullary sponge kidney, polycystic kidney disease	Abnormal CT	Family history of renal cystic disease
Renovascular disease	Renal artery embolus, vein thrombus, AV fistula	Atrial fibrillation, dehydration, bruit
<b>Nonglomerular Surgical</b>		
Urinary tract infection	Urine dip with LCE, Nit. positive urine culture, elevated WBC	Dysuria, fever
Urolithiasis (renal, ureteral, or bladder stone)	Demonstrated on imaging such as CT, ultrasound, KUB	Flank pain, pelvic pain, vomiting, infection, renal obstruction
Urologic tumor (kidney, ureter, bladder, urethra)	Demonstrated on CT, cystoscopy, ureteropyeloscopy	Constitutional, irritative symptoms, pain if obstructed, blood clots
Enlarged prostate or benign prostatic hyperplasia	Enlarged prostate on examination or cystoscopy	Irritative and obstructive voiding symptoms
Radiation cystitis	Generally gross hematuria, friable tissue on cystoscopy	Irritative voiding symptoms, history of pelvic radiation
Urothelial strictures (ureter or urethra)	Demonstrated on ureteroscopy, pyelography, cystoscopy, or urethrography	Flank pain, renal insufficiency, bladder outlet obstruction

ANA, Antinuclear antibodies; ASO, antistreptolysin O; AV, atrioventricular; CT, computed tomography; Ig, immunoglobulin; KUB *kidney, ureter, bladder radiograph*, LCE *leukocyte esterase*, WBC, white blood cell.

catheterization or have an indwelling urinary catheter or suprapubic tube. Additionally, a urine sample with excessive squamous cells is a sign of contamination, and catheterization may be required for an adequate specimen. A urine dipstick can be performed in the office setting, but all samples should be sent for microscopic analysis. As mentioned previously, attention should be paid to dysmorphic erythrocytes, red blood cell casts, and the presence of protein. A urine culture should be performed based on the clinical presentation and findings of urinalysis. Urine cytology should not be used in the initial evaluation of microscopic hematuria but may have clinical utility in evaluating patients with irritative voiding symptoms or persistent microhematuria after a comprehensive urologic evaluation. The laboratory workup should include an evaluation of the serum creatinine. Additional helpful tests are serum electrolytes and a complete blood count.

Patients with a urinary tract infection should be treated appropriately and should have a urinalysis repeated in 2 to 6 weeks after treatment. Patients with an identified etiology such as urolithiasis should have a reevaluation of urine after the stone has been passed or treated.

A urologic evaluation of the upper and lower urinary tract is compulsory for patients with gross hematuria. Given the high prevalence of asymptomatic microscopic hematuria (>3 RBC/HPF) and lower rate of malignancy in this population, risk stratification should be performed to guide diagnostic evaluation and limit the potential for patient harm. Patients should be categorized as low, intermediate, and high risk based on factors in Table 2. Low-risk patients should undergo cystoscopy and renal

ultrasound or repeat urinalysis within 6 months to assess for persistence of the microscopic hematuria. An abnormal repeat urinalysis should prompt reclassification as intermediate or high risk and full evaluation should be performed. Cystoscopy and renal ultrasound (intermediate risk) or multiphasic computed tomography (high risk) are indicated for the evaluation of these risk groups. While contrasted computed tomography is preferred for evaluation of the upper tracts, a contraindication may exist for some patients due to allergy or renal insufficiency. In this scenario, a urologist can determine whether magnetic resonance imaging or retrograde pyelography is appropriate.

### Differential Diagnosis

The differential diagnosis of hematuria includes glomerular diseases, nonglomerular medical diseases, and nonglomerular surgical diseases. Table 1 shows a differential diagnosis for hematuria.

Hematuria is considered to be from a malignant source until proven otherwise.

### Therapy, Monitoring, and Complications

Therapy, monitoring, and complications for hematuria are dependent on the etiology. It is important that hematuria not be ignored even when treated empirically. For example, it is important to recheck a urinalysis after a course of antibiotics for a presumed urinary tract infection. Often, the transient nature of hematuria fools clinicians into thinking that an intervention or observation without the appropriate workup is adequate. Unfortunately, this can result in significant morbidity from the progression of disease, especially in the case of urothelial malignancies.

**TABLE 2** Microhematuria Risk Stratification

LOW RISK (ALL OF THE FOLLOWING):	INTERMEDIATE RISK (ANY OF THE FOLLOWING):	HIGH RISK (ANY OF THE FOLLOWING):

Etiologic classifications are also fraught with problems. Hiccup is not a disease, but a symptom. Literally, there is no known disease that has not been associated with hiccups. Although the categories psychogenic, organic, and idiopathic are most commonly used in practice, the situation most commonly encountered is that of hiccup of unknown (idiopathic) origin. In this context, “idiopathic” describes one’s inability to demonstrate, rather than the absence of, an organic origin.

## Epidemiology

During intrauterine life, hiccups are universally present, their incidence peaking in the third trimester. They can also be seen regularly in the newborn, the frequency of occurrence decreasing slowly over the first year of life. In adults, occasional transient hiccup is also so frequent that it can be viewed as physiologic. Persistent and chronic idiopathic singultus, the pathologic forms, are rare, their prevalence being estimated at 1 in 100,000. Males are almost exclusively affected (the male-to-female patient ratio is approximately 80:1), suggesting a hormone (estrogen) protective effect. The incidence increases with age. The psychogenic form, though less frequent overall by one order of magnitude, is believed to be more prevalent in females, with an even distribution among all age groups; however, data to support this view are almost nonexistent.

## Pathophysiology

The universality of hiccups during fetal life begs the question of purposefulness. As early as 1887, it was suggested that hiccups might represent a necessary and vital primitive reflex that would permit intrauterine training of the diaphragm without aspiration of amniotic fluid. During intrapartum and postpartum maturation, higher centers would then suppress this primitive reflex. Immaturity or damage to the central nervous system would favor the persistence or reappearance of the reflex. The putative reflex arch includes autonomic afferent fibers (the majority vagal fibers) from the digestive tract to a putative medullary hiccup center and motor efferent fibers via the phrenic nerve (diaphragm) and other branches of the vagus nerve to the intrinsic muscles of the larynx adducting the vocal cords. In an analogy with the vomiting center, the assumed role of the medullary hiccup center is to coordinate and fine-tune the sequence of events required for hiccupping; it is therefore a “pattern generator.” The concept described, though useful for the purpose of designing a quasi-rational treatment protocol for hiccup, is neither proven nor generally accepted.

Another school of thought that questions the assumption that hiccupping is a reflex phenomenon suggests instead a similarity with cardiac arrhythmias: hiccups would therefore be due to arrhythmias of the breathing center. Still other researchers work on the assumption that hiccup is a myoclonic event, or that it represents brainstem seizures. These views are not necessarily mutually exclusive, because hiccup is not primarily a disease but a symptom, possibly representing different pathophysiologies.

## HICCUPS

Method of

Georg A. Petroianu, MD, PhD

## Mechanistic Description

Hiccup (Latin, *singultus*) is caused by an involuntary, usually repetitive and rhythmic, spasmodic contraction of the diaphragm (or hemidiaphragm) and accessory inspiratory muscles followed shortly (within 35 msec) by the sudden closure of the glottis. The forcefully inspired air meeting a closed glottis causes the typical hiccup sound. Occasional hiccups are generally perceived as being “funny”; however, hiccupping of extended duration can be incapacitating. Its most common direct consequence is esophagitis, due to concomitant relaxation of the lower esophageal sphincter favoring reflux, but extended hiccupping can also lead to wound dehiscence, depression, weight loss, malnutrition, insomnia, and exhaustion. The possibility of developing tardive dyskinesia weighs against the routine use of this drug.

## Classifications

Most classifications use arbitrary time limits to categorize hiccupping. Generally hiccups lasting less than 1 day are considered transient (acute), those lasting less than 1 week are labeled persistent, and hiccupping for more than 1 week is described as chronic. A simplified categorization draws the line at 48 hours: any hiccupping episode lasting longer is described as chronic. The practical value of these classifications is questionable; by the time the practitioner sees the patient, almost invariably the case involves persistent or chronic hiccup forms requiring drug therapy. The exceptions (in terms of time between appearance and presentation) are hiccup forms presenting immediately postoperatively or in critical care units. Brief episodes of hiccupping, as experienced by the vast majority of people at some point in time, are certainly physiologic. The point of transition to a pathologic form is not well defined. The rule of thumb of hiccup therapy, however, is that the longer the duration of the hiccupping, the less amenable it will be to nonpharmacologic interventions.

## Evaluation of the Hiccup Patient

Hiccup is a symptom associated with a multitude of pathologies. The practitioner must take the hiccupping patient seriously, and for the purpose of finding and treating hidden pathology, persistent and chronic hiccups should be investigated. No consensus exists, however, concerning the extent of such investigations. Even the most enthusiastic users of modern imaging technologies will in most cases end up with a working diagnosis of chronic idiopathic singultus. Nonetheless, a detailed history, a thorough physical examination, and basic laboratory and diagnostic procedures are essential.

### History

Ask about previous episodes, as well as precipitating and alleviating factors. The patient who describes vomiting as a “cure” for previous hiccup episodes gives a telltale sign that acidity is an etiologic factor, and omeprazole is a drug to consider. If the patient indicates that hyperventilation is a “sure bet” to worsen his or her hiccups, you can assume that drugs lowering the excitability of the nervous system are likely to help. Elucidating present drug consumption (medical and recreational) is essential: aripiprazole (Abilify), benzodiazepines, barbiturates, alcohol, and steroids are well-known hiccup inducers.

### Physical Examination

Foreign bodies in the external auditory canal can induce hiccups, so look in the ears. Examine neck, chest, and abdomen, looking for possible sources of irritation (infection, neoplastic processes, or both) to the vagus and phrenic nerves and the diaphragm. Perform a neurologic examination, keeping in mind the association of hiccup with multiple sclerosis and intracranial processes.

### Laboratory and Diagnostic Procedures

An upright chest x-ray, together with complete blood count (CBC) with differential, will help exclude neoplastic or infectious disease. An electrocardiogram (ECG) will help exclude pericarditis and malfunctioning pacemakers, and electrolyte and urea determinations will exclude known metabolic causes (hyponatremia and uremia).

To what extent magnetic resonance imaging (MRI), ultrasound scanning, or endoscopic examinations are necessary is a judgment call, and no generalizations are possible; they might occasionally be indicated.

## Nonpharmacologic Interventions

A multitude of nonpharmacologic interventions to terminate hiccup belong to the public-domain hiccup “mythology” or have been described in the medical literature as case reports. Though usually effective in terminating bouts of acute hiccup, they are mostly ineffective in cases of hiccupping that has been present for an extended period. The common denominator of these maneuvers (also used to terminate paroxysmal supraventricular tachycardia) is their ability to directly or indirectly increase efferent vagal activity; the increased parasympathetic tone has a limiting effect on hiccupping. Interestingly, estrogens are also considered to be parasympathomimetic, which offers a plausible explanation of why the singultus prevalence in females is much lower than in males.

## Pharmacologic Interventions

Probably only a few drugs in the *Physician’s Desk Reference* have not been tried in the therapy of singultus, and anyone who looks hard enough at the literature will be able to find anecdotal support for the use of almost any drug. However, prospective controlled studies to support the use of a particular therapy are very few and rare.

Conceptually, all drugs potentially successful in the therapy of chronic hiccups work either by decreasing the input from the

gastrointestinal tract to a (putative) hiccup center or by decreasing the excitability of the nervous system and therefore the output from the (putative) hiccup center.

### Sedative-Hypnotics

Both benzodiazepine and barbiturate  $\gamma$ -aminobutyric acid receptor type A (GABA<sub>A</sub>) agonists have been tried for treatment of hiccups. The consensus is that these substances not only are ineffective but can actually worsen the clinical picture, producing a situation similar to the paradoxical excitation seen with the use of sedatives and explained by inhibitory effects on inhibitory centers.

### Antiemetics

Following up on the analogy between the vomiting center and hiccup center as pattern generators, “setron”-class antiemetics (5-HT<sub>3</sub> receptor antagonists) have been tried, with no success. Anecdotal evidence hints at possible worsening of the hiccup under the influence of ondansetron (Zofran).<sup>1</sup>

### Analeptics

The use of analeptics derives from the concept that hiccup is a suppressed primitive reflex. Analeptics potentiate the central suppression. Although some success has been reported with methylphenidate (Ritalin),<sup>1</sup> caffeine produced failure.

### Anticonvulsants

Anticonvulsants (phenytoin [Dilantin],<sup>1</sup> carbamazepine [Tegretol],<sup>1</sup> valproate [Depacon]<sup>1</sup>) have been used to try to suppress hiccups. Considering the multitude of pharmacodynamic effects of anticonvulsants, it is not surprising that some success was achieved.

### Antipsychotics

Historically, chlorpromazine (Thorazine) has been the most widely used drug for treatment of hiccup, and it is the only drug approved by the FDA for the disorder. Aliphatic phenothiazines such as chlorpromazine have strong sedative, hypotensive, and anticholinergic properties and mild to moderate extrapyramidal effects. For hiccup control, results are mixed at best, and in view of the side effects, routine use is not warranted. Haloperidol (Haldol),<sup>1</sup> a butyrophenone derivative, has also been used for hiccup control; again, results are mixed at best, and the possibility of developing tardive dyskinesia weighs heavily against the routine use of this drug.

### Antidepressants

The tertiary amine tricyclic antidepressant amitriptyline (Elavil)<sup>1</sup> is one of the oldest players in the therapy of hiccup; its use was being suggested in the mid-1960s. As with anticonvulsants, considering the multitude of pharmacodynamic effects of tricyclic antidepressants, it is not surprising that some success was achieved with these drugs. Their effectiveness is not related to their ability to inhibit monoamine uptake, but probably to their sodium channel blocking properties.

### Calcium Channel Blockers

Nifedipine (Adalat)<sup>1</sup> is the dihydropyridine derivative most commonly used for hiccup control. Nimodipine (Nimotop)<sup>1</sup> has also been tried for the same purpose. Interestingly, anecdotal reports about the use of calcium for the same purpose also exist.

### Sodium Channel Blockers

The local anesthetic class Ib antidysrhythmic lidocaine (Xylocaine)<sup>1</sup> and its oral analogue mexiletine (Mexitil)<sup>1</sup> have been used for hiccup control, with mixed results.

<sup>1</sup>Not FDA approved for this indication.

## GABA<sub>B</sub> Agonists

Among the substances acting on the nervous system, baclofen (Lioresal)<sup>1</sup> has by far the best credentials in the treatment of chronic hiccup. It is one of the very few substances proven in clinical studies (albeit with small patient numbers) to be efficacious. This  $\gamma$ -aminobutyric acid receptor type B (GABA<sub>B</sub>) agonist, normally used to lower an increased muscle tone (spasticity), has also been shown to suppress hiccups in an animal (cat) hiccup model. GABA<sub>B</sub> agonists, by reducing transmitter release, are generally able to depress complex reflexes.

## Antacids

Lowering the acidity of the stomach using H<sub>2</sub>-receptor blockers or proton pump inhibitors conceptually decreases the input from the gastrointestinal tract to the hiccup center. Omeprazole (Prilosec)<sup>1</sup> has been shown in a limited number of trials to be effective in hiccup treatment.

## Gastrokinetic Drugs

One of the few reliable methods to induce a physiologic hiccup in humans is rapidly drinking an ice-cold can of beer on a hot summer day. Although it is highly debatable whether it has to be beer, stomach distention by carbon dioxide induces hiccups. Conversely, reducing stomach distention by using a gastrokinetic drug is helpful in alleviating hiccups. The strongest evidence available for the usefulness of a gastrokinetic drug was for cisapride (Propulsid); however, this selective serotonin 5-HT<sub>4</sub>-receptor agonist was withdrawn from the market because of its propensity to prolong the QT interval and induce torsades de pointes. The available alternative is the related benzamide metoclopramide (Reglan),<sup>1</sup> a mixed dopamine receptor antagonist, 5-HT<sub>4</sub>-receptor agonist, and cholinesterase inhibitor, with a long tradition in the treatment of hiccups, going back to the late 1960s. The possibility of developing tardive dyskinesia weighs against the routine use of this drug.

## Physical Interventions

### Phrenic Nerve Destruction

Irreversible surgical destruction of the phrenic nerve cannot be recommended. Even if hiccup relief is achieved after unilateral local anesthetic blockade of the phrenic nerve without serious compromise in respiratory function, the long-term effects of phrenic nerve destruction are unpredictable. Possible effects include both hiccup reappearance—even after bilateral phrenic nerve transection—and deterioration in respiratory function. More recently, diaphragmatic (phrenic) pacing has been described; however, experience is very limited.

### Hypercapnia

Rebreathing in a paper bag is a well-known and reliable remedy for hyperventilation tetany. The increase in blood CO<sub>2</sub> levels (hypercapnia) thus induced leads to mild acidosis and thus to a liberation of calcium ions from the protein binding. The increase in plasma-free calcium decreases neuronal excitability, thus terminating not only the tetany but possibly also hiccups. It was suggested that abolishing the venous-arterial CO<sub>2</sub> gradient is required for efficacy of the method. A more high-tech version of this is the induction of normoxic hypercapnia in ventilated patients.

### Positive End-Expiratory Pressure

Also practicable only in intubated patients is the application of high positive end-expiratory pressure (PEEP), a high-tech version of the Valsalva maneuver.

## Nasogastric Tube

Gastric decompression via a nasogastric tube can terminate hiccups.

## Treatment

The treatment algorithm described is based on the assumption that correctable organic causes have been excluded or treated.

We start therapy with omeprazole (Prilosec)<sup>1</sup> 20 to 40 mg orally (PO) daily. If after 7 days no satisfactory change has occurred, baclofen (Lioresal)<sup>1</sup> is introduced. With baclofen, a “start low, go very slow” approach is indicated in order to avoid excessive drowsiness, weakness, and fatigue. The maximum daily dose is 45 mg. Quite often, patients are already on a proton pump inhibitor (PPI) when presenting. In these cases, immediate introduction of baclofen and continuation of the PPI are recommended. In our experience, the time of response to the combination therapy omeprazole plus baclofen is unpredictable; however, all changes that we observed happened within the first 6 months, and the vast majority within the first 6 weeks. If the desired result is achieved, we continue therapy for another 6 months, after which a very cautious weaning from baclofen is attempted. In cases where the combination therapy omeprazole plus baclofen is not (or not entirely) satisfactory, the addition of gabapentin (Neurontin)<sup>1</sup> or pregabalin (Lyrica)<sup>1</sup> “on the top” can be attempted. As with baclofen, with gabapentin or pregabalin a “start low, go slow” approach is indicated, the maximum dose of 400 mg three times daily or pregabalin 100 mg three times daily used in such cases being reached after 3 weeks. An inverse approach with PPI plus gabapentin or pregabalin as initial combination is also possible.

In addition to any pharmacologic therapy, the practitioner must convey to the patient the feeling that he or she understands and appreciates the seriousness of the condition. Compliance with the treatment is required from the patient, who must understand that success can take time. Lifestyle and habit changes are also required. The hiccup patient must limit the size of meals and avoid carbonated beverages and “gas-forming” foods.

The approach presented here represents our experience in the treatment of chronic singultus. The views expressed are neither guidelines nor regulations.

<sup>1</sup>Not FDA approved for this indication.

## HOARSENESS AND LARYNGITIS

Method of  
Lee Akst, MD

### CURRENT DIAGNOSIS

- The general term to describe vocal difficulty is dysphonia. Hoarseness is a specific term for rough voice quality, which is one type of dysphonia. Laryngitis signifies laryngeal inflammation, which is one possible cause of dysphonia.
- An accurate history and physical examination guide the diagnosis of voice complaints. Although many portions of the examination for dysphonia can be done in a general setting, videostroboscopy is often necessary for diagnosis and may be available only in specialized laryngology offices.
- The most common cause of acute hoarseness is viral laryngitis. Symptoms are self-limited and usually resolve within 2 weeks.
- Dysphonia persisting for longer than 2 weeks suggests the possibility of another diagnosis, such as vocal cord paralysis, neoplasm, phonotraumatic lesion, or chronic laryngitis.
- Indications for referral of a patient with voice complaints to an otolaryngologist include dysphonia that persists for longer than 2 weeks, that is of acute onset during voicing, or that is accompanied by other symptoms such as otalgia, dysphagia, or difficulty breathing.

### CURRENT THERAPY

- Appropriate treatment of voice complaints depends on accurate diagnosis.
- Supportive therapy is all that is necessary for most cases of acute laryngitis associated with viral upper respiratory tract infections.
- Laryngopharyngeal reflux is a common cause of chronic laryngitis, and appropriate therapy often requires twice-daily administration of proton pump inhibitors for at least 2 months.
- Microlaryngeal phonosurgery may be indicated for some patients with benign phonotraumatic lesions.
- Vocal cord medialization can rehabilitate the voice in a patient with unilateral vocal cord paralysis.
- Many patients with dysphonia benefit from voice therapy, alone or in combination with other treatment strategies.

Voice is an essential component of communication. Vocal difficulty is very distressing to patients and can have a negative impact on physical, social, and emotional qualities of life. To understand the pathophysiology, evaluation, and treatment of voice complaints, it is important to understand the anatomy and physiology of normal voice production. Looking first at how good voice quality is achieved makes it readily apparent how alterations in vocal fold vibration, symmetry, or closure can lead to various vocal difficulties.

To aid discussion of voice complaints, clarification of terminology is necessary. Although “hoarseness” is a term that most patients use to describe any type of voice complaint and “laryngitis” is the presumptive explanation that many patients provide for their symptoms, each of these terms has a more precise meaning. Dysphonia is the general term for vocal difficulty. Hoarseness implies a rough or raspy change in voice quality and is one type of dysphonia. Other categories include limited vocal projection, strained vocal effort, and change in pitch—each of which may

occur with or without vocal roughness. The term “laryngitis” specifically describes inflammation of the larynx. This inflammation may be acute or chronic, and again it describes some but certainly not all cases of dysphonia. This distinction will be made clear as the evaluation and management of dysphonia are described.

### Normal Laryngeal Function

The larynx plays a central role in voice production by serving as a vibrating instrument that turns airflow from the lungs into sound. The sound is shaped into intelligible speech through the resonating and articulating functions of the pharynx and oral cavity. The ability of the larynx to create vibration and serve as a sound source is a function of its complex, layered microanatomy. The deeper layers of the vocal fold include the thyroarytenoid muscle and the vocal ligament, which position the more superficial layers of the superficial lamina propria and epithelium during phonation. Compared with the fibrous nature of the vocal ligament, the superficial lamina propria is a loose gelatinous layer whose pliability allows for voice production.

During inspiration (Figure 1A), the vocal folds are abducted so that air can move past the larynx without resistance. During phonation (Figure 1B), the vocal folds are held in an adducted position while the lungs drive air toward the larynx. Air pressure builds in the subglottis, beneath the vocal folds, until it overcomes the forces of vocal fold closure, pushes past the vocal folds, and generates negative pressure in its wake as it moves past the larynx. A combination of the vocal folds’ intrinsic viscoelasticity and the negative pressure created through Bernoulli’s effect draws the vocal fold edges back together, allowing subglottic pressure to rebuild and the cycle to repeat. Repeated cycles of opening and closing at the level of the vocal fold edges generate a so-called mucosal wave, which travels from the inferior edge of each vocal fold up across the medial and superior edges (Figure 1C). These waves may repeat hundreds of times each second, depending on pitch. This cycled opening and closing of the vocal folds during phonation imparts pressure waves to the air column that moves the vocal folds, generating sound. The ability of vocal folds to vibrate easily and symmetrically in this very rapid fashion allows for clear, smooth voicing.

### Evaluation of Dysphonia

Central to the evaluation of dysphonia is the understanding that any disruption of vocal fold closure, symmetry, or vibration impairs the ability of the vocal folds to generate a clear sound source. Most voice complaints arise from anatomic or functional limitations in glottal closure or mucosal wave formation, although other parts of the respiratory tree are also responsible for components of the voice. General points concerning evaluation of dysphonia are discussed in this section, with specific causes discussed afterward.

### History

A careful history can provide many clues that point toward the proper diagnosis in patients with dysphonia. Although many patients offer the complaint of “hoarseness” as a general term, a careful historian distinguishes between complaints related to voice quality, vocal projection, vocal effort or strain, vocal fatigue, and so on. Two questions that can help a patient organize his or her own thoughts related to poor voice are “What abnormal things does your voice do now that it did not do before?” and “What normal things did your voice do before that it no longer can do?” The acuteness of onset, duration, severity, and progression of any complaint should be determined.

The history should also determine what other factors or events might have caused or exacerbated the dysphonia. Recent sources of laryngeal inflammation might include intubation, excessive voice use, or upper respiratory tract infection. Baseline conditions that foster chronic laryngeal inflammation include environmental allergies, rhinitis, and laryngopharyngeal reflux. Laryngopharyngeal reflux can exist in the absence of heartburn, with reflux-associated inflammation of the larynx and pharynx providing symptoms of globus pharyngeus, throat clearing, nonproductive cough, effortful swallowing, and even mild dysphagia in association with dysphonia.

**Figure 1** A, Normal vocal folds in abducted position for inspiration. B, Normal vocal folds in adducted position for phonation. C, Displacement of the vocal fold medial edges creates mucosal wave propagation during phonation and produces voice.

Concerning the possibility of laryngeal malignancy, any patient with dysphonia should be asked about smoking and alcohol use, because these are risk factors for squamous cell carcinoma. Another important question in distinguishing inflammatory dysphonia from a mass lesion of the vocal fold concerns whether there are any periods of normal voice or the dysphonia is constant—inflammation may wax and wane, but dysphonia associated with mass lesions is usually progressive and unremitting. Finally, the history should elicit other possible head and neck complaints, including dyspnea, stridor, dysphagia, odynophagia, otalgia, sore throat, and pain with speaking (odynophonia). If hoarseness is associated with some of these symptoms for longer than 2 weeks, the suspicion of malignancy is increased.

#### Physical Examination

The physical examination for patients with dysphonia includes a complete head and neck evaluation with focus on the larynx and laryngeal function. Although much of the head and neck examination can be performed in a general setting, some portions of the laryngeal examination require specialized equipment found only in some otolaryngology offices that specialize in voice care. Routine head and neck evaluation should include systematic examination of the ears, nose, oral cavity, oropharynx, and neck.

Complaint of otalgia in the setting of an unremarkable ear examination suggests a possibility of referred pain from a lesion of the larynx or pharynx, and is concerning for possible malignancy. Edematous and erythematous nasal mucosa suggests rhinitis, with the possibility of postnasal drip contributing to laryngeal inflammation. Tremor of the tongue or palate might suggest neurologic disorder, whereas pharyngeal erythema and exudate suggest possible acute infection. Pachydermia (cobblestoning) of the posterior pharyngeal wall suggests the possibility of laryngopharyngeal reflux. Tenderness with manipulation of the hyoid bone suggests tension of the strap muscles and correlates closely with complaint of odynophonia and the possibility of muscle tension dysphonia. A neck mass might represent either metastatic lymphadenopathy from a laryngeal malignancy or a primary lesion which itself compresses the recurrent laryngeal nerve and causes paralytic dysphonia. Surgical scarring along the neck suggests the possibility that prior thyroid surgery, carotid endarterectomy, or anterior approach to the cervical spine might have led to vocal fold paralysis.

#### Laryngeal Examination

Beyond a general examination of the head and neck, there should be directed evaluation of the larynx and laryngeal function. The examiner should listen to the voice carefully, because vocal characteristics such as roughness, breathiness, strain, vocal breaks, and diplophonia (pitch instability, with two different pitches present simultaneously) can help guide the differential diagnosis of dysphonia. Visual examination of the larynx has many forms, ranging from mirror examination to flexible fiberoptic laryngoscopy to videostrobolaryngoscopy.

Mirror examination offers an adequate view of the vocal folds in many patients but may be limited by patient tolerance,

physician inexperience, and the inherently limited ability of this technique to brightly illuminate the larynx or record the examination for later review. Flexible laryngoscopy is routinely available in almost all otolaryngology offices, is well tolerated by patients, and offers good views of the larynx that can be recorded with appropriate equipment. Mirror examination and flexible laryngoscopy are limited to observation of vocal fold motion and anatomy but cannot observe laryngeal function because they do not visualize vibration of the vocal folds. To examine vocal fold vibration, videostroboscopy uses a strobe light to create the impression of slow-motion analysis of mucosal waves. Stroboscopy is typically available only in selected otolaryngology practices in which laryngologists specialize in the treatment of voice disorders.

#### Other Testing

Videostroboscopic evaluation, combined with a thorough history and routine physical examination, can establish the diagnosis for almost all patients with voice complaints, but further testing is sometimes indicated. For instance, electromyography is used by some laryngologists for further evaluation of vocal fold paralysis or paresis. More commonly, radiographic studies are used for further evaluation of some voice complaints. Computed tomography (CT) scans are ordered most often in the evaluation of suspected laryngeal neoplasms and for patients with vocal fold paralysis.

In the case of neoplasm, CT scanning is useful to assess the extent of the primary lesion and to evaluate possible metastatic cervical lymphadenopathy. In patients with laryngeal malignancy, chest radiography is also important to assess for pulmonary metastases. For patients with vocal fold paralysis who do not have a clear history of surgical injury of the recurrent laryngeal nerve, a CT scan from skull base to thoracic inlet identifies possible lesions along the course of the recurrent laryngeal nerve. Central problems are less likely, but if they are suspected as a cause of vocal fold paralysis, then magnetic resonance imaging of the brain may be indicated as well.

#### Types of Dysphonia

Although not comprehensive, the conditions discussed here account for the vast majority of voice complaints. Some patients with voice complaints have more than one condition, and not every patient will fit neatly into a single category. Nevertheless, understanding how each of these conditions creates dysphonia, and knowing which particular history and physical examination findings might be associated with each cause, can help a physician to appropriately diagnose and manage voice complaints.

#### Acute Laryngitis

Acute laryngitis is the most common cause of hoarseness and dysphonia. It is most often viral in nature, and onset of laryngeal symptoms may be associated with other symptoms of upper respiratory tract infection, including fever, myalgia, sore throat, and rhinorrhea. Viral inflammation of the vocal folds leads to diminished and more effortful vocal fold vibration, yielding a voice characterized by increased effort and a harsh, strained quality with decreased projection. Characteristic findings on laryngoscopy

include vocal fold edema and erythema with decreased amplitude of the mucosal wave. Treatment of acute viral laryngitis is supportive, with counseling for hydration, humidification, and mucolytics. Symptoms generally are self-limited and resolve within 2 weeks. During this time, patients should be instructed to use the voice in a comfortable fashion, rather than straining or pushing to get loudness, because pushing behaviors may lead to the development of persistent muscle tension dysphonia.

Bacterial or fungal infections also cause acute laryngitis in rare cases. With appropriate physical findings and in the right clinical setting, antibiotic or antifungal therapy may be used to treat these conditions. Amoxicillin-clavulanate (Augmentin) is often the antibiotic of choice, and fluconazole (Diflucan) is a commonly used antifungal agent.

### Chronic Laryngitis

Chronic laryngitis is the nonspecific condition of prolonged laryngeal inflammation; the term itself does not indicate an etiology for the inflammation. Among the many possible sources for this inflammation are mechanical irritation from traumatic coughing or prolonged speaking, chemical irritation from environmental irritants (e.g., smoking, inhaled medications), and irritation from postnasal drip or laryngopharyngeal reflux. More than one cause may exist simultaneously. Issues related to cigarette use, excessive voice use, medication effect, and rhinitis can be identified with careful history taking. Laryngopharyngeal reflux is a very common source of chronic laryngitis. It may manifest with several nonspecific symptoms, such as throat irritation, globus pharyngeus, frequent throat clearing, and nonproductive cough, with or without accompanying heartburn. Because vocal fold inflammation increases with continued mechanical trauma, the hoarseness of chronic laryngitis typically gets worse with prolonged voice use and improves with voice rest. Examination findings in chronic laryngitis include generalized laryngeal edema and erythema, and careful inspection may also reveal interarytenoid hyperplasia, subglottic edema, laryngeal ventricular obliteration, and an increase in thick glottic secretions.

Treatment of chronic laryngitis is tailored to the cause of the inflammation. Vocal hygiene with moderate voice use and instructions to reduce throat clearing and coughing may diminish mechanical irritation, and smoking cessation is recommended to any smoker with laryngeal complaints. Several studies have suggested that an appropriate trial of proton pump inhibitors for treatment of laryngopharyngeal reflux includes twice-daily therapy for at least 2 months, in contrast to the once-daily dosing often used for typical heartburn complaints. Lifestyle counseling to limit consumption of caffeine, carbonation, alcohol, and acidic foods can improve reflux, and attention to hydration and humidification decreases the viscosity of glottic secretions. For patients who are troubled by vocal difficulties associated with chronic laryngitis, referral to a speech-language pathologist for voice therapy can improve compliance with suggested lifestyle changes and help foster vocal improvement.

### Vocal Fold Paralysis

The dysphonia in cases of vocal fold paralysis usually relates to poor vocal fold closure (Figure 2). The result is a breathy voice with limited projection and increased vocal effort. The farther from midline the immobile vocal fold, the more air leaks through the incompetent glottal valve without being turned into sound. Patients whose immobile vocal fold sits in a lateral position may have severely weak and breathy voices, whereas patients whose immobile vocal fold sits near midline may have a perceptually near-normal conversational voice and complain only of mild increase in effort, vocal fatigue, or problems with loud projection. Because of their glottal insufficiency, patients may complain of “running out of air” with prolonged speech. Impaired glottal closure may also decrease airway protection during swallowing, so patients with vocal fold paralysis need to be questioned about aspiration as well. Whereas rehabilitation of poor voice may be elective, patients with increased aspiration risk need prompt therapy.

**Figure 2** Vocal fold paralysis prevents the right vocal fold from closing to midline and creates dysphonia.

Evaluation of vocal fold paralysis includes identification of the cause of paralysis. Surgical injury to the recurrent laryngeal nerve accounts for almost half of all cases of unilateral vocal fold paralysis, and cervical or thoracic neoplasm and idiopathic paralysis account for most of the remaining cases. In a patient without a clear surgical history explaining the paralysis, CT scanning from skull base to mediastinum can identify any possible lesions along the course of the recurrent laryngeal nerve. In those patients whose histories suggest other possible causes (e.g., central neurologic injury, Lyme disease), further investigations, such as magnetic resonance imaging of the brain or blood work may be indicated as well. Some physicians perform laryngeal electromyography to help with the prognosis of paralysis or to differentiate neurologic injury from cricoarytenoid joint fixation; however, this study is neither standardized nor routine in many practices. Although flexible laryngoscopy alone may be satisfactory to document vocal fold immobility, stroboscopy can be added to investigate the impact of glottal insufficiency on vocal cord vibration and possible vocal fold flutter.

Treatment of vocal fold paralysis might include any combination of voice therapy, injection laryngoplasty, transcervical medialization laryngoplasty, and laryngeal reinnervation. Depending on the cause of the paralysis, some patients experience gradual recovery with synkinetic reinnervation or recovery of purposeful vocal fold motion over a period of several months. Based on the degree of voice and swallowing handicap, treatment of patients with vocal fold paralysis may be optional rather than necessary. Voice therapy can help teach patients to produce a stronger voice despite the paralysis, but by itself will not help a paralyzed vocal cord to recover motion. Various medialization techniques have been developed to help reposition an immobile vocal fold in the midline, where the contralateral mobile vocal fold can provide for complete glottal closure and lead to improved voice and swallowing. Injection medialization can be performed in the office or in the operating room, with temporary or permanent materials; if recovery of vocal fold motion is thought possible, then temporary injection is preferred. Transcervical medialization is a permanent but reversible surgical technique performed by otolaryngologists that repositions an immobile vocal fold in the midline. Laryngeal reinnervation offers the possibility of midline positioning of the immobile vocal fold with restored tone and bulk of the vocal fold musculature; however, because results may not mature for several months, this technique is less commonly performed than either injection or transcervical medialization.

### Phonotraumatic Lesions: Nodules, Polyps, and Cysts

During vibration, vocal folds are subject to the shearing stresses of vibration. Although vocal fold structure is designed to accommodate these stresses in most circumstances, patients with vocal abuse or excessive voice use are at risk for development of lesions as the result of cumulative phonotrauma. Depending on the location and nature of these lesions, they are categorized as nodules, polyps, or cysts.

**Figure 3** A large right hemorrhagic polyp, which can impair vocal fold vibration.

**Figure 4** Symmetrical polypoid degeneration of the bilateral vocal folds, characteristic of Reinke's edema.

Vocal fold nodules are areas of fibrovascular scarring that are located just beneath the epithelium, at the level of the basement membrane and superficial lamina propria. They are typically bilateral and symmetrical, sitting at the junction of the anterior one third and the posterior two thirds of each vocal fold. Polyps are typically unilateral lesions that may be edematous or fibrous in nature and may contain hemorrhage (Figure 3). They usually are exophytic and extend outward from the vocal fold epithelium, although the fibrous base of a polyp may extend into the superficial lamina propria of a vocal fold. In contrast to an epithelial-based lesion such as a polyp, a vocal fold cyst is a subepithelial encapsulated lesion that sits entirely within the vocal fold; its size may exert a mass effect that deforms the medial edge of the involved vocal fold. These cysts are occasionally noted as congenital lesions in children, but in adults they are more often caused by traumatic occlusion of the ducts of the seromucinous glands within the larynx.

Nodules, polyps, and cysts cause dysphonia by disturbing vocal fold vibration, leading to rough voice quality. These lesions get larger as traumatic voice use accumulates, and vocal roughness usually becomes more severe and more constant as the lesions progress. Because vibration is more easily disturbed at high pitch, performers with these lesions may notice that high pitch is affected first. Effort of phonation often increases, but projection remains intact. Lesions large enough to limit vocal fold closure may also cause a slightly breathy voice quality. Because patients with excessive voice use are at risk for these lesions, a history of social and occupational voice demands is valuable in cases of suspected phonotrauma.

Treatment for these lesions always begins with voice therapy designed to modify the patient's voice use so as to diminish trauma. Voice therapy may be all that is necessary to allow resolution of some early traumatic changes, particularly in the case of edematous nodules. If dysphonia persists despite voice therapy and other conservative measures, surgery may be considered. Surgery with the goal of voice preservation and restoration (phonosurgery) is typically performed by otolaryngologists who specialize in the care of persons with vocal difficulties. The goal of phonosurgery for these lesions is to remove the lesion that impairs vibration while preserving as much of the remaining, pliable superficial lamina propria as possible, so that vocal fold vibration can be restored.

### Reinke's Edema

Reinke's edema, also known as polypoid corditis, is a benign swelling of the vocal folds that is most commonly seen in patients with a long-term smoking history. The edema, a reaction to long-term irritation, accumulates within the superficial lamina propria. The edema is most often bilateral and occurs diffusely along the entire length of the vocal fold, rather than being limited to a more discrete area, as is seen with phonotraumatic polyps (Figure 4). As vocal fold mass increases with disease progression, the pitch

of the voice decreases, and this is the change in voice most associated with Reinke's edema. A classic presentation of this condition is a female in her fifth or sixth decade of life who provides a long history of smoking and progressive deepening of her voice. In rare circumstances, the vocal folds gradually accumulate enough edema to compromise the airway, so breathing complaints should be evaluated as well.

Because a significant smoking history is also a risk factor for vocal fold leukoplakia and malignancy, good visualization of the vocal folds is necessary to evaluate for other lesions in these patients. If benign edema of the vocal folds is truly the only lesion noted, management depends on the degree to which voice quality is disturbing to the patient or the degree to which the airway is narrowed. Smoking cessation can lead to stabilization of pitch at its current level, and phonosurgery to remove excess vocal fold mass can help lead to normalization of pitch and improve the airway. Phonosurgery may be performed with cold instruments or with the pulsed photoangiolytic lasers, an emerging therapy; in either case, there is a risk of creating a vocal fold scar that might limit vocal fold vibration even as vocal fold contours are improved.

### Recurrent Respiratory Papillomatosis

Recurrent respiratory papillomatosis (Figure 5) is a benign laryngeal neoplasm that is caused by the human papilloma virus. It is the most common source of hoarseness in children, although adults also may be affected. As the lesions grow on the laryngeal epithelium, they create hoarseness and sometimes effortful voice by disrupting vocal fold vibration, particularly if the lesions are located along the medial edge of either vocal fold. Large and bulky lesions may lead to airway compromise, and advanced disease may spread throughout the mucosa of the upper aerodigestive tract rather than being limited to the larynx. Although accurate diagnosis depends on histopathologic analysis, a diagnosis of benign papilloma can be suspected from the characteristic appearance of the vascular fronds, which can be seen under magnified visualization in the office or in the operating room.

Treatment of recurrent respiratory papillomatosis is surgery, which is performed with a carbon dioxide laser, microdebrider, cold instruments, or the emerging technology of pulsed potassium titanyl phosphate (KTP) laser. As its name implies, the condition is recurrent: Even though surgery may reduce or remove the papilloma temporarily, the tissue continues to harbor the papilloma virus, and the disease usually grows back. Because repeated surgeries are expected, the goal of any single procedure is to remove as much disease as possible while limiting surgical scarring of the vocal folds. Scarring created as a result of surgery is cumulative, and over time patients develop persistent dysphonia caused as much by repeated surgeries as by recurrence of the disease. An ability to treat epithelial lesions while limiting scarring at the level of the superficial lamina propria is one main advantage of pulsed laser photoangiolytic; that these pulsed laser procedures can be

**Figure 5** Recurrent respiratory papillomatosis, whose presence along each vocal fold medial edge disrupts sound production.

performed in the office as well as the operating room is another. To help limit the need for repeated surgical procedures, adjunct medical therapies such as interferon and cidofovir are sometimes used for treatment of advanced disease.

### Vocal Cord Cancer

In 2008, an estimated 12,250 new cases of laryngeal cancer and 3,670 deaths attributable to laryngeal cancer occurred in the United States. The annual incidence of laryngeal cancer is 6.4 cases per 100,000 for men and 1.3 cases per 100,000 for women. Smoking is the single largest risk factor for laryngeal cancer, and excessive alcohol use has a synergistic effect as a risk factor as well. Survival rates for laryngeal cancer depend on the stage of the tumor at the time of diagnosis, which is a function of tumor size and possible tumor spread to the cervical lymph nodes or distant metastatic sites. Cancers that occur on the medial edge of the vocal fold produce dysphonia while still small, and many laryngeal cancers are diagnosed early.

The dysphonia associated with laryngeal cancer is constant, progressive, and unremitting, without the intermittent vocal improvement that may occur in inflammatory conditions. The presence of dysphagia, odynophagia, otalgia, hemoptysis, or unexplained weight loss further increases the index of suspicion for malignancy. Cervical lymphadenopathy is associated with advanced tumors. Diagnosis may be suspected on the basis of laryngeal examination and is confirmed with biopsy. The presence or absence of mucosal waves on the involved vocal fold on videostroboscopic examination can help predict the depth of the lesion. Both a CT scan of the neck and chest radiographs are indicated to assess for tumor size and spread. Early cancers are treated with surgery or radiation therapy, with similar cure rates. Emerging technologies such as pulsed photoangiolytic lasers may allow for surgical treatment of early disease with better preservation of surrounding normal tissue. More advanced tumors are usually treated with a combination of radiation therapy and surgery or chemotherapy.

Leukoplakia, or a raised white plaque on the epithelial surface, is a visual marker for the likely presence of dysplasia or carcinoma in situ. As a very early lesion, vocal fold leukoplakia may manifest with mild dysphonia or may be found incidentally on head and neck examination performed for other reasons. This early disease may take many years before progressing to invasive carcinoma, and recognition of leukoplakia presents an opportunity for early treatment to prevent progression of disease. Pulsed laser photoangiolysis has emerged as a state-of-the-art therapy for treatment of this epithelial lesion with preservation of the underlying vocal fold pliability.

### Neurologic Disorders and the Voice

Neurologic conditions that affect the voice usually do so by causing poor coordination of vocal fold motion. Spasmodic

dysphonia, for instance, leads to involuntary spasms that bring the vocal folds either tightly together (adductor spasmodic dysphonia) or apart (abductor spasmodic dysphonia) during phonation. These spasms lead to vocal breaks that are strained or breathy, respectively. Although the cause of spasmodic dysphonia is thought to lie within the central nervous system, the gold standard treatment of botulinum toxin is targeted at the end organ. Injection of botulinum toxin (Botox)<sup>1</sup> into appropriate laryngeal muscles can weaken these muscles and diminish the spasm.

Vocal fold tremor is a neurologic disorder that is distinct from spasmodic dysphonia. Its hallmark is tremulous voice quality caused by tremor of the larynx, which may occur both during phonation and at rest. Vocal fold tremor may exist alone or as part of systemic tremor. Botulinum toxin<sup>1</sup> can decrease the amplitude of the tremor but may exacerbate the loss of projection that many tremor patients also have as a complaint. Medications such as anxiolytics or  $\beta$ -blockers that are used to treat systemic tremor may also improve the voice in patients with vocal fold tremor without worsening hypophonia.

### Functional Voice Disorders

Functional dysphonia may exist by itself or in combination with an anatomic or neurologic source of dysphonia. The most common form of functional voice disorder is muscle tension dysphonia, which describes inappropriate hyperfunction of the supraglottic muscles. This hyperfunction often occurs in response to another source of hoarseness, as the patient tries to force out a strained voice with improved projection rather than accept the limited voice quality that may accompany the other disorder. The hyperfunction may then become an entrenched habit separate from the original pathology. In this sense, a classic scenario for muscle tension dysphonia is a patient who strains to speak more loudly during an acute laryngitis episode and whose strained, squeezed voice pattern persists even after the acute laryngitis has resolved. Patients with muscle tension dysphonia may complain of odynophonia as tension in the involved supraglottic muscles leads to muscular pain with prolonged speaking. Once other lesions have been evaluated, the treatment of muscle tension dysphonia is expert voice therapy with an emphasis on decreased hyperfunction.

### Presbylaryngis

Presbylaryngis is the term that is used to describe the aging voice. It typically manifests in the seventh or eighth decade but can develop earlier. Acoustically, presbylaryngis results in a characteristic thinned voice, often with decreased projection and increased vocal strain. The condition occurs as cumulative voice use leads to traumatic thinning of the superficial lamina propria, particularly at the mid-cord level. This loss of superficial lamina propria leads to deficiency at the medial edge of each vocal fold, and a spindle-shaped defect in glottal closure may be noticed with close evaluation. Many patients with a complaint of presbylaryngis find that appropriate voice therapy to address breath support and vocal projection leads to satisfactory improvement in the voice without altering the vocal fold anatomy. For those patients who remain unsatisfied with their voice after therapy, vocal fold medialization procedures can restore straight vocal cord edges and may lead to improved projection; however, currently available injectables and implants that address contour defects cannot restore pliability.

### Conclusion

Understanding the anatomy and physiology of normal voice production provides a framework through which dysphonia can be evaluated. Application of this knowledge during the history and physical examination guides the diagnosis of hoarseness and allows clinicians to distinguish among conditions

<sup>1</sup>Not FDA approved for this indication

as varied as acute laryngitis, benign phonotraumatic lesions, vocal fold paralysis, and laryngeal cancer as part of a differential diagnosis. Videostrobolaryngoscopy allows evaluation of vocal fold function as well as structure and can confirm diagnosis. As with any condition, accurate diagnosis directs appropriate therapy. Because no further evaluation or management is necessary for acute viral laryngitis, many patients with hoarseness require no more than a careful history and physical examination. However, if dysphonia persists for longer than 2 weeks or is accompanied by other laryngopharyngeal symptoms that are not thought to be related to an upper respiratory tract infection, referral should be made to an otolaryngologist for further evaluation.

## LEG EDEMA AND VENOUS STASIS

Method of

David D. Ortiz, MD

### CURRENT DIAGNOSIS

- Chronic, lower extremity pitting edema due to increased venous pressure
- Usually bilateral; can be unilateral and asymmetric
- Must be differentiated from congestive heart failure, edema due to hypoproteinemia from hepatic or renal disease, lymphedema, cellulitis, deep venous thrombosis (DVT) and lipedema

### CURRENT THERAPY

- Compression stockings and walking exercises
- Horse chestnut seed extract<sup>7</sup> 600 mg daily to reduce venous stasis symptoms
- Topical emollients and short courses of topical steroids for stasis dermatitis
- Compression bandages, noncompression bandages with zinc oxide paste (Unna boot), and pentoxifylline<sup>1</sup> 400 mg three times daily for venous ulcers
- Surgical treatment (sclerotherapy, stripping and ligation, endovenous ablation) for saphenous vein incompetence, nonhealing venous ulcers, and more severe disease

<sup>7</sup>Available as dietary supplement.

<sup>1</sup>Not FDA approved for this indication.

## Pathophysiology

The clinical manifestations of venous stasis in the lower extremities are caused by venous hypertension, which is a result of venous valve reflux, venous obstruction, or both. Normally, the combination of functioning venous valves and lower extremity skeletal muscle contraction causes a decrease in venous pressure throughout the venous system. In patients with nonfunctioning or incompetent venous valves, venous reflux occurs, transmitting higher venous pressure to the superficial veins and to the skin microcirculation. This produces edema due to leakage caused by increased hydrostatic pressure, stasis dermatitis, and staining of the skin resulting from hemosiderin deposition. The fluid leakage and increased venous pressure on the vascular endothelium leads to inflammatory mediator release into the surrounding tissue, which can lead to venous wall and valvular damage, remodeling, and valve incompetence.

## Prevention

Risk factors for chronic venous disease include advancing age, family history, sedentary lifestyle, prolonged standing, smoking, high estrogen states, pregnancy, obesity, lower extremity trauma, and a history of venous thrombosis (postthrombotic syndrome). Therefore an active lifestyle, smoking cessation, maintaining a normal body-mass index, and reducing the risk of venous thrombosis (following evidence-based guidelines) during travel, hospitalization, surgery, and hormonal treatment can reduce the probability of developing chronic venous disease. For patients who have been diagnosed and treated for DVT, the use of compression stockings reduces the risk of developing postthrombotic syndrome.

## Clinical Manifestations

The clinical manifestation of venous stasis in the lower extremities include discomfort, swelling, varicose veins, skin changes, nocturnal cramps, and ulceration. Leg edema seen in venous stasis is usually pitting, begins at the ankle and ascends into the legs, worsens with prolonged standing, and is relieved by leg elevation. Varicose veins are dilated, bulging superficial veins that may be asymptomatic, though patients are usually concerned about their cosmetic appearance. The skin changes seen in venous stasis are skin hyperpigmentation caused by hemosiderin deposition, stasis dermatitis, and venous ulceration.

Stasis dermatitis is characterized by irritated reddish-brown colored skin on the ankles and lower legs. Plaques, fissures, and ulcers may be present. Symptoms may include itching and pain. Stasis dermatitis may be confused with cellulitis and a number of other dermatologic conditions, and cellulitis and secondary infection may be a complication.

## Diagnosis

A comprehensive history and physical examination should be performed to evaluate for other causes of leg edema. The history should include questions about chronic diseases, medications, personal and family history of clotting disorders, previous surgeries, trauma, and any history of malignancy and/or radiation treatment. Acute (<72 hours) swelling is characteristic of DVT, infections, or trauma, while chronic swelling is more likely a result of venous insufficiency or chronic medical conditions. Bilateral leg edema may be caused by congestive heart failure, hypoalbuminemia (either from renal losses or hepatic disease), myxedema from hypothyroidism, bilateral venous insufficiency, or pulmonary hypertension. Unilateral swelling is more suggestive of primary or secondary venous or lymphatic compromise. Chronic venous disease can present as both unilateral or bilateral leg edema, and it may be symmetric or asymmetric. Leg edema may also be caused by medications, such as calcium-channel blockers. The physical examination should include an evaluation of the heart, lungs, and abdomen.

for signs of heart failure (jugular-venous distention and lung crackles) and evidence of liver disease (ascites, scleral icterus) as well as a detailed examination of the lower extremities. Localized swelling of the calf may indicate DVT, infection, or trauma, while diffuse swelling is more likely a result of a systemic process. Lipedema (fat deposition that causes nonpitting leg edema) can be differentiated from other cases of leg edema because it does not involve the feet. Lymphedema resulting from lymphatic fluid buildup can be diagnosed by a positive Stemmer sign, which is the inability of the examiner to pinch the skin of the dorsum of the foot. Skin changes such as dryness, ulcers, erythema, and warmth should be noted. Pitting, the indentation remaining in the swollen area after pressure is applied, should be documented.

A thorough pulse examination of the lower extremities should be performed. In patients with signs and/or symptoms of peripheral artery disease (PAD) and in patients with venous ulcers, the ankle-brachial index (ABI) should be measured.

If an obvious cause is not found on the initial physical examination, diagnostic testing can be helpful to elicit the underlying diagnosis or to confirm a suspected diagnosis and guide treatment. A complete blood count and an evaluation of hepatic enzymes, renal function, thyroid function, albumin level, brain natriuretic peptide (in suspected heart failure), and albuminuria/proteinuria should be performed. A D-dimer level can be helpful in ruling out DVT in the appropriate clinical context. If congestive heart failure or pulmonary hypertension is suspected, an echocardiogram should be performed, and in patients with signs or symptoms of sleep apnea, a polysomnogram should be performed as well. In patients with lower limb swelling without a clear etiology, duplex ultrasonography is the imaging modality of choice to assess for vascular and nonvascular causes of leg edema. If ultrasonography does not reveal a cause and a vascular etiology is still suspected, magnetic resonance angiography (MRA) or computed tomography angiography (CTA) should be considered.

### Therapy (or Treatment)

Conservative management should be the initial treatment for patients diagnosed with venous stasis. Weight reduction, exercise, and smoking cessation should be encouraged. Compression stockings with graduated compression along with walking exercise are the mainstay of conservative management. Stockings with compression pressures of 20 to 30 mm Hg are recommended for patients with mild to moderate disease. Higher-pressure stockings (30 to 40 mm Hg and 40 to 50 mm Hg) are recommended for patients with more severe disease and venous ulcers. Knee-length stockings are better tolerated by most patients than thigh-length stockings, and the former should be recommended as first-line treatment as studies have not shown any difference in outcomes between thigh-length and knee-length stockings.

Horse chestnut seed extract (escin),<sup>7</sup> at a dose of 300 mg once or twice daily (equivalent to 50 to 100 mg of escin daily) has been shown to improve the symptoms of venous stasis. Phlebotonics, such as diosmin,<sup>7</sup> calcium dobesilate,<sup>2</sup> and rutosides,<sup>7</sup> may reduce the edema in venous stasis but do not appear to improve ulcer healing or quality-of-life measures in patients with venous stasis.

For patients with saphenous vein incompetence, more severe disease, or persistent symptoms despite conservative management, referral for surgical treatment should be considered.

Sclerotherapy, ligation, stripping of the veins, and endovenous ablation may improve cosmetic symptoms and promote venous ulcer healing in patients in whom first-line therapy has not been effective.

### Monitoring

In patients with a history of venous ulceration, regular follow-up is recommended to monitor for ulcer recurrence, promote continued lifestyle modifications, provide patient education, and ensure treatment compliance. Cardiovascular risk factors should be monitored and treated according to current guidelines.

### Complications

In chronic venous disease, the most common complications are stasis dermatitis and venous ulcerations. For venous ulcers, compression bandages using higher pressures (40 mm Hg) and nonelastic compression bandages using a zinc oxide paste (Unna boot) have been shown to improve ulcer healing rates. Silver-based dressings may also be more effective than other types of dressings for the healing of venous ulcers. Pentoxifylline<sup>1</sup> 400 mg three times daily, used along with compression, improves ulcer healing rates. Simvastatin (Zocor, generic)<sup>1</sup> 40 mg once daily, in addition to standard therapy, has also been shown to improve ulcer healing rates.

Stasis dermatitis may be treated with skin emollients and short courses of topical steroids. Topical antibiotics are not indicated for stasis dermatitis unless there is evidence of infection.

<sup>2</sup>Not available in the United States.

<sup>7</sup>Available as dietary supplement.

<sup>1</sup>Not FDA approved for this indication.

## CURRENT DIAGNOSIS

- Always use history and physical examination and consider imaging or laboratory studies to rule out life- or function-threatening pathologies before merely providing symptomatic treatment.

### Acute Pain

- Acute pain has a sudden onset, is usually nociceptive (somatic, visceral) in nature, and likely is due to apparent injury or medical condition.
- It can last up to 3 months and can demonstrate hypersympathetic signs of tachycardia, elevated blood pressure, dilated pupils, or diaphoresis.

### Chronic Pain

- Chronic pain is usually gradual in onset, lasts more than 3 months, and rarely serves any purpose. It can manifest with hyperalgesia (hurts more than it should) or allodynia (hurts when it should not, e.g., light touch).
- Vegetative symptoms such as depression, fatigue, or anorexia may be present.
- A significant neuropathic component may be present.
- Psychiatric and social or socioeconomic issues may be exacerbating factors.
- Examples can include headaches, low back pain, osteoarthritis, and fibromyalgia.
- While opioids might be appropriate for some conditions or situations, in general, they are proving to be neither as safe nor as effective for chronic, non-cancer pain as had been believed.

### Quality

- Quality of the pain (e.g., sharp, dull, radiating, deep, superficial, lancinating, tingling, burning) is an important factor in determining the best management modalities.
- Quality plays a role in ruling in or ruling out severe disease that can require urgent surgical or other interventions rather than analgesics or adjunctive medications or therapies.

### Severity

- Severity of the pain can be rated on a variety of scales such as numerical (0 to 5, 0 to 10), analogue (marked on a line with a range from no pain to the worst possible pain), or facial expression (smiles to grimaces, available for children and the elderly or patients with dementia).
- Functional scales (fully satisfactory function to debilitated) may be more helpful in determining the impact of the pain on the person's life.

## CURRENT THERAPY

- Acute pain commonly responds to simple analgesics of the nonopioid, opioid, or combination varieties. Rest, ice, compression, and elevation (RICE) are helpful for acute inflammatory conditions and injuries.
- Chronic pain, because of its complexity, often requires multiple modalities. Pharmacologic options include nonopioid, opioid, adjuvant, or botanical medications. Nonpharmacologic options include physical therapy, chiropractic care, transcutaneous electrical nerve stimulation (TENS) unit, acupuncture, or surgical or anesthesia interventions.
- Adjuvant medications are drugs that are used for pain but do not have pain treatment as their primary indication, and they are often the most effective agents in neuropathic and/or chronic pain.

- Opioids are sometimes safer for long-term use, but the individual's risk for falls must be considered in the elderly, as opioids can increase this risk, and the risks of overdose and other adverse effects rise with increasing age and duration of exposure. For many chronic conditions such as low back pain, the evidence supporting the use of opioids is lacking, with efficacy often superseded by nonopioid medications. The risk of addiction **MUST** be considered before starting opioids on any patient. From 1999 to 2017, overdose death rates have increased from 8.2 to 29.1/100,000 in males and from 3.9 to 14.4 in females; 67.8% of the 70,237 drug overdose deaths in 2017 involved opioids, and the rates were highest in the 25 to 54-year-old age range. According to the CDC, nearly 2 million Americans above the age of 12 years abused or were dependent on opioids in 2014.
- Nonsteroidal antiinflammatory drugs (NSAIDs) carry a risk for GI and cardiac complications, especially in the elderly and those with a history of CAD or GI ulcers or gastritis.
- The patient **must** be involved in and cooperative with the treatment plan. Honesty and trust are necessary components of a therapeutic physician-patient relationship.
- Do not underestimate the placebo effect. If the patient feels that a harmless treatment is beneficial, take advantage of it.
- If the patient is not improving adequately, consult a surgeon if the source of pain is an operable condition, or consult a pain specialist if surgical intervention is not appropriate.

## Epidemiology

Although estimates vary, approximately 50 million Americans experience chronic pain and incur costs and overall economic impact is estimated as high as \$635 billion per year. Pain is the most common symptom that causes patients to pursue medical evaluation and management. The prevalence of several common pain syndromes including headaches, facial pain, abdominal pain, pelvic pain, and low back pain is slightly higher in women than in men because there are gender variations in the perception, coping, and reporting of pain. Pain tends to be undertreated in women, people of color, children, and the elderly, and it is underreported in nonverbal or cognitively impaired children and adults.

## Risk Factors

Traumatic injury is a cause of acute pain and a risk factor for chronic pain. Patients who have mastectomy, laminectomy, thoracotomy, or amputations are at risk for pain syndromes. Chronic musculoskeletal conditions such as arthritis, spinal stenosis, degenerative disk disease, or fibromyalgia; infectious diseases including HIV or varicella zoster; neuropathies from diagnoses such as diabetes, B<sub>12</sub> deficiency, or multiple sclerosis; treatment with certain chemotherapies or isoniazid (INH) without adequate vitamin B<sub>6</sub>; psychiatric disorders such as depression, anxiety, or posttraumatic stress disorder (PTSD), especially as a consequence of domestic violence; or autoimmune disorders including lupus and rheumatoid arthritis can predispose the individual to chronic pain. Although the risk of pain increases with age, pain should not be considered a usual part of aging until it is appropriately evaluated. A motor vehicle accident or work-related injury or other condition where secondary gain is a possibility, especially if there is no apparent injury, raises the consideration of malingering.

## Pathophysiology

Injury or potential injury is detected by nociceptors in the peripheral nervous system, and the signal is then transmitted through the dorsal horn of the spinal cord up to the brain for processing. The three primary classes of opioid receptors are the mu, kappa, and delta receptors, which are located in areas throughout the

central and peripheral nervous system. Upon binding these receptors, opioids block calcium channels and modulate the nociceptive pathways. The hyperstimulation of chronic pain (often via the N-methyl-D-aspartate [NMDA] receptor and the resultant increase in intracellular calcium are neurotoxic due to lowering the neuronal firing threshold and increasing firing frequency. This neurotoxicity can lead to ongoing pain in the absence of physical insult. Additionally, NMDA receptor activation can increase pre- and post-synaptic substance P while downregulating the mu receptors. This can decrease the efficacy of mu-agonists, as there are fewer receptors to bind. Neuropathic pain can result from chronic pain or from physical or pathophysiologic injury or changes to the nerve, as in diabetic neuropathy or other neuropathies.

### Prevention

The best prevention is a safe and healthy lifestyle. The combination of healthy diet and exercise has been demonstrated to improve pain in osteoarthritis better than either intervention alone, and maintaining a healthy weight can help prevent the arthritis in the first place. Smoking and obesity (odds ratio increasing with BMI) have been associated with chronic pain. Relative to people of normal weight, rates of recurring pain were 20% higher in the overweight, 68% greater with class I obesity, 136% more in class II obesity, and 254% more in the morbidly obese.

Regarding safety, wearing seat belts while driving or using appropriate safety equipment at work and during recreational activities can help reduce the severity of injuries should they occur. Proper body mechanics are important as well.

### Clinical Manifestations

Manifestations of pain depend on the location and underlying cause. In the acute setting, the patient can have tachycardia, elevated blood pressure, or diaphoresis, whereas chronic pain can manifest with vegetative symptoms of depression, fatigue, anorexia, or insomnia.

### Diagnosis

Pain is most commonly a symptom rather than a disease in and of itself, so it behooves the provider to pursue treatable causes, especially red flag conditions, in addition to providing symptomatic treatment. The history regarding onset (shorter or longer than 3 months), exacerbating or remitting factors, quality, radiation, severity, and timing of the pain (constant versus intermittent), in addition to any associated signs or symptoms such as fever, nausea, vomiting, or diarrhea, can help the provider in that regard. The physical examination is a key component in ruling out life- or function-threatening disorders. Is there tenderness, swelling, bruising, erythema, or deformity? Are strength, reflexes, and sensation intact? Does the patient demonstrate a consistent demeanor (grimace or other signs of pain) and gait (antalgic versus normal) when moving from the waiting area to the examination room and out to the parking lot? The choice to use laboratory studies or imaging is determined by the location of the pain and the structures or organs that might be in that area. When determining severity, "What does the pain keep you from doing?" (which uses function as the measure of impairment and treatment efficacy rather than a subjective pain score to guide therapy) may be a much more helpful question than "How bad is your pain?" If function is not improving, that could be considered a treatment failure, and medications and therapy should be adjusted rather than continuing the same regimen.

### Differential Diagnosis

The differential diagnosis for all types of pain is far too extensive for the brevity of this chapter, but in addition to the plethora of physical diagnoses to be considered, the provider must consider that chronic fatigue, depression, and domestic abuse can manifest as a chronic pain syndrome.

## Treatment

### Nonpharmacologic

Physical therapy for chronic pain (for recent-onset low back pain, relief was statistically but not clinically significant as compared to usual care), TENS units, chiropractic care, and regular exercise have shown benefit in certain conditions. Cognitive behavioral therapy (CBT) and mindfulness training improve function more than pain, and CBT, acupuncture, and mind-body therapies (e.g., yoga, tai chi, mindfulness-based stress reduction) provide safer options that may be both beneficial and cost-effective. Surgery may be required, and interventions such as nerve blocks or epidural injections may also be of benefit. Kyphoplasty and vertebroplasty have fallen out of favor. Aerobic exercise and water therapy are helpful for fibromyalgia, but the patient must not overexert because this can exacerbate the pain.

### Pharmacologic

#### Nonopioid Analgesics

Acetaminophen (Tylenol) is generally a safe and effective medication provided the total daily dose for adults remains less than 3 g/day. For osteoarthritis of the hips and knees, acetaminophen provides modest short-term benefit, and it is not generally effective for the management of low back pain. However, due to its relative safety as compared to other medications, it is certainly worth a try. Chronic use can increase the likelihood of transaminase elevations 4-fold, so this is a consideration when patients are using other potentially hepatotoxic medications. There is an IV preparation available (Ofirmev), but the only benefit of the IV over the oral preparations is shorter onset of action. Both the absorption and the action of acetaminophen are augmented by caffeine, so caffeine is utilized in multiple over the counter (OTC) and prescription medications (e.g., Excedrin or Fioricet).

Numerous NSAIDs are available, but none has been shown to be superior to another except for the convenience of dosing daily versus every 6 hours. All are generally safe in the acute setting but should be used with caution if needed long term, and they should be avoided altogether for long-term use in the elderly or patients with cardiovascular, renal, or peptic ulcer disease. This caution includes the cyclooxygenase (COX)-2-specific drugs. Naproxen seems to have the best cardiac profile while the COX-2 drugs tend to have the best GI profile. Misoprostol (Cytotec) or proton pump inhibitors can be used for GI prophylaxis.

Topical agents such as diclofenac (Flector 1.3% Patch, Voltaren 1% Gel), menthol, camphor, lidocaine, and capsaicin (Zostrix Cream, Qutenza 8% Patch) are effective in some patients.

#### Opioids (Table 1)

For patients with inadequate response to the nonopioid analgesics, opioids are an option (see Table 1). However, the proven efficacy for cancer pain and palliative care as well as some acute pain conditions cannot be extrapolated to chronic pain syndromes. The benefits of opioids in some conditions (e.g., chronic low back pain), and the overall safety of opioids have been called into question due to the dramatic increase in opioid abuse and opioid overdose deaths. Recent research has demonstrated a 2- to 3-fold increase in all-cause mortality with chronic opioid use and up to 11-fold increase if using more than 200 mg/day morphine equivalent dose (MED) and/or sustained-release or long-acting (methadone) preparations. Additionally, risk of overdose death is increased to 3.7- to 4.6-fold at doses of 50 to 100 mg/day MED and as high as 9-fold increased risk for MED >100 mg/day as compared to MED of less than 20 mg/day. These risks are further escalated by co-administration of benzodiazepines or gabapentinoids. A prescription for naltrexone should be considered if the patient is using >50 mg MED per day, and it is highly recommended if using >100 mg MED per day. A useful calculator to calculate MED can be found at <http://www.agencymeddirectors.wa.gov/calculator/dosecalculator.htm>

According to the CDC, opioids were implicated in 71% of the pharmaceutical overdose deaths in 2013, and 60% were legally prescribed by a single provider. Opioids might be a safer option in the elderly as compared to NSAIDs, but they can increase fall risk. They should be avoided in patients with untreated sleep apnea because of increased risk for complications, especially in combination with benzodiazepines. This risk increases with age with as much as an eightfold increase for those older than 80 years of age. The risk of postoperative respiratory depression also increases with age. The risks of using chronic opioids likely outweigh the benefits in the management of headache, fibromyalgia, and chronic low back pain, according to a 2014 position paper from the American Academy of Neurology.

The risks and the adverse outcomes (abuse, addiction, overdose, and death) related to this class of medications culminated in the release of guidelines with twelve recommendations from the CDC in March 2016 for the prescribing of opioids for chronic pain. A brief summary of the author's recommendations: (1) Nonpharmacologic therapy and nonopioids are preferred for chronic pain. (2) Benefits of opioids on pain and function need to outweigh the risks. Screen for risk of dependence. (3) Establish treatment goals with the patient and discuss plan to discontinue opioids if treatment fails. (4) On initiation, use immediate release rather than ER/LA (extended release, long-acting) preparations. (5) Use the lowest effective dose, and reassess risks if dose is increased, especially if greater than 50 mg MED per day. (See [Table 1](#) for equivalent doses.) (6) Acute pain should be treated acutely; less than 3 days usually but no more than 7 days. (7) Reassess within 1 to 4 weeks of initiation of treatment or dose escalation and at least every 3 months thereafter. Discontinue if benefits do not justify risk. (8) Consider prescribing naloxone if there is concurrent benzodiazepine use, a history of overdose, or MED >50 mg/day. (9) Use state drug monitoring programs at initiation and at least every 3 months. (10) Obtain a urine drug screen at initiation and at least annually. Nothing but the prescribed medications should be present. (Additionally, consider testing periodically for the presence of prescribed NSAIDs and adjuvant medications to assess compliance with the whole treatment plan rather than just the opioid.) (11) Avoid concurrent with benzodiazepines. (12) Offer or arrange evidence-based treatment for patients with opioid use disorder.

The value of these guidelines was affirmed by several organizations; however, the levels of evidence did not necessarily substantiate the CDC's strength of recommendations. Since approval, some of these guidelines have been treated as "absolutes" by various states legislatures and third-party payers. Multiple unintended consequences of the resultant rapid-tapering of patients' dosages of opioids have come to light, including worsened mental health and increased risk of overdose and suicide. Additionally, some patients have suffered needlessly. As a result, the CDC is revising the guidelines, with the draft recommendations available for comment in the Federal Register until April 2022 and the final version possibly accessible at the end of 2022. Opioids have a role in pain management, and guidelines can be helpful in achieving the dual goal of safety and efficacy; however, guidelines must be used in the context of the individual patient.

In addition to these steps, multiple drugs have been formulated with "abuse-deterrent" properties. Preparations that meet the FDA's Guidance for Industry regarding abuse-deterrent opioids include: OxyContin (oxycodone), Targiniq ER<sup>2</sup> (oxycodone/naloxone), Embeda (morphine/naltrexone), Hysingla ER (hydrocodone), MorphaBond ER (morphine), Xtampza ER (oxycodone), and Arymo ER (morphine). Unfortunately, there are no generic opioids with FDA-approved abuse-deterrent labeling.

Tramadol (Ultram, ConZip) is a weak mu-agonist and an inhibitor of norepinephrine and serotonin uptake, a quality that

gives it a niche in the treatment of neuropathic and radicular pain.<sup>1</sup> It is the only opioid studied for fibromyalgia in a randomized trial. While it was found to be beneficial, this is likely due to its inhibition of serotonin and norepinephrine uptake rather than its weak mu-agonism. A study has demonstrated an increased risk for hypoglycemia, notably in the first 30 days of treatment with tramadol.

Codeine is a prodrug that must be converted to morphine to be effective, and about 10% of the population lacks the cytochrome P450 2D6 enzyme that makes the conversion, resulting in poor analgesic response. Owing to the need for conversion, doses exceeding 60 mg do not increase benefit because the enzyme system is saturated. Avoid prescribing codeine to children, as deaths have been reported, even with the use of age- and weight-appropriate dosages, as a result of the hypermetabolism of codeine to morphine.

Morphine is the prototype for the opioids. It is extremely versatile, it can be given via almost any route, and it is available in multiple dosages and preparations ranging from liquid to daily sustained release. Hydromorphone (Dilaudid, Exalgo) shares similar qualities but is more potent. Hydrocodone is only available in a sustained-release oral form (Zohydro ER, Hysingla ER), and in combination with acetaminophen (Norco). It was rescheduled by the DEA to schedule II in 2014. It had been the number-one prescribed medication in the United States for several years until the rescheduling, which led to >20% reduction in prescriptions and >16% reduction in tablets dispensed.

Methadone (Dolophine) is the longest acting of the opioids at a half-life of 23 hours, although the duration of action can be variable. It is active as an NMDA receptor antagonist, inhibits norepinephrine and serotonin uptake, and is an agonist at the mu receptor. Therefore, methadone can be effective when other opioids fail, especially in the case of chronic or neuropathic pain, where the NMDA receptor is more of a factor in pain control. It must be used with caution ([Table 2](#)) because it can prolong the QT interval and has an increased dose-dependent risk of respiratory depression as compared to other opioids.

Meperidine (Demerol) is relatively weak compared to morphine and others, and it is limited by poor oral bioavailability, a 48-hour acute pain indication, and the neurotoxicity of one of its metabolites, normeperidine (renally cleared, so it is contraindicated in renal patients). Other opioids are safer and more effective, so its use should be limited.

The mu agonists, other than codeine, meperidine, and tramadol, do not technically have a ceiling dose; however, the dose should be limited to the lowest effective dose (ideally <50 mg morphine equivalents per day), keeping in mind the possible adverse effects and increased risk of death with higher doses. In a 2020 study in the journal *Pain*, opioid dose escalation was not associated with improvements in chronic musculoskeletal pain. In the purely palliative or hospice patient, the dosage may be titrated to effect until the pain is relieved or side effects limit the dosage.

The mixed agonist-antagonists such as nalbuphine (Nubain), pentazocine (Talwin), and butorphanol (Stadol) tend to have a higher incidence of hallucination and confusion, and because they are agonists at kappa and delta receptors and antagonists at the mu receptor, they can produce withdrawal symptoms in patients who are routinely taking mu agonists. The partial agonist buprenorphine (Butrans patch, Subutex, Buprenex) is dose limited because it has a maximal effective dose as well as a potential to cause QT prolongation.

Patients who are taking opioids on a chronic basis should use a stimulant laxative such as senna with or without docusate, because fiber and dietary modification are usually inadequate for opioid-induced constipation, and fiber can aggravate the problem. Lubiprostone (Amitiza) can be used for opioid-induced constipation at the 24 mcg twice-daily dose. Naloxegol (Movantik),

<sup>2</sup>Not available in the United States.

<sup>1</sup>Not FDA approved for this indication.

**TABLE 1** Opioid Analgesics, Equianalgesic Table

OPIOID	ADMINISTRATION		PROPERTIES
	PARENTERAL	ORAL	
<b>Buprenorphine</b>			
Butrans transdermal patch: 5, 7.5, 10, 15, 20 µg/h weekly patches Subutex* SL tab and film: 2, 8 mg Belbuca buccal strip: 75, 150, 300, 450, 600, 750, 900 µg per strip, dosed every 12 to 24 hours (see detailed prescribing instructions) Buprenex injection: 0.3 mg/mL	0.3 mg (IV) Patch: MED <30 mg/day = 5 µg/h patch 30–80 mg/day = 10 µg/h patch; >80 mg/day: do not use	Oral buprenorphine, with or without naloxone (Suboxone, Subutex) and long-acting injection (Sublocade) are limited to treatment of opiate addiction  Requires training, approval, and new DEA number	Partial agonist Can cause QT prolongation C-III FDA warning regarding dental problems with the SL tabs, films, patches.
<b>Codeine</b>			
Tablet: 15, 30, 60 mg Oral solution: 15 mg/5 mL	130 mg	180 mg	Prodrug converted by liver to morphine About 10% of population cannot convert, and some are rapid metabolizers, resulting in increased levels of morphine Ceiling dose is 60 mg/dose
<b>Fentanyl</b>			
Duragesic 72 h patch: 12, 25, 37.5, 50, 62.5, 75, 87.5, 100 µg/h	~100 µg/h	—	Patch for those who cannot swallow Patient <i>must</i> have subcutaneous fat, because drug is lipophilic
Actiq or Oralet lozenge: 200, 400, 600, 800, 1200, 1600 µg Fentora buccal tab or Abstral SL tab: 100, 200, 300, 400, 600, 800 µg Subsys sublingual spray: 100, 200, 400, 600, 800 µg/spray. Lazanda nasal: 100, 300, 400 mcg/spray. Fentanyl injection: 50 mcg/mL.	No conversion for lozenges or buccal tabs; various formulations are not bioequivalent, so use caution when switching from one formulation to another; <i>must</i> start at lowest dose and titrate	~½ × daily morphine dose, disregarding units, e.g., 200 mg morphine PO/day = 100 µg/h patch	Lozenge or buccal tab for transmucosal use No cheap forms available Buccal formulations <i>only</i> indicated for breakthrough cancer pain in the opioid tolerant; can be rapidly fatal in opioid naïve patients.
<b>Hydrocodone</b>			
Tab: 2.5, 5, 7.5, 10 mg with a max of 325 mg APAP per tablet (Norco) or with 200 mg ibuprofen (Vicoprofen 7.5/200; Ibudone 5/200, 10/200; Reprexain 2.5/200, 5/200, 10/200); Zohydro ER: 10, 15, 20, 30, 40, 50 mg/cap q 12 h; Hysingla ER: 20, 30, 40, 60, 80, 100, 120 mg tabs q 24 h; Solution: with APAP 7.5/325, 10/325 per 15 mL.	N/A	20 mg	C-II as of 2014, so refills and phone orders are no longer allowed. Metabolized to hydromorphone and others
<b>Hydromorphone (Dilaudid)</b>			
Tab: 2, 4, 8 mg Liquid: 1 mg/mL Suppository: 3 mg SR† 24-h tab (Exalgo): 8, 12, 16, 32 mg Injection: 1, 2, 4, 10 mg/mL pre-filled syringes and 1, 2, 4 mg/mL vials.	1.5 mg	7.5 mg	Good alternative to morphine, especially if using SC by continuous infusion (>20 mg/h) Active glucuronide metabolites
<b>Meperidine (Demerol)</b>			
Tab: 50, 100 mg Syrup: 50 mg/5 mL	100 mg	300 mg	Indicated for <i>acute</i> use <i>only</i> (i.e., <48 h) Contraindicated with MAOI and/or renal disease: neurotoxic metabolite normeperidine can cause seizures and death
<b>Methadone (Dolophine)</b>			
Tab: 5, 10, 40 mg Oral liquid: 1, 2, 10 mg/mL* 40 mg dispersible tab (Methadose)—restricted use in United States, mostly for detox or addiction maintenance dosing		Variable conversion ratios (see Table 2): converted by oral morphine equivalent dose	At least 3 mechanisms: mu agonist, NMDA receptor antagonist, norepinephrine-serotonin reuptake inhibition

**TABLE 1** Opioid Analgesics, Equianalgesic Table—cont'd

OPIOID	ADMINISTRATION		PROPERTIES
	PARENTERAL	ORAL	
<b>Morphine</b>			
Tab: 15, 30 mg Liquid: 10, 20, or 100 mg/5 mL (Roxanol) SR† 12-h tab (MS Contin): 15, 30, 60, 100, 200 mg SR† 24-h cap (Kadian): 10, 20, 30, 50, 60, 80, 100, 200 mg SR† cap with naltrexone (Embeda): 20/0.8, 30/1.2, 50/2, 60/2.4, 80/3.2, 100/4 mg Suppository: 5, 10, 20, 30 mg	10 mg	30 mg	The longest-acting opioid Cheap: ~ 1¢ /mg Can cause QT prolongation Torsades de pointes is more likely with IV dosing STRONGLY consider risks before prescribing. Safety guidelines available from the American Pain Society.
<b>Oxycodone</b>			
Tab: 5, 10, 15, 20, 30 mg Liquid: 5 mg/5 mL or 20 mg/mL (OxyFast) SR† 12-h tab (generic, OxyContin): 10, 15, 20, 30, 40, 60, 80 mg Multiple combinations w/APAP (Percocet, Endocet, Tylox) SR† 12-h w/APAP 7.5/325 (Xartemis XR)	N/A	20 mg	Equal potency but a little more bioavailable than morphine Caution in liver disease: T½ extends up to 4 × normal. Metabolized to oxymorphone: 40 × more potent than oxycodone ER/LA. Opioids require REMS.
<b>Oxymorphone</b>			
Tab: 5, 10 mg (Opana); in opioid-naïve patients, starting dose > 20 mg/day is not recommended	1 mg	10 mg	Potentiated by cimetidine (Tagamet), MAOIs, and other CNS depressants 10% bioavailability Caution with CrCl < 50 or with liver impairment Take 1 h before or 2 h after food (food increases absorption)

\*Only approved in the United States for the treatment of opioid dependence.

†Sustained-release formulations should never be crushed.

APAP, Acetaminophen (*N*-acetyl-*p*-aminophenol); *bid*, two times per day; CNS, central nervous system; *CrCl*, creatinine clearance; *IM*, intramuscular; *IV*, intravenous; *MAOI*, monoamine oxidase inhibitor; *MED*, morphine equivalent dose; *NMDA*, *N*-methyl-*D*-aspartate; *po*, by mouth; *pr*, per rectum; *prn*, as needed; *qw4h*, every four hours; *q6h*, every 6 hours; *q8h*, every 8 hours; *qAC*, before meals; *qd*, daily; *qHS*, at bedtime; *SC*, subcutaneous; *tid*, three times per day.

**TABLE 2** Morphine and Methadone Equivalents

MORPHINE (DAILY REQUIREMENT)	METHADONE EQUIVALENT
<500 mg	5:1
500–1000 mg	10:1
>1000 mg	20:1

Acute pain: methadone = morphine (1:1). Chronic pain: The above conversion is for illustration of the complexity of methadone use. A more detailed table should be referenced before prescribing, and methadone should be used with extreme caution because of the risk for cardiac complications and respiratory depression. Many sources recommend starting at 10% of the calculated equianalgesic dose of methadone.

naldemedine (Symproic), and methylnaltrexone (Relistor) are peripheral rather than central mu antagonists, so they are indicated for managing opioid-induced constipation without negatively impacting pain control. Bisacodyl should not be used chronically due to its potential to damage the myenteric plexus of the gut and cause severe and permanent impairment of colonic motility; however, for PRN use, it can be quite effective with the suppository having quicker onset of action than the tablet.

**Adjuvant Drugs**

Adjuvant medications are drugs that are useful in the management of pain but do not have pain treatment as an indication. Some adjuvant medications such as duloxetine (Cymbalta) and

pregabalin (Lyrica) have received an FDA indication for diabetic peripheral neuropathic pain. Tricyclic antidepressants are useful for chronic pain and they have the benefit, unlike duloxetine, of working at the lowest doses rather than having to titrate to the maximum dose to gain benefit.

Several anticonvulsants have demonstrated efficacy in the management of pain, most notably gabapentin (Neurontin)<sup>1</sup>, pregabalin (Lyrica), and carbamazepine (Tegretol)<sup>1</sup>. Others have been tested in trials, but these three have the most evidence to support their use. Gabapentin and pregabalin have the benefit of not requiring monitoring of blood levels or for marrow, liver, or renal toxicities. Gabapentin (Neurontin)<sup>1</sup> has been beneficial using a single dose of 1200 mg preoperatively, notably in combination with celecoxib (Celebrex)<sup>1</sup>, in reducing postoperative opioid requirements in mastectomy, laminectomy, and thoracotomy patients. The benefits of the gabapentinoids, a.k.a.  $\alpha$ -2- $\delta$ -ligand calcium channel blockers, in peripheral neuropathies have been inappropriately extrapolated to pain related to radiculopathy. Significant benefits in lumbar and cervical radiculopathy have not been demonstrated in randomized trials.

Corticosteroids can be beneficial in inflammatory conditions, nerve or spinal cord compression, or increased intracranial pressure due to neoplasms. Any can help, but blood pressure elevations and fluid retention can be problematic in all but dexamethasone (Decadron)<sup>1</sup>, which lacks mineralocorticoid activity. Steroids also have the downside of elevating blood glucose and, in long-term use, causing osteoporosis and a host of other problems, including Cushing syndrome.

Muscle relaxants may be beneficial if muscle spasm is a source of pain, but there is insufficient evidence to determine relative efficacy or safety. Of these, two stand out: metaxalone (Skelaxin), which lacks the black-box warning for the operation of heavy equipment, and tizanidine (Zanaflex), which can antagonize  $\alpha_1$  receptors in the spinal cord to provide additional pain relief. In chronic use, the patient will need to be monitored for anemia and leukopenia with metaxalone and for liver abnormalities with tizanidine. Cyclobenzaprine (Flexeril) plus naproxen was not superior to naproxen alone for low back pain.

Calcitonin (Miacalcin)<sup>1</sup> has shown very modest benefit for pain due to osteoporotic vertebral compression fractures, but it shows no benefit for compression fractures due to bone metastasis.

Ziconotide (Prialt) has demonstrated benefit as well as safety for long-term pain management, but it is limited to only intrathecal use owing to gastrointestinal side effects.

Caffeine can modulate pain via action upon adenosine receptors that are involved in nociception. It is found in several over-the-counter analgesics, notably for migraine treatment. Regarding alternative medications, riboflavin,<sup>7</sup> butterbur,<sup>7</sup> and coenzyme Q10 (CoQ10)<sup>7</sup> are effective for migraine prophylaxis. Glucosamine,<sup>7</sup> S-adenosylmethionine (SAM-e)<sup>7</sup>, methylsulfonylmethane (MSM),<sup>7</sup> and willow bark<sup>7</sup> are likely effective for arthritic and low-back pain.

Acetyl-L-carnitine (ALC)<sup>7</sup> had demonstrated efficacy in diabetic neuropathy at 2 to 3 g/day. Capsaicin 0.075% cream (Zostrix) and 8% patch (Qutenza) have demonstrated benefit for peripheral neuropathy,<sup>1</sup> post-herpetic neuralgia, and HIV-associated neuropathy.<sup>1</sup>

Numerous medications in multiple drug classes have been studied for fibromyalgia, but many of the trials are small and/or of poor quality. Of these drugs, duloxetine (Cymbalta), pregabalin (Lyrica), and milnacipran (Savella) have received an FDA indication for fibromyalgia; gabapentin (Neurontin)<sup>1</sup>, ondansetron (Zofran)<sup>1</sup>, and naltrexone (Depade, Revia)<sup>1</sup> demonstrated modest benefit. The greatest benefit seems to be achieved by duloxetine and tricyclic antidepressants.

The use of cannabinoids has become legal in some states; however, their use for the management of pain is somewhat controversial, as the evaluating these drugs are often of low to

modest quality. A 2015 systematic review and meta-analysis showed mild reductions in pain, but the comparison groups were placebo rather than standard care. Additionally, cannabinoids are not without adverse effects, including impacts on cognition, motivation, reaction time, and psychosis in a 2016 review. Negative impacts could be even greater as unintended consequences of medical and/or recreational use come to light. Isolation of the various compounds such as cannabidiol and  $\beta$ -caryophyllene from others like  $\Delta$ 9-tetrahydrocannabinol (THC) could improve benefit, including oral administration, while limiting adverse physical and psychological effects. The cannabinoids do show some promise, but they need to be studied further and subjected to the same scientific rigor as any other medication in the FDA approval process. A 2020 systematic review and meta-analysis did not demonstrate a benefit of adding cannabinoids to opioids for the management of pain related to advanced cancer.

### Monitoring

Controlled-substance agreements are beneficial in setting the boundaries for the use of opioid pain relievers (Figure 1). Routine visits are necessary to document ongoing need for and adequate response to the prescribed regimen. Routine drug screening is beneficial for monitoring compliance with the opioid as well as nonopioid medications. However, the provider needs to be aware of the metabolites of the different drugs. Hydromorphone (Dilaudid) and oxycodone (Opana) are metabolites of hydrocodone (Norco) and oxycodone (Percocet, Endocet, OxyContin), respectively. All states except Missouri have prescription-monitoring programs that allow providers to monitor for the use of multiple providers and pharmacies to obtain controlled medications. Rules governing the prescribing and use of controlled substances vary among states, so the provider should be knowledgeable of local regulations as well as federal DEA requirements.

### Complications

The Centers for Disease Control and Prevention (CDC) reported in 2011 that opioid pain relievers were involved in 73.8% of the 20,044 prescription drug overdose deaths. By 2017, overdose deaths increased to 70,237 with 47,600 (67.8%) involving opioids. Of the 47,600 overdoses, deaths were mostly driven by synthetic opioids other than methadone (i.e., fentanyl, fentanyl analogs, and tramadol [60%], followed by heroin [32.5%], natural and semi-synthetic, for example, hydrocodone and oxycodone [30.5%], and methadone [6.7%]). (Percentages do not equal 100% due to some deaths involving more than one drug.) There are over 130 opioid overdose deaths per day in the United States. From 1999 to 2017, overdose death rates have increased from 8.2 to 29.1/100,000 in males and from 3.9 to 14.4 in females, and the rates were highest in the 25- to 54-year-old age range. Medicaid populations are at greater risk of opioid overdose than non-Medicaid populations, and prescription drug overdose death rates are higher in the more rural and impoverished counties. A 2020 study demonstrated that more than 25% of opioid overdoses in the United States involve children and adolescents.

In addition to the deaths, there is a significant cost burden of substance abuse treatment admissions, with the 2008 rates being six times the 1999 rate. Nonmedical use of opioids represents up to \$78.5 billion in healthcare costs, lost productivity, addiction management, and legal and law enforcement involvement. Drug addiction is very real, and about 15% of patients may be genetically predisposed to addiction; therefore, clinicians should strongly consider this in their risk/benefit analysis before exposing a patient to these powerful medications. About 25% of opioid-managed chronic pain patients misuse the medications, and about 10% develop opioid use disorders. Using a tool such as the Opioid Risk Tool may be helpful in determining the risk of addiction in a particular individual.

Long-term safety of opioids has not been demonstrated, and chronic use has been associated with sleep disorders, adrenal

<sup>1</sup>Not FDA approved for this indication.

<sup>7</sup>Available as a dietary supplement

## Controlled Substances Agreement Template

1. This agreement is provided to prevent misunderstandings about policies regarding medications designated by the DEA as "controlled substances" that you will be taking for pain management or other medical conditions.
2. I understand that my provider is consenting to treat me based on this Agreement.
3. I understand that if I break this Agreement, my provider might stop prescribing these medications, whether by tapering my medication, discontinuing the medication and prescribing another medication to treat the withdrawal symptoms, or discontinuing the medication and referring me to a detoxification program.
4. I will communicate fully and honestly with my provider about the character and intensity of my pain, the effect that my pain has on my daily life and how well the medication is helping to relieve my pain. I will take the medication ONLY as prescribed and for the treatment of my physical pain as opposed to emotional or psychological distress (i.e., to get high).
5. My physician may prescribe other medications (adjuvant medications) or non-pharmacological therapies (physical therapy, TENS unit, etc.) to help with certain aspects of pain such as muscle spasm, burning, tingling or radiating pain. I will comply with this treatment with the same diligence as is expected for my controlled medication.
6. I will not use ANY illegal substances or any legal medication not prescribed to me. Additionally, I understand that alcohol, although legal, should not be used in conjunction with my medication as the combination could be fatal.
7. I will not share, sell or trade my medications with anyone.
8. I will use only one provider and one pharmacy for my medications unless otherwise agreed upon with my provider.
9. I am responsible for my own prescriptions and medications. I will safeguard my written prescription and medications from loss or theft, understanding they will not be replaced. I will secure my medication in a lock box or safe out of the reach of children at all times.
10. I understand that refills of my prescriptions will be made at the time of an office visit or during regular office hours and never during evenings or weekends when the office is closed.
11. I authorize my provider and my pharmacy to cooperate fully with any city, state and/or federal law enforcement agency in the investigation of any possible misuse, sale or other diversion of my medications.
12. I agree to submit to a blood or urine test, if requested by my provider, in order to determine my compliance with my medication program.
13. I understand that the use of these medications may adversely affect my ability to drive, operate machinery or perform certain tasks, and I agree not to attempt these tasks under the influence of medication. Additional risks include low testosterone, depression, sleep disturbances, constipation, respiratory depression, and death.
14. I understand that smoking cessation and a healthy lifestyle can be helpful in achieving control of pain. I will strive toward smoking cessation, a healthy diet, and exercise as my condition allows.
15. I agree to these guidelines, and they have been fully explained to me. All of my questions and concerns regarding treatment have been adequately answered.

I agree to use \_\_\_\_\_ pharmacy, *and only this pharmacy*, for my prescriptions for controlled substances.

This Agreement entered on this date: \_\_\_\_\_

Patient / Parent / Guardian signature: \_\_\_\_\_

Provider signature: \_\_\_\_\_

**Figure 1** Controlled substances agreement.

suppression, and hypogonadism (and secondary erectile dysfunction and depression) among other problems. Conversely, the rapid tapering of opioids can cause needless suffering, both mentally and physically. Like any potentially harmful medication, the risks and benefits of that drug for a particular individual must be considered, using guidelines and the best available evidence to help achieve our goals.

## PALLIATIVE AND END-OF-LIFE CARE

Method of

Steven A. House, MD

### CURRENT DIAGNOSIS

- Any symptom can be in the realm of palliative care. Rapid identification and aggressive management of symptoms are important in maintaining the patient's quality of life.
- Palliative care is treatment that is focused on pain and symptom management, as well as quality of life for patients and their families. It can be rendered at any point in the course or treatment of illness, whether that illness is life limiting/threatening or not.
- Hospice is a philosophy and method of care that is completely focused on symptom management, quality of life for patients and families, and the transition at the end of life.

### CURRENT THERAPY

- Recommend that all adult patients, regardless of current health status, execute advance directives (living will, power of attorney for healthcare, healthcare surrogate, etc.) to help ensure that their treatment wishes and end-of-life care goals are met.
- For patients with life-threatening (e.g., progressing cancer) or life-limiting (e.g., patients with severe chronic obstructive pulmonary disease [COPD] or heart failure, requiring dialysis, or residing in a nursing home) illness, consider a Physician Order for Life-Sustaining Treatment (POLST) or Medical Order for Scope of Treatment (MOST) form (the name varies by state). These forms are used to convert the salient points of advance directives into medical orders so that they are immediately actionable by nurses or emergency medical services if the situation arises.
- Advance care planning discussions are billable under Medicare: 99497 for the first 30 minutes and 99498 for each additional 30 minutes.
- The best palliative care involves an interdisciplinary approach by physicians, nurses, counselors, chaplains, and others for the optimal management of symptoms (whether the suffering is physical, emotional, spiritual, existential, or practical) and family support.
- Early addition of palliative care to the overall treatment plan can improve survival and quality of life.
- Cancer pain is an indication for opioid therapy because opioids have proven efficacy in this scenario. For detailed information on opioids, see [Table 1](#) in chapter titled "Pain". Multiple modalities may be required for optimal pain control.
- For patients using opioids chronically, initiate a stimulant laxative such as sennosides (Senokot, Ex-Lax) or lubiprostone (Amitiza) as the opioid's companion. Peripheral mu antagonists such as methylaltrexone (Relistor), naldemedine (Symproic), or naloxegol (Movantik) are indicated for refractory opioid-induced constipation.
- Control nausea because it can contribute to anorexia, weight loss, and functional decline. The antiemetic drugs (e.g., ondansetron [Zofran], granisetron [Kytril], palonosetron [Aloxi], dolasetron [Anzemet]) or the combination netupitant/palonosetron (Akyzreo) are superior to the other classes of antiemetics in the settings of chemotherapy administration and postanesthesia. For uncomplicated nausea, prochlorperazine (Compazine) was found to be superior to promethazine (Phenergan).

- Dyspnea can be improved by providing a fan, a cooler room, and a view to the outside and avoiding confined spaces. Opioids, benzodiazepines, and/or other agents, depending on the situation, might be required. Thoracentesis can be palliative when an effusion is the source of dyspnea.
- Delirium must be evaluated for potential causes. Delirium with or without agitation can occur in up to 80% of patients, depending on the underlying condition. Medications are common causes, but pain and multiple other conditions can cause it as well. Medications such as haloperidol (Haldol)<sup>1</sup>, chlorpromazine (Thorazine, brand discontinued),<sup>1</sup> or olanzapine (Zyprexa, Zyprexa Zydis)<sup>1</sup> can be helpful in many patients, but haloperidol is by far the cheapest alternative and a good place to start.
- Chlorpromazine is the only medication with the US Food and Drug Administration (FDA) indication for hiccups.
- Feeding tubes do not improve outcomes in late-stage dementia and can contribute to suffering.

<sup>1</sup>Not FDA approved for this indication

## Epidemiology

There are more than 2.8 million deaths in the United States annually, and the total deaths were even higher in 2020 due to COVID-19, with a total of 3.36 million, up 17.7% from 2019. The most recent year for which mortality data are available is 2020, and cardiovascular disease is the top cause of death, followed by all cancers combined, COVID-19, unintentional injuries, chronic obstructive pulmonary disease (COPD), congestive heart failure, cerebrovascular disease, chronic kidney disease, and chronic liver disease, among others. The ranking was unchanged from 2016. Any of these disease processes can have a significant symptom burden that worsens with disease progression.

Life has 100% mortality, so individuals should take the time to plan for it. The consequences of failing to plan for the transition to end-of-life care include increased psychological distress, medical treatments that are inconsistent with individual preferences, increased utilization of healthcare resources that have little therapeutic benefit while being very costly in dollars, as well as quality of life, and a more difficult bereavement for survivors.

Cardiopulmonary resuscitation has poor outcomes under the best of circumstances (~15%), but it is even worse in patients with late-stage cancer, with only approximately 2% surviving to hospital discharge. Outcomes are also poor for the other noncardiac diseases listed previously and decline further with age and comorbidities.

## Risk Factors

Factors associated with worse pain or less symptom control are being female, elderly, or a child and race other than white. Historically, these groups have received less pain medication than white males for very similar diagnoses. These trends should be reversing. Lacking advance directives and failing to have such discussions with family members are related to receiving excessive and/or unbeneficial interventions/treatments.

## Pathophysiology

A patient's symptoms can be caused by the underlying disease itself, mechanical encroachment on other organs and structures (e.g., bowel obstruction, neuropathic pain from nerve destruction, bone metastasis), becoming more sedentary or bedbound, medications, and/or tumor necrosis factor, neurokinin-1, and other inflammatory cytokines. Therefore symptoms may have different etiologies and pathophysiology depending on the underlying disease state. Such a review would be far too extensive for this section.

## Prevention

Encourage all adult patients, regardless of current health status, to execute advance directives (living will, power of attorney for healthcare, healthcare surrogate, etc.) to help ensure that their treatment wishes and end-of-life care goals are met. These

discussions are billable under Medicare using CPT 99497 for the first 30 minutes face to face with patient, family members, and/or surrogate and 99498 for each additional 30 minutes. For patients with life-threatening (e.g., progressing cancer) or life-limiting (e.g., severe COPD or heart failure, dialysis-dependent, or nursing home residents) illness, consider a Physician Order for Life-Sustaining Treatment (POLST) or a Medical Order for Scope of Treatment (MOST) form (forms vary by state). They are used to convert the salient points of advance directives into medical orders so that they are immediately actionable by nurses, emergency medical services, and others if the situation arises.

Ascertain the patient's/family's goals of care, and assess whether those goals are realistic under the circumstances. Evaluate whether a particular intervention will help achieve that goal. For example, if a patient's goal is to take a child on a special vacation, this cannot be achieved if the patient remains in the hospital receiving chemotherapy that is not working. Another example is a nursing home resident with dementia whose family just wants them "to be kept comfortable" but is considering feeding tube placement. Placing a feeding tube in advanced dementia does not improve outcomes and might require physical restraints to keep the patient from removing the tube. Therefore feeding tube placement will negatively impact the goal of comfort.

When maintaining comfort and improving quality of life become the primary goals, assist patients and their families with the transition to hospice care. Hospice is grossly underused, with median and average lengths of service of only 24 days and 71 days, respectively. Referrals are too often made excessively late, with 28% of patients having 7 or fewer days of service; therefore all of the benefits of hospice cannot always be fully realized in such a short time.

Palliative and end-of-life care, like all medical care, needs to be influenced by all four major aspects of medical ethics: autonomy (patient/surrogate has the right to pursue aggressive treatment, as well as to refuse treatment, even if that treatment could be considered life sustaining), beneficence (do "good" for the patient), non-maleficence ("do no harm"), and justice (appropriate distribution of finite resources to do the most good for the most people). These four ethics can come into conflict at times, especially with the emphasis on autonomy above the other three in the healthcare system in the United States. Hospitals and other medical facilities should have specific policies regarding medical futility, and ethics committees can be helpful in difficult or unusual cases.

## Clinical Manifestations

Common symptoms in palliative care include pain, nausea with or without vomiting, dyspnea, delirium, constipation, dysphagia (cannot swallow food, fluids, or medications), and general functional decline (i.e., requiring more assistance with transfers, toileting, and self-care). Anorexia and lack of thirst are very common, notably in the last few hours to days of life, but anorexia can also be a side effect of medications. Intervening with intravenous (IV) fluids or nasogastric feeding can exacerbate symptoms (secretions, dyspnea, pain, nausea) and worsen outcomes. Weight loss is commonly observed. Medications for diabetes and other disorders can often be discontinued at this stage to help avoid side effects, drug interactions, and adverse reactions (e.g., hypoglycemia).

As patients enter the last hours of life, they might experience decreased level of consciousness, agitated delirium, mottling of the extremities beginning distally and moving proximally, changes in breathing (Cheyne-Stokes, rapid and shallow, Kussmaul, or agonal), decreased or absent oral intake, and/or skin cool to touch.

## Diagnosis

Diagnosis and prognosis will vary widely depending on the underlying disease processes, but in palliative care, much of the diagnosis (symptom identification) is based on history. Any patient with symptom burden is a candidate for palliative care, whether the symptoms are physical, psychological, spiritual, or existential. The Edmonton Symptom Assessment Scale ([https://www.centralhealthline.ca/healthlibrary\\_docs/ESASrevised.pdf](https://www.centralhealthline.ca/healthlibrary_docs/ESASrevised.pdf)) rates each of 11 different symptoms on a scale of 0 to 3, for a total score

**TABLE 1** Coanalgesic and Adjuvant Treatments for Pain: Adult Dosages**Nonsteroidal Antiinflammatory Drugs**

Celecoxib (Celebrex) 200 mg PO daily or 100–200 mg PO bid; maximum: 400 mg/d  
 Diclofenac sodium (Voltaren, Voltaren XR) 50–75 mg PO bid; injection (Dyloject) 37.5 mg IV q6h prn; maximum: 150 mg/d; Diclofenac epolamine topical (Flector patch 1.3%); apply 1 patch to most painful area bid  
 Ibuprofen (Motrin, Advil) 400–800 mg PO tid; maximum: 3200 mg/d  
 Ketorolac Nasal (Sprix) 15.75 mg/spray  
 <65 years old and <50 kg: 1 spray in one nostril q6h prn. Maximum: 4 sprays/d ×5 days  
 <65 years old and ≥50 kg: 1 spray in each nostril q6h prn. Maximum: 8 sprays/d ×5 days  
 Ketorolac Oral & Injection  
 10 mg PO q4h prn. Maximum: 40 mg/day ×5 days  
 Single dose: 30–60 mg IM or 15–30 mg IV  
 Multiple dose: if <65 years old and >50 kg, 30 mg IM/IV q6h prn. Maximum: 120 mg/d ×5 days  
 Or if >65 years old or <50 kg, 15 mg IM/IV q6h prn up to 60 mg/d ×5 days  
 Naproxen (Naprosyn, EC-Naprosyn) 250–500 mg PO bid prn; maximum: 1500 mg/d  
 Naproxen sodium (Aleve, Anaprox) 220–550 PO q12h prn; maximum: 1650 mg/d

**Bisphosphonates—Usually Provide Analgesia Within a Week and Last Up to 3 Months**

Pamidronate (Aredia)  
 Malignant hypercalcemia: 60–90 mg (depending on the severity of hypercalcemia) IV ×1  
 Osteolytic lesions (multiple myeloma) or bone metastases: 90 mg IV monthly  
 Zoledronic acid (Zometa)  
 Malignant hypercalcemia: 4 mg IV ×1  
 Osteolytic lesions (multiple myeloma) or bone metastases: 4 mg IV q3–4 weeks

**Radiopharmaceuticals—usually provide analgesia within 1–2 weeks and lasting 1–6 months. Dosing determined by radiation oncologist.****Antidepressants**

Tricyclics  
 Amitriptyline (Elavil)<sup>1</sup> 25–100 mg qhs. Can increase to 150 mg daily for pain.  
 Nortriptyline (Pamelor)<sup>1</sup> 25–100 mg qhs. Up to 150 mg/d.  
 Start low and titrate as needed. Use with caution in the elderly.

**Serotonin and Norepinephrine Reuptake Inhibitors**

Duloxetine 60 mg/d; >60 mg rarely more effective for pain, but can titrate higher for comorbid anxiety and/or depression if needed  
 Venlafaxine (Effexor)<sup>1</sup> 37.5–225 mg daily. Start low and titrate.  
 Selective norepinephrine reuptake inhibitors—can be used to improve coexisting anxiety and/or depression.

**Antiepileptic Drugs**

Gabapentin (Neurontin)<sup>1</sup> 300–1200 mg tid. Maximum: 3600 mg/d. Start 300 mg qhs ×2–3 days, then bid ×2–3 days, then tid. May start with 100 mg qhs in the elderly.  
 Pregabalin (Lyrica) 50–300 mg bid. Maximum: 600 mg/d. Start low and titrate for effect, using the lowest effective dose.

**General Anesthesia/Sedation**

Ketamine (Ketalar)<sup>1</sup> 0.1–0.2 mg/min IV (no bolus). This dosage is an adjunct to opioid therapy for severe uncontrolled pain and NOT intended to achieve general anesthesia. However, the clinician should seek assistance from anesthesiology or palliative care specialists. Hospital policies may vary.

<sup>1</sup>Not US Food and Drug Administration approved for this indication.

*bid*, Two times per day; *IM*, intramuscular; *IV*, intravenous; *q4h*, every four hours; *q6h*, every 6 hours; *q8h*, every 8 hours; *qAC*, before meals; *qd*, daily; *qHS*, at bedtime; *po*, by mouth; *pr*, per rectum; *prn*, as needed; *SC*, subcutaneous; *tid*, three times per day.

of 0 to 33. This scale gives an idea of overall symptom burden. The Karnovsky and Palliative Performance Scales ([http://www.npcrc.org/files/news/karnovsky\\_performance\\_scale.pdf](http://www.npcrc.org/files/news/karnovsky_performance_scale.pdf)) range from 0% (deceased) to 100% (fully functional) rated on ambulation, activity and evidence of disease, self-care, oral intake, and level of consciousness. A score of approximately 40% is often associated with appropriateness for hospice. Hospice eligibility in the United States is solely based on a life expectancy of 6 months or less if the disease progresses on its expected course. The National Hospice and Palliative Care Organization (NHPCO; <https://www.nhpc.org/>) has devised some prognostic criteria for a variety of diagnoses including dementia, amyotrophic lateral sclerosis (ALS), acquired immune deficiency syndrome (AIDS), congestive heart failure, end-stage liver or kidney disease, COPD, and so on. Although not fully validated, the criteria can help to guide the clinician in discussions with patients/families. “Hospice” is commonly associated with cancer; however, according to the NHPCO, dementias accounted for 20.9% of Medicare hospice decedents in 2019, followed by respiratory diseases (7.1%), cardiovascular disease (6.4%), and cancer (4.9%). The median

length of stay is still quite poor at 18 days, essentially unchanged over the past several years, while the average length of stay has increased by 6 days over the same time frame. There are various prognostic scoring systems for different disease states, and the Palliative Prognosis Score can help to determine the prognosis for patients with terminal cancer. In addition, the American Cancer Society (<https://www.cancer.org/>) has 5-year survival rates for various stages of numerous cancers on its website.

**Differential Diagnosis**

Because this chapter discusses management of symptoms for a plethora of different diseases, the differential diagnosis of all symptomatic disease processes is far beyond its scope. However, when assessing various symptoms, treatment options can be selected based on the probable source. Is the pain new or in a new location, or is it in the same area, radiating, or worsening? Are the nausea/vomiting due to chemotherapy, anesthesia, metabolic disorders, bowel obstruction, anxiety, increased intracranial pressure, or something else? Is the constipation opioid induced, due to poor intake, a result of using fiber without adequate fluid intake, or caused by

another issue altogether? Is the dyspnea due to pleural effusion (may respond to thoracentesis far better than it would respond to medications), anxiety (could use selective serotonin reuptake inhibitors [SSRIs], hydroxyzine [Vistaril], benzodiazepine, cognitive behavioral therapy), airway obstruction (might use bronchoscopy, suction, or bronchodilators rather than other medications), excessive secretions (could treat with anticholinergic medications such as glycopyrrolate [Robinul] or scopolamine), or other cause?

## Therapy

To meet the needs of all forms of suffering (physical, emotional/psychological, spiritual, existential), an interdisciplinary approach using physicians, nurses, chaplains, counselors, social workers, and others is essential. For all patients entering palliative care, and especially hospice care, all of their medications should be evaluated for risk and benefit and then prioritized based on the goals of care. In one study, patients with a life expectancy of less than 1 year taking a statin for primary or secondary prevention were randomized to continue or stop the statin. The average number of days until death was 229 after discontinuation versus 190 for continuation; thus survival and quality of life improved at a lower cost. Consider discontinuing statins, some oral hypoglycemic agents (notably sulfonylureas due to risk of hypoglycemia), or oral anticoagulants such as warfarin (Coumadin), apixaban (Eliquis), or dabigatran (Pradaxa) if risks now outweigh benefits. As the end of life approaches, discontinue other medications that are not essential for symptom control or quality of life, have more risks than benefits, or contribute to symptom burden (e.g., cholinesterase inhibitors) at this advanced stage of the disease.

Clinicians might withhold or withdraw treatments, but they should never withdraw “care.” Providers can change from “doing everything possible to cure a patient” to “doing everything possible to maintain comfort and quality of life.” This is more than semantics. Consider turning off the defibrillator component of a pacemaker-defibrillator to avoid unnecessary shocks. The pacer can remain on because it can improve some symptoms while not prolonging life.

## Pain

For a detailed review of medications used for pain, especially opioids, see chapter titled “Pain.” This section will focus on cancer pain and end-of-life pain.

### Pain of All Types

Opioids have demonstrated efficacy for cancer-related pain in numerous clinical trials. Methadone (Dolophine) can be effective when other opioids have failed, but it should be used with caution and by those familiar with its use due to variable pharmacokinetics and an increased risk of respiratory depression as compared to other opioids. A 2020 systematic review and meta-analysis did not demonstrate a benefit of adding cannabinoids to opioids for the management of pain related to advanced cancer. Additionally, medical cannabis did not improve insomnia in adults with chronic pain. Ideally, as cannabis becomes more available for research, some high-quality, randomized, controlled trials can be conducted to evaluate efficacy, appropriate dose ranges, the best THC:CBD ratios, and safety. Acupuncture and/or accupressure were associated with improved pain scores and reduction of opioid requirements in cancer patients.

### Bone Pain

The bone pain due to metastatic lesions is partly due to prostaglandin release; thus coanalgesics such as nonsteroidal antiinflammatory drugs or adjuvant medications such as corticosteroids, (e.g., dexamethasone<sup>1</sup> or prednisone<sup>1</sup>) can be particularly helpful. Bisphosphonates such as zoledronic acid (Zometa) and pamidronate (Aredia) usually provide analgesia within a week that lasts up to 3 months. Monthly dosing may be required. In addition, radiopharmaceuticals such as strontium-89 (Metastron), samarium-153 (Quadramet), and phosphorus-32 (Phosphocol P-32) may be helpful for cancer-related

bone pain, with analgesia usually beginning within 1 to 2 weeks and lasting 2 to 6 months. Their benefit is derived from significant uptake by areas of high bone turnover to provide internal, localized radiation. Radium-223 (Xofigo; indication limited to castration-resistant prostate cancer with bone metastasis) emits alpha radiation rather than the beta radiation of the three aforementioned agents, and it is more selective for metastatic lesions. External-beam radiation treatment (EBRT) achieves pain relief in more than 75% of patients with analgesia beginning in 1 to 2 weeks and lasting 2 to 6 months. The appropriateness and dosing of radiopharmaceuticals and EBRT are determined by a radiation oncologist. The radiation oncologist might choose a single large fraction of EBRT rather than multiple small fractions if survival is expected to be greater than 3 months or if prolonged treatment will present too much hardship (transportation, increased suffering, time off work for caregivers, etc.) on the patient/family.

### Neuropathic Pain

Neuropathic pain can have multiple causes, such as nerve invasion/compression, medication toxicities, human immunodeficiency virus (HIV), and complications of diabetes. Adjuvant medications that have proven efficacy, but not necessarily an indication for use by the US Food and Drug Administration (FDA), include antidepressants such as amitriptyline (Elavil)<sup>1</sup>, duloxetine (Cymbalta), and venlafaxine (Effexor)<sup>1</sup>, anticonvulsants such as pregabalin (Lyrica) and gabapentin (Neurontin)<sup>1</sup>, or, for highly refractory cases (due to significant risk, side effects, and/or legality), ketamine (Ketalar)<sup>1</sup> or cannabinoids<sup>1</sup>. Topical agents such as capsaicin (Capzasin-HP, Salonpas Gel Patch Hot) have evidence to support their use in diabetic neuropathy. Highly active antiretroviral therapy can decrease viral load and improve symptoms of AIDS, including those of HIV-related neuropathy.

### Visceral Pain

Octreotide (Sandostatin) can be used for the severe abdominal cramping and diarrhea associated with carcinoid tumors (can overproduce serotonin) or VIPomas (overproduce vasoactive intestinal peptide) or off-label for abdominal pain and other symptoms related to malignant bowel obstruction. An interventional radiologist or pain specialist could provide additional options, such as celiac plexus blocks or thoracoscopic splanchnicectomy, for refractory abdominal pain, notably in patients with pancreatic cancer.

### Dyspnea

Dyspnea is a sensation of breathlessness, and the only measure is a patient’s self-report. It does not correlate well with respiratory rate, blood gas measurements, or pulse oximetry. The potential causes are many, and they should be considered before merely managing the symptom. The cause can determine the therapy. Anxiety can be managed with SSRIs or benzodiazepines. Airway obstruction could be relieved by suction or bronchoscopy. Hypoxemia has numerous causes that would have to be considered, but supplemental oxygen could help. Pleural or pericardial effusions could be drained. Pneumonia can be treated with antibiotics, pulmonary edema can be managed with diuretics and opioids, and pulmonary embolus can respond to anticoagulants. Transfusions can be helpful for dyspnea due to significant anemia (hemoglobin <7 g/dL) resulting from hemorrhage or myelosuppression. Bronchospasm usually responds to inhaled  $\beta_2$  agonists. If underlying causes are addressed, either by management or recognizing that treatment would not achieve the goals of care, symptom control is appropriate. The use of pharmacologic interventions such as opioids, benzodiazepines, or other medications for breathlessness in advanced cancer is not supported by the evidence; however, for patients who have tried other options without relief, a trial of medications is appropriate. Nebulized morphine<sup>1</sup> is no better than saline. Excessive secretions can be managed with scopolamine or glycopyrrolate.<sup>1</sup> The latter is preferred in the elderly because it does not cross the blood-brain barrier. For nonpharmacologic interventions, see [Box 1](#).

<sup>1</sup>Not FDA approved for this indication

<sup>1</sup>Not FDA approved for this indication

**BOX 1** Nonpharmacologic Interventions for Dyspnea

- Reassure, work to manage anxiety.
- Behavioral approaches: relaxation, distraction, hypnosis.
- Limit the number of people in the room.
- Open window.
- Eliminate environmental irritants.
- Keep line of sight clear to outside.
- Reduce room temperature, but avoid chilling the patient.
- Introduce humidity.
- Reposition, elevate the head of the bed, keep patient turned.
- Educate and support the family.

**Nausea/Vomiting**

The treatment of nausea and vomiting depends on the underlying cause. For chemotherapy-related nausea/vomiting, the 5HT<sub>3</sub> receptor antagonists are far more effective than other classes of antiemetics. The 5HT<sub>3</sub> class includes ondansetron (Zofran), granisetron (Sancuso, Sustol), dolasetron (Anzemet), and palonosetron (Aloxi). In addition, there is a combination of netupitant/palonosetron (Akynzeo), which combines a 5HT<sub>3</sub> antagonist for acute-phase nausea/vomiting and a substance P/neurokinin-1 receptor antagonist (NK1RA) for the delayed phase, and it should be given with dexamethasone (Decadron)<sup>1</sup>. Its only indication is for prophylaxis of chemotherapy-related nausea/vomiting, especially with highly emetogenic chemotherapy. The combination demonstrated superiority over palonosetron alone. Rolapitant (Varubi), another NK1RA, has a longer half-life than netupitant, with fewer drug interactions. Aprepitant (Emend) is an NK1RA with fosaprepitant (Emend injection) as its IV alternative. Olanzapine (Zyprexa)<sup>1</sup> was more effective than aprepitant and noninferior to fosaprepitant in the setting of highly emetogenic chemotherapy, whereas it is far more cost-effective than either NK1RA and serves as a better acute antiemetic than metoclopramide (Reglan). Prochlorperazine (Compazine) was found to be superior to promethazine (Phenergan) for uncomplicated nausea/vomiting (Table 2).

**Constipation**

Constipation is quite common in palliative care, and it is easier to prevent than to treat. It is one of the primary side effects of opioids that does not attenuate with time. For routine constipation, almost any laxative will do. Polyethylene glycol 3350 (MiraLax, GlycoLax) daily with as-needed sennosides (Senokot) or bisacodyl (Dulcolax) is one example of a simple regimen. If the patient is taking medications that have constipation as a side effect, such as anticholinergic medications or calcium channel blockers, they should be discontinued if possible. Opioid-induced constipation is due to the interaction of opioids with the mu receptors in the gut, thus leading to poor motility. It can be prevented for the most part if a stimulant laxative is initiated simultaneously with the opioid. Senna is safe for long-term use, but bisacodyl can damage the myenteric plexus over time. The chloride-channel activator lubiprostone (Amitiza) and the guanylate cyclase activator linaclotide (Linzess)<sup>1</sup> increase intestinal fluid secretion and motility, and the peripheral mu antagonists methylnaltrexone (Relistor) and naloxegol (Movantik) are indicated for use by the FDA to treat refractory opioid-induced constipation. Alvimopan (Entereg)<sup>1</sup> is another peripheral mu antagonist, but its primary indication is for ileus, especially postoperatively. Fiber and bulking agents should be avoided because they can worsen the problem (Table 3).

**Anxiety**

There are numerous reasons for patients receiving palliative care to be anxious, whether undergoing painful/unpleasant but curative interventions, suffering uncontrolled pain or dyspnea, or progressing toward hospice. Fear and uncertainty about the future

are common causes, and they can be related to physical, psychological, social, spiritual, or practical (finances, managing home responsibilities) issues. Excessive alcohol or caffeine use can exacerbate anxiety, which may present with agitation, insomnia, restlessness, sweating, tachycardia, hyperventilation, panic disorder, worry, tension, and/or psychosomatic symptoms. For patients with expectation of cure or longer survival, SSRI or serotonin and norepinephrine reuptake inhibitor (SNRI) antidepressants can be beneficial. Venlafaxine (Effexor ER) has the shortest half-life, and steady state can be reached in 4 to 7 days. Benzodiazepines are helpful for shorter life expectancy, or they can be used until the antidepressants take effect. Diazepam (Valium) has a long duration of action due to numerous active metabolites, but it is slower in onset, as is clonazepam (Klonopin)<sup>1</sup>. Alprazolam (Xanax) has very rapid onset but short duration of action. Lorazepam (Ativan) strikes a happy medium between speed of onset and duration of action. Counseling and cognitive behavioral therapy are effective, especially in combination with medications.

**Delirium**

Delirium is a waxing/waning state of confusion that can be characterized by anxiety, disorientation, cognitive dysfunction, and hallucinations. There is also a catatonic variety of delirium. This condition can be caused by many things, but a short list would include constipation/impaction, hypoxemia, infection, electrolyte abnormalities, medications (including benzodiazepines and opioids), and pain. If a cause is identified and corrected but the patient is still symptomatic, haloperidol (Haldol)<sup>1</sup>, chlorpromazine (Thorazine)<sup>1</sup>, or olanzapine (Zyprexa)<sup>1</sup> can be helpful; however, haloperidol is by far the cheapest alternative and a good place to start. It can be given intravenously or orally, or it can be given subcutaneously (off-label).

**Hiccups**

Hiccups (singultus) is a common nuisance that can become quite distressing, especially if persistent (>48 hours) or intractable (>1 month). For patients with pain in the chest or abdominal regions, hiccups can make pain difficult to control in addition to being a bothersome symptom that can significantly decrease quality of life. Chlorpromazine, at 25 to 50 mg PO up to four times per day prn, is the only FDA-approved medication for hiccups, but haloperidol<sup>1</sup> is a viable and much cheaper alternative, as is metoclopramide (Reglan)<sup>1</sup>. Gabapentin (Neurontin)<sup>1</sup> and phenytoin (Dilantin)<sup>1</sup> have been used with some success, notably in cases with a central nervous system etiology. Many other medications, including baclofen (Lioresal)<sup>1</sup>, have been tried without much success (i.e., some improvement in symptoms but did not eliminate the hiccups). Nonpharmacologic methods (e.g., breath holding, hyperventilation, gargling) are worth trying, but evidence is lacking for any particular intervention.

**Monitoring**

Patients should be reevaluated routinely for the adequacy of pain and symptom control, as well as for their ability to cope with the underlying disease, symptom burden, and functional decline. The family needs to be assessed for additional stressors and coping mechanisms, as the family's adjustment, or lack thereof, can be detrimental to the patient's condition. If opioids or benzodiazepines are being used, the supply needs to be monitored for any signs of aberrant use by the patient and/or the family and visitors. In addition, patients can be monitored for excessive sedation or respiratory depression, especially when using methadone with or without a benzodiazepine. The FDA has issued a warning regarding coadministration of benzodiazepines and opioids as a cause of worsened respiratory depression, so these patients in particular should be monitored.

**Palliative Sedation**

For symptoms refractory to all other measures and with a life expectancy of less than 2 weeks, palliative sedation can be considered, after informed consent, without hastening death according to one study.

<sup>1</sup>Not FDA approved for this indication<sup>1</sup>Not FDA approved for this indication

**TABLE 2** Antiemetics**Antipsychotics/Dopamine Antagonists**

Chlorpromazine (Thorazine) 10–25 mg PO q4h prn. Can use 25–50 mg IM q3h prn, but change to PO as soon as possible. Also available as 25 mg or 100 mg (can be halved) suppositories that can be given every 6 hours as needed.  
 Haloperidol (Haldol) 0.5–5 mg PO/IV bid–tid prn (off-label for nausea/vomiting); maximum 100 mg/d, but use lowest effective dose.  
 Good choice when also managing delirium.  
 Metoclopramide (Reglan) 5–10 mg PO/IV q6h prn  
 Olanzapine (Zyprexa) 5–10 mg PO daily–bid prn (off-label for nausea/vomiting)  
 Prochlorperazine (Compazine) 5–10 mg PO/IM/IV q6h prn; maximum 10 mg/dose, 40 mg/d. Suppository, 25 mg PR q12h prn

**Antihistamines**

Hydroxyzine (Atarax, Vistaril) 25–100 mg PO q6h prn or IM q4h prn  
 Meclizine (Antivert, Bonine) 25–100 mg/d PO divided bid–tid prn (off-label)  
 Promethazine (Phenergan) 12.5–25 mg PO/PR/IM/IV q4h prn. Use with caution IV: can cause necrosis and gangrene.

**Antiserotonin (5HT<sub>3</sub> Antagonists)**

Granisetron (Granisol, Sancuso [transdermal], Sustol [sustained release SC injection]) 2 mg PO ×1 or 1 mg PO q12h ×2 doses given within an hour before chemotherapy. If IV, 10 mcg/kg IV ×1 within 30 min before chemotherapy. Transdermal, apply 1 patch (3.1 mg/24 h) ×1 24 h before chemotherapy and leave on for up to 7 days. If SC, 10 mg SC q 7 days (give with dexamethasone [Decadron]<sup>1</sup>).  
 Ondansetron (Zuplenz, Zofran, Zofran ODT) 8 mg PO q8h for nausea/vomiting; 24 mg PO ×1 30 min before highly emetogenic chemotherapy.  
 Palonosetron (Aloxi) 0.25 mg IV ×1 or 0.5 mg PO<sup>2</sup> ×1 30 min before chemotherapy.

**Antineurokinin (NK1 RA)**

Aprepitant (Emend), fosaprepitant (Emend injection) 125 mg PO ×1 day 1 of chemotherapy, then 80 mg PO daily ×2 days. Or 150 mg IV ×1 30 min before chemotherapy.  
 Netupitant/palonosetron (Akynzeo) 300/0.5 mg, 1 capsule 1 h before highly emetogenic chemotherapy.  
 Rolapitant (Varubi) 180 mg PO ×1, 1–2 h before chemotherapy.  
 Netupitant/palonosetron is already a combination, but all NK1RAs should be given with an HT3RA and dexamethasone<sup>1</sup> before highly emetogenic chemotherapy.

**Cannabinoid Receptor Agonists**

Dronabinol (Marinol, Syndros) 2.5–10 mg PO bid prn. Syndros is available as a 5 mg/mL solution.  
 Nabilone (Cesamet) 1–2 mg PO bid prn; maximum: 2 mg PO tid  
 Both drugs are indicated for chemotherapy-related nausea/vomiting refractory to other drugs. Significant psychiatric adverse events are possible.

**Unknown Mechanism**

Trimethobenzamide (Tigan) 300 mg PO or 200 mg IM q6h prn

<sup>1</sup>Not FDA approved for this indication.

<sup>2</sup>Not available in the United States.

*bid*, Two times per day; *IM*, intramuscular; *IV*, intravenous; *q4h*, every four hours; *q6h*, every 6 hours; *q8h*, every 8 hours; *qAC*, before meals; *qd*, daily; *qHS*, at bedtime; *po*, by mouth; *pr*, per rectum; *prn*, as needed; *SC*, subcutaneous; *tid*, three times per day.

**TABLE 3** Laxatives**Osmotic**

Lactulose (Kristalose) 10 g per 15 mL; 15–30 mL daily or BID, maximum 60 mL/day (40 g/day)  
 Magnesium citrate (1.745 g/30 mL) 195–300 mL/d PO daily or divided bid; maximum: 300 mL/d  
 Magnesium hydroxide (milk of magnesia), 400 mg/5 mL; 30–60 mL (2400–4800 mg) PO daily PRN. Maximum 60 mL/day, can be divided 2–4 doses per day.  
 Polyethylene glycol 3350 (MiraLax), 17 g in 8 oz. liquid PO daily

**Stimulant**

Bisacodyl (Dulcolax) 5 mg tabs 1–3 PO daily prn or 10 mg suppository PR daily prn  
 Sennosides (Senna) 8.6 mg tabs; 2–4 tabs PO bid; maximum: 4 tabs PO bid

**Secretory**

Linaclotide (Linzess)<sup>1</sup> 145 mcg PO daily. Stimulates cGMP production to increase intestinal fluid secretion and motility.  
 Lubiprostone (Amitiza) 24 mcg PO bid. Activates chloride channel to increase intestinal fluid secretion and motility.  
 Plecanatide (Trulance)<sup>1</sup> 3 mg PO daily. Stimulates cGMP production to increase intestinal fluid secretion and motility.

**Peripheral Mu-Receptor Antagonists**

Methylnaltrexone (Relistor) 8–12 mg SC qod prn (or 0.15 mg/kg SC qod prn). Maximum: 1 dose/24 h  
 Naldemedine (Symproic) 0.2 mg PO daily  
 Naloxegol (Movantik) 25 mg PO daily

<sup>1</sup>Not US Food and Drug Administration approved for this indication.

*bid*, Two times per day; *IM*, intramuscular; *IV*, intravenous; *q4h*, every four hours; *q6h*, every 6 hours; *q8h*, every 8 hours; *qAC*, before meals; *qd*, daily; *qHS*, at bedtime; *po*, by mouth; *pr*, per rectum; *prn*, as needed; *SC*, subcutaneous; *tid*, three times per day.

## Physician-Assisted Suicide

Although this practice has been legalized in several states, the American Medical Association's Council on Ethical and Judicial Affairs has determined that physician-assisted suicide (PAS), as opposed to "aid in dying," is the most accurate description of the practice and that the AMA's current policy forbidding PAS should be upheld. Similarly, in 2017 the American College of Physicians (ACP) also determined that PAS is contradictory to the physician's role in the physician-patient relationship. The Hospice & Palliative Nurses Association (HPNA) takes the position that PAS is not part of palliative care. The NHPCO issued a statement opposing all forms of "Legally Assisted Death" in November 2018 (and updated in June 2021), citing numerous reasons for their rationale. Notable among these is that PAS does not meet the World Health Organization (WHO) definition of palliative care (i.e., "intends to neither hasten nor postpone death"). Conversely, the American Academy of Family Physicians (AAFP) and the American Academy of Hospice and Palliative Medicine (AAHPM) have taken a neutral stance.

## Complications

Emergencies do exist within the palliative care and hospice settings. Spinal cord compression, hypercalcemia, superior vena cava syndrome, seizures, airway obstruction, hemorrhage, or acute worsening or crisis in pain or other symptom are examples. Management will depend on the patient's goals of care and stage of illness; however, uncontrolled symptoms should always be addressed. Having dark-colored linens and towels are good to have on hand for patients at risk for hemorrhage, because the blood does not appear as dramatic or traumatic for the patient and family as it would on white or light-colored materials.

## PALPITATIONS

Method of

Rebecca Katzman, MD; Justin Bailey, MD; and Caroline Beyer, MD

### CURRENT DIAGNOSIS

- History and physical examination
- Electrocardiogram
- Complete blood count (CBC)
- Thyroid-stimulating hormone (TSH)
- Complete metabolic panel

### CURRENT THERAPY

- Dependent on underlying etiology. See [Table 5](#).

Palpitations are the unpleasant sensation or awareness of one's own heartbeat. Patients may feel a racing heart, skipped heartbeats, or pounding in the chest or neck. Palpitations have been described as a "flip-flop" or "fluttering" in the chest. Palpitations may be due to cardiac arrhythmia, nonarrhythmic cardiac disease, drugs, other medical conditions, or psychiatric disease. Cardiac arrhythmias and anxiety account for a majority of cases. Palpitations may be completely benign or a manifestation of a potentially fatal arrhythmia.

## Epidemiology

Palpitations (ICD-10-CM R00.2) are a common presenting complaint in a primary care office or the emergency department. They affect all genders and ages. Up to 16% of patients in general medical settings report palpitations, and up to 18% of cardiology outpatient visits are for cardiac arrhythmias. The most common etiologies of palpitations are cardiac arrhythmias (43%) and anxiety/psychiatric (31%). In outpatient clinics psychiatric etiologies are slightly more common; in emergency department settings cardiac causes are increasingly likely. The underlying cause of palpitations in 15% of patients cannot be identified.

Nearly 90% of patients who have palpitations have recurrent symptoms. Overall, 1-year mortality does not appear to be significantly increased, but patients report a moderate impact on their quality of life.

Although arrhythmias are frequently found to be the underlying cause of palpitations, it is important to note that many patients with arrhythmias do not have any symptoms.

## Differential Diagnosis

The differential for palpitations is broad but can generally be broken down into cardiac versus noncardiac causes. Cardiac causes may be further divided into structural or arrhythmic causes. Noncardiac causes include medications and drugs, high-output states, and certain medical conditions. Gastroesophageal reflux or esophageal spasm may present as a brief intermittent episode of tightness or pounding in the chest. See [Table 1](#) for a full listing of causes.

Psychiatric causes may account for up to one-third of presentations; palpitations can occur with panic attacks, generalized anxiety, depression, and somatization. However, it is important to note that psychiatric illness can coexist with cardiac or other medical causes.

Cardiac arrhythmias often present as palpitations. Nearly any arrhythmia or change from a sinus rhythm can produce this sensation. A less common condition in otherwise healthy patients is inappropriate sinus tachycardia (IST), demonstrated by an elevated resting heart rate, an exaggerated heart rate response to exercise, or both. IST is thought to be due to abnormal autonomic control and response. Long-QT syndrome, both congenital/familial and medication-induced, may predispose to ventricular tachyarrhythmias, including the often-fatal torsades de pointes.

**TABLE 1** Differential Diagnosis for Palpitations

	CARDIAC		NONCARDIAC	
<i>Arrhythmias</i>	Atrial fibrillation	<i>Medications</i>	Digoxin [Lanoxin]	
	Atrial flutter		Beta agonists (e.g., albuterol [Proventil])	
	Benign ectopy (premature ventricular contractions, premature atrial contractions)		Vasodilators	
	Nonsustained ventricular tachycardia		Anticholinergics	
	Supraventricular tachyarrhythmias (e.g., atrioventricular reentrant tachycardia)		Hydralazine	
	Inappropriate sinus tachycardia		Over-the-counter nasal decongestants (e.g., pseudoephedrine [Sudafed])	
	Long-QT syndrome			
	Torsades de pointes	<i>Substances</i>	Caffeine	
<i>Structural abnormalities</i>	Mitral regurgitations		Alcohol	
	Aortic insufficiency		Cocaine	
	Mitral valve prolapse		Amphetamines	
	Hypertrophic obstructive cardiomyopathy		Nicotine	
<i>Other</i>	Pericarditis		<i>Systemic conditions</i>	Hyperthyroidism
	Pacemaker-mediated tachycardia			Pheochromocytoma
	Vasovagal syncope	Anemia		
		<i>High output states</i>	Hypoglycemia	
			Mastocytosis	
			Gastroesophageal reflux	
			Esophageal spasm	
			Fever	
			Pregnancy	
			Paget's disease	
		<i>Psychiatric conditions</i>	Extracardiac shunt	
			Exercise	
			Stress	
			Panic attack	
		Generalized anxiety		
		Depression		
		Somatization		

**Risk Factors**

Structural cardiac disease, including valvular disease, may predispose patients to arrhythmias and palpitations. **Box 1** lists symptoms and risk factors that indicate an increased likelihood that palpitations are due to an underlying arrhythmia.

**Pathophysiology**

An arrhythmia is caused by the disruption of the normal electrical impulse that originates at the sinoatrial node and is conducted to the atrioventricular node, then through the His-Purkinje system to depolarize the ventricles. Disruption may occur anywhere along this pathway. Underlying structural disease, prior ischemia, congenital abnormalities in myocytes, or electrical pathways affect a normal electrical conduction pathway. Palpitations that are due to supraventricular or ventricular tachyarrhythmias often result from sympathetic stimulation and catecholamine surges.

**BOX 1** Indicators of Arrhythmic Etiology of Palpitations

**Increased Likelihood of Underlying Arrhythmia**

- Known structural or valvular cardiac disease
- Visible neck pulsations
- Palpitations that affect sleep
- Palpitations that occur at work
- Subjective feeling of irregular heart rate
- Duration of palpitations more than 5 min
- Male gender
- Older age

**Decreased Likelihood of Underlying Arrhythmia**

- Family history of panic disorder
- Duration of palpitations less than 5 min

Palpitations involving skipped or premature beats are often a sensation that results from the following episode of systole when stroke volume is increased secondary to the prolonged length of the preceding diastole and increased ventricular inotropy.

### Clinical Assessment

The keys to evaluation are a history and physical, a 12-lead electrocardiogram (ECG), and a basic laboratory evaluation including an evaluation of the thyroid gland. Clinicians must identify which patients are more likely to have underlying arrhythmia and require further evaluation. A good clinical history includes age of onset, description of palpitations, frequency, duration, timing, position, and associated symptoms, including dizziness, presyncope, and syncope. The clinical history should include a thorough medication review, including over-the-counter medications, alcohol and tobacco use, and illicit substance use. An increasing number of medications are being found to cause QT prolongation, especially when used in combination, and may predispose the patient to ventricular arrhythmias (see Table 2 and Box 2). A physical examination should be performed but may be limited, as clinicians rarely have the opportunity to examine a patient during an episode of palpitations.

### Diagnostic Testing

A 12-lead ECG should be performed in all patients. It is appropriate to do limited laboratory evaluation with a complete blood count (CBC), thyroid-stimulating hormone (TSH), and complete metabolic panel (CMP or Chem-14) to identify anemia, thyroid disease, and electrolyte abnormalities that predispose to arrhythmias. Etiology can be determined in 40% of patients from this limited evaluation (see Tables 3 and 4).

Traditionally, ambulatory cardiac monitoring has been done via a Holter monitor. Patients keep a diary of the time and characteristics of their symptoms. This method is appropriate for patients who have daily palpitations. The monitor is worn for 24 to 48 hours. If symptoms are not present during the time the monitor is being worn, the test will be unrevealing. In addition, Holter monitoring may uncover arrhythmias (most commonly benign ectopy) that are unrelated to patient symptoms.

## BOX 2 Medications That Cause QT Prolongation

- Cardiac Antiarrhythmics
  - Amiodarone (Cordarone)
  - Disopyramide (Norpace)
  - Procainamide
  - Quinidine
  - Sotalol (Betapace)
  - Diuretics
  - Sympathomimetics
  - Vasodilators
- Antibiotics
  - Fluoroquinolones
  - Macrolides
- Psychiatric
  - Phenothiazines
    - Chlorpromazine (Thorazine)
    - Promethazine (Phenergan)
    - Prochlorperazine (Compazine)
    - Fluphenazine (Prolixin)
    - Trifluoperazine (Stelazine)
  - Selective serotonin reuptake inhibitors
  - Tricyclic antidepressants
  - Haloperidol (Haldol)
  - Amphetamines
  - Anticholinergics
  - Antihistamines
  - Protease inhibitors
  - Methadone (Dolophine)

If arrhythmia is suspected in a patient but 24 to 48 hours is insufficient time to record an event, it is recommended that the patient be evaluated with an event (loop) monitor or a patch monitor for at least 2 weeks. These ambulatory monitors record continuously but only save data from the specific interval when the patient or program settings activate the monitor (e.g., 2 min before and after an episode of palpitations). Some of these monitors transmit real-time information to a central monitoring system and others store data on the device itself for analysis after completion of the recording period. In patients with infrequent palpitations but known severe heart disease, an implantable loop recorder is an option. These monitors are implanted subcutaneously, typically in the left pectoral region, and usually are left in place for 1 year. As with other loop event recorders, they save data when activated by the patient or the device settings and transmit the information to an external system.

**TABLE 2** History and Physical Examination Clues to the Etiology of Palpitations

CLUES FROM HISTORY OR EXAMINATION	SUGGESTED DIAGNOSIS
Onset in childhood or adolescence	<ul style="list-style-type: none"> <li>• AV nodal reentrant tachycardia</li> <li>• Wolff-Parkinson-White syndrome</li> <li>• Idiopathic ventricular tachyarrhythmia</li> </ul>
Onset in older adult Description of irregular rate	Atrial fibrillation
Feeling of “fluttering”	Prolonged tachyarrhythmia
Pounding in the neck Exaggerated “a” wave in jugular venous pulse	AV dissociations
Midsystolic click followed by late systolic murmur	Mitral valve prolapse
Holosystolic murmur along left sternal border that increases with Valsalva	Hypertrophic obstructive cardiomyopathy Left ventricle outflow tract obstruction
Pale conjunctiva	Anemia
Exophthalmos Goiter	Thyrotoxicosis
Gravid abdomen	Pregnancy

AV, Atrioventricular.

**TABLE 3** ECG Findings Suggestive of Diagnosis of Palpitations

ECG FINDINGS	SUGGESTED DIAGNOSIS
Irregularly irregular rhythm Absent P waves	Atrial fibrillation
Delta wave Short PR interval Widened QRS	Wolff-Parkinson-White syndrome
Short PR	AV nodal reentrant tachycardia
QT interval >460 m/s in women, >440 m/s in men	Predisposition to ventricular tachyarrhythmias, including torsades de pointes
Left ventricular enlargement with left atrial abnormality	May be a focus for atrial fibrillation

AV, Atrioventricular; ECG, electrocardiogram.

**TABLE 4** Diagnostic Considerations in the Evaluation of Palpitations

FINDINGS	FURTHER EVALUATION
Arrhythmia or predisposition to arrhythmia seen on ECG	Echocardiogram to look for structural heart disease
Palpitations brought on by exertion	Exercise stress test (avoid dobutamine if suspect arrhythmia)
Suspected arrhythmia, but none identified on ECG	Ambulatory cardiac monitoring <ul style="list-style-type: none"> <li>• Holter monitor (24–48 h)</li> <li>• Continuous loop event recorder</li> <li>• Patch recorder</li> <li>• Implantable loop recorder</li> </ul>
Associated dizziness, syncope, presyncope	Referral to cardiologist for electrophysiology study
Known cardiac dysfunction, structural or valvular abnormality	Referral to cardiologist for electrophysiology study
Family history of sudden cardiac death	Referral to cardiologist for electrophysiology study

Panic disorder or anxiety is a diagnosis of exclusion. A patient with anxiety or other psychiatric illness may have a significant underlying arrhythmia. The catecholamine increase in patients with psychiatric disorder in times of stress or intense emotional experience may be proarrhythmogenic. These patients should undergo evaluation for arrhythmia, especially in the presence of risk factors, before having all of their symptoms attributed to their psychiatric illness.

Patients who have palpitations associated with dizziness, presyncope, or syncope in whom the diagnosis is not apparent should be referred for evaluation by a cardiologist. This sort of palpitation is the kind most likely to be associated with ventricular tachycardia or other serious arrhythmia.

Palpitations may occur more frequently during pregnancy, which is a high-output state. Postpartum cardiomyopathy is a structural disease that is unique to this population. Because pregnant women also have an increased risk of new arrhythmias, including atrial fibrillation, persistent palpitations should be evaluated thoroughly.

### Treatment

Treatment should be focused toward the underlying cause of the palpitation.

Discussion of the management of specific causes of palpitations, including anemia, thyrotoxicosis, and hypoglycemia, can be found elsewhere. Chronic management of atrial fibrillation is also beyond the scope of this article.

**TABLE 5** Treatment of Specific Causes of Palpitations

CAUSE OF PALPITATIONS	TREATMENT
Medication or drug	Stop offending agent
Premature atrial contractions	Decrease caffeine and alcohol Tobacco cessation Beta blockers may reduce symptoms of PAC
Ectopy (PVCs)	Beta blockers <ul style="list-style-type: none"> <li>• <i>Metoprolol Succinate</i> [Toprol XL]<sup>1</sup> 50 mg PO daily</li> <li>• <i>Atenolol</i> [Tenormin]<sup>1</sup> 50 mg PO daily</li> </ul> Nondihydropyridine calcium channel blockers <ul style="list-style-type: none"> <li>• <i>Verapamil</i> [Calan SR]<sup>1</sup> 240 mg/day PO</li> <li>• <i>Diltiazem</i> [Cardizem CD]<sup>1</sup> 120 mg/day PO</li> </ul> Antiarrhythmic agents have been shown to reduce PVCs but may increase mortality especially in patients with previous myocardial infarction.
AVNRT Orthodromic AVRT SVT of unknown etiology	Vagal maneuvers (carotid massage, Valsalva, dive reflex) <i>Adenosine</i> [Adenocard] 6 mg IV bolus over 1–2 s, increased up to 12 mg IV every 1–2 min as needed for two doses If ineffective can reasonably consider: <ul style="list-style-type: none"> <li>• <i>Verapamil</i> [Isoptin] 5–10 mg IV over 2 min, repeated in 30 min as necessary, then infusion at 0.005 mg/kg/min</li> <li>• <i>Diltiazem</i> [Cardizem], 0.25 mg/kg IV over 2 min, repeat bolus of 0.35 mg/kg 15 min later if first dose is tolerated but does not produce desired reduction in heart rate. Can then be run as a continuous infusion at a rate of 5–15 mg/h</li> <li>• <i>Metoprolol Tartrate</i> [Lopressor]<sup>1</sup> 2.5–5 mg IV bolus over 2 min, repeated at 5 min intervals up to three doses</li> </ul> <i>Esmolol</i> [Brevibloc] 500 mcg/kg IV bolus over 1 min, followed by 50 mcg/kg/min continuous infusion. Can titrate up in 50 mcg/kg/min increments every 4 min to maximum 200 mcg/kg/min with repeat bolus doses between each rate change.
Antidromic AVRT	<i>Procainamide</i> <sup>1</sup> 20–50 mg/min up to total 17 mg/kg
Focal atrial tachycardia or multifocal atrial tachycardia	<i>Metoprolol Tartrate</i> [Lopressor] <sup>1</sup> 2.5–5 mg IV bolus over 2 min, repeated at 5 min intervals up to three doses <i>Verapamil</i> [Isoptin] 5–10 mg IV over 2 min, repeated in 30 min as necessary, then infusion at 0.005 mg/kg/min
Atrial fibrillation/flutter with rapid ventricular response	<i>Metoprolol Tartrate</i> [Lopressor] <sup>1</sup> 2.5–5 mg IV bolus over 2 min, repeated at 5 min intervals up to three doses <i>Esmolol</i> [Brevibloc] 500 mcg/kg IV bolus over 1 min, followed by 50 mcg/kg/min continuous infusion. Can titrate up in 50 mcg/kg/min increments every 4 min to maximum 200 mcg/kg/min with repeat bolus doses between each rate change. <i>Verapamil</i> [Isoptin] 5–10 mg IV over 2 min, repeated in 30 min as necessary, then infusion at 0.005 mg/kg/min <i>Diltiazem</i> [Cardizem], 0.25 mg/kg IV over 2 min, repeat bolus of 0.35 mg/kg 15 min later if first dose is tolerated but does not produce desired reduction in heart rate. Can then be run as a continuous infusion at a rate of 5–15 mg/h
Preexcited atrial fibrillation	<i>Procainamide</i> <sup>1</sup> 20–50 mg/min up to total 17 mg/kg <i>Ibutilide</i> [Corvert] 0.01 mg/kg (<60 kg) or 1 mg (≥60 kg) IV over 10 minutes
Ventricular Tachycardia	Synchronized cardioversion

<sup>1</sup>Not FDA approved for this indication. AVNRT, Atrioventricular nodal reentry tachycardia; IV, intravenous; PAC, premature atrial contraction; PVC, premature ventricular contraction; PO, per os (by mouth); SVT, supraventricular tachycardia.

Table 5 outlines the treatment of specific causes of palpitations. Referral to a cardiologist is appropriate for patients with supra-ventricular tachyarrhythmias, long-QT syndrome, or palpitations associated with syncope/presyncope, as these are more likely to be ventricular arrhythmias.

Patients with potentially malignant ventricular tachyarrhythmias (e.g., frequent premature ventricular depolarizations, up to 3–10 per hour with some repetitive forms) are at increased risk for sudden cardiac death, but there is little evidence that treating with antiarrhythmics decreases mortality; in fact, some evidence suggests that these drugs actually increase mortality via proarrhythmic mechanisms. In these patients, consider a referral to a cardiologist for evaluation for an implantable cardiac defibrillator.

## PHARYNGITIS

Method of

Ruth Weber, MD, MSEd

### CURRENT DIAGNOSIS

- Patients prioritize symptom relief over microbiologic cure.
- Most pharyngitis is viral; microbiologic confirmation is required for group A  $\beta$ -hemolytic streptococcus pharyngitis diagnosis.
- In adults, throat culture is not necessary if rapid antigen detection test is negative.
- Stop presumptive antibiotic therapy if throat culture results are negative for group A  $\beta$ -hemolytic streptococcus.

### CURRENT THERAPY

- Penicillin is the drug of choice for group A  $\beta$ -hemolytic streptococcus pharyngitis. A first-generation cephalosporin or macrolide is indicated if the patient is allergic to penicillin.
- Treatment is necessary for 10 days to eradicate group A  $\beta$ -hemolytic streptococcus from the pharynx.
- Amoxicillin can be substituted for penicillin. Patients older than 12 years may be treated with once-daily amoxicillin (Moxatag).
- Patients are not infectious after 24 hours of appropriate antibiotic treatment.

## Epidemiology

Pharyngitis is common and has substantial medical and societal costs. “Sore throat” accounts for more than 7 million outpatient visits by children annually. The estimated total cost of pharyngitis in children is \$540 million per year.

**TABLE 1** Pharyngitis: Distribution of Causative Organisms (All Age Groups)

PATHOGEN	PERCENTAGE OF POPULATION
Group A $\beta$ -hemolytic streptococcus	15–30
Rhinovirus	20
Adenovirus	2–5
Coronavirus	2–5
Coxsackievirus	2–5
Group C $\beta$ -hemolytic streptococcus	2–5
Herpes simplex virus	2–5
Influenza virus	2–5
<i>Chlamydia trachomatis</i>	< 1
<i>Corynebacterium diphtheriae</i>	< 1
Epstein-Barr virus	< 1
Human immunodeficiency virus	< 1
<i>Arcanobacterium haemolyticum</i>	< 1
<i>Mycoplasma</i> spp.	< 1
<i>Neisseria gonorrhoeae</i>	< 1

An estimated 30% of childhood pharyngitis is caused by group A  $\beta$ -hemolytic streptococcus (GABHS). In temperate climates, pharyngitis occurs in outbreaks during winter and early spring, predominantly involving children 5 to 15 years of age. GABHS is uncommon in preschool-aged children and in adults. Group C  $\beta$ -hemolytic streptococcus pharyngitis occurs mainly in college students and young adults.

Of other causes of pharyngitis (Table 1), gonococcal pharyngitis is most common in older adolescents and young adults. Transmission is by oral-genital contact. If gonococcal pharyngitis is diagnosed in a prepubertal child, sexual abuse must be considered.

## Risk Factors

The major risk factors for GABHS pharyngitis are age and exposure such as in crowded schools or through household contacts. Oral sexual activity is implicated in gonococcal pharyngitis. Swimming pools have been implicated in transmission of group C and D  $\beta$  streptococcal pharyngitis.

## Pathophysiology

Pathogenic strains of *Streptococcus pyogenes* can be differentiated by Lancefield antigens and by hemolysis on blood agar. The strain containing group A antigen and displaying  $\beta$  hemolysis causes pharyngitis (GABHS). The M protein is responsible for virulence. The M protein cross-reacts with cardiac myosin and laminin, potentially causing rheumatic heart disease. More than 100 M-protein serotypes have been identified. Some streptococcus strains produce erythrogenic toxins, causing the rash of scarlet fever. Patients develop lifelong immunity to one serotype after infection, but reinfection with a different serotype is possible.

## Prevention

GABHS is transmitted by droplet spread. No evidence supports other forms of transmission. Patients and household/close contacts should be educated on minimizing droplet spread to reduce the transmission of GABHS.

Phase I trials have been completed on a multivalent vaccine targeting streptococcus M proteins that cause pharyngitis, invasive disease, and rheumatic fever.

## Clinical Manifestations

The type of pharyngitis cannot be identified by history and clinical findings. Microbiologic confirmation is necessary to diagnose GABHS pharyngitis.

### Group A $\beta$ -Hemolytic Streptococcal Pharyngitis

In patients age 3 years to adult, sudden onset of sore throat, pain on swallowing, and fever (101°F–104°F) suggest GABHS pharyngitis. Nausea and vomiting can also occur in school-aged children. Clinical signs can include tonsillar erythema with or without exudate, anterior cervical lymphadenitis, soft palate petechiae, red swollen uvula, and scarletiform rash. Infants rarely present with exudative pharyngitis but have coryza with excoriation and crusting of the nares. Posttonsillectomy patients with GABHS can have milder symptoms and clinical signs.

Patients with suppurative complications of GABHS have unusually severe symptoms, with neck swelling, drooling, and “hot potato” voice. The clinician must look for peritonsillar abscess and infections in the parapharyngeal and submandibular spaces (Ludwig’s angina).

### Scarlet Fever

Some strains of GABHS produce a pyogenic exotoxin that causes scarlet fever in susceptible patients. The clinical signs and symptoms are identical to GABHS pharyngitis plus development of the characteristic rash within 24 to 48 hours of symptom onset. The fine, papular, bright red rash blanches with pressure, begins on the neck, and spreads to the extremities and trunk. It is more pronounced in creases and feels rough, with a goose-pimple appearance. The punctate rash spares the face, but patients have flushed cheeks and forehead with pallor around the mouth. The rash fades in 3 to 4 days and is followed by desquamation. After desquamation of an initial white coating, the tongue has a classical strawberry appearance caused by edematous papillae.

### Poststreptococcal Glomerulonephritis

Renal symptoms of hypertension, edema, and hematuria can occur 1 to 3 weeks after GABHS pharyngitis. Glomerulonephritis is an autoimmune response to M proteins. It is not preventable by antibiotics.

### Viral Pharyngitis

Coryza, hoarseness, cough, diarrhea, viral exanthem, anterior stomatitis, and conjunctivitis can indicate a viral etiology for pharyngitis. Adenovirus infections can cause fever for 7 days, and conjunctivitis can persist for 14 days. Adenoviral outbreaks are often associated with swimming pools.

Enterovirus pharyngitis (coxsackievirus, echovirus, enterovirus) occurs in summer and fall. Fever, cervical adenopathy, and erythema of the tonsils are common, but exudates are rare. Herpangina (Coxsackie virus A/B) manifests with fever and painful papulovesicular lesions in the posterior oropharynx that resolve in 7 days. Hand-foot-and-mouth disease (Coxsackie virus A-16) manifests with painful vesicles and ulcers in the mouth plus painful vesicles on the palms, soles, and occasionally trunk. Lesions resolve in 7 days.

Primary oral herpes simplex infection occurs in young children. It manifests as acute gingivostomatitis, with ulcerating vesicles on the anterior mouth and lips but not on the posterior pharynx. High fever with intense pain is common, and dehydration can occur. Symptoms last for 14 days.

## Diagnosis

It is necessary to obtain microbiologic confirmation of infection before treating GABHS pharyngitis. If the clinical symptoms suggest GABHS pharyngitis, a throat culture or rapid antigen detection test (RADT) are indicated. If the clinical symptoms suggest viral pharyngitis, the pretest probability of GABHS infection is low, and a diagnostic test should not be performed.

Several methods for determining the probability of GABHS infection have been proposed. The Centor criteria (for adults) are

widely accepted. A score of 1 is given for each of the following characteristics: tonsillar exudate, tender anterior cervical adenopathy, history of fever, and an absence of cough. A score of 3 or more indicates a positive predictive value for GABHS of 40% to 60%. A score of 0 to 1 indicates a positive predictive value for GABHS of 1% to 5%.

Throat culture is the gold standard for diagnosing GABHS infection. The tonsils and the posterior pharynx should be aggressively swabbed. Other areas of the mouth should not be touched when obtaining the culture. The culture should be obtained before beginning antibiotic therapy, because even a single dose of antibiotics can cause the culture to be negative. The swab is plated on a sheep’s blood agar plate and incubated. The plate must be read at both 24 and 48 hours of incubation. When done correctly, the throat culture has 90% to 95% sensitivity. Although throat culture is considered the gold standard for diagnosing GABHS infection, it does not differentiate a carrier state from clinical infection.

RADT has high specificity but low sensitivity. The many tests available have different performance characteristics. In children aged 5 to 15, a throat culture should be performed if the RADT test is negative to identify patients who have a false-negative RADT result. In adults, throat culture is not necessary after a negative RADT because of the low incidence of GABHS and extremely low risk of acute rheumatic fever. The use of RADT has allowed clinicians to begin antibiotic therapy early in those with a positive test. This decreases the risk of spread of GABHS, allows earlier return to school or work, and modestly improves clinical signs and symptoms.

Streptococcal antibody testing has no value in the acute diagnosis of GABHS pharyngitis. Testing has some value in confirming prior GABHS infection in patients in whom acute rheumatic fever or acute poststreptococcal glomerulonephritis is suspected. The two antibodies that can be identified are antistreptolysin O (ASO) and antideoxyribonuclease B (ARB). Positive, elevated, or increasing titers are confirmation of recent GABHS infection. ASO titers rise within a week of infection and peak 3 to 6 weeks after infection. ARB titers rise within 1 to 2 weeks of infection and peak at 6 to 8 weeks. In some patients titers remain elevated for prolonged periods; therefore a doubling of the titer in 6 weeks is necessary for diagnosing prior GABHS infection.

## Differential Diagnosis

### Infectious Mononucleosis

Classically a triad of severe sore throat, lymphadenopathy, and fever (up to 104°F) in 15- to 25-year-olds, mononucleosis begins with a prodrome of chills, sweats, fever, and malaise. Clinical signs include enlarged tonsils; posterior and anterior cervical, axillary and inguinal adenopathy; and hepatosplenomegaly. Approximately 15% of patients present with jaundice and 5% with rash. Patients with mononucleosis who are treated with amoxicillin (Amoxil)<sup>1</sup> often develop a pruritic maculopapular rash. Complete blood count (CBC) shows an absolute lymphocytosis with greater than 10% atypical lymphocytes. Within 2 to 3 weeks, the heterophile antibody test (Mono Spot) becomes positive. The antibody test has a higher false-negative rate in children than in adults. If a false-negative test is suspected, an IgM antibody to viral capsid antigen is indicated to confirm the diagnosis.

### Acute Retroviral Syndrome

Primary infection with HIV can manifest as a syndrome of fever, nonexudative pharyngitis, arthralgia, myalgia, and lymphadenopathy. Some 40% to 80% of patients develop a rash. HIV antibodies are negative. Assay for HIV type 1 RNA or p24 antigen is positive.

### *Neisseria gonorrhoea*

*N. gonorrhoea* pharyngitis is usually asymptomatic and associated with oral sexual practices. The diagnosis is confirmed by isolating

<sup>1</sup>Not FDA approved for this indication.

the organism on Thayer-Martin medium. All patients should be screened and treated for coinfection with chlamydia.

### Lemierre's Syndrome

Lemierre's syndrome is a rare etiology of severe pharyngitis caused by *Fusobacterium necrophorum*. Infection spreads from the pharynx to include the surrounding tissues, with subsequent thrombophlebitis of the internal jugular vein.

### Treatment

A major therapeutic decision is to determine if whether the patient needs an antibiotic in addition to symptomatic treatment.

The goal of treatment of viral pharyngitis is control of symptoms, especially relief of pain. Nonsteroidal antiinflammatory drugs are slightly superior to acetaminophen (Tylenol) for pain relief. No evidence supports the use of Chinese herbs for symptom relief. A single dose of corticosteroids (oral dexamethasone<sup>1</sup> 0.6 mg/kg—maximum dose 10 mg) may provide pain relief, for moderate to severe symptoms. Short term oral corticosteroid use is associated with an increased risk of sepsis, venous thromboembolism, and fracture in adults <65. The risk of recurrent dosing of corticosteroids has not been determined. Many patients mistakenly believe that antibiotic therapy relieves pain. Ancillary treatment options include rest, adequate fluid intake, and antipyretic medications.

The goals of antibiotic treatment of GABHS pharyngitis are to decrease infectivity and prevent suppurative and other complications, especially acute rheumatic fever. Symptoms generally improve within 3 to 4 days without treatment. Delay of treatment of GABHS pharyngitis for up to 9 days after symptoms begin does not appear to increase the risk of acute rheumatic fever, and a delay of 24 to 48 hours while awaiting culture results does not increase the risk of acute rheumatic fever. Early treatment of GABHS pharyngitis does reduce infectivity, lessens morbidity, and promotes early return to normal activities. Nevertheless, criteria for initiating antibiotics remain controversial.

The choice of antibiotic is determined by the bacteriology of GABHS, clinical efficacy, patient adherence to treatment regimen, adverse effects, and cost. It is not recommended to initiate antibiotics while awaiting throat culture results in children. However, if an antibiotic is started it must be discontinued if the culture is negative.

Penicillin remains the antibiotic of choice for GABHS pharyngitis. GABHS has never shown resistance to penicillin or cephalosporins. Amoxicillin<sup>1</sup> can replace penicillin for treatment. (Liquid amoxicillin has a better taste than liquid penicillin.) In the penicillin-allergic patient, a first-generation cephalosporin or macrolide may be substituted. In some areas of the United States up to 8% of GABHS is resistant to macrolides and less than 1% is resistant to clindamycin (Cleocin). Antibiotics should be given for 10 days to eradicate GABHS from the pharynx. At this time, short-course ( $\leq 5$  days) treatment cannot be recommended, except with azithromycin (Zithromax).

No clear evidence supports antibiotic treatment for group C or group G streptococcal pharyngitis. Treatment might shorten the course of infection. Treatment options are identical to those for GABHS pharyngitis.

### Treatment Regimens

- Oral penicillin: PenicillinVK (Veetids)<sup>1</sup>: 40 mg/kg/day (up to adult dose of 1000 mg/day) in divided doses two or three times daily for 10 days.
- Amoxicillin<sup>1</sup>: 50 mg/kg/day (up to adult dose of 1000 mg/day) twice daily for 10 days; the FDA has approved amoxicillin ER tab (Moxatag) for patients older than 12 years at 775 mg once a day.
- Penicillin G benzathine (Bicillin-LA): Patients weighing less than 27 kg, 600,000 units IM; patients weighing 27 kg or more, 1.2 million units IM once. Penicillin G is used for pa-

tients who are unlikely to complete a full 10-day course of oral medication and for those with a personal or family history of rheumatic fever.

- First-generation oral cephalosporin: Cephalexin (Keflex) 25 to 50 mg/kg/day (up to adult dose of 1000 mg/day) twice daily for 10 days. This regimen should be used if the patient is allergic to penicillin; shorter courses are not FDA approved.
- Macrolides should be used if the patient is allergic to penicillin: Erythromycin 20 to 40 mg/kg/day (up to adult dose of 1000 mg/kg/day) in three or four doses for 10 days. Azithromycin (patients older than 6 months): Day 1: 10 mg/kg once (up to adult dose of 500 mg); days 2 to 5: 5 mg/kg once daily (up to adult dose of 250 mg/day). The dose of azithromycin is not established in infants younger than 6 months.

Tetracycline, sulfonamides, and older fluoroquinolones are not recommended because of high rates of resistance. All patients should be considered infectious until they have completed 24 hours of antibiotic therapy.

### Monitoring

In general, follow-up throat cultures or RADT for patients successfully treated for GABHS pharyngitis (i.e., test for cure) are not necessary. An additional RADT or throat culture is required if symptoms do not abate, symptoms recur, or the patient had previous rheumatic fever.

Patients who have repeated symptomatic episodes of GABHS have either recurrent new infections or are carriers of GABHS, with repeated superimposed viral infections.

GABHS carriers have positive cultures for GABHS without clinical symptoms. Approximately 20% of school-aged children are carriers. GABHS carrier status is suspected if the clinical picture is of viral pharyngitis but the patient has positive RADT or cultures both when symptomatic and when asymptomatic. Carriers do not respond to antibiotics and have no serologic response to ASO and anti-DNA B. These patients do not need to be identified or treated. These patients do not develop rheumatic fever and are not important in the spread of GABHS to others.

Patients with repeated GABHS pharyngitis have a clinical picture of recurrent bacterial pharyngitis. They respond to antibiotics and have negative RADT and culture when they are asymptomatic. They have a serologic response to ASO and anti-DNA B. Prophylactic antibiotics are not recommended for these patients. Tonsillectomy may be considered when infection attack rates do not decrease over time and no other explanation of recurrent infection can be found. Meta-analyses have found inconclusive evidence of benefit from tonsillectomy compared to nonsurgical treatment.

Patients with GABHS pharyngitis who remain symptomatic and continue to have positive cultures should receive a second course of antibiotics, with either the same antimicrobial agent or intramuscular penicillin. If a patient experiences repeated infections and there is concern that the GABHS infection is being spread among close contacts, all close and family contacts should be cultured, and only those who are positive should be treated. Family pets are not reservoirs and do not spread disease.

Mass screening should be considered in outbreaks of GABHS in a closed or semiclosed community or in outbreaks of acute rheumatic fever or poststreptococcal glomerulonephritis.

Non-GABHS pharyngitis (i.e., group C or G  $\beta$ -hemolytic streptococcus) is not associated with rheumatic fever, and no evidence supports treatment or follow-up culture.

### Complications

The complications of GABHS pharyngitis can be classified as suppurative and nonsuppurative.

Suppurative complications occur when the infection spreads to cause conditions such as lateral pharyngeal abscess, cervical lymphadenitis, sinusitis, otitis media, retropharyngeal abscess, Lemierre's syndrome, and mastoiditis. Appropriate treatment of GABHS with antibiotics decreases these complications.

<sup>1</sup>Not FDA approved for this indication.

Nonsuppurative complications include acute rheumatic fever, acute poststreptococcal glomerulonephritis, and poststreptococcal reactive arthritis. Acute rheumatic fever occurs 2 to 3 weeks after GABHS pharyngitis. It is not seen after GABHS skin infections. Starting antibiotics within 9 days of symptoms can prevent acute rheumatic fever. Acute poststreptococcal glomerulonephritis can occur 10 days after pharyngeal infection and 21 days after skin infection. Antibiotics do not alter the attack rate. Poststreptococcal reactive arthritis is similar to other reactive arthritis, and the attack rate is not altered by antibiotics.

Potential complications from treatment of GABHS pharyngitis include anaphylactic reaction to antibiotics and antibiotic resistance.

## PRURITUS

Method of

Hassan Bencheqroun, MD

### CURRENT DIAGNOSIS

- A careful history and physical examination will reveal a clear exposure, a sick contact, a recent travel, or clues to a systemic disease.
- Antihistamines are effective in treating histamine-mediated pruritus, but they are less effective in mechanisms involving serotonin, leukotrienes, etc.
- Initial testing in the absence of improvement with nonpharmacologic methods or antihistamine should include complete blood counts, thyroid-stimulating hormone, renal and liver panel, human immunodeficiency virus (HIV) test, and chest radiograph.
- Chronic pruritus may precede a systemic illness, especially in older adults. Hodgkin lymphoma is the malignant disease most strongly associated with pruritus and occurs in up to 30% of patients diagnosed with pruritus.

### CURRENT THERAPY

- Acute and localized pruritus may resolve with nonpharmacologic methods, such as skin hydration with hypoallergenic, alcohol-free, and fragrance-free moisturizing creams; decreasing the length of showers and baths as well as the temperature of the water; identifying material that may irritate the skin either in jewelry or clothing items; and avoiding scratching.
- Wound care of scratch lesions includes any cellulitic portions.
- First-line pharmacologic treatments may include the use of antihistamine and antipruritic creams. Antipruritic agents may be used as second-line treatments.
- In the absence of improvement, the management of chronic pruritus should be directed at the underlying cause, or targets on the pruritic cascade—from blockade of intracellular and intercellular signaling pathways in the skin to the modulation of neurotransmission.

Pruritus is defined as an unpleasant sensory perception that causes the desire to scratch. While it shares similarities with pain, the neurophysiology of pruritus is distinct: pain causes withdrawal, whereas pruritus induces the reflex of reaching out and scratching.

## Classification

Pruritus can be distinguished as acute or chronic, with the latter defined by the International Forum for the Study of Itch (IFSI) as lasting for 6 or more weeks.

Despite many classifications over the years, there is no uniform, clinically based classification of pruritic diseases to assist in the diagnosis and management of patients with pruritus. The classification chosen for this chapter focuses on clinical signs and distinguishes between the disease with and without primary or secondary skin lesions.

1. Group 1: Pruritus of primary diseased, inflamed skin
2. Group 2: Pruritus of primary nondiseased, noninflamed skin
3. Group 3: Pruritus with chronic secondary scratch lesions

## Pathophysiology

The sensation of pruritus stems from a number of different causes. It is generally transmitted through slow-conducting unmyelinated C fibers and free pruriceptive cutaneous nerve endings located superficially in the skin, which appear to be more sensitive to pruritogenic substances than pain receptors. Histamine, neuropeptide substance P, interleukin 31 (mostly in atopic dermatitis), serotonin (a key component in several diseases), bradykinin, mast cell tryptase, and other unknown mediators (e.g., in uremic pruritus, cholestatic pruritus) may be involved in the genesis of pruritus. Impulses are transmitted from the dorsal root ganglion to the spinothalamic tract. Pruritus then generates a spinal reflex response, the scratch, which is as innate as a deep tendon reflex. Other pathogenic mechanisms include neuropathic (e.g., herpes zoster), acute traumatic stress (following burns and skin grafts), chronic pruritus increasingly seen in the elderly including paraneoplastic, and immune-mediated (atopic dermatitis). Lastly, opioids are known to modulate the sensation of pruritus, both peripherally and centrally.

## Clinical Manifestations

Pruritus is among the most common symptoms in dermatology. While often overlooked, it is in fact rated by patients as the most quality-of-life–altering symptom of the underlying disease. Other associated symptoms depend on the etiology and may include urticarial skin lesions, dry skin, jaundice, and thyroid-related symptoms. Left untreated, itch and its associated scratching increase the risk of chronic skin changes and secondary infection.

## Differential Diagnosis

The patient's workup further places him or her in one of the following categories:

1. Primary diseased, inflamed skin
  - **Inflammatory:** Atopic and contact dermatitis, psoriasis, dry skin, drug reactions
  - **Infectious:** Mycotic, bacterial and viral infections, folliculitis, scabies, pediculosis, arthropod reactions, and insect bites
  - **Autoimmune:** Bullous dermatoses, especially dermatitis herpetiformis, bullous pemphigoid, and dermatomyositis
  - **Dermatoses of pregnancy**
  - **Neoplasms:** Cutaneous T-cell-lymphoma (especially erythrodermic variants), cutaneous B-cell lymphoma, leukemic infiltrates of the skin
2. Primary nondiseased, noninflamed skin
  - Endocrine and metabolic diseases: Chronic renal failure, liver diseases/cholestasis, hyperthyroidism, malabsorption, perimenopausal pruritus
  - Infectious diseases: HIV infection, helminthosis, parasitosis
  - Hematologic and lymphoproliferative diseases, iron deficiency, polycythaemia vera, Hodgkin and non-Hodgkin lymphoma

- Visceral neoplasms of the cervix, prostate, or colon, carcinoid syndrome
  - Pregnancy: Pruritus gravidarum with and without cholestasis
  - Drug-induced pruritus: Opioids, ACE-inhibitors, amiodarone, hydrochlorothiazide, estrogens, simvastatin, hydroxyethyl starch, allopurinol
3. Pruritus with chronic secondary scratch lesions (The underlying origin may be a systemic disease or a skin disease.)
- Neurogenic origin (without neuronal damage), such as hepatic itch
  - Neuropathic diseases (neuronal damage causes itch)
  - Multiple sclerosis, neoplasms, abscesses, cerebral or spinal infarcts, brachioradial pruritus, postherpetic neuralgia, vulvodinia, small fiber neuropathy
  - Somatoform pruritus (e.g., obsessive-compulsive disorders)

### Therapy

- Basic measures to lessen drying of skin: Limit bathing to short, cool showers with soap applied only to oily skin areas. A mild moisturizing cream is preferably applied immediately after bathing to lock in moisture. The patient's home should be humidified, especially during dry, cold winter months. Avoid contact irritants, such as wool, fiberglass, and detergents.
- Topical corticosteroids, oral melatonin<sup>7</sup>, and clonidine (Catapres)<sup>1</sup> showed some efficacy in reducing nocturnal itching or improving sleep quality in nocturnal pruritus.
- Many topical and systemic medications are available, but must be chosen according to existing comorbidities, possible interactions and side effects, and patient's compliance. Ultraviolet therapy may be administered in certain cases.
- Nonspecific therapy: A wheal and flare response is a marker of histamine-induced pruritus in patients with urticaria or an allergic dermatitis. These patients benefit from long-acting antihistamines. Concurrent H1 and H2 blockers increase therapeutic effectiveness. Also exercises focused on learning to disengage patient's attention away from pruritus or pain in chronic pruritus improves the symptoms.
- Specific antipruritic therapies target several points in the pruritic cascade—from blockade of intracellular and intercellular signaling pathways in the skin to the modulation of neurotransmission.
  - Nemolizumab<sup>5</sup>, an anti-IL-31 A receptor monoclonal antibody, was shown in a Phase II trial to induce a decrease of pruritus intensity in active treatment group when compared to placebo in atopic dermatitis patients.
  - Neurokinin 1 receptor antagonists such as aprepitant (Emend)<sup>4</sup> showed potential activity in chronic pruritus. Novel derivatives with longer half-life time, such as serlopitant<sup>5</sup> or tradipitant<sup>5</sup>, are currently investigated in clinical trials.
- Future treatments also include bile acid transport inhibitors, phosphodiesterase-4 inhibitors, and nerve ion channels modulators.
- Treatment specific: Itching gradually recedes as the primary systemic condition improves.

### Complications

Pruritus is accompanied by intense scratching. Skin may thicken, displaying lichen simplex chronicus: a localized skin thickening often appearing over the posterior neck, extremities, scrotum, vulva, anus, and buttocks. In prurigo nodularis, a variant of lichen simplex chronicus, some nodules develop over areas within easy scratching reach, such as the extensor arms and legs. Impetigo may result from superinfected excoriations in patients with atopic dermatitis.

<sup>1</sup>Not FDA approved for this indication.

<sup>3</sup>Investigational drug in the United States.

<sup>7</sup>Available as a dietary supplement.

## RHINITIS

Method of

Masayoshi Takashima, MD; and Omar G. Ahmed, MD

### Introduction

Rhinitis is defined as inflammation of the nasal mucous membranes. Despite the definition of rhinitis, there are both inflammatory and noninflammatory forms of rhinitis. Rhinitis presents as one or more of the symptoms of nasal congestion, sneezing, itching, rhinorrhea, and/or postnasal drainage. It can be divided into allergic rhinitis (AR) and nonallergic rhinitis (NAR). Often patients will have a mixed rhinitis, which has components of both allergic and nonallergic disease. AR is nasal inflammation that is mediated by immunoglobulin (Ig)E to environmental allergens. NAR is defined by non-IgE-mediated perennial symptoms. NAR shares symptoms with AR but is only distinguishable by negative allergy tests. NAR includes a broad group of diseases including vasomotor rhinitis, gustatory rhinitis, NAR with eosinophilia syndrome (NARES), occupational rhinitis, hormonal rhinitis, drug-induced rhinitis, atrophic rhinitis, and infectious rhinitis.

Most research still classifies AR according to its seasonality or its perennial nature. Seasonal AR is commonly caused by pollen allergens; perennial AR is mainly caused by dust mites and animal dander. AR can be further classified as mild or moderate/severe. Mild rhinitis is rhinitis that does not impair work, school, daily functioning, or sleep. Moderate to severe rhinitis interferes with activities of daily living, quality of life, and/or sleep. Episodic AR occurs with sporadic inhalant aeroallergen exposure not typically encountered by the patient's usual indoor and outdoor environments. Both AR and NAR can also be classified based on symptom frequency, intermittent (<4 days/week or <4 consecutive weeks/year) versus persistent (>4 days/week and >4 consecutive weeks/year).

Local allergic rhinitis (LAR) is a newly defined entity found in nonatopic patients. LAR is characterized by local inflammatory reactions including local eosinophils and localized IgE in response to aeroallergens. LAR does not show significant skin-prick testing reactions, and patients have negative systemic IgE reactions to aeroallergens.

Rhinitis may be viewed by some as a trivial disease, but it places a significant financial burden on society. The estimated direct and indirect costs to society of rhinitis were around \$11.58 billion in 2002. There is a significant loss of work and school days and

decreased productivity and school performance. It is estimated at least 20% to 33% decrease in productivity when patients with AR have an exacerbation of their symptoms. Patients also report significant decreased quality of life related to their rhinitis symptoms including disturbed sleep, daytime somnolence, fatigue, irritability, depression, impairment of physical and social functioning, impairment of attention and memory, and learning deficits. Appropriate recognition, diagnosis, and treatment can help alleviate these economic and societal costs.

### Epidemiology/Risk Factors

The National Health and Nutrition Survey (NHANES II and III) suggests that the overall prevalence of IgE sensitivity might be increasing. Of the patients evaluated for rhinitis in the United States, 43% (58 million people) have allergic disease, 23% (19 million people) have nonallergic disease, and 34% (26 million people) have mixed rhinitis. It is estimated the prevalence of physician-diagnosed AR is up to 20% of the population and 17% to 52% for NAR. Seventy percent of allergic patients develop the disease in childhood (20 years and younger) as opposed to NAR patients, 70% of whom develop disease in adulthood. Approximately two-thirds of NAR patients have vasomotor rhinitis, and one-third have NARES. NAR has a female predominance.

### Pathophysiology

#### Allergic

Allergic rhinitis is the result of an IgE-mediated, type I hypersensitivity allergic reaction in response to an inhaled allergen. Allergens are proteins derived from airborne particulate matter, including dust mite feces, pollens, animal dander, and cockroach particles. Antigen presenting cells (APCs) engulf allergens, break them down, and then present these peptides to T cells (TH0). These cells differentiate into the TH2 subtype and generate cytokines that regulate B lymphocytes and sequester inflammatory cells (including eosinophils). B lymphocytes produce IgE, which attach to mast cells and basophils and render them sensitized. When mast cells and basophils are exposed to the specific allergen, they degranulate and release a host of inflammatory mediators including histamine and prostaglandin. Histamine stimulates histamine type I (H1) receptors on nerve endings that cause pruritus, sneezing, and increased secretions, which constitute the early phase response of AR (minutes to 1 hour).

Eosinophils produce interleukin (IL)-5, which acts to promote activation and survival of other eosinophils. Eosinophils also produce toxic products, which damages the mucosal cells and causes nasal congestion. This damage occurs several hours after allergen exposure and constitutes the late phase.

#### Nonallergic Rhinitis

The nasal mucosa has two major functions: One is trapping inhaled particles through mucus production and the second is humidifying inhaled air through a complex vascular system. The mucus glands and the vascular system are regulated by the parasympathetic and the adrenergic nervous systems. Sensory nerves are stimulated by irritants in the nose through the use of a sensory receptor called a nociceptor. The nociceptive signal generates a neural reflex in the central nervous system (CNS) controlling sympathetic and parasympathetic tone in the nasal mucosa. Parasympathetic stimulation results in mucus production. Sympathetic stimulation causes vasoconstriction, which empties venous cavities. Lack of sympathetic tone causes venous engorgement and nasal congestion.

Symptomatic NAR is an exaggeration of a normal defensive mechanism. Inflammation in the nose causes an upregulation of this neural activity, resulting in the exaggerated response (also known as neural hyperresponsiveness). Hyperresponsive parasympathetic efferent nerves trigger glandular activation in the nasal mucosa, leading to vasodilation and mucus production. Excessive mucus production anteriorly causes rhinorrhea and posteriorly causes postnasal drip. This hyperresponsiveness can be due to structural or functional components of the nasal

mucosa altered through genetic or pathologic factors. NAR is often associated with hyperreactivity of the nasal mucosa but the exact mechanisms is often different based on the specific type of NAR. Broadly speaking, NAR is defined as rhinitis independent of an IgE-mediated mechanism.

### Infectious Rhinitis

Most infectious causes of rhinitis occur as a viral upper respiratory infection. Viruses may account for more than 95% of acute rhinitis infections, but it can be difficult to distinguish viral from bacterial infections. Viral rhinitis infections often cause nasal mucosal edema, impairment of the ciliary movement, and often obstruction of the sinonasal cavities. Duration of symptoms greater than 7 to 10 days is used clinically to distinguish viral from bacterial rhinitis/rhinosinusitis.

### Clinical History

The best diagnostic tool in the evaluation of rhinitis is the clinical history. Information regarding previous evaluation and treatment should be elicited. A positive family history of rhinitis points toward allergic disease. The history of symptoms should include questions regarding congestion; sneezing; rhinorrhea; sore throat; dry throat; cough; itchy, red, or tearing eyes; voice changes; sinus symptoms of drainage; pressure or pain; snoring; ear pain or loss of hearing; and smelling difficulty.

When gathering the details of each symptom, evaluate the onset (such as those in childhood), frequency (episodic vs. persistent), pattern (seasonality), characteristics of secretions, triggers, severity (to include quality of life evaluation), and associated geographic location or environment (home vs. work). Once a trigger is identified, history needs to be gathered even further to evaluate the possibility of modifying the exposure.

### Physical Examination

As with any disease process, the physical examination provides clues into the diagnosis (Table 1). Although the physical examination in rhinitis patients should focus on the nasal mucosa, other body areas should be examined to rule out other processes. For example, the tympanic membranes should be examined for mobility, retraction, erythema, and Eustachian tube dysfunction. Examination of the eyes in AR might show conjunctival edema, erythema, and/or cobblestoning with excessive lacrimation. Patients with AR may also have darkening of the skin of the lower eyelids, which is also called “allergic shiners.”

A nasal examination is essential for the diagnosis of rhinitis. Otolaryngologists will often use nasal endoscopy to evaluate the sinonasal cavity, but it is not necessary to diagnose different forms of rhinitis. Allergic and nonallergic nasal mucosa often will have a similar appearance with boggy, enlarged, and erythematous inferior turbinates. Bluish turbinates with allergic stranding are more common in AR. Evidence of excessive watery-clear mucus and postnasal drainage are also common findings to rhinitis. Other examination findings, which can occur in conjunction with rhinitis, are nasal polyps, sinusitis, septal deviation, septal perforation, and crusting. Looking for elongated facies, mouth breathing, and a high arch in the palate may provide a clue to the severity of the nasal obstruction in children. The tonsils and adenoids should be examined for enlargement. Posterior nasal drainage and cobblestoning in the oropharynx are common findings in rhinitis patients.

The skin examination provides useful information in the patient with AR. Atopic dermatitis or urticaria may be findings associated with allergic disease. The skin should be evaluated for dermatographism because these patients will not be able to be evaluated for allergic disease using skin-prick testing.

### Diagnosis

The diagnosis of AR, NAR, and infectious rhinitis is based largely on history and physical examination. Other diagnostic testing can be performed to aid in providing a more definitive diagnosis or to rule out other causes.

**TABLE 1** Clinical Manifestations of Rhinitis

TYPE OF RHINITIS	CLINICAL FINDINGS
Allergic rhinitis	<ul style="list-style-type: none"> <li>• Symptoms of palatal itching, nasal itching, ocular symptoms, or sneezing</li> <li>• Allergic shiners, allergic salute, bluish boggy turbinates, mucosal stranding</li> </ul>
Vasomotor rhinitis	<ul style="list-style-type: none"> <li>• Predominantly intermittent nasal obstruction and rhinorrhea</li> <li>• Symptoms triggered by temperature, exercise, and environmental stimuli (odors, smoke, and dust).</li> </ul>
NARES	<ul style="list-style-type: none"> <li>• More intense symptoms, paroxysms of flares including sneezing, watery rhinorrhea, nasal itching, congestion, and hyposmia</li> <li>• Eosinophils on a nasal smear, but lack other allergic evidence by skin-prick testing</li> </ul>
Gustatory rhinitis	<ul style="list-style-type: none"> <li>• Nasal congestion and rhinorrhea associated with ingestion of foods and, sometimes, alcoholic beverages</li> </ul>
Atrophic rhinitis	<ul style="list-style-type: none"> <li>• Nasal crusting, dryness, and fetor due to glandular cell atrophy</li> <li>• Patients may have abnormally wide nasal cavities with associated squamous metaplasia</li> </ul>
Occupational rhinitis	<ul style="list-style-type: none"> <li>• Symptoms of nasal congestion and rhinorrhea triggered by an occupational exposure</li> <li>• Symptoms improve when away from occupation</li> <li>• Common substances leading to symptoms include irritating chemicals, grain dust, ozone, laboratory animal antigens, and wood</li> </ul>
Hormonal rhinitis	<ul style="list-style-type: none"> <li>• Symptoms of nasal congestion and rhinorrhea associated with pregnancy and/or menstrual cycle</li> <li>• Resolves 2 weeks postdelivery</li> </ul>
Drug-induced rhinitis	<ul style="list-style-type: none"> <li>• Symptoms of rhinorrhea and congestion caused by certain medications including ACE inhibitors, phosphodiesterase-5 selective inhibitors, alpha-receptor antagonists, and phentolamine</li> </ul>
Rhinitis Medicamentosa	<ul style="list-style-type: none"> <li>• Symptoms of severe rebound nasal congestion caused by prolonged and repetitive use of topical nasal decongestants</li> </ul>
Infectious rhinitis	<ul style="list-style-type: none"> <li>• Symptoms of acute-onset nasal congestion and rhinorrhea most often caused by virus. Bacterial overgrowth from virus-induced inflammation can lead to bacterial rhinosinusitis</li> </ul>

ACE, Angiotensin-converting enzyme; NARES, nonallergic rhinitis with eosinophilia syndrome.

AR is confirmed by IgE reactivity to environmental allergen sensitivity through skin-prick testing. When skin-prick testing is difficult to interpret or if it is not feasible, serum-allergen-specific IgE testing can be used. Nasal smears looking for eosinophils are not recommended for routine use in the diagnosis of AR. Other testing available for evaluation of rhinitis includes nasal endoscopy and radiologic imaging. Nasal endoscopy is reserved for those with atypical symptoms or an inadequate response to treatment. Radiologic imaging, such as computed tomography (CT) and magnetic resonance imaging (MRI), is used to evaluate anatomic structure and for evidence of concomitant rhinosinusitis. If a provider suspects a cerebrospinal fluid (CSF) leak, the rhinorrhea can be evaluated for beta transferrin protein, which is present only in CSF.

## Differential Diagnosis

The differential for chronic rhinitis symptoms includes AR, NAR and the many subtypes described earlier, and mixed rhinitis. Many different pathologic conditions can present similarly to rhinitis including chronic sinusitis with and without nasal polyps; ciliary dyskinesia syndrome; anatomic abnormalities such as deviated septum or septal perforation; sinonasal tumors; nasal turbinate hypertrophy; cerebrospinal fluid rhinorrhea; pharyngonasal reflux; systemic disorders such as vasculitis, sarcoidosis, and autoimmune disorders; aspirin intolerance, and other medication side effects.

## Treatment

### Overall

Current guidelines in treatment of rhinitis do not take cost into consideration. However, the individual treatment goals should be based on factors such as age, route of administration preference (i.e., nasal vs. oral), severity, seasonality, side effects, cost, benefit to comorbid conditions, and onset of action. For example, onset of action is an important consideration for an individual who has more episodic symptoms. Also, individual patients respond differently to treatment regimens within a given group.

### Avoidance

Due to the lack of high-quality evidence, implementation of avoidance measures is largely based on panel recommendations. In addition, the ubiquitous nature of allergens may limit the effectiveness of the avoidance measures. For dust mites, encasing pillows and bedding in dust mite-resistant materials may be beneficial. Pollen is seasonal and can be minimized by keeping the windows closed, using air conditioning, and limiting outdoor exposure. Using particulate filters in the home can also assist in reducing overall allergen load of pollens and dust. Avoiding basements and lowering household humidity may reduce the amount of mold exposure patients receive. Pet avoidance can only be reached by ridding the house of the pet altogether. Other, less effective measures include limiting exposure of the pet to the house and/or bedroom.

### Oral Medications

#### Oral Antihistamine

Oral antihistamines block H1 receptors, thereby reducing nasal and palatal itching, rhinorrhea, sneezing, conjunctivitis, and urticaria. They are recommended in the treatment of AR. However, nasal congestion is not treated well with oral antihistamines. First-generation oral antihistamines are poorly selective for H1 receptors. The sedative effects of these antihistamines result from crossing the blood-brain barrier; they have been linked to industrial accidents and contribute to loss of function at work and school. Given there is no evidence of increased efficacy over second-generation antihistamines, it is not recommended to use these medications. Second-generation H1 antagonists (e.g., cetirizine [Zyrtec, generic], levocetirizine [Xyzal, generic], fexofenadine [Allegra, generic], loratadine [Claritin, generic], desloratadine [Clarinex, generic]) have excellent evidence for therapeutic efficacy and are considered first line in the treatment of AR. They particularly help the systemic symptoms associated with AR. These medications may have some role in the treatment of NAR because of their anticholinergic properties, but consideration must be given to these systemic properties, including dry mucous membranes, blurry vision, constipation, tachycardia, and urinary retention. A combination of intranasal corticosteroid treatment with oral antihistamines may be effective for sneezing and rhinorrhea in NARES.

#### Leukotriene Receptor Antagonists

Currently leukotriene receptor antagonists (LTRAs) are not recommended as first-line treatment for AR and are only recommended if other first-line treatments have failed. These medications were originally found to have benefits in the treatment of asthma and thus are prescribed for concomitant asthma and AR. Montelukast (Singulair, generic) is the only US Food and

Drug Administration (FDA) approved form of LTRA that is clinically efficacious in perennial and seasonal AR and asthma. Montelukast is approved for children 6 months and older and has a pregnancy category B rating. However, because of the potential rare neuropsychiatric side effects including sleep disturbances, depression, anxiety, aggression, psychotic reactions, and suicidal behavior this class of medications are used as second line. Currently LTRAs have no role in the treatment of NAR.

### Oral Decongestants

Oral decongestants such as pseudoephedrine reduce nasal congestion and can temporarily relieve symptoms. They can cause significant side effects including insomnia, anorexia, irritability, palpitations, and elevation in blood pressure. They are not routinely used for the treatment for AR and NAR but can help temporarily alleviate symptoms of nasal congestion in severe disease.

### Systemic Corticosteroids

Systemic corticosteroids are only recommended for the treatment of severe or intractable AR. A short 5-to 7-day course is recommended in severe cases to help decrease inflammation and improve symptoms. A prolonged course greater than 3 weeks can lead to serious side effects including adrenal suppression. They have no role in the treatment of NAR.

### Intranasal Medications

**Intranasal Corticosteroid.** Intranasal corticosteroids (INCs) are first-line treatment for moderate to severe AR and most NAR conditions. They penetrate the nasal mucosa with the result of decreased neutrophil chemotaxis, decreased eosinophil chemotaxis, reduced mast cell mediator release, and reduced basophil mediator release. Fluticasone (Flonase, generic) and beclomethasone (Beconase AQ) are the only two topical INCs approved by the FDA for NAR. In general, this class of medications are well tolerated with minimal systemic side effects.

INC side effects include irritation, bleeding, and perforation of the nasal septum; rarely, local candidiasis is seen with INC use. No single INC preparation is more efficacious than, or has any relevant difference from, any other. INC has negligible hypothalamic-pituitary-adrenal axis suppression, and systemic burden is clinically insignificant.

**Intranasal Antihistamine.** Azelastine (Astepro, generic) and olapatadine (Patanase, generic) are nasal sprays approved by the FDA for AR and NAR. Azelastine, considered a first-line treatment for AR, is available in 0.1% and 0.15% formulations and is thought to improve symptoms because of its antiinflammatory properties. This medication has been shown to diminish eosinophil activation and adhesion molecule expression and suppresses generation of inflammatory cytokines. Azelastine may also reduce neurogenic excitation from olfactory stimuli. These medications have a faster onset of action than INCs and are as effective in the treatment of nasal symptoms. They are more effective and have a faster onset of action than oral antihistamines for the treatment of nasal symptoms associated with AR. Intranasal antihistamine (INA) does not produce a significant amount of sedation, but side effects include headache, epistaxis, bitter taste, and nasal irritation.

**Combination Intranasal Antihistamine and Intranasal Corticosteroids.** The combined use of INCs and intranasal topical antihistamines is considered to be an effective treatment for both AR and NAR. It is more effective than either medication alone. The combination of the two medications can be given separately or through a combined spray with azelastine (137 mcg) and fluticasone propionate (50 mcg) called Dymista. It is currently recommended to use combination INAs and INCs for moderate to severe AR or NAR<sup>1</sup> that is resistant to monotherapy. The combination therapy is more effective in relieving total nasal symptom

score including nasal congestion and obstruction than either drug alone.

**Intranasal Anticholinergic.** Ipratropium bromide (Atrovent) is the only FDA approved intranasal anticholinergic that inhibits parasympathetic function in the nasal mucosa. The parasympathetic blockade reduces the output of secretions from seromucous glands in the nose. It is mainly used in the treatment of anterior watery rhinorrhea but has a very limited role in reducing postnasal drip, nasal congestion, or sneezing. This medication is especially helpful in gustatory rhinitis and vasomotor rhinitis where there is a specific trigger for the onset of rhinorrhea. Patients can take this medication prophylactically prior to exposure of the known trigger or irritant to help control symptoms.

**Nasal Cromolyn.** Cromolyn (NasalCrom, generic) is a mast cell stabilizer and inhibits the release of mast cell mediators that promote IgE-mediated AR. It should be given prophylactically prior to allergen exposure in order to reduce symptoms of AR from episodic allergen exposure. It has a favorable safety profile and is considered if first-line treatments are not effective. Cromolyn has very limited usefulness for NAR conditions.

**Nasal Saline.** Using nasal saline to irrigate the nasal cavities helps remove mucus, enhance ciliary movement, remove allergic and irritant particles, and moisturize the dry nasal passages. There are multiple delivery methods including nose spray, bottle, pump, irrigation, or nebulizer. However, the delivery method, volume, and isotonic or hypertonic use has not been established for the treatment of AR. There is evidence that saline irrigation for AR may reduce patient-reported disease severity compared with no saline irrigation at 3 months of treatment.

### Topical Decongestants

Topical decongestants reduce congestion but have no effect on itching, sneezing, or rhinorrhea. Oxymetazoline (Afrin, generic), a common topical decongestant, causes nasal vasoconstriction and can be used as a rescue medication for severe nasal congestion symptoms. There is risk for rebound congestion with prolonged use greater than 2 to 3 days and is not routinely recommended for the treatment of AR and NAR.

### Surgery and Procedures for Allergic and Nonallergic Rhinitis

The role of surgery in the treatment and management of both AR and NAR is to improve symptoms that occur as a result of the disease processes rather than treat the underlying disease. Patients with symptoms of nasal obstruction and congestion will get improvement with septoplasty (if deviated and causing obstruction) and turbinate reduction. There are multiple methods to reduce the inferior turbinate, which include minimally invasive radiofrequency ablations to partial resection of the turbinate. Recently there is evidence that reduction of enlarged nasal septal swell body and nasal vestibular swell bodies can improve symptoms of nasal congestion.

Traditionally, patients with vasomotor rhinitis can also be treated with endoscopic Vidian or posterior nasal neurectomy, which improves rhinorrhea and nasal obstruction in 90% of patients. There are risks involved in this surgery including dry eye and cheek and palate numbness, which usually resolve within 6 months of the procedure. This surgery has fallen out of favor to newer in-office techniques including cryoablation and radiofrequency ablation of the posterior nasal nerve (Clarifix and Rhinaer). These procedures can be done under local anesthesia and have shown to significantly improve total nasal symptom score including nasal congestion and rhinorrhea. They are FDA approved for the treatment of chronic rhinitis and vasomotor rhinitis.

### Anti-IgE

Omalizumab (Xolair) is a monoclonal antibody available for the treatment of poorly controlled asthma, but it might have a role

<sup>1</sup>Not FDA approved for this indication.

in the treatment of AR.<sup>1</sup> Omalizumab binds to IgE, hindering its relationship with inflammatory cells. Omalizumab only binds to circulating IgE and not bound IgE. Due to its high cost, reports of anaphylaxis, and its injectable-only formulation, omalizumab has a limited role in AR treatment.

### Immunotherapy

Allergen extract immunotherapy has been used in the treatment of respiratory allergic disease since 1911, and its efficacy has been documented since the 1970s. The amount of allergen in each immunotherapy dose is slowly increased with each dose until a maintenance phase is reached. Immunotherapy is an effective treatment for AR and is the only treatment proven to alter the course of allergic disease. Debate exists regarding which form of immunotherapy is superior (subcutaneous vs. sublingual). Contraindications to immunotherapy include beta blocker use, due to complications in treating anaphylaxis, and uncontrolled underlying diseases, such as uncontrolled asthma.

Subcutaneous immunotherapy uses the injectable form of allergen extract. Adequate treatment usually consists of a 3- to 5-year course of immunotherapy. Subcutaneous immunotherapy is indicated in those patients for whom medications and avoidance measures are inadequate, as well as those with only a few relevant allergens. The inherent risk of subcutaneous immunotherapy is systemic anaphylaxis; therefore it is dosed in the physician's office. The rate of local reactions in subcutaneous immunotherapy is 0.6% to 58% and systemic reactions is 0.06% to 0.9%. Subcutaneous immunotherapy is covered by most insurance plans.

Studies for local-route immunotherapy (noninjected), many of which were carried out in Europe, have only been undertaken in adults. Local routes of immunotherapy include sublingual, local nasal, oral, and bronchial.

Sublingual immunotherapy was approved by the FDA in April 2014. The risk profile is low and therefore can be dosed at home. The rate of local reactions with sublingual immunotherapy is 0.2% to 97% and systemic reactions is 0.056%. Multiple large meta-analyses have found noninferiority when comparing sublingual to subcutaneous immunotherapy. Some medical allergy providers use subcutaneous extracts (aqueous) as sublingual therapy, but this is an off-label use.

### Monitoring

The provider should consider stepping down treatment when the patient's symptoms have been controlled. The Total Nasal Symptom Score (TNSS) is a subjective assessment of the patient's specific symptoms, including rhinorrhea, nasal congestion, sneezing, and pruritus, and can be used to assess effectiveness of medications. The Rhinoconjunctivitis Quality of Life Questionnaire can also be used. Consideration for referral to an allergist might be extended to patients who have had a prolonged course, secondary infections, polyps, or other comorbid conditions including chronic sinusitis and asthma, or if immunotherapy is a consideration.

<sup>1</sup>Not FDA approved for this indication.

## SPINE PAIN

Method of

David Borenstein, MD; and Federico Balagué, MD

### CURRENT DIAGNOSIS

- Most spine pain is mechanical in origin in 95% or more of patients.
- Symptoms of mechanical acute spine pain resolve in most patients in 1 to 8 weeks.
- Most patients with spine pain do not require laboratory tests or radiographs to achieve resolution of their symptom of spine pain.

### CURRENT THERAPY

- Localized neck or low back pain
- Encouragement to remain active out of bed
- Patient education about the natural history to improvement
- Reassurance about the incidence of resolution
- Effective oral drug therapy: nonsteroidal antiinflammatory drugs (NSAIDs), analgesics, muscle relaxants
- Physical therapy with exercise program
- Radicular pain
- Encouragement to remain active out of bed
- Patient education about the potential for improvement
- Efficacy of oral drug therapy: NSAIDs, analgesics, muscle relaxants, corticosteroids, antiseizure medication, epidural corticosteroid injections
- Physical therapy: Mackenzie exercises for disk herniation
- Surgical decompression for cauda equina, progressive motor weakness, or intractable pain

Spine pain is a common symptom that is diagnosed and treated by a wide variety of healthcare professionals. The interest in this medical problem is not limited to its incidence as a patient problem but also stems from the likelihood of spine pain being experienced by the treating physician as well. The good news about spine pain is that the vast majority of patients (about 90%) improve over 2 months with minimal intervention, but relapses are frequent. The bad news is that the smaller number of patients who develop chronic spine pain use more than the majority of health resources expended on this expensive medical problem. The goal of therapy is to relieve spine pain while it is acute so that chronic pain does not develop.

The axial skeleton may be divided into cervical, thoracic, lumbar, sacral, and coccygeal locations. The lumbar and cervical areas are the most mobile and at greatest risk for damage. These two areas will be the primary subjects of this article.

### Epidemiology

Spine pain is the most common musculoskeletal complaint worldwide and produces direct and indirect costs of hundreds of billions of dollars each year in the United States. More than 80% of the world's population at some time during their lives will have an episode of low back pain. An estimated 20% of the US population has back pain every year. Neck pain occurs at a variable rate ranging from 0.055/1000 person-years (disk herniation with radiculopathy) to 213/1000 person-years (self-reported neck pain). Thoracic spine pain is relatively rare compared with the incidence of pain in the other two locations in the axial skeleton.

Persons of all ages develop spine pain. Younger people are at risk for developmental problems (idiopathic scoliosis, spondylolysis, spondylolisthesis), and older patients develop disorders associated with degeneration of spinal structures (osteoarthritis, spinal stenosis).

### Risk Factors

Psychosocial factors are stronger predictors of incident low back pain than mechanical factors in adolescent populations. In adults, psychosocial difficulties are risk factors for chronicity more strongly related to outcome than any clinical or mechanical variables. Previous episodes of spine pain are strong predictors of future ones.

Studies of cohorts of twins have shown that nonspecific low back pain is more than 60% genetically determined, and work and leisure-time physical activities play a minor role. Other environmental factors, such as smoking and obesity, have not been shown to be a predictor of the development of spine pain on a consistent basis.

### Pathophysiology

Most of the structures of the axial skeleton receive sensory input. The presence of anatomic alterations in these structures is not sufficient to predict the presence of pain. In general, spine pain is referred to as nonspecific because no definite pain generator can be identified. The nociceptive inputs generated by musculoskeletal structures are referred to as *somatic pain*.

In the first few decades of life, muscular sprains and strains of the paraspinal muscles in the lumbar and cervical regions are the most likely source of spinal pain. These muscular injuries occur when lifting in a position that places stress on paraspinal structures. Often the spine is in an awkward position and is mechanically disadvantaged. The subsequent muscle injury results in reflexive muscular contraction that can recruit muscles in the same myotome. Tonic contraction approximates the damaged components of the muscle but results in relative anoxia that causes the production of anaerobic metabolites that stimulate nociceptors. The number of recruited muscles may be extensive, manifested by severe spinal stiffness and limitation of motion. Most of these soft-tissue injuries to the muscle heal spontaneously without any long-term structural alterations.

Simultaneously, as people age, intervertebral disks become flatter as the nucleus pulposus loses its absorbency and the annulus fibrosus fissures and degenerates. The process results in the loss

of disk integrity. Degeneration of normal biomechanical and biochemical disk properties results. Biomechanical insufficiency inevitably results in a transfer of stresses posterior to the facet joints and ligaments that are ill suited to assume compressive, tensile, and shear loads. Osteophytes form in response to these abnormal pressures, compromising the space for the neural elements. Disk degeneration itself might not be a painful process until alterations in facet joint alignment result in the onset of articular pain.

Spondylolysis is a developmental abnormality associated with a stress fracture in the growth plate of the pars interarticularis. This abnormality may be discovered as a radiographic abnormality in an asymptomatic patient. An increased risk of low back pain occurs with spondylolisthesis, the abnormality associated with instability of spinal elements in the setting of spondylolysis.

Pain generation in the axial skeleton may be somatic or neuropathic in origin. The joints, ligaments, muscles, fascia, blood vessels, and disks can be the source of localized somatic spine pain. Somatic pain, when it does radiate, tends to be less focused in distribution and exacerbated by specific positions of the spine.

Neuropathic or radicular pain is the sensation generated by damage of neural elements. Intervertebral disk herniation with compression of spinal nerve roots causes neural inflammation resulting in neuropathic and radicular pain. Radicular pain follows the path of the corresponding spinal nerve root. In addition to pain, sensory deficits and muscle weakness can occur, depending on the intensity of the nerve compression. In the setting of chronic low back pain, the role of the central nervous system in mediating persistent symptoms has been highlighted increasingly in the medical literature.

### Prevention

Since the turn of the century, epidemiologic studies in adolescents have reported nonspecific spine pain at an incidence similar to that in adult populations. This finding suggests that primary prevention must be given at a very early age to have any chance of efficacy.

Among papers reporting on primary prevention, only exercise has shown effectiveness, with effect sizes ranging from 0.39 to 0.69. Other techniques, such as stress management, shoe inserts, back supports, education, and reduced lifting, were found ineffective. Some evidence in favor of occupational interventions (exercise with or without educational component) has been recently reported.

### Clinical Manifestations

The most common symptoms of spinal disorders are regional pain and decreased range of motion associated in a minority of patients with radiating pain. For the majority of patients, pain has mechanical characteristics: Its intensity increases with physical activity, movements, or some postures and decreases with rest. However, it has been demonstrated that nocturnal pain is not uncommon in the absence of serious, specific spinal disorders. The precise topography of pain is often difficult for the patient to describe, and its interpretation is difficult owing to the overlap of the cutaneous projections between adjacent spinal levels and the similarities between dermatomes, myotomes, and sclerotomes.

### Diagnosis

The diagnosis of spine pain is based upon the patient's history and physical examination. The history and physical examination should include a description of the pain that is as detailed as possible (e.g., past episodes, precise location, beginning of symptoms, factors increasing or decreasing pain intensity, radiating pain, neurologic symptoms, systemic symptoms), patient's medical history (e.g., past spinal surgery, neoplasia, corticosteroid treatments), and a limited physical examination focused on the posture of the spine, range of motion, muscle contraction, pain on palpation or percussion, and a brief neurologic examination.

Besides the high rate of false-positive results and financial costs, imaging studies have a negative effect on a patient's quality of life. Therefore unless there is a clear-cut surgical indication or a suspicion of an underlying life-threatening disorder, no imaging studies should be ordered on the first encounter for a patient with acute nonspecific low back or neck pain. Similarly, laboratory testing is not required unless a patient presents with clinical symptoms that suggest a systemic illness (e.g., fever, weight loss).

### Differential Diagnosis

A number of guidelines are available in the literature to help a clinician in the diagnosis and treatment of patients with spine pain. The purpose of these approaches is to differentiate the vast majority of patients with mechanical disorders who will improve with noninvasive therapy without the need for radiographic or laboratory investigation from the small minority with a specific cause of spinal pain.

Traditionally, red flags have been used to identify patients with a systemic disorder causing spine pain. The red flags have included questions regarding prior history of cancer, weight loss, prolonged morning stiffness, bladder dysfunction, and bowel dysfunction. The presence of these findings suggests a diagnosis of malignancy, infection, spondyloarthropathy, or cauda equina syndrome, respectively. A study has reported that red-flag disorders occur so infrequently and have so many false-positive findings as not to be helpful in the primary care setting at the initial visit. The one exception was spine pain associated with osteoporotic vertebral compression fractures.

Despite the findings of this one report, clinicians need to be mindful of patients who would be harmed to a significant degree by delayed therapy. The disorders that require expeditious evaluation and treatment are intraabdominal vascular disorders with tearing pain and hemodynamic instability (expanding aortic aneurysm); cauda equina syndrome with bilateral sciatica; saddle anesthesia; bladder or bowel incontinence (lumbar space-occupying compressive lesions); and cervical myelopathy with balance difficulties, autonomic dysfunction, and hyperreflexia with spasticity and Babinski's sign (cervical space-occupying compressive lesions). These disorders require expeditious vessel repair or decompression surgery.

The differential diagnosis of mechanical low back pain (Table 1) and mechanical neck pain (Table 2) includes disorders ranging from muscle strain and herniated disk to scoliosis and whiplash injuries. The age of patients, pain pattern with

exacerbating and mitigating factors, tension signs, and findings of plain radiographs can help differentiate among these common causes of spine pain.

*Nonspecific* is a term used commonly to describe the pain associated with mechanical disorders. On occasion, physicians have confused the use of "nonspecific" as meaning an absence of pathology causing pain associated with mechanical disorders. The "nonspecific" designation refers to the inability to identify the specific pain-generating anatomic structure, not the absence of somatic pain.

### Therapy

Many mechanical disorders of the spine are self-limited in duration, with a vast majority of patients improving gradually over time (Box 1). This progression to "natural healing" makes placebo look efficacious in many clinical trials investigating therapies for spine pain. This situation results in evidence-based reviews of spine pain therapies revealing very few categories that have a clinically significant impact on improvement. Nonetheless, physicians need to make therapeutic choices for their patients despite this relative paucity of evidence. Therapy for spine pain includes controlled physical activity, nonsteroidal antiinflammatory drugs (NSAIDs), skeletal muscle relaxants, local and epidural corticosteroid injections, and long-term pain therapy. Surgical intervention is reserved for patients who have surgically correctable abnormalities and who have cauda equina syndrome, increasing motor weakness, spasticity, or intractable pain.

The treatment of an individual patient has to be tailored based on the patient's expectations and preferences. Goals of the treatment should be clearly defined, and the patient should be informed about the expected benefits and side effects of the treatment at the first encounter. A short trial limited to a few days may be a good start.

Self-management with education of the patient about maintaining physical activities as tolerated has been encouraged for neck and low back pain. Information on nonpharmacologic pain-management strategies and daily life activities may be provided by healthcare providers, but patients adhere more to the former than to the latter.

Exercises are slightly effective for pain and function in patients with chronic low back pain. No specific form of exercise is clearly better than others. Simply walking has shown an efficacy similar to exercising.

The use of manipulative physical techniques in the care of patients with spine pain remains controversial. The absence of clear-cut distinctions between manipulative techniques with or without thrust adds to the confusion when one analyzes the efficacy of manual therapy treatments. Overall there is some clinical trial evidence in favor of spinal manipulation for acute low back pain.

**BOX 1** Management of Low Back Pain**Acute (3–6 Weeks)**

First consultation: gather information on core outcome domains.

Rule out pain of nonspinal origin.

Rule out specific causes (red flags).

No routine imaging.

Inform and reassure the patient. Advise to stay active and continue daily activities, if possible, including work.

Prescribe analgesia, if necessary. First choice: acetaminophen; second choice: NSAIDs.

Consider adding muscle relaxants (short course) or referring for spinal manipulation.

Avoid overmedicalizing, especially in patients with favorable outcome.

Be aware of yellow flags: inappropriate attitudes and beliefs about back pain, inappropriate pain behavior, emotional problems.

**Subacute (6–12 Weeks) Reassessment**

Bear in mind minimum clinically important difference of core outcome tools.

Consider patients' expectations.

Consider yellow flags if outcome is not favorable.

Reassess regularly by valid outcome tools to evaluate response to treatment.

Focus on function.

Give priority to active treatments.

Consider multidisciplinary program in occupational setting for workers with subacute low back pain and sick leave (>4–8 weeks).

**Chronic (3–12 Weeks)**

Repeat thorough clinical examination.

In cases of low impairment and disability, simple evidence-based therapies (e.g., exercises, medication, brief interventions) might be sufficient.

In cases of more-severe disability or chronicity, give priority to multidisciplinary approaches (biopsychosocial).

*NSAID*, Nonsteroidal antiinflammatory drug.

From Balagué F, Mannion AF, Pellisé F, Cedraschi C: Clinical update: Low back pain. *Lancet* 369(9563):726–728, 2007.

NSAIDs have short-term efficacy for both acute and chronic low back pain; however, the effect sizes are not very large. The efficacy of these drugs for patients with radicular pain has not been evaluated well enough to make general recommendations. No single class of NSAIDs has superiority to another. Cyclooxygenase 2

(COX-2) inhibitors have a better gastrointestinal (GI) safety profile but no greater efficacy. A patient's response cannot be predicted, and a trial-and-error approach is often necessary.

Opiates have not demonstrated any favorable influence in the outcome of low back pain patients. Side effects are quite common and the risk of addiction is real. When these kinds of drugs are effective, the improvement is more important in pain intensity than in terms of function. Muscle relaxants do have some efficacy for acute and chronic low back pain, but the effect size is limited. Long-term use of muscle relaxants can affect cognitive function due to their strong anticholinergic effects.

Antidepressants are not generally prescribed owing to an inconsistent improvement of patients. For patients with chronic low back pain and depression, an optimized antidepressant treatment shows a better effect on depression than on pain and functional capacity. Duloxetine (Cymbalta), a serotonin and norepinephrine reuptake inhibitor, is approved by the US Food and Drug Administration for the indication of chronic low back pain.

Evidence is lacking to support the prescription of systemic corticosteroids. However, corticosteroids have the advantage of not being toxic to the kidneys. Oral corticosteroids may be considered in patients with radicular pain from a herniated disk or spinal stenosis where epidural injections are relatively contraindicated (chronic warfarin therapy).

Some patients will have persistent neuropathic pain despite surgical decompression or as a result of postsurgical fibrosis. Opioid therapy is ineffective in many patients with chronic neuropathic pain. Antiseizure medicines, such as gabapentin (Neurontin)<sup>1</sup> and pregabalin (Lyrica), have efficacy in peripheral neuropathic pain. These same medicines are prescribed in patients with chronic neuropathic radicular pain with the hope that the mechanisms that work with peripheral neuropathy will also work for spine pain patients. Although the evidence of benefit for nonperipheral neuropathic pain has been limited. Other medicines including antidepressants (duloxetine [Cymbalta],<sup>1</sup> tricyclic antidepressants) have been tried when other drugs have been ineffective.

Epidural, selective nerve root, or facet joint injections have not shown adequate efficacy to be recommended on a regular basis. However, a limited number (two or three) of spinal injections may be attempted for patients with radicular pain who do not improve with oral medication.

Spinal surgery is indicated for disk herniation with radicular compromise, cervical or lumbar spinal stenosis with myelopathy or neurogenic claudication, and unstable spondylolisthesis. Controversy remains, however, concerning the relative benefit of surgical versus medical therapy for radiculopathy. Discectomy significantly shortens (by about 8 weeks) the acute phase of pain associated with radiculopathy. However, studies with longer follow-up periods have never shown a clear difference between

<sup>1</sup>Not FDA approved for this indication.

conservative and surgical therapies. Some studies have shown that intensive, multidisciplinary, conservative programs can be compared with surgical fusion procedures for patients with spinal instability.

For the most chronically disabled spine pain patients only, intensive multidisciplinary programs including, among others, physical reconditioning and cognitive-behavioral methods, have shown effectiveness.

### Monitoring

From the standpoint of monitoring the efficacy of the treatment, five main dimensions have been recommended to evaluate the outcome of patients with spine pain. The intensity of pain is relevant but so is the perceived functional capacity, generic health status, work disability, and satisfaction with treatment. Many tools are available for the evaluation of each specific dimension. The clinician who decides to start using any specific tool needs to know, among other information, the minimal clinically meaningful changes for each tool, because differences that may be statistically significant when comparing two groups of patients may be irrelevant at the individual patient level. For example, in terms of intensity of pain, the threshold usually accepted is 3.5 to 4.7 and 2.5 to 4.5 out of 10 for patients with acute and chronic pain, respectively.

Precisely evaluating several domains with specific tools is rather time consuming. However, for busy clinicians, there are brief instruments (core set of measures) with roughly seven or eight questions that include all the previously mentioned dimensions and that have been properly validated. One example is the Core Outcome Measure Index (COMI).

### Complications

The clinician should inform the patient about the possible side effects of therapies as they are initiated. At subsequent visits, specific questions regarding the potential side effects are asked. For example, the presence of hypertension, peripheral edema, and hepatic and renal dysfunction need to be evaluated in patients who are taking chronic NSAID therapy.

In addition, a majority of NSAIDs have potential GI toxicity including mild mucosal irritation, ulcers, and perforations. Hematologic and neurologic toxicity are quite variable depending on the prescribed drug. Cardiovascular toxicity may clearly be an issue, particularly for long-term treatments. The benefit of persistent use of NSAIDs for patients with chronic spine pain needs to be weighed against the increased risk of toxicities.

Besides the risks of addiction or death, the use of opiates induces constipation and urinary retention that may be a serious problem for some patients. These drugs can also produce drowsiness, headache, nausea, or vomiting.

Antidepressants also produce drowsiness and anticholinergic symptoms during the first couple of weeks of use. These drugs have specific side effects including tachycardia, weight gain, or sexual problems.

## TINNITUS

Method of

Kenneth S. Yew, MD, MPH

### CURRENT DIAGNOSIS

- Tinnitus is most commonly associated with hearing loss or exposure to loud noise.
- In addition to history and examination, most patients will benefit from an audiogram.
- Unilateral or pulsatile tinnitus, focal neurologic or otologic findings, and tinnitus with vertigo warrant imaging and further evaluation.
- Patients should be evaluated for distress from tinnitus, insomnia, depression, and anxiety.

### CURRENT THERAPY

- Although no cure exists for tinnitus, education and support at initial diagnosis will help to alleviate fears, dispel misconceptions, and guide expectations of treatment.
- Hearing amplification for patients with significant hearing loss can frequently resolve tinnitus.
- Cognitive behavioral therapy (CBT)—either online or in person—can relieve distress in patients with chronic tinnitus.
- Tinnitus distress should be monitored and comorbid insomnia, depression, and anxiety treated.

## Definition and Epidemiology

Tinnitus is defined as a perceived sound without an external cause. It can be classified in several ways. By a traditional method of classification, the most common type of tinnitus is subjective, defined as tinnitus without a corresponding sound on auscultation. Objective tinnitus on the other hand, can be heard by the examiner as well as the patient. The 2014 American Academy of Otolaryngology–Head and Neck Surgery Foundation (AAO-HNSF) tinnitus guideline classifies tinnitus as primary or idiopathic if, after investigation, no cause other than the presence of sensorineural hearing loss (SNHL) can be determined and secondary if it is “associated with a specific underlying cause (other than SNHL) or an identifiable organic condition.” Both the traditional and AAO-HNSF classifications see tinnitus from the perspective of the examiner or investigator. Another common classification is dual, based on whether the patient has non-pulsatile or pulsatile tinnitus. Tinnitus that can be modulated by movement of the head, neck, jaw, or a limb is considered to have a somatosensory component, which is detectable in up to 83% of patients with tinnitus.

Epidemiologic studies of tinnitus have assessed different age groups, definitions, and durations. Tinnitus is estimated to affect 10% to 19% of adults and to be more common with age, peaking in the sixth and seventh decades to as high as 34.4%. A minority of patients report being bothered by their tinnitus, ranging from 6% to 20%, or about 1% overall. Men have a higher prevalence than women in most studies. Pulsatile tinnitus represents less than 10% of all presentations. Prevalence for childhood tinnitus is often similar to that for adults, but some studies show a much higher prevalence. Tinnitus is often not self-reported by the pediatric population.

## Risk Factors and Etiologies

The most common causes of subjective tinnitus are SNHL and occupational or leisure-time noise exposure. Other etiologies of subjective tinnitus include the following:

1. Otologic—Conductive hearing loss, cholesteatoma, Meniere disease, vestibular schwannoma (VS), traumatic cerumen removal
2. Somatic—Temporomandibular joint (TMJ) dysfunction, head or neck injury
3. Ototoxic drugs—Anti-inflammatory agents (aspirin, non-steroidals), antimalarials (quinine, chloroquine), antimicrobials (aminoglycosides, macrolides, tetracyclines, other), anti-neoplastic agents, loop diuretics, local anesthetics, and other
4. Tobacco—Current or prior smoking
5. Genetic—Moderate genetic component noted in chronic tinnitus
6. Infectious
7. Metabolic/cardiovascular—Associations with hyperlipidemia, hypertension, diabetes mellitus, thyroid disease, obesity and vitamin B12 deficiency observed in epidemiologic studies
8. Neurologic—Multiple sclerosis, vestibular migraine, tension headache, type I Chiari malformation, spontaneous intracranial hypotension, and brain-stem stroke
9. Psychiatric—Stress. Most studies have found an association between chronic tinnitus and depression/anxiety symptoms. More severe tinnitus is associated with a greater likelihood of depression and/or anxiety. Neither depression nor anxiety has been demonstrated to cause tinnitus. (Data partially adapted from Yew, 2014.)

The most common causes of pulsatile tinnitus include idiopathic, neoplasms, arterial, venous, and middle ear pathology. Specific causes include the following:

1. Neoplasm—Paraganglioma, VS, meningioma, dermoid tumor
2. Arterial—Dural arteriovenous fistula, arteriovenous malformation, tortuosity or aneurysm, atherosclerotic plaque, congenital abnormality, fibromuscular dysplasia
3. Venous—Idiopathic intracranial hypertension, sigmoid sinus dehiscence or diverticulum, jugular or sigmoid sinus venous thrombosis, venous hum
4. Otologic—Superior canal dehiscence, patulous eustachian tube, otosclerosis

5. Myoclonus—Stapedius, tensor tympani or palatal muscles
6. Hyperdynamic states or increased bone vascularity—pregnancy, anemia, thyrotoxicosis, Paget disease, bone invading tumors or hemangiomas
7. Somatosensory

## Pathophysiology

Tinnitus is thought to arise from an intricate interaction between peripheral and central mechanisms. Although the inciting event for tinnitus may be hearing loss or cochlear damage, the actual generation and maintenance of tinnitus occurs centrally, involving both auditory and nonauditory pathways. Decreased input from the peripheral auditory system alters the excitatory/inhibitory balance within the central auditory processing system. This, in turn, may cause signal hyperactivity and increased synchrony between neural centers as the brain tries to maintain its pre-hearing loss state, a process called “homeostatic plasticity.” These processes may account for a phenomenon called *central gain*, in which the central auditory system becomes hypersensitive. Human and animal studies suggest a role for the brain’s emotional/cognitive areas—including the temporal, parietal, sensorimotor and limbic cortices—in the pathogenesis of tinnitus. Limbic nonauditory and auditory pathway interactions have been found in tinnitus patients using multiple functional imaging modalities, but not all investigators have confirmed differences between patients with and without tinnitus. Frontostriatal circuits appear to be critical in the development and maintenance of both tinnitus and chronic pain, consistent with the view that tinnitus, phantom limb pain, and central pain sensitization may share common pathways. The perception of tinnitus also seems to reside in somatic memory. The medial geniculate body in the thalamus is posited as the site of connection between sound perception, the auditory cortex, and the limbic system. A number of theoretical models of tinnitus psychopathology exist, but as yet none has been found to account for all findings in patients with tinnitus.

## Prevention

Hearing conservation, careful use of ototoxic drugs, and smoking cessation should help to prevent tinnitus. Maintaining a healthy weight and engaging in regular physical activity should reduce tinnitus by preventing obesity and the development of metabolic risk factors. Industrial hearing conservation programs are well established; however, leisure time noise exposure is now associated with more hearing loss than occupational exposure. The use of hearing protection while firing weapons and using power tools should be encouraged. Personal listening devices (PLDs) represent the greatest current risk to hearing. A recent systematic review of studies examining short- and long-term hearing effects in PLD users found evidence of significantly poorer hearing thresholds in long-term PLD users compared with nonusers. Keeping volume settings to no more than 60% or 70% of maximum should comply with current World Health Organization guidelines to limit leisure noise to less than 70 dB for continuous exposure and less than 85 dB for up to 2 hours/days, respectively.

## Clinical Manifestations

Patients report an abrupt or insidious onset of a sound in one or both ears that is continuous or intermittent. The sound may be a ringing, buzzing, roaring, or clicking; it may be high or low pitched. The tinnitus may have a pulsatile quality. Its severity and persistence may vary from transient and mild to chronic and severe. If sought carefully, the pitch or loudness of the tinnitus may be modulated by moving the head, neck, or jaw. Headache or recent head or neck injury can precede certain causes of tinnitus. Other otologic symptoms include preexisting hearing loss, hearing loss or ear fullness during tinnitus, vertigo, noise annoyance, or ear pain. How bothersome tinnitus is to patients varies by its severity and the presence of coexisting depression or anxiety symptoms.

## Diagnosis

The evaluation of patients presenting with tinnitus in a primary care setting includes a thorough history and focused examination. Most patients need an audiogram and some will require imaging or standardized tinnitus impact investigations.

## History

Description—Onset, pitch, quality, unilateral/bilateral, loudness, continuous/intermittent, pulsatile/nonpulsatile

Associated symptoms—Hearing loss, vertigo, otalgia, ear fullness, hyperacusis, headache, neck or TMJ pain, visual disturbance, gait problem, weakness, or paresthesia

Provocative/palliative factors—Stress; change in tinnitus with head, neck, or jaw movement

Past history—Prior tinnitus, hearing loss, occupational/leisure noise exposure, recent head, neck, or ear injury; bruxism; current or recent medications; medical history, tobacco use

Family history—Chronic tinnitus, Meniere disease or otosclerosis

Impact—Degree of tinnitus distress, insomnia, or lifestyle interference

## Examination

General—Blood pressure, body mass index

Head—Masticatory muscle or TMJ tenderness; tinnitus changed by head, face, or jaw movement or contraction

Eye—Nystagmus if vertigo history and papilledema if headache history

Ear—Cerumen impaction, otorrhea, cholesteatoma, retrotympenic mass\*

Neck—Neck mass, tenderness

Neurologic—Cranial nerves; neurologic exam if neurologic symptoms, headache, vertigo, or pulsatile tinnitus

Psychologic—Screen for depression and anxiety if mood symptoms or bothersome tinnitus

For pulsatile tinnitus—

1. Palpate pulse—ask patient to tap out the tinnitus frequency.
2. Pulse asynchronous—consider patulous eustachian tube or myoclonic etiologies.
3. Pulse synchronous—auscultate for bruits over mastoid, preauricular area, temple, orbits, carotids, and for cardiac murmurs.

Although SNHL is the most common etiology for tinnitus, it is important to evaluate for other etiologies during the initial evaluation. Brief intermittent nonpulsatile tinnitus without associated headache, neurologic symptoms, hearing loss, or vertigo may be observed without further evaluation. Patients

\* If a retrotympenic mass suspected, the patient should be referred for a microscopic otologic exam prior to imaging.

with recent onset of nonbothersome pulsatile tinnitus without history of hypertension, obesity, new vision changes, ipsilateral subjective or objective hearing loss, and normal otoscopic findings may be considered for a month or two of observation. If symptoms persist or worsen, pursue imaging and/or specialty referral. Recent loud noise exposure, use of an ototoxic medication, or head/neck trauma can inform the diagnosis and guide both therapy and prognosis. Headache should prompt a careful search for findings suggestive of vestibular migraine, idiopathic intracranial hypertension, or spontaneous intracranial hypotension. Unilateral tinnitus with vertiginous symptoms with or without hearing loss suggests vestibular migraine, Meniere disease, or VS. An abrupt onset is more often seen in somatosensory tinnitus, migraine, Meniere disease, and brainstem stroke or transient ischemic attack.

Tinnitus with a somatosensory component is suggested if the patient is able to change the tinnitus by movement or muscle contraction, especially if he or she has had a recent head or neck injury, coincident onset of musculoskeletal pain and tinnitus, bruxism, or TMJ pain.

An audiogram should be obtained for patients with unilateral or pulsatile tinnitus, suspicion of hearing loss or tinnitus lasting over 6 months, and is an option for patients with tinnitus of less than 6 months. A criterion for asymmetric hearing loss to optimize sensitivity for VS is an average 10 dB difference over the frequencies 1 to 8 kHz.

No reviewed guideline recommends laboratory testing to evaluate patients with tinnitus. Laboratory investigation in patients presenting with tinnitus can be guided by clinical suspicion and existing preventive services screening guidelines.

Table 1 lists imaging options for patients with tinnitus. Specialty consultation is helpful to evaluate the myriad causes of pulsatile tinnitus. Magnetic resonance imaging may be uncomfortable for patients with tinnitus with noise sensitivity. In such cases, contrast-enhanced computed tomography is an alternative.

Patients should be asked how bothered they are by their tinnitus. If bothersome tinnitus is endorsed, then it is helpful to learn how the tinnitus is interfering with the patient's sleep, work, concentration, mood, and quality of life. This understanding will guide subsequent education, support, evaluation, and therapy. Validated questionnaires to assess tinnitus impact and monitor therapeutic response include the Tinnitus Handicap Inventory (THI), screening THI (THI-S) and Tinnitus Functional Index (TFI). The National Institute for Health and Care Excellence (NICE) tinnitus guideline highlights the TFI as it assesses global tinnitus impact, hearing acuity, sleep, anxiety, and depression. The TFI is available at <https://apps.ohsu.edu/research/tech-portal/technology/view/1004796>.

**TABLE 1** Imaging for Patients with Tinnitus

PRESENTATION OF TINNITUS	IMAGING CHOICE	COMMENT
Uncomplicated, bilateral, and nonpulsatile	None	Hearing loss symmetric if present. No other indications for imaging, such as stroke/TIA symptoms, acute vestibular syndrome, focal neurologic exam, or retrotympenic mass.
Bilateral and nonpulsatile with asymmetric hearing loss by audiogram or unilateral and nonpulsatile	MRI of head and IAC	Vestibular Schwannoma risk ~2% if asymmetric hearing loss by audiogram.
Pulsatile	MRI with contrast/MRA of head and IAC CT of head and IAC and CTA	If negative and there is concern for dAVF, consider 4D-CTA if available or DSA. Add MRV if concern for venous etiologies or IIH. MRI more sensitive for neoplasms.
Pulsatile with suspicion of retrotympenic mass by microscopic examination or temporal bone disease	CTA of head and IAC with temporal bone reconstruction	

CT, Computed tomography; 4D-CTA, dynamic computed tomographic angiography; dAVF, dural arteriovenous fistula; DSA, digital subtraction angiography; IAC, internal auditory canal; IIH, idiopathic intracranial hypertension; MRA, magnetic resonance angiography; MRI, magnetic resonance imaging; MRV, magnetic resonance venography; TIA, transient ischemic attack.

## Differential Diagnosis

Brief spontaneous tinnitus, also called “transient ear noise,” is a benign, fleeting, high-pitched, unilateral sound of unknown cause sometimes accompanied by a sensation of hearing loss. The tonal quality of tinnitus must be distinguished from the voices or music heard in an auditory or musical hallucination. Musical hallucinations can be experienced by people with SNHL or more rarely as a manifestation of epilepsy.

## Treatment

Goals for treating patients with tinnitus are to help them understand that tinnitus is common, normally benign, and can improve over time; if it is chronic, therapies exist to help such patients live well with it. [Table 2](#) lists evidence-based tinnitus therapies. Observation with support and education after negative diagnostic workup can be sufficient if tinnitus is not bothersome. In a recent observational study of patients with intrusive tinnitus, the provision of a standardized bundle of tinnitus information to all patients was associated with a nearly a fourfold drop in patients who requested further formal treatment for their tinnitus. Patient interview studies document that tinnitus support and education is beneficial at every stage of care. However, as many as 82.6% patients with tinnitus surveyed worldwide felt that their tinnitus was managed “not very effectively” or “not at all.” As there is still no cure for tinnitus, part of this dissatisfaction may stem from their expectations of therapy. When US audiologists and their patients were asked about treatment goals, audiologists endorsed reduced tinnitus awareness, stress, and anxiety, whereas their patients wanted reduced tinnitus loudness or its elimination. Accurate, supportive education about tinnitus and its treatment is essential to help patients develop informed expectations. [Table 3](#) lists selected patient education resources for tinnitus.

Aside from hearing amplification and CBT, no other therapy has proven effectiveness for tinnitus. Sound therapy to help distract from or mask tinnitus may be helpful for individual patients, but evidence of its overall efficacy is limited. Tinnitus Retraining Therapy (TRT) classically combines sound-enrichment therapy and directive counseling. It can be combined with amplification. Although its individual components may be beneficial, combined TRT has not proven superior in reducing tinnitus distress compared with usual care. Many medications as well as mineral and herbal supplements have been studied for the treatment of tinnitus, but none have proven beneficial. Available studies of acupuncture for tinnitus treatment are limited by methodologic flaws, precluding its recommendation as an effective tinnitus therapy. A variety of neuromodulation techniques to treat tinnitus have been studied; however, the studies have been small and relatively brief, with heterogeneous results. Patients with a somatosensory component to their tinnitus may experience relief from physical or dental splint therapies.

CBT targets thoughts and emotions to affect behavior. Drawing attention to inaccurate thoughts and thought patterns aided by a skilled therapist can help patients develop a more beneficial response to their tinnitus. Other cognitive-based approaches that have been studied for tinnitus include mindfulness-based CBT (MBCT) and acceptance and commitment therapy (ACT). All of these therapies have been shown to decrease the severity and distress of tinnitus but have not improved quality of life or mitigated tinnitus annoyance or loudness, depression, anxiety, or sleep. The one exception is ACT, which, compared with control patients, was found to decrease tinnitus-associated depression. Limited access to CBT therapists is an issue for many patients. Online CBT and ACT effectively reduces tinnitus severity and distress, although in-person therapy tends to have a larger effect.

**TABLE 2** Treatment for Patients with Chronic Tinnitus

TREATMENT	COMMENT
Support and education—in addition to providing printed or online materials, provide teaching at time of evaluation.	Help patients understand what tinnitus is and that it is typically benign. Explain that tinnitus is a result of not a cause for hearing loss. Reassure that it may persist but can improve over time. Discuss the potential for medications to cause or worsen tinnitus. Discuss prevention of tinnitus. Discuss no cures at present but management helpful to relieve distress. Review beneficial treatments and treatments unlikely to benefit.
Amplification.	Offer if hearing loss is affecting communication and consider for hearing loss without communication difficulties. Do not offer without documented hearing loss.
Sound therapy—via an in-ear or wearable device, environmental sound, smartphone, etc.	Option to offer but there is limited current evidence of efficacy.
Medications.	Avoid. Currently there is no evidence for efficacy of any medication to improve tinnitus. Medication may help with insomnia, depression, or anxiety if present.
Psychological therapies.	CBT is the most effective therapy for reducing tinnitus distress and severity. The NICE guideline suggests a stepped approach beginning with online CBT, then group therapy, then individual CBT.
Combination therapies—Tinnitus retraining therapy with amplification, with or without sound therapy.	Current evidence does not support additional efficacy of this widely practiced approach beyond usual care.
Neuromodulation—Repetitive transcranial magnetic stimulation (rTMS), transcranial direct current stimulation (tDCS), transcutaneous vagal nerve stimulation (tVNS), acoustic neuromodulation therapy and others.	Experimental. Insufficient evidence of efficacy from short-term small studies.
Other therapies—Acupuncture, herbal, vitamins, minerals and other dietary supplements.	Ineffective or inconclusive.
Treatments for somatosensory tinnitus.	Some evidence for oromyofascial therapy, dental occlusal splints, physical therapy, and relaxation training.

CBT, Cognitive behavioral therapy; NICE, National Institute for Health and Care Excellence. Data from NICE, AAO-HNSF and European tinnitus guidelines.

## Monitoring

Response to therapy can be assessed by clinical impression or a validated instrument like the TFI. As tinnitus can be associated with depression, use of a depression screening instrument such as the PHQ-9 and inquiring about suicidal ideation is recommended, especially for patients with at least moderately distressing tinnitus. If distress from tinnitus is not improving or worsens, review the completeness of the workup and discuss with the patient a referral for CBT or tinnitus specialty evaluation. Fortunately, although the severity of tinnitus may fluctuate, over time it tends not to worsen and may improve.

## Complications

Carefully monitoring the level of a patient’s distress from tinnitus, diagnosing treatable etiologies, and recognizing and treating comorbid conditions such as depression, insomnia, and anxiety will help to avoid most complications. Care to ensure follow-up and consultation for patients presenting with pulsatile tinnitus is important as up to one-third of them can have an underlying neoplasm or vascular etiology with potential for complications including vision loss, stroke, or hemorrhage. It is unknown if tinnitus is a risk factor for future dementia in a person with SNHL or if screening for dementia in this setting will improve outcome.

## ALLERGIC REACTIONS TO INSECT STINGS

Method of

James M. Quinn, MD

### CURRENT DIAGNOSIS

Classify reaction based upon clinical manifestations

- Local reactions
  - Uncomplicated “usual” local reaction—mild redness, pain, and swelling limited to area of sting
  - Large local reaction—redness, pain, and swelling extending beyond area of sting
- Systemic reactions
  - Cutaneous only—flushing, urticaria, angioedema (excluding tongue, throat, larynx)
  - Anaphylaxis (cutaneous symptoms and/or respiratory symptoms, gastrointestinal symptoms, cardiovascular symptoms, uterine cramping, etc.)

### CURRENT THERAPY

- Local reactions
  - Uncomplicated local reaction
    - H1 antihistamines, analgesics, cold compress
    - Discuss avoidance measures
  - Large local reaction
    - H1 antihistamines, analgesics, cold compress, avoidance measures
    - Discuss avoidance measures
    - Further evaluation, testing, epinephrine autoinjectors optional
- Systemic reactions
  - Cutaneous only
    - Based upon clinical situation and prior history
    - H1 antihistamines, epinephrine in some circumstances
    - Discuss avoidance measures
    - Further evaluation, testing, epinephrine autoinjectors optional
  - Anaphylaxis
    - Epinephrine intramuscularly
    - Consider adjunctive therapy—antihistamines, bronchodilators, intravenous fluids, vasopressors, oxygen, other supportive measures.
    - Provide epinephrine autoinjectors
    - Discuss avoidance measures
    - Consider further evaluation, testing, consideration of immunotherapy

### Pathophysiology

The pathophysiology of insect sting reactions varies based upon the classification. Uncomplicated local reactions are due to direct toxic effects of the venoms. Venom components include enzymes,

vasoactive amines, peptides, and other contents that directly lead to local cell death, tissue destruction, vasodilatation, altered hemostasis, and inflammation.

Fire ant stings initially follow the pattern of the uncomplicated local reactions described. Fire ant venom is unique in containing highly basic pH piperidine alkaloids. Piperidine alkaloids lead to local tissue necrosis and a pathognomonic sterile pseudopustule at the center of an otherwise uncomplicated local reaction.

Large local reactions result from an immunologic response rather than simply direct toxic effects. The reaction is a broader and more sustained immunologic late-phase response to specific antigens in the venom. It is often (up to 80% of cases) associated with and possibly mediated by venom-specific immunoglobulin E (IgE).

Systemic reactions are characterized by signs and symptoms occurring distantly from the sting site. Onset is generally rapid and can include cutaneous, respiratory, cardiovascular, gastrointestinal, and/or other symptoms. Systemic reactions are the result of mast cell degranulation from venom specific-IgE binding. Mast cells release a wide array of vasoactive amines, prostaglandins, leukotrienes, platelet activating factor, and other cytokines. These lead to vasodilatation, capillary leak, edema, bronchospasm, etc.

There are clinical situations when patients should be suspected of having an underlying mast cell disorder as a pathophysiologic contributor. These include very severe anaphylaxis, hypotension, severe anaphylaxis without cutaneous symptoms, and patients without detectable IgE.

### Prevention

Prevention focuses on avoidance of stings. General strategies that may be effective include using professional exterminators for known nests with periodic reinspections; wearing fully closed-toe shoes or sandals outdoors (include socks for fire ant prevention); use of caution when or avoidance of eating or drinking outdoors, especially drinking from closed or opaque containers or straws; vigilance in wooded areas, around flowering plants, and garbage; and wearing shoes, socks, long pants, long sleeves, and hats when gardening or performing other “at-risk” outdoor activity. If the history of the sting or diagnostic testing identifies the suspected insect, teach patients about the habits and nesting of the specific insect.

Stinging insects are the Hymenoptera order and include the Apidae (bee) family of honeybees and bumblebees; the Vespidae (wasp) family of hornets, yellow jackets, and paper wasps; and the Formicidae (ant) family of the imported fire ant. Honeybees and bumblebees are generally not aggressive. They feed on nectar from flowering plants and will sting only in self-defense such as stepping barefoot on a bee in a field or with an accidental close encounter. Bees will also sting after a direct threat to their nests. Bees nests can be found in commercial hives, tree hollows, old logs, or, less commonly, in the walls of buildings. Africanized honeybees, found primarily in the southern third of the United States, differ only in that they are far more aggressive in defense of their hives. Massive and persistent retaliation can result simply from the vibration of lawn equipment several yards from their hive. The stingers of bees are barbed and often result in retention of the stinger and venom sac at the sting site. A retained stinger can occur, although less commonly, with wasps.

Yellow jackets are scavengers, seeking food wherever available—at picnics, around garbage containers, in soda cans, etc. They are highly aggressive and may sting even if unprovoked. Their nests are found underground, in rotted wood, or in wall spaces. In many areas of the country, yellow jackets are the most common cause of stings.

Hornets and paper wasps generally are not aggressive and do not sting unless defending their nests. Paper wasp nests are classically thin, paper-like honeycomb structures found under the eaves of homes, windowsills, and railings. Hornet nests are typically grayish paper mâché structures hanging from tree limbs. There are several species of hornets and wasps that have black and yellow coloring that can make them difficult to distinguish from yellow jackets and bees, making simple visual identification unreliable.

Imported fire ants are extremely aggressive, especially in defense of their nest. Fire ants are endemic to the southern United States. Fire ant nests are built underground and generally capped by a mound of overlying loose soil. Individual ants can sting multiple times and the disturbed mound easily spills out hundreds to thousands of workers prepared to sting in defense of the nest.

### Clinical Manifestations

Classification of insect sting reactions based upon the clinical manifestations is important to the diagnostic and therapeutic approach. Most insect sting reactions can be classified as local or systemic. Local reactions are further subdivided as uncomplicated local reactions or as large local reactions. Systemic reactions can be further subdivided as cutaneous only or as anaphylaxis.

Uncomplicated local reactions are the expected usual reaction and are characterized by mild redness, pain, itching, and swelling limited to the area of sting generally not larger than 5 to 10 cm. These local reactions begin immediately after the sting and generally resolve over several hours but may linger up to 48 hours. Uncommonly, the pain, burning, or itch of an isolated fire ant sting goes unnoticed, but the sterile pseudopustule appears within 24 hours of the sting.

Large local reactions occur in approximately 5% to 15% of insect stings. These reactions are generally defined as larger than 10 cm or a patient's palm and can progress, involving an entire limb. Large local reactions generally begin within 6 to 12 hours, peak within 24 to 48 hours, and resolve within 3 to 10 days. Large local reactions commonly recur with repeat stings.

Systemic reactions occur in approximately 1% to 7% of stings. Systemic cutaneous-only reactions are limited to flushing, urticaria, and angioedema (excluding the airway—tongue, throat, larynx). Most systemic reactions in children are cutaneous only, whereas most systemic reactions in adults are anaphylactic.

Systemic anaphylaxis occurs in 1% to 3% of stings. Anaphylaxis is defined as the acute onset (minutes to several hours) of symptoms after a sting and include two or more of the following organ systems: cutaneous (pruritus, flushing, urticaria, angioedema), respiratory (shortness of breath, chest tightness, cough, stridor, wheezing), cardiovascular (light headedness, syncope, tachycardia, hypotension), or gastrointestinal (abdominal pain, nausea, vomiting, diarrhea). In addition, anaphylaxis can be defined as the acute onset of hypotension after exposure to a known allergen for the patient.

Toxic reactions can occur due to large numbers of stings (>20 to 50 flying Hymenoptera stings in an adult). Toxic signs and symptoms are often delayed and can include myalgia, fevers/chills, headache, rhabdomyolysis, renal failure, hemolysis, diffuse intravascular coagulation, acute respiratory distress syndrome, and death. The lethal dose for a 60-kg adult has been estimated at more than 1100 honeybee stings.

There are also unusual and rare reactions of unknown pathophysiology that include glomerulonephritis, Guillain-Barré syndrome, seizures, and serum sickness.

### Diagnosis

Categorizing the type of reaction is essential for risk assessment, diagnostic evaluation, and treatment planning. History of the event, signs and symptoms, and response to therapy are important and will allow the reaction to be accurately categorized as uncomplicated local, large local, systemic cutaneous-only, or systemic anaphylaxis.

Patients experiencing uncomplicated local reactions are not at increased risk of anaphylaxis and do not require additional diagnostic evaluation.

Patients experiencing large local reactions generally do not require additional diagnostic evaluation because they have a small relative risk of future anaphylaxis. Despite the common occurrence of venom specific IgE, only 4% to 10% of patients with a history of large local reactions go on to develop a systemic reaction, and only less than 5% go on to develop anaphylaxis after repeat stings.

Patients with systemic cutaneous-only reactions generally do not require additional diagnostic evaluation because they also have a small relative risk of future anaphylaxis. Only 10% to 15% of children with systemic cutaneous-only reactions have recurrent cutaneous-only reactions and less than 3% go on to have anaphylaxis. For adults with cutaneous-only reactions, there is a less than 3% to 5% risk of progression to anaphylaxis after resting.

There may be special situations when patients with large local or systemic cutaneous-only reactions are at increased risk and would benefit from referral to consider additional diagnostic testing, epinephrine autoinjectors, and possible immunotherapy. Special situations include frequent stings, high-risk medical conditions, at-risk medications ( $\beta$ -blockers, angiotensin-converting enzyme [ACE] inhibitors), impaired quality of life, and/or imported fire ant stings. Data regarding future risk of repeat fire ant stings are not robust, and multiple sting attack rates are high. In these patients, the decision regarding evaluation and therapy is based on a risk-benefit discussion with the patient.

Patients with systemic anaphylaxis after stings should undergo referral for further diagnostic testing. Patients with systemic reactions to stings have a 25% to 75% chance of another systemic reaction with the highest rates of recurrence seen with more severe reactions. Systemic anaphylaxis to insect stings can be fatal. Insect stings account for up to 20% of all fatalities due to anaphylaxis and estimates are that 40 (and likely more) patients die annually from insect sting anaphylaxis in the United States.

Additional diagnostic testing may commonly include prick and intradermal skin testing, serologic assessment of specific IgE, and serum tryptase.

### Therapy and Monitoring

Uncomplicated local reaction should be cleaned, and any retained stinger carefully removed. Symptomatic therapy with antihistamines, analgesics, and cold compresses can be administered. Patients should also be given advice regarding avoidance measures to prevent future stings. In the case of fire ant stings, the pseudopustule is sterile and bacteriostatic; it should not be unroofed or opened.

Large local reactions should be approached similarly to uncomplicated local reactions with symptomatic therapy. For patients with frequent painful and/or debilitating large local reactions, the unstudied method of a short burst of oral corticosteroids for 3 to 7 days is sometimes used. Efficacy with immunotherapy for large local reactions has been demonstrated in early trials, but further study is needed. Unneeded antibiotic therapy for cellulitis should be avoided. Cellulitis is unlikely at 24 to 48 hours when patients commonly present. Later presentations of large local reactions can make distinguishing cellulitis more difficult. However, after 48 hours, many large, local reactions are plateauing or improving while infection would be expected to worsen. In addition, presence of fever would suggest infection.

Systemic cutaneous-only reactions (flushing, urticaria, angioedema not involving the airway) may require a more nuanced approach. Because of the low risk of developing additional symptoms, patients with a history of prior cutaneous-only reactions can be appropriately treated with antihistamines and close observation if they present again with cutaneous-only reactions. On the other hand, patients with a history of anaphylaxis who may initially present with cutaneous-only symptoms should immediately be treated with injectable epinephrine because of the significant risk that additional symptoms will develop.

Those patients with large local reactions or systemic cutaneous-only reactions and in whom special situations exist may be given epinephrine autoinjectors, recommended to wear medical identification information, and referred to an allergist/immunologist for consideration of further evaluation.

Systemic anaphylaxis to insect stings should be treated acutely in the same way as anaphylaxis from any cause. The drug of choice, epinephrine 1 mg/mL (1:1000), should be injected intramuscularly preferentially in the lateral thigh with 0.3 to 0.5 mg in adults and 0.01 mg/kg up to 0.3 mg in children without delay. Transport to a fully capable emergency medical facility should be undertaken as soon as practicable. As available, adjunctive therapies with antihistamines, bronchodilators, intravenous fluids, vasopressors, oxygen, and other supportive measures can be considered after the administration of epinephrine based on the clinical scenario. These adjunctive therapies should not be used as a substitute for possible repeat doses of epinephrine if additional epinephrine is available and indicated. Epinephrine administration should not be delayed because delayed use of epinephrine has been associated with fatal reactions in humans. In addition, animal models demonstrate that advanced anaphylaxis can become refractory to epinephrine. Patients with a rapid and complete response to initial therapy should generally be observed for 3 to 6 hours. Prolonged observation or admission should be considered for patients with severe, prolonged, or refractory symptoms.

After acute treatment but before discharge, patients should be given an epinephrine autoinjector (Auvi-Q, EpiPen) and instructed in the proper technique for use. Patients should be instructed in basic avoidance strategies to prevent future stings and offered medical identification information. Patients should understand the significant risk of recurrence and the need to follow up for additional testing and consideration for immunotherapy. If additional evaluation identifies specific IgE to the stinging insect, immunotherapy can be offered. Immunotherapy to stinging insects is quite effective in reducing the risk of a systemic reaction while on immunotherapy and provides longer lasting risk reduction for many years after completing 3 to 5 years of immunotherapy.

## ANAPHYLAXIS

Method of

Justin Greiwe, MD; and Jonathan A. Bernstein, MD

### CURRENT DIAGNOSIS

- There is no universal agreement on the definition of anaphylaxis or the criteria for diagnosis.
- A comprehensive clinical history of the events surrounding the reaction provides the most valuable data along with a detailed review of current medications, recently ingested foods and/or drugs, insect stings, and physical activities before or after the event.
- While anaphylaxis remains primarily a clinical diagnosis, measurement of selected biomarkers (most commonly serum tryptase) has been used in research and clinical settings to assist in confirming this reaction.
- Cutaneous or serum-specific immunologic testing should only be performed to confirm or exclude a suspected agent under the supervision of an allergy specialist trained to interpret the meaning of the test results. Random testing to a large panel of foods or other allergens without a specific history has low diagnostic utility.

### CURRENT THERAPY

- Prompt administration of intramuscular epinephrine is the gold-standard first-line medication for the treatment of anaphylaxis. Delay in treatment with epinephrine has been associated with increased morbidity and mortality.
- Patients with severe reactions can have massive fluid shifts that can occur rapidly due to increased vascular permeability which require aggressive fluid resuscitation.
- Additional treatments are considered supportive and include the addition of H1 and H2 antihistamines for itching, urticaria, and gastrointestinal complaints; albuterol for bronchospasm; oxygen; and placing the patient in the Trendelenburg position.
- Corticosteroids are not useful for the acute treatment of anaphylaxis since these medications take 4 to 6 hours to reach maximum effectiveness and there is a lack compelling evidence that corticosteroids reduce anaphylaxis severity or prevent biphasic reactions.

## Introduction

Anaphylaxis is an acute, potentially life-threatening multisystem reaction caused by the sudden systemic release of preformed mediators from mast cells and basophils which include histamine, tryptase, chymase, heparin, histamine-releasing factor, and platelet-activating factor (PAF). Cellular activation also stimulates the production of lipid-derived newly formed mediators, such as prostaglandins and cysteinyl leukotrienes. These reactions are frequently, but not always, mediated by an immunologic mechanism involving two or more organs and/or are associated with hypotension or upper respiratory compromise. Other clinical manifestations include flushing, pruritus, urticaria, angioedema, shortness of breath, wheezing, nausea, vomiting, and diarrhea. Risk of death is mainly from cardiovascular collapse or asphyxiation caused by laryngeal edema. Drugs (nonsteroidal antiinflammatory drugs [NSAIDs]/antibiotics), foods, and Hymenoptera venom stings are the most common triggers; however any agent capable of inciting a sudden, systemic degranulation of mast cells can lead to anaphylaxis.

Various organizations have attempted to clarify the definition of anaphylaxis but with no consensus agreement. Experts from the

**TABLE 1** Comorbidities and Risk Factors for the Development of Anaphylaxis

**Age:** infants are at risk because manifestations might not be detected; teenagers are at risk because of “risky behavior”; elderly are at risk because of medical comorbidities and increased use of medications such as  $\beta$ -blockers leading to more severe cardiovascular symptoms at presentation

**Gender:** anaphylaxis is more common overall in females

**Drugs:** medications may impact severity of symptoms and response to treatment (see [Table 2](#))

**Comorbid Conditions:** asthma, other respiratory diseases (e.g., chronic obstructive pulmonary disease, interstitial lung disease), cardiovascular disease, mast cell disorder (e.g., systemic mastocytosis)

**Route of Administration:** oral antigens are less likely to trigger anaphylaxis than parenteral antigens

**Geography:** prescription rates for self-injectable epinephrine devices are greater in northern than in southern states; living in a rural environment may affect incidence

**Atopy:** risk factor for anaphylactic and anaphylactoid reactions in general

**Exposure History:** the longer the interval since previous antigen exposure, the less likely a reaction will occur; previous anaphylactic reaction

**Other Factors:** active infections (e.g., upper respiratory tract infection, fever), physical exertion, premenstrual status, delayed administration of epinephrine, substance abuse (impairs judgement and can diminish recognition of symptoms), mental illness not well controlled

National Institute of Allergy and Infectious Disease (NIAID) and Food Allergy and Anaphylaxis Network (FAAN) met in 2005 and published diagnostic criteria for anaphylaxis. Controversy arose shortly thereafter with the World Allergy Organization (WAO) claiming that the published definition of anaphylaxis might exclude patients with clinical manifestations expressed by a single system only. Subsequent criteria published by Sampson et al. attempted to address this concern by adding single system caveats. Regardless of the continuing debate, the NIAID/FAAN criteria has been validated in real-world emergency room settings, establishing an accurate diagnosis of anaphylaxis with a sensitivity of 95% and a specificity of 71%.

### Epidemiology

The prevalence of anaphylaxis in industrialized countries is estimated to range between 1.6% to 5.1%; however, rates seem to be increasing. In one study the majority (80.2%) of anaphylaxis cases were triggered by food, principally peanut and tree nut, indicating that increased rates of anaphylaxis might coincide with increasing rates of food allergy worldwide. Given increased prevalence rates, accurate recognition and management of anaphylactic episodes is of the utmost importance as a delay in treatment can lead to increased morbidity and mortality. In this regard, several consensus guidelines, including the American, European, and WAO guidelines, have been published to simplify this task.

### Risk Factors

Anaphylactic reactions are becoming increasingly more common with an estimated 1500 fatalities/year caused by anaphylaxis in the United States. Comorbidities and concurrent medications may impact the severity of symptoms and response to treatment in patients experiencing anaphylaxis. Risk factors for the development of anaphylaxis and medications that may impact severity of symptoms and response to treatment are reviewed in [Tables 1 and 2](#). Risk factors for fatal reactions include adolescence, a history of a previous anaphylactic reaction, allergy to peanut or tree nuts, history of asthma, absence of cutaneous symptoms, and delayed administration of epinephrine.

**TABLE 2** Concurrent Medications That May Impact Severity of Symptoms and Response to Treatment

Possibly put patient at risk for more serious, treatment resistant anaphylaxis\*

- $\beta$ -adrenergic blockers
- $\alpha$ -adrenergic blockers
- Angiotensin-converting enzyme (ACE) inhibitors
- Angiotensin II receptor blockers
- Some tricyclic antidepressants (e.g., amitriptyline)
- Monoamine oxidase inhibitors

Potentially affect recognition of anaphylaxis

- Sedatives, hypnotics, antidepressants, ethanol, recreational drugs

Exacerbate anaphylaxis symptoms by causing nonimmunologic mast cell activation

- Ethanol, opiates, nonsteroidal anti-inflammatory drugs

*\*Evidence of impact for most of these medications are still controversial/debatable, and expert opinion continues to shift with regard to the safety of these medications in anaphylaxis, especially with regard to concurrent use during aeroallergen and venom immunotherapy. A recent systematic review and meta-analysis of studies that assess the influence of  $\beta$ -blockers and ACE inhibitors on anaphylaxis suggest that the quality of evidence showing that the use of these medications increases the severity of anaphylaxis is low owing to differences in the control of confounders arising from the concomitant presence of cardiovascular diseases*

While rare and typically limited to hempseed ingestion, anaphylaxis to cannabis or marijuana has been increasingly reported as these products gain more traction in the medical community and through legalization. Multiple cannabis allergens have been sequenced, four of which are accepted by the WHO/IUIS Allergen Nomenclature Subcommittee (Can s 2, Can s 3, Can s 4, Can s 5). Allergic sensitization can result from inhaling, smoking, touching, and eating cannabis, with increased risk for those who work in the industrial manufacture of these products. Hempseed exposures can be inadvertent as it can be found hidden in foods and drinks, and there have been reports of cross-reactivity between marijuana and certain foods including cherry, tangerine, peach, tomato, and hazelnut. However, the importance and relevance of these allergens have not been well established.

### Pathophysiology

Most anaphylactic reactions are mediated by immunoglobulin E (IgE); however, not all episodes can be attributed to this mechanism. The WAO uses the term “immunologic anaphylaxis” to describe IgE-mediated, IgG-mediated, and immune complex/complement-mediated reactions. “Nonimmunologic anaphylaxis” (previously referred to as anaphylactoid reactions) is caused by agents or events that induce sudden degranulation of mast cells or basophils without the involvement of immunoglobulins like IgE.

### Prevention

Avoidance of the confirmed trigger is the best way to prevent recurrence of anaphylaxis. For foods, this means educating patients about reading food labels, informing family and friends about these reactions, and being vigilant about avoiding the food(s) when eating in public establishments. Other triggers are more difficult to avoid such as venomous stinging insects or not possible in the case of idiopathic anaphylaxis (IA). In rare instances, an infection may require treatment with an antibiotic known to cause anaphylaxis in a patient. If there are no equally efficacious alternatives (i.e., penicillin for syphilis), an allergist/immunologist may perform skin testing to penicillin major and if available, minor determinants to confirm the allergy, and if positive, perform penicillin desensitization. This procedure involves relatively rapid administration of increasing amounts of the antibiotic under carefully controlled conditions by trained personnel with emergency therapy readily available until the target dose is reached. Thus desensitization results in tolerance which allows the allergic patient to take the medication without a reaction.

Immunologic changes associated with immunotherapy are complicated, but the goal is to induce immune tolerance. The mechanism for inducing tolerance for different antigens is still poorly elucidated but is believed to occur by increasing regulatory T cells resulting in increased production of inhibitory cytokines like interleukin (IL)-10, transforming growth factor  $\beta$  (TGF- $\beta$ ), or both. IL-10 and TGF- $\beta$  encourage the shift of antibody production from IgE toward the noninflammatory isotypes IgG4 and IgA, respectively. IL-10 is also involved in the reduction of proinflammatory cytokine release from mast cells, eosinophils, and T cells, as well as elicitation of tolerance in T cells by means of selective inhibition of the CD28 costimulatory pathway which effectively reduces lymphoproliferative responses to allergens. There also seems to be a shift in the immune response from a Th2 to a Th1 cytokine profile later in the immunotherapy course possibly mediated by the increased production of IL-12.

Long-term preventive measures include venom immunotherapy for Hymenoptera stinging insects (honey bee, wasp, yellow jacket, yellow hornet, white faced hornet) and food immunotherapy (oral, sublingual) for IgE-mediated food allergies. It is essential to recognize and manage poorly controlled comorbid conditions such as asthma and other respiratory diseases, cardiovascular disease, mastocytosis, and mast cell activation syndrome that may increase the risk for anaphylaxis. Administration of certain medications such as  $\beta$ -blockers and possibly angiotensin-converting enzyme (ACE) inhibitors (see Table 2) are associated with a greater risk for severe anaphylaxis by interfering with the therapeutic response to epinephrine and should be avoided if possible. This is especially true for the administration of therapeutics that place the patient at increased risk for anaphylaxis such as allergen immunotherapy (i.e., subcutaneous, sublingual, and venom immunotherapy).

### Clinical Manifestations

Anaphylaxis is an acute multiorgan system reaction that generally begins within seconds to minutes but can be delayed occurring anywhere from 1 to 24 hours later after exposure to a trigger. The most common organ system involved is the skin or mucous membranes with >90% of patients presenting with some combination of pruritus, urticaria, and/or angioedema and erythema. Anaphylaxis, by nature, is unpredictable and heterogeneous in its presentation so it may be mild and resolve spontaneously or it may be severe and progress to significant respiratory or cardiovascular compromise. To help classify the severity of anaphylactic reactions, the WAO developed a universal 5-stage grading system. It was intended to more accurately assess when epinephrine should be administered during subcutaneous immunotherapy (SCIT), but has since been used to better classify all forms of systemic reactions. Each grade is based on the organ system involved defined as cutaneous, conjunctival, upper respiratory, lower respiratory, gastrointestinal, cardiovascular, or other, and the severity is based on clinical judgement (Table 3).

Anaphylaxis can present as a uniphasic response, biphasic response, or as being refractory to treatment, all of which need to be considered and recognized by the clinician evaluating these patients. Biphasic anaphylaxis is defined as a potentially life-threatening recurrence of symptoms after the resolution of the initial immediate anaphylactic episode without re-exposure to the causative agent. The delayed portion of the biphasic reaction typically occurs within 12 hours but has been reported to occur up to 72 hours after resolution of initial symptoms. Biphasic reactions have been reported to develop in up to 21% of anaphylactic episodes (all ages) and in up to 15% of children. Biphasic reactions seem to be associated with the severity of the initial anaphylactic episode. Rarely, the onset of anaphylaxis will be delayed beginning hours rather than minutes after exposure to the causative agent. This is especially true for red meat allergy, also called mammalian meat allergy or  $\alpha$ -gal allergy. This condition is characterized by development of an IgE antibody directed against a mammalian oligosaccharide epitope, galactose- $\alpha$ -1,3-galactose (“ $\alpha$ -gal”) after a lone star tick bite which contains the  $\alpha$ -gal protein. Patients typically do not develop symptoms until several hours (4 to 6 hours or even longer) after eating red meat.

**TABLE 3** World Allergy Organization Subcutaneous Immunotherapy Systemic Reaction Grading System

#### Grade 1:

*Symptom(s)/sign(s) of 1 organ system present*

**Cutaneous:** generalized pruritus, urticaria, flushing, or sensation of heat or warmth

*or*

**Angioedema** (not laryngeal, tongue or uvular)

*or*

**Upper respiratory:** rhinitis (e.g., sneezing, rhinorrhea, nasal pruritus, and/or nasal congestion)

*or*

**Throat-clearing** (itchy throat)

*or*

**Cough** perceived to originate in the upper airway, not the lung, larynx, or trachea

*or*

**Conjunctival:** erythema, pruritus, or tearing

**Other:** nausea, metallic taste, or headache

#### Grade 2:

*Symptom(s)/sign(s) of more than 1 organ system present*

*or*

**Lower respiratory:** asthma: cough, wheezing, shortness of breath (e.g., less than 40% PEF or FEV1 drop, responding to an inhaled bronchodilator)

*or*

**Gastrointestinal:** abdominal cramps, vomiting, or diarrhea

*or*

**Other:** uterine cramps

#### Grade 3:

**Lower respiratory:** asthma (e.g., 40% PEF or FEV1 drop NOT responding to an inhaled bronchodilator)

*or*

**Upper respiratory:** laryngeal, uvula, or tongue edema with or without stridor

#### Grade 4:

**Lower or upper respiratory:** respiratory failure with or loss of consciousness

*or*

**Cardiovascular:** hypotension with or without loss of consciousness

#### Grade 5: Death

FEV1, forced expiratory volume in one second; PEF, peak expiratory flow.

### Diagnosis

There is no universal agreement on the definition of anaphylaxis or the criteria for diagnosis. Table 4 summarizes the NIAID/FAAN criteria established in 2005 which continues to be generally accepted today.

While anaphylaxis remains primarily a clinical diagnosis, measurement of selected biomarkers has been used in research and clinical settings to assist in confirming this reaction. Plasma histamine, platelet activating factor, and serum tryptase can be obtained in certain situations; however, there are specific collection timeframes that need to be strictly adhered to for the result to be valid. Serum tryptase is the most commonly used biomarker to distinguish anaphylaxis from other conditions with a similar presentation (i.e., carcinoid syndrome, vasovagal reactions, seizures). Acute elevation of serum tryptase secondary to mast cell degranulation can occur through an IgE-mediated mechanism (i.e., venom and drug allergy) or direct degranulation of mast cells through a non-IgE mediated mechanism (i.e., NSAIDs or opiates). Tryptase can rise in serum or plasma as early as 15 minutes after clinical onset of anaphylaxis and should be collected between 30 minutes and 2 hours after symptom-onset if possible. Samples collected before or after this window are less accurate due to diminished sensitivity. Previous studies have questioned the sensitivity of serum tryptase in food-induced reactions; however a recent prospective study suggests that serum tryptase is a valuable tool in food allergic reactions as well

**TABLE 4** Diagnostic Criteria for Anaphylaxis

Anaphylaxis is highly likely when any 1 of the following 3 criteria is met:

1. Sudden onset of symptoms (minutes to several hours) with involvement of skin and/or mucosa (e.g., generalized hives, itching or flushing, swollen lips/tongue/uvula), AND at least one of the following:
  - Respiratory symptoms or signs (e.g., shortness of breath, wheezing, cough, hypoxemia)
  - Hypotension or other symptoms of target-organ dysfunction (e.g., collapse, incontinence)
2. Sudden onset of 2 or more of the following after exposure to a likely allergen or other trigger for that patient (minutes to several hours):
  - Skin or mucosal membrane symptoms
  - Respiratory symptoms
  - Hypotension or other symptoms of target-organ dysfunction
  - Gastrointestinal symptoms such as abdominal pain or vomiting
3. Hypotension occurring acutely (minutes to several hours) after exposure to a known or established allergen for that patient. Hypotension is defined as the following:
  - Adults: Systolic blood pressure < 90 mm Hg, or a decrease > 30% from patient's baseline
  - Infants and children: Low systolic blood pressure (age-specific) or a decrease > 30% in systolic pressure

Modified from Weller KN, Hsieh FH. Anaphylaxis: highlights from the practice parameter update, *Cleve Clin J Med* 89(2):106–111, 2022.

and correlates with symptom severity. There is still debate on how serum tryptase can be used effectively in diagnosing anaphylaxis or mast cell activation with different studies quoting different cutoff values. Data on cutoffs specifically for food allergy are even harder to come by (Table 5).

According to this study comparing peak tryptase reaction levels at 2 hours with baseline is essential in correct interpretation, and a rise in tryptase of 30% above baseline is associated with a food allergic reaction. It is important to note that a normal serum tryptase level does not exclude anaphylaxis as the diagnosis.

A comprehensive clinical history of the events surrounding the reaction provides the most valuable data along with a detailed review of current medications, recently ingested foods and/or drugs, insect stings, and physical activities before or after the event. This approach oftentimes uncovers the appropriate trigger; however, in many cases no clear trigger can be identified. More accurate diagnostic testing can be utilized in some cases when the patient or clinician suspects a specific antigen as the triggering agent. Cutaneous or serum specific immunologic testing should only be performed to confirm or exclude a suspected agent under the supervision of an allergy specialist trained to interpret the meaning of the test results. Random testing to a large panel of foods or other allergens (i.e., venoms) without a specific history has a low diagnostic utility and can result in more questions rather than answers given the high rate of false positive reactions reported, especially for foods. If diagnostic skin testing is performed, it should be delayed for at least 3 to 4 weeks after the event to obtain an accurate test result in order to allow for recovery of skin mast cells. In certain cases there may be no validated cutaneous or in vitro test to detect the potential for an IgE-mediated reaction. In these circumstances, a graded challenge or provocation test can safely be carried out under the supervision of an experienced allergist in a setting that is fully equipped to respond to any potential medical emergency including anaphylaxis. Unlike desensitization, graded challenges do not work by modifying the allergic response to the agent. Therefore patients who tolerate a graded challenge is an indication that they are not allergic to the specific agent administered.

## Differential Diagnosis

Anaphylaxis can sometimes be difficult to recognize because it can mimic other conditions and is variable in its presentation. Common conditions that mimic anaphylaxis are included in Table 6. It is beyond the scope of this review to discuss in detail clonal and nonclonal mast cell disorders, but these conditions should be considered in a patient presenting with anaphylaxis, especially in the context of a stinging insect venom allergic reaction.

## Therapy (or Treatment)

Prompt administration of intramuscular epinephrine is the gold-standard first-line medication for the treatment of anaphylaxis. Delay in treatment with epinephrine has been associated with increased morbidity and mortality. Epinephrine autoinjectors (EAI [Auvi-Q (kaléo, Richmond, VA), EpiPen Jr, EpiPen (Mylan Inc, Canonsburg, PA)]) are commercially available in three different concentrations in the United States: 0.1 mg (7.5 to 14 kg body weight), 0.15 mg (15 to 30 kg), and 0.3 mg (>30 kg). Epinephrine can be administered intramuscularly (preferred) or subcutaneously every 5 to 15 minutes but can be given more frequently if deemed appropriate. The recommended adult dose of 1:1000 (1 mg/mL) epinephrine is 0.2 to 0.5 mg (mL), whereas the pediatric dose is 0.01 mg/kg (0.01 mL/kg/dose of 1 mg/mL solution), with a maximum dose of 0.3 mg. If not administered through an autoinjector, the epinephrine dose should be drawn up using a 1 mL syringe and injected intramuscularly into the mid-outer thigh. A higher dose (e.g., 0.5 mL) within the recommended dose range should be considered in patients with severe anaphylaxis.

Patients with severe reactions can have massive fluid shifts that can occur rapidly due to increased vascular permeability which require aggressive fluid resuscitation. Additional treatments are considered supportive and include the addition of H1 and H2 antihistamines for itching, urticaria, and gastrointestinal complaints; albuterol for bronchospasm; oxygen; and placing the patient in the Trendelenburg position. Corticosteroids are not useful for the acute treatment of anaphylaxis since these medications take 4 to 6 hours to reach maximum effectiveness. Despite this, corticosteroids are often used in the emergency treatment of anaphylaxis under the assumption that these medications may be beneficial in preventing biphasic reactions. A comprehensive literature review of 31 studies recently reported that biphasic reactions were more likely to occur in moderate to severe anaphylaxis or when anaphylaxis was not treated with timely epinephrine. Due to the potential adverse effects of corticosteroids and lack of compelling evidence demonstrating an effective role in reducing anaphylaxis severity or preventing biphasic anaphylaxis, the authors do not advocate their routine use for treatment of anaphylaxis. The appropriate observation period after an anaphylactic event often depends on the severity and duration of the initial reaction as well as the patient's response to treatment, previous reaction history, associated comorbidities, and access to medical care. Patients with moderate to severe anaphylaxis should be observed for a minimum of 4 to 8 hours; however, milder presentations can be observed for a shorter time period. All patients with a history of anaphylaxis should be given a prescription for an EAI along with instructions for self-administration and an allergy action plan specific to their trigger.

## Monitoring

The main tenants of anaphylaxis management and prevention are simple in theory but difficult in practice. Complete avoidance of the triggering agent provides protection from future episodes however, accidental exposures can occur, especially for food induced anaphylaxis. Other conditions like IA occur randomly with no known triggers making avoidance impossible. While episodes of IA tend to decline in frequency over time, patients experiencing more frequent attacks often benefit from daily prophylactic treatment with H1 and/or H2 antihistamines, leukotriene receptor antagonist (LTRA), and oral prednisone as needed. In refractory cases omalizumab (Xolair)<sup>1</sup> has been shown to be effective as well.

<sup>1</sup>Not FDA approved for this indication.

**TABLE 5** Proposed Optimal Cutoffs for Tryptase Elevations Signifying Mast Cell Activation or Anaphylaxis

AUTHOR	CRITERIA FOR TRYPTASE INCREASE	CRITERIA IDENTIFY
Phadia AB, 2008	Values above 11.4 ng/mL (upper 95th percentile)	Raised tryptase
Valent et al., 2012	20% plus 2 ng/mL over baseline level	Mast cell activation
Enrique et al., 1999	Levels >8.23 ng/mL	Anaphylaxis
Brown et al., 2009	Increase of 2 µg/L	Anaphylaxis
Egner et al, 2016	Threshold increment of 20%	Mast cell mediator release
Wongkaewpothong et al., 2014	Delta tryptase 0.8 µg/L	Anaphylaxis

**TABLE 6** Differential Diagnosis of Anaphylaxis

SYSTEM	DIFFERENTIAL DIAGNOSIS
Cutaneous	acute generalized urticaria, acute angioedema, ACE inhibitor angioedema, hereditary/acquired angioedema, carcinoid syndrome, postmenopause, Red man syndrome
Cardiac	vasovagal syncope, myocardial infarction, arrhythmia, shock
Respiratory	asthma or COPD exacerbation, vocal cord dysfunction syndrome, laryngospasm, pulmonary embolism, inhaled foreign body (infants/toddlers)
Psychological	panic attacks or acute anxiety, Munchausen syndrome
Other	mastocytosis and mast cell activation syndrome, pheochromocytoma, capillary leak syndrome, scombroid fish ingestion, hypoadrenergic or hyperadrenergic paroxysmal orthostatic tachycardia (POTS), hereditary alpha tryptasemia

ACE, Angiotensin-converting enzyme; COPD, chronic obstructive pulmonary disorder.

Carrying an EAI at all times provides patients with quick access to life-saving treatment; however, adherence has historically been poor. The predicament of poor adherence to medical treatment is a well-recognized problem; however in anaphylaxis the consequences of nonadherence can be fatal. One study from 2008 demonstrated that 48% of children prescribed an EAI did not have the device available at school, and of those with the medication on site, 78% of the autoinjectors were kept in the nurse's office or by another administrator not in close proximity to the child. Real-world data from a 2018 survey also demonstrated a poor level of adherence in patients and caregivers to anaphylaxis treatment guidelines which recommend carrying more than one EAI at all times. Most (82%) did not carry two EAIs at all times, mainly due to keeping one EAI in another location; 84% respondents said they kept at least one EAI at home; however, few patients and caregivers kept more than one. More than half of the respondents (64%) said they received counseling with an emphasis on always having one EAI and keeping another in a different location, but only 27% reported counseling that emphasized always having two EAIs available. It is important to recognize that a second epinephrine dose may be required in 16% to 36% of patients; therefore a more concerted effort should be made by physicians to properly educate patients and caregivers on the importance of following standard treatment guidelines. According to a 2018 study, only 26% of milk-allergic children in the U.S. had a current EAI prescription, the lowest reported rate among the top nine food allergies.

While poor patient adherence deserves some of the blame, evidence suggests that prescribers are equally responsible for this omission. Among 208 patients identified with anaphylaxis, 64.4% were seen in the emergency department and discharged home, but only 36.6% were prescribed an EAI, and only 31.3% were referred

to an allergy specialist for further evaluation. Another retrospective cross-sectional descriptive study of patients 21 years old or younger who received care for anaphylaxis reported that EAIs were prescribed to only 63%, and referral to an allergist was recommended to only 33%. Both of these studies suggest that emergency department physicians may be missing an important opportunity to empower patients with the ability to self-administer treatment for a recurrent episode and to prevent future anaphylactic reactions by not referring patients for specialized follow-up care. Finally, a comprehensive analysis of 10,184 anaphylaxis incidents using the European anaphylaxis register revealed that in the early 2000s 27.1% of patients with anaphylaxis treated by a health professional received epinephrine while only 14.7% of lay or self-treated cases were treated with an EAI. Progress was tracked over the next decade and epinephrine administration from a health professional almost doubled to 30.6% in 2015–2017 but no significant change was found in the lay emergency respondents group.

Failing to follow published guidelines for the treatment of anaphylaxis is another barrier to timely and appropriate treatment. Often-times antihistamines are used as first-line agents in the treatment of an anaphylactic reaction and is the most common reason providers report for not using epinephrine, leaving patients at increased risk for life-threatening sequelae. It should be reiterated that antihistamines have no effect on arresting true anaphylactic reactions and should only be used for symptomatic relief of associated pruritus and urticaria.

Reasons for patients and caregivers not to carry or use their EAIs or to delay administration are multifaceted and complex. Teenagers and young adults are at highest risk of fatal anaphylaxis-related reactions due to delayed epinephrine injection. Cost can be a difficult barrier for patients to overcome either related to having no insurance, high insurance co-pays, and/or deductibles. The cost of the best-known autoinjector, EpiPen, made headline news in recent years when pricing rose to more than \$600/2-pak by 2016. Bad press followed by public outcry led the manufacturer to produce a generic version for half the cost. Potential barriers for not carrying an EAI are summarized in [Table 7](#).

Since many patients who have been prescribed an EAI do not routinely carry one, and emergency rooms fail to prescribe them, it is essential that life-saving EAIs be readily available in community spaces and public venues. To improve access to life-saving treatment, there is an increasing effort to distribute nonspecific EAIs to public locations including schools, parks, pools, airports, public venues, and shopping malls. In 2013, President Obama signed the "School Access to Emergency Epinephrine Act," which encouraged, but did not require, all states to adopt stock epinephrine regulations for schools. Several drug companies like Mylan Specialty (EpiPen-4Schools) and Kaléo ("Q Your School") are providing free stock EAIs for schools to help improve access to epinephrine in the event a person experiences anaphylaxis in an academic setting. According to a recent EpiPen4Schools survey sponsored by Mylan Specialty, in each academic year, one in every six U.S. schools will have a student or staff member experience anaphylaxis. About 1140 episodes of anaphylaxis occurred across 6574 U.S. schools with most (89.5%) incidents involving students. More reactions were seen in high school students, who tend to be at higher risk, and food was the trigger for a majority (60%) of the reactions. Other triggers include

**TABLE 7** Reasons for Patients and Caregivers Not to Carry or Use Their Epinephrine Autoinjectors or to Delay Administration

- Never prescribed
- Cost
- Inconvenience
- Lack of perception of need of the medication
  - many do not use device for years so may not think it is essential or forget how to use it properly
- Poor knowledge of appropriate use
- Lack of familiarity with different brands of autoinjectors
- Mistakenly believe EAI might be available for emergency use in many public spaces
- History of mild allergic reaction
  - might think they are not at risk for a potentially fatal reaction
- Emotional/behavioral
  - embarrassment, feeling different
- Having been OK after a past reaction without treatment
- Wait for antihistamine to work
- Rely on other medications
- Don't want to go to the emergency department
- Needle phobia

EAI, Epinephrine autoinjectors.

environmental, medication, and insect stings or bites; however, 22% of severe reactions were from unknown triggers. EAIs (both stock and personal) were used to treat 77% of anaphylactic events reported. Overall this survey revealed that not only are anaphylactic events a relatively common occurrence in schools, but also that the risk extends beyond those with diagnosed allergies. A quarter of the individuals who experienced anaphylaxis in a school setting had no known allergies. The previously stated data tend to further support the need for stock EAIs in schools, and training for staff on when and how to use them.

With increased availability of epinephrine in public settings there needs to be a focus on increased educational initiatives for the people administering life-saving treatment. Just having epinephrine available does not improve outcomes during an anaphylactic event. Healthcare professionals, first responders, and the general public need to be able to recognize classic anaphylactic symptoms and know how to properly initiate treatment. Unfortunately, when these groups are surveyed, anaphylaxis is still under-recognized and undertreated (Table 8).

Recent anaphylaxis guidelines published in the 2020 Practice Parameter Update answered five PICO questions using GRADE methodology. The first question addressed the risk of developing a biphasic reaction related to anaphylaxis and what is an appropriate observation time in the ED to monitor for a biphasic reaction. The recommendation was to take the severity of the initial anaphylaxis reaction and/or the use of one or more doses of epinephrine into account in determining the risk for a biphasic reaction and to have an extended observation period in patients considered high risk for a biphasic reaction. The second question addressed the treatment of an anaphylaxis reaction with antihistamines and glucocorticoids to prevent a biphasic reaction and recommended against this approach as epinephrine is considered more effective in this regard. The third and fourth questions asked whether patients with a history of chemotherapeutic or radiocontrast reactions should be treated with antihistamines and glucocorticoids to prevent subsequent reactions. With respect to chemotherapeutic agents this treatment was recommended; however, for radiocontrast reactions it was not, as evidence suggests using a low or iso-osmolar agent is sufficient for preventing a subsequent reaction. Finally the fifth question asked whether pretreatment with antihistamines and glucocorticoids should be used for patients undergoing rush allergen immunotherapy and the recommendation was in favor of this approach. It is important to emphasize that all of these recommendations were conditional, and the rating of evidence was very low, emphasizing the need for well designed studies to investigate best practices for the management of anaphylaxis.

**TABLE 8** Are Healthcare Professionals and First Responders Able to Appropriately Recognize and Treat Anaphylaxis?

SURVEY	RESULTS
1114 pediatric emergency medicine physicians	<ul style="list-style-type: none"> <li>• 93.5% correctly identified epinephrine as the treatment of choice for anaphylaxis</li> <li>• 66.9% used the intramuscular (IM) route of administration</li> <li>• 37.4% admitted affected patients for observation</li> <li>• Many discharge patients home after an abbreviated period</li> </ul>
468 pediatricians (41%) responded to the survey	<ul style="list-style-type: none"> <li>• 70% agreed that the clinical scenario was consistent with anaphylaxis</li> <li>• 72% chose to administer epinephrine</li> <li>• 56% of respondents agreed with both the diagnosis of anaphylaxis and treating with epinephrine</li> <li>• 70% did not recognize that a 30-min observation period after anaphylaxis was too short</li> </ul>
7822 physicians, allied health, medical students, and other health professionals	<ul style="list-style-type: none"> <li>• 80% of responders correctly identified the case of anaphylaxis with prominent skin and respiratory symptoms</li> <li>• 55% correctly recognized the case without skin symptoms as anaphylaxis</li> <li>• 23% of responders correctly selected risk factors for anaphylaxis</li> </ul>
3537 paramedics	<ul style="list-style-type: none"> <li>• 98.9% correctly recognized a case of classic anaphylaxis</li> <li>• 2.9% correctly identified the atypical presentation</li> <li>• 46.2% identified epinephrine as the initial drug of choice</li> <li>• 38.9% chose the IM route of administration                             <ul style="list-style-type: none"> <li>• 60.5% identified the deltoid as the preferred location</li> <li>• 11.6% correctly identified the thigh</li> </ul> </li> <li>• ~98% were confident they could recognize and manage anaphylaxis                             <ul style="list-style-type: none"> <li>• 39.5% carry EAIs on response vehicles</li> </ul> </li> <li>• 95.4% were confident they could use an EAI                             <ul style="list-style-type: none"> <li>• 36.2% stated that there were contraindications to epinephrine administration in anaphylactic shock</li> </ul> </li> </ul>

EAI, Epinephrine autoinjectors.

In general, good clinical practice requires consideration of risk versus benefit of treatment and should take into account patient preference when appropriate.

**Management of Complications**

In general, anaphylactic reactions resolve without any major complications. Even though the prevalence rates of anaphylaxis seem to be increasing, fatal outcomes are rare, making up less than 1% of total mortality risk. In older patients, cardiovascular complications like atrial fibrillation and myocardial infarction can arise during anaphylaxis, but these events are also infrequent.

**COVID-19 Vaccines and Anaphylaxis**

Since the onset of the pandemic caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), three vaccines have been utilized in the United States to help curb the spread of this extremely infectious virus. The Pfizer-BioNTech and Moderna COVID-19 vaccines are messenger RNA vaccines, also called mRNA vaccines, and the Johnson & Johnson/Janssen COVID-19 vaccine is a viral vector vaccine. As with all vaccines, there is a low but recognizable risk of anaphylaxis. Given the circumstances with which these vaccinations were released, the safety and efficacy of these novel products have been under intense

scrutiny since their implementation and have been monitored closely by the national Vaccine Adverse Event Reporting System (VAERS). Soon after vaccination programs were started, cases of anaphylaxis following administration of the Moderna and Pfizer-BioNTech vaccines began to be reported. Early accounts in the United States, gathered through January 18, 2021, demonstrated low risks of anaphylaxis for both vaccines: 4.7 cases/million for the Pfizer-BioNTech vaccine and 2.5 cases/million for the Moderna vaccine. Continued safety monitoring of all three COVID-19 vaccines has confirmed that anaphylaxis following vaccination is a rare event, with a recent study ranking COVID-19 vaccines fifth in reported anaphylaxis rates (10.67 cases/106 doses) behind rabies, tick-borne encephalitis, measles-mumps-rubella-varicella, and human papillomavirus vaccines (70.77, 20, 19.8, and 13.65 cases per 106 vaccine doses, respectively). The CDC's current estimate for anaphylaxis rate in the United States is approximately 5 people/million vaccinated. Although rates of anaphylaxis to COVID-19 vaccines are low, locations administering these vaccines are required to adhere to CDC guidelines, including screening recipients for contraindications and precautions, having necessary supplies and staff members available to manage anaphylaxis, implementing recommended postvaccination observation periods, and immediately treating suspected anaphylaxis with intramuscular epinephrine injection.

## Conclusion

Anaphylaxis is a common medical condition affecting both adult and pediatric populations and its incidence and prevalence continue to increase. Prompt recognition and treatment with epinephrine administered in a timely manner remains the mainstay of treatment for anaphylaxis. Preventive measures including patient education, immunotherapy when appropriate, antigen avoidance, and optimal management of comorbid conditions is important in preventing recurrences. There is a concerning lack of knowledge and preparedness for management of anaphylaxis at all care levels that needs to be better addressed.

## DRUG HYPERSENSITIVITY REACTIONS

Method of

Miriam Chan, PharmD; Ann M. Aring, MD; and  
Kristen Rundell, MS, MD

### CURRENT DIAGNOSIS

- Detailed history should include past medical history; current diagnosis; previous and current medication use, including over-the-counter drugs and herbals as well as other nonprescribed medications; duration of the medication use; any similar reactions in the past.
- Physical examination should include vitals, temperature, and skin examination for rash.
- Laboratory testing should be conducted based on symptoms that may include complete blood count (CBC) with differential, eosinophils, sedimentation rate, liver enzymes, international normalized ratio (INR), C-reactive protein (CRP), and diagnostic skin biopsy or testing.

### CURRENT THERAPY

- For life-threatening anaphylaxis reaction, start basic life support using pneumatic ACB (airway, compression, breathing) and give epinephrine immediately.
- Discontinue the offending drug if medically possible. Try drug substitution if warranted.
- An alternative option is to reduce the dose or frequency of the drug.
- Start symptomatic treatment based on the type of reaction and the offending medication.
- Some reactions may respond to treatment with antihistamines, H<sub>2</sub> blockers, or steroids.

**TABLE 1** Classification of Drug Hypersensitivity Reactions

TYPE	MECHANISM	CLINICAL FEATURES	TIMING OF REACTIONS	EXAMPLES
Type I (IgE mediated)	Drug-IgE complex binds to mast cells	Urticaria, angioedema, bronchospasm, pruritus, GI symptoms, anaphylaxis	Immediate (minutes to hours after drug exposure, depending on the route of administration)	$\beta$ -lactam antibiotic
Type II (cytotoxic)	Specific IgG or IgM antibodies directed at drug-hapten-coated cells	Hemolytic anemia, neutropenia, thrombocytopenia	Variable	Penicillin (hemolytic anemia), heparin (thrombocytopenia)
Type III (immune complex)	Antigen-antibody complexes	Serum sickness, vasculitis, drug fever	1–3 weeks after drug exposure	Penicillin (serum sickness), sulfonamides (vasculitis), azathioprine (drug fever)
Type IV (delayed, cell mediated)	Activation and expansion of drug-specific T cell	Prominent skin findings: Contact dermatitis, morbilliform eruptions	2–7 days after exposure	Topical antihistamine, penicillin, sulfonamides

## Epidemiology

Drug hypersensitivity reactions are one of the many different types of adverse drug reactions (ADRs). ADRs are common, yet the more severe reactions have been estimated to cause 3% to 6% of hospital admissions. More than 100,000 deaths annually are caused by serious ADRs, making these reactions one of the leading causes of death in the United States. Early detection of all ADRs can potentially improve patient outcomes and lower health care costs.

## Classifications

An ADR is a broad term that refers to any predictable or unpredictable reaction to a medication. A predictable (type A) reaction is dose dependent and is related to the known pharmacologic properties of the drug. Predictable reactions account for about 80% of all ADRs. An example of a type A reaction is gastritis that results from taking nonsteroidal antiinflammatory drugs (NSAIDs). The remaining 20% of ADRs are caused by unpredictable (type B) reactions. Type B reactions occur in susceptible individuals. These are hypersensitivity reactions that are different from the pharmacologic actions of the drug; they are results of interactions between the drug and the individual human immune system. Type B reactions can be further divided into drug intolerance, drug idiosyncrasy, drug allergy (immunologically mediated), and pseudoallergic reactions (anaphylactoid reactions). This chapter will focus on these type B drug hypersensitivity reactions.

## Pathophysiology

Several mechanisms may play a role in the underlying etiology of immunologic drug reactions. The Gell and Coombs classification system was the original system to describe four predominant immune mechanisms. These four reaction types are listed as type I reactions (IgE mediated), type II reactions (cytotoxic), type III reactions (immune complex), and type IV reactions (delayed, cell mediated). Table 1 provides a detailed description of this classification. Type I and IV reactions are more common than type II and III reactions. Most drugs cause one type of reaction, whereas certain drugs, such as penicillin, can induce all four types of reactions.

The Gell and Coombs classification has recently been revised to reflect the functional heterogeneity of T cells. Under the new system, type IV reactions are further subclassified into four categories: IVa (macrophage activation), IVb (eosinophils), IVc (CD4<sup>+</sup> or CD8<sup>+</sup> T cells), and IVd (neutrophils). Nevertheless, many common hypersensitivity reactions cannot be classified in this system because of the lack of knowledge of their immune mechanism or a mixed mechanism.

A new concept of drug interaction with immune receptors has recently been developed by Pichler and colleagues. It is called the *p-i concept* (pharmacologic interaction with immune receptors). In this concept, a drug binds noncovalently to a T-cell receptor and stimulates an immune response, which can cause inflammatory reactions of different types. The stimulation of the T cell is enhanced by

the additional interaction with the major histocompatibility complex molecule. This is direct stimulation of memory and effector T cells, and no sensitization is required. The skin has a high concentration of effector memory T cells, which can be rapidly stimulated by antigen penetration. The skin also possesses a dense network of dendritic cells that act as antigen-presenting cells and increase hypersensitivity reactions. As a result, clinical symptoms by *p-i* drugs may appear more rapidly. Some severe reactions—such as Stevens-Johnson syndrome (SJS), toxic epidermal necrolysis (TEN), the drug rash with eosinophilia and systemic symptoms (DRESS) syndrome, or hypersensitivity syndrome—are believed to be *p-i* related. Examples are abacavir (Ziagen) hypersensitivity syndrome and SJS/TEN from carbamazepine (Tegretol).

## Risk Factors for Hypersensitivity Drug Reactions

The chemical structure and molecular weight of the drug may help predict the type of hypersensitivity reaction. Larger drugs with greater structural complexity are more likely to be immunogenic. However, drugs with small molecular weight (< 1000 Da) can elicit hypersensitivity reactions by coupling with carrier proteins to form hapten-carrier complexes. Other drug-related factors include the dose, route of administration, duration of treatment, repetitive exposure to the drug, and concurrent illness. Topical and intravenous drug administrations are more likely to cause hypersensitivity reactions than are oral medications.

Patient risk factors include age, female gender, HIV infection or immunocompromised, atopy, specific genetic polymorphisms, previous drug hypersensitivity reactions, and inherent predisposition to react to multiple unrelated drugs.

## Clinical Manifestations

Drug hypersensitivity reactions can manifest in a great variety of clinical symptoms and diseases. While some reactions are mild and often unnoticed, others, such as anaphylaxis, can be severe and even fatal. Dermatologic symptoms are the most common physical manifestation of allergic drug reactions. Drug hypersensitivity reactions can also affect various internal organs, causing diseases such as hepatitis, nephritis, and pneumonitis. The noncutaneous physical findings are generally nonspecific and may not be helpful and even delay the diagnosis and management decisions.

## Dermatologic Symptoms

The most common allergic drug reactions affect the skin and can cause a variety of different exanthems. The most common skin reaction is the classic “drug rash,” which is a morbilliform eruption originating on the trunk. Other dermatologic symptoms include urticaria, angioedema, acne, bullous eruptions, fixed drug eruptions, erythema multiforme, lupus erythematosus, photosensitivity, psoriasis, purpura, vasculitis, and pruritus. The most severe forms of cutaneous drug reactions are Stevens-Johnson

syndrome (SJS), toxic epidermal necrolysis (TEN), and drug rash with eosinophilia and systemic symptoms (DRESS) syndrome.

### Stevens-Johnson Syndrome

SJS is a systemic disorder that has cutaneous manifestations. SJS was previously thought to be synonymous with erythema multiforme major. There are now criteria that separate the two disorders. In contrast to erythema multiforme, the target lesions associated with SJS have only two rings. The inner ring may have urticaria, pustules, or necrotic lesions surrounded by macular erythema. It is a T-cell-mediated toxic reaction to the basement membrane of the epidermal cells. There is massive and widespread apoptosis, for which there are several associated cytokines. The recent theories suggest that there are two pathways, one that consists of granule-mediated exocytosis (perforin and granzyme B), and one that consists of Fas-Fas ligand interaction associated apoptosis for the keratinocytes. More recent data suggest that granulysin, which is a cationic cytolytic protein released by T lymphocytes, may play a role as well.

Interestingly, HLA genotype may predispose patients to SJS or TEN. Those patients with the HLA-B1502 found among the Han Chinese population may be associated with increased risk for developing SJS/TEN and use of carbamazepine.

SJS and TEN are on the same continuum. The definition of epidermal detachment and desquamation of epidermal cells is less than 10% of the body surface area for SJS and more than 30% for TEN. There is an overlapping diagnosis of SJS/TEN for the 10% to 30% category. To help differentiate from other ADRs, there is often a prodromal period in which a patient may have a cough and a fever. The lesions may occur up to 4 weeks after exposure to the drug. In addition, the lesions may be limited to the trunk; however, they more commonly involve the palmar surface of the hands and the dorsum of the feet, as well as the mucous membranes.

The most common drug classes associated with SJS and TENs are sulfonamides, cephalosporins, imidazole agents, and oximac derivatives. Drugs such as carbamazepine, phenytoin (Dilantin), valproic acid (Depakote), lamotrigine (Lamictal), allopurinol (Zyloprim), nevirapine (Viramune), peramivir (Rapivab), and quinolones have been reported to cause SJS/TEN. In a retrospective chart review of 64 patients who had a diagnosis of SJS/TEN, Miliszewski et al. identified allopurinol as the single most common offending agent (20% of cases). According to the US Food and Drug Administration (FDA) Safety Alerts in 2013, acetaminophen has been associated with SJS, TEN, and acute generalized exanthematous pustulosis (AGEP). The evidence supporting causality primarily comes from a small number of cases reported in the medical literature.

The treatment is immediate cessation of the culprit drug and symptomatic treatment. Glucocorticoids are controversial and depend on the course and extent of the disease.

### Toxic Epidermal Necrolysis

As previously stated, TEN is the cell-mediated disorder that involves more than 30% of the body surface. This is the more-severe form of the ADR: the mortality rates may be as high as 50%, mostly from sepsis. Patients are usually admitted to the burn unit for electrolyte and infection management. Glucocorticoids are contraindicated. There have been mixed results using IV immunoglobulin (IVIG)<sup>1</sup> in these patients. The IVIG is believed to inhibit the Fas-Fas ligand, which is the underlying mechanism for the basement membrane separation.

### Drug Rash with Eosinophilia and Systemic Symptoms

DRESS syndrome or drug-induced hypersensitivity syndrome (DIHS) is a rare, life-threatening drug-induced reaction with a mortality rate of 10%. Therefore it is important to recognize the signs and symptoms early to initiate treatment. Most patients will have fever, lymphadenopathy (75%), eosinophilia, and an erythematous morbilliform rash on the face and body in addition to liver and multiorgan damage. The symptoms can occur 2 to 6

weeks after the drug administration. There are many drugs that can cause DRESS syndrome such as allopurinol, sulfonamides, and psychotropic medications. Based on literature review, DRESS syndrome is increasingly being recognized by psychiatrists. Carbamazepine is the most frequently reported etiology; however, DRESS syndrome is also seen with lamotrigine, phenytoin, valproate, and phenobarbital. The treatment is drug withdrawal, systemic corticosteroids, topical treatment for lesions, and supportive care, often in the ICU or burn unit.

### Acute Generalized Exanthematous Pustulosis

Acute generalized exanthematous pustulosis (AGEP) is a rare ADR that presents as a fever and small nonfollicular pustules on a widespread erythematous background. AGEP may closely mimic pustular psoriasis clinically. The presence of acanthosis and papillomatosis and a personal or family history of psoriasis favor a diagnosis of pustular psoriasis. Exposure to medication, especially antibiotics with a short latency from the initiation of the drug, favors AGEP. The eruption usually occurs within 24 hours of the initiation of the drug, and healing occurs quickly after the discontinuation of the drug. Lesions heal within 2 weeks of discontinuation without scarring. The exact mechanism of drug-specific T lymphocytes is unknown, yet IL-3 and IL-8 may be the trigger for neutrophil-activating cytokines in the skin.

### Acute Interstitial Nephritis

Acute interstitial nephritis (AIN) is an important cause of acute kidney injury (AKI). More than two thirds of AIN cases are caused by drug hypersensitivity reactions. Drugs most commonly associated with AIN include antibiotics (particularly  $\beta$ -lactam, fluoroquinolones, and rifampicin), NSAIDs, proton pump inhibitors, phenytoin, allopurinol, and 5-aminosalicylates.

The clinical presentation of drug-induced AIN is highly variable and depends on the class of drug involved. Patients with AIN may be asymptomatic with elevation in creatinine or blood urea nitrogen or abnormal urinary sediment. When present, symptoms are nonspecific. The “classic” triad of fever, rash, and eosinophilia is present in less than 5% to 10% of patients. Each individual component of the triad also occurs at various rates.

A diagnosis of AIN should be considered in any patients with unexplained AKI, clinical manifestations of a hypersensitivity reaction, and a history of exposure to any drug associated with AIN. A definitive diagnosis of AIN is established by kidney biopsy. AIN is characterized by interstitial inflammation, tubulitis, edema, and, in some cases, eventual interstitial fibrosis. The precise disease mechanism is unclear, but the presence of T lymphocytes in the inflammatory infiltrate suggests a type IV hypersensitivity response.

Early recognition is crucial as patients can ultimately develop chronic kidney disease. The mainstay of therapy is timely discontinuation of the causative agent. If AIN persists, corticosteroids may be used to improve kidney function. However, available data on corticosteroids are inconclusive, and randomized controlled trials are needed to confirm the benefits of corticosteroids in the treatment of AIN.

### Evaluation

Because the history is essential for determining whether a patient is experiencing a drug hypersensitivity reaction, it is important to review all medications and the timeline of exposure. This includes any over-the-counter medications, herbal supplements, or occasional-use medications. Occasional-use medications may include NSAIDs, acetaminophen, cold medications, and so forth. It is important to establish a temporal relationship to the onset of the medication and the initiation of the symptoms. Oftentimes, the medication may have been discontinued before the appearance of the first symptom, so a review of medications from several weeks before the symptoms is also important. In addition, because the host immune response plays a role in some of the IgE-mediated reactions, it is important to review any immunocompromising chronic or acute illnesses or states that the patient may have or is currently experiencing. This includes HIV, chronic obstructive

<sup>1</sup>Not FDA approved for this indication.

pulmonary disease (COPD), asthma, chemotherapy, and pregnancy. For some ADRs, HLA type may be important. A patient's known genetic predisposition needs to be taken into account as well. A thorough history will also need to include any organ system or symptom that may be related to the suspected ADR.

A physical examination should augment and help to establish the working diagnosis of the type of ADR and the potentially offending drug. This should include vital signs of temperature, respiratory, and hydration status. The skin examination is important, as are appropriate evaluation and documentation of the type of lesion or lesions present. An examination of the oral mucosa and the conjunctiva of the eye should be done. Any lymphadenopathy, petechiae, or pallor should be noted.

Laboratory testing may be obtained to confirm or rule out a diagnosis. This may include a chest x-ray, CBC with differential, possible skin biopsy, liver function testing, creatinine, and electrolyte testing. A sedimentation rate and CRP testing may also be useful. Although additional autoimmune or antibody testing may be done, caution is suggested. There may not be a high yield on these tests, and they can be quite costly for patients.

## Management

### Anaphylaxis

Anaphylaxis can be a fatal drug hypersensitivity reaction because of its rapid onset. It is often underrecognized and undertreated because it can mimic other conditions and is variable in its presentation. However, respiratory compromise and cardiovascular collapse are of greatest concern, because they are the most common causes of death. Urticaria and angioedema are the most common manifestations but may be delayed or absent. The more quickly anaphylaxis occurs after exposure to the offending agent, the more likely the reaction is to be severe and potentially life threatening.

Most anaphylaxis episodes are IgE-mediated reactions resulting in a sudden mast cell and basophil degranulation. This sudden release of mediators affects the cutaneous, pulmonary, cardiac, GI, vascular, and neurologic systems. Medications are a common trigger of anaphylaxis in adults. Most cases of IgE-mediated drug anaphylaxis in the United States are due to penicillins and cephalosporins. Antibiotics are also the most common cause of perioperative anaphylaxis because skin eruptions may be missed in patients who are draped during surgery. Some anaphylaxis reactions involve other immunologic mechanisms. Administration of blood products (e.g., IVIG, animal antiserum) can cause an anaphylactoid reaction due, at least in part, to complement activation. Activation of the complement cascade can cause mast cell/basophil degranulation. Anaphylaxis episodes can also occur independently of any immunologic mechanism. Certain drugs, such as opioids, dextrans, and protamine, can cause a direct release of histamine and other mediators from mast cells and basophils. Finally, there are acute systemic reactions without any obvious triggers or mechanisms (idiopathic anaphylaxis).

Anaphylaxis is a clinical diagnosis with a short window of treatment time available. Therefore laboratory testing is limited and may not be of much value. Initially, the patient will describe flushing, pruritus, and a sense of impending doom. Some patients will have dyspnea, dizziness, syncope, or GI symptoms of diarrhea and abdominal cramping. Most patients will have cutaneous symptoms of flushing, urticaria, or angioedema. Some patients will progress to respiratory or cardiovascular complications.

The goal of therapy should be early recognition and treatment with epinephrine to prevent a progression to life-threatening respiratory or cardiovascular failure. The immediate intervention should include stopping the offending drug if possible, epinephrine injection, basic life support, high-flow oxygen, cardiac monitoring, and IV access. Epinephrine is the drug of choice for anaphylaxis. The therapeutic actions of epinephrine include  $\alpha$ -1-adrenergic vasoconstrictor effects (decreases mucosal edema, thereby relieving upper airway obstruction, and increases blood pressure to prevent shock),  $\beta$ -1 adrenergic effects (increases rate and force of cardiac contractions), and  $\beta$ -2 effects (increases bronchodilation and decreases the release of mediators of inflammation from mast cells/basophils).

Delayed epinephrine administration has been associated with fatalities. Intramuscular epinephrine in the thigh results in high-plasma concentrations and is preferred in the setting of anaphylaxis. The recommended dose of epinephrine is 0.3 mg (1 mg/mL) IM every 5 minutes. Typically, only one or two additional doses are needed. Patients in shock should receive epinephrine by slow IV infusion at 2 to 10 mcg/min with the rate titrated according to response and the presence of continuous hemodynamic monitoring. Patients taking beta-blockers may be resistant to treatment with epinephrine. In this case, glucagon<sup>1</sup> 1 to 5 mg IV over 5 minutes should be administered because its cardiac effects are not mediated through beta-receptors.

Adjunctive therapies for the treatment of anaphylaxis include antihistamines and corticosteroids. Consider an inhaled beta-agonist if wheezing. Diphenhydramine (Benadryl), an H<sub>1</sub> antihistamine, may be given intravenously at the dose of 25 to 50 mg. If an H<sub>2</sub> blocker is considered, give ranitidine (Zantac)<sup>1</sup> 50 mg/20 mL as an IV infusion over 5 minutes. Use of both diphenhydramine and ranitidine is superior to diphenhydramine alone. Corticosteroids are used to prevent a potential late-phase reaction that may occur in up to 23% of adults with anaphylaxis. There is no proven best dose or route of steroid therapy. The most common dosage is prednisone 20 to 60 mg daily for 3 to 5 days.

### Angioedema

Angioedema is characterized by a deep dermal, subcutaneous, mucosal swelling. Many patients present with both urticaria and angioedema. Angioedema can progress rapidly from a mild swelling of the oral mucosal to a life-threatening laryngeal edema. With this rapid sequence of events, the most important part of treatment is obtaining and maintaining a patent airway. Epinephrine 0.3 mg IM every 10 minutes should be administered to patients who present with anaphylaxis, respiratory distress, or severe laryngeal edema. Once the airway is patent, the patient should be treated with H<sub>1</sub> antihistamines, H<sub>2</sub> blockers, and steroids. The milder cases may be treated similarly to other allergic reactions. H<sub>1</sub> antihistamines such as diphenhydramine and hydroxyzine (Atarax) are effective in relieving pruritus but can cause significant sedation. Therefore second-generation H<sub>1</sub> antihistamines<sup>1</sup> (loratadine [Claritin], cetirizine [Zyrtec], desloratadine [Clarinex], fexofenadine [Allegra]) are often chosen for outpatient therapy. Doxepin (Sinequan),<sup>1</sup> a tricyclic antidepressant with potent H<sub>1</sub> and H<sub>2</sub> blocker activities, can be used as an alternative to H<sub>1</sub> antihistamines. However, it should not be used as first-line treatment for acute urticaria and angioedema because of its significant side effects of severe sedation, dry mouth, and weight gain. Corticosteroids are used in patients who are not responsive to antihistamines. For most patients, a short course of oral prednisone is adequate.

In drug-induced angioedema, the offending drug should be stopped and avoided. Further trial of the medication is not recommended, because the patient will respond more quickly and with more severe symptoms on reintroduction. The patient should be counseled, and epinephrine 0.3 mg in an auto-injectable device (EpiPen, Auvi-Q, Adrenaclick) may be prescribed in case of recurrence in the future.

### Specific Drugs

Almost all drugs can cause a drug hypersensitivity reaction. However, certain drugs are more frequently associated with specific types of reactions. Some of the more commonly used drugs are discussed here in more detail.

#### Antibiotics

##### Penicillin

Penicillin allergy is the most well-known drug allergy and also the most costly ADR. Although most drugs usually have type I and type IV reactions, penicillin may cause all four types of allergic drug reactions. The rate of penicillin-induced anaphylaxis after intravenous administration is approximately 1 to 2 per 10,000 treated patients.

<sup>1</sup>Not FDA approved for this indication.

Only about 10% of patients who report a penicillin drug allergy actually have a true immunologic response. IgE antibodies in patients with documented IgE-mediated acute penicillin reaction decline with time, resulting in 80% patients tolerating penicillin after 10 years. Patients with a penicillin allergy label are more likely to be treated with broad-spectrum or second-line antibiotics. Inappropriate use of antibiotics is linked to increased antibiotic resistance and adverse health outcomes. There is an increasing focus on penicillin allergy delabeling as an integral part of antimicrobial stewardship. Algorithms are available to clarify a patient's allergy status and expedite the evaluation for true penicillin allergy. Trubiano et al. recently developed a clinical decision tool, PEN-FAST, to aid risk stratification of patients with penicillin allergy and facilitate appropriate delabeling and prescribing strategies.

Penicillin skin testing is the best method for diagnosing an IgE-mediated penicillin allergy. A commercially available product, PRE-PEN, contains benzylpenicilloyl polylysine (PPL), which is a major antigenic determinant of penicillin. Minor determinants are metabolic derivatives of penicillin that may also produce an immune response. The current recommendations for penicillin skin testing are to administer both the major determinant (PPL) and the minor determinants (penicillin G). These two tests identify approximately 90% to 97% of the currently allergic patients. Patients with a history of penicillin allergy but negative skin test should be given an oral 250-mg amoxicillin challenge and observed for 1 hour following the skin test. If the skin test and oral challenge are both negative, the risk for IgE-mediated anaphylaxis is almost zero.

In general, patients who report symptoms consistent with an immediate or type I reaction or are skin-test positive to penicillin should not receive penicillin. Desensitization should be considered if penicillin is the treatment of choice for an infection and no acceptable nonpenicillin alternatives are available. Patients should be desensitized in a hospital setting. Desensitization involves administering incremental doses of oral penicillin every 15 minutes for a total of 4 to 12 hours, after which time the first dose of penicillin is given. For intravenous desensitization, three drug concentrations of penicillin are infused in 12 steps. Penicillin desensitization protocols are available in the review article by Castells et al. Desensitization is temporary and only lasts for two dosing intervals of the drug before the desensitization needs to be repeated.

### Penicillin and Cephalosporin Cross-Reactivity

The rate of cross-reactivity between penicillin and cephalosporins has been historically cited to be as high as 10%. Recent data suggest that the rate may be much lower. The degree of cross-reactivity is highest between penicillins and first-generation cephalosporins, which have identical R-group side chains. In this case amoxicillin would be cross-reactive with cefadroxil (Duricef) and cefprozil (Cefzil), whereas ampicillin would be with cefaclor and cephalexin. Because of the differences in the chemical structures, second- and third-generation cephalosporins (cefdinir [Omnicef], cefuroxime [Ceftin], cefpodoxime [Vantin], and ceftriaxone [Rocephin]) are unlikely to be associated with cross-reactivity with penicillin. According to the latest guidelines for acute otitis media from the American Academy of Pediatrics and American Academy of Family Physicians, alternative initial antibiotics in patients with penicillin allergy include cefdinir, cefuroxime, cefpodoxime, or ceftriaxone.

Patients with penicillin allergy who have a negative skin-test result to penicillin (major and minor determinants) may safely receive cephalosporins. Cephalosporin treatment of patients with penicillin allergy who did not have a severe or recent penicillin reaction history shows a reaction rate of 0.1%. Use cephalosporin with caution in patients who report an immediate or accelerated penicillin allergy or those with a positive skin test to penicillin.

### Sulfonamides (Sulfa Drugs)

Beside penicillins, sulfonamide antibiotics are the second most common cause of drug-induced allergic reactions. They commonly cause a delayed maculopapular/morbilliform eruption. Acute urticarial reactions (IgE mediated) to sulfamethoxazole

(SMX) or trimethoprim (TMP) are relatively infrequent; the incidence of skin rash resulting from SMX-TMP (Bactrim) in healthy subjects is estimated to be 3%. Sulfonamides are also the most common cause of SJS and TEN.

Patients with HIV have the greatest risk of sulfonamide-induced allergic reactions. The typical reaction to SMX-TMP in patients with HIV is a generalized maculopapular eruption that occurs during the second week of treatment and is usually accompanied by pruritus and fever. Because SMX-TMP is the drug of choice for a number of HIV-associated infections such as *Pneumocystis carinii* pneumonia and spontaneous bacterial peritonitis, several methods of desensitization have been devised to administer SMX-TMP to patients with HIV with a history of allergic reaction to the drug.

There are three classes of sulfonamides based on chemical structure: sulfonylarylamines (including sulfa antibiotics), non-sulfonylarylamines, and sulfonamide-moiety-containing drugs. A sulfonylarylamine has a sulfonamide moiety directly attached to a benzene ring with an amine ( $-NH_2$ ) moiety at the N4 position. A nonsulfonylarylamine also has a sulfonamide moiety attached to a benzene ring, but it does not have an amine group at the N4 position. A sulfonamide-moiety-containing drug has a sulfonamide group that is not connected to a benzene ring. Table 2 presents a list of sulfonamide-containing drugs based on their chemical structure.

The N4 amine is critical for the development of delayed reactions to sulfa antibiotics. Given the important chemical differences between drugs containing sulfa antibiotics and sulfa in nonantibiotics, the risk of cross-reactivity is extremely unlikely. A retrospective cohort study by Strom and colleagues showed that approximately 90% of patients with sulfa antibiotic allergy did not have a reaction to a sulfonamide nonantibiotic. Patients with allergic reactions to sulfa antibiotics are also more likely to

**TABLE 2** Classification of Sulfonamides Based on Chemical Structure

#### Drug

#### Sulfonylarylamines

<i>Antibiotics:</i>	<i>Antiinflammatory:</i>
Sulfadiazine	Sulfasalazine (Azulfidine)
Sulfamethoxazole	Protease Inhibitors:
Sulfisoxazole	Darunavir (Prezista)
Sulfapyridine	Fosamprenavir (Lexiva)

#### Nonsulfonylarylamines

<i>Carbonic Anhydrase Inhibitors:</i>	<i>Sulfonylureas:</i>
Acetazolamide (Diamox)	Chlorpropamide
Brinzolamide (Azopt)	Glimepiride (Amaryl)
Dorzolamide (Trusopt)	Glipizide (Glucotrol)
Methazolamide (Neptazane)	Glyburide (Diabeta)
<i>Cyclooxygenase 2 (COX-2) Inhibitors:</i>	Tolbutamide
Celecoxib (Celebrex)	Tolazamide (Tolinase)
<i>Loop Diuretics:</i>	<i>Other Agents:</i>
Bumetanide (Bumex)	Mafenide (Sulfamylon)
Furosemide (Lasix)	Probenecid
Torsemide (Demadex)	Tamsulosin (Flomax)
<i>Thiazides Diuretics:</i>	Tipranavir (Aptivus)
Chlorothiazide (Diuril)	
Chlorthalidone	
Hydrochlorothiazide	
Indapamide (Lozol)	
Metolazone (Zaroxolyn)	

#### Sulfonamide-Moiety-Containing Drugs

<i>5-HT Agonists:</i>	<i>Other Agents:</i>
Naratriptan (Amerge)	Ibutilide (Corvert)
Sumatriptan (Imitrex)	Simeprevir (Olysio)
	Sotalol (Betapace)
	Topiramate (Topamax)
	Zonisamide (Zonégren)

experience allergic reactions to the other types of sulfonamides, but this is not because of cross-sensitivity. There is no reliable skin test to rule out or confirm sulfa allergy. Some experts recommend avoiding all classes of sulfonamides in patients with serious reactions such as SJS, TEN, or anaphylaxis to any one sulfonamide.

Most diuretics are sulfonamide derivatives. The only diuretics that are not in this group are the potassium-sparing diuretics (triamterene [Dyrenium], spironolactone [Aldactone], amiloride [Midamor]) and ethacrynic acid (Edecrin). Dapsone is a sulfone that is chemically unrelated to sulfonamides. *It should also be noted that sulfates, sulfur, and sulfites are chemically unrelated to sulfonamides and do not cross-react.*

### Angiotensin-Converting Enzyme Inhibitors

Angiotensin-converting enzyme inhibitors (ACEIs) have two major adverse effects: cough and angioedema. The cough is typically dry and nonproductive. The incidence of ACEI-induced cough has been reported to be 5% to 35%. Cough occurs more commonly in women, African-Americans, and Asians. The onset of cough ranges from within hours of the first dose to months after the initiation of therapy. The diagnosis is confirmed by the resolution of cough, usually within 1 to 4 weeks after discontinuation of the ACEI; however, the cough can linger for up to 3 months. The cause for ACEI-induced cough is unclear but might be related to bradykinin, substance P, or another mechanism. Angiotensin II receptor blockers (ARBs) are not associated with an increased incidence of cough and can be used as an alternative to ACEIs. Because the cough may persist for several months after stopping the ACEI, starting the ARB is not a contraindication at this time, yet the cough may persist through the initiation of the new drug.

The incidence of angioedema with ACEIs is approximately 0.1% to 0.7%. With the widespread use of ACEIs, angioedema has become a growing problem. ACEI-induced angioedema is more common in patients who are over age 65, black, or female. Angioedema frequently involves swelling of the face or upper airway and can be life threatening or fatal. It can occur within days, months, or even years after the start of treatment. However, nearly 60% of cases occur within the first week of therapy. ACEIs cause angioedema by direct interference with the degradation of bradykinin, thereby increasing bradykinin levels and leading to increased vascular permeability, inflammation, and activation of nociceptors. Bradykinin is also a prominent mediator in hereditary angioedema. Therefore ACEIs are contraindicated in patients with hereditary angioedema.

ARBs directly inhibit the angiotensin receptor and do not interfere with bradykinin degradation. Theoretically, they can be relatively safe alternatives for patients with a previous history of ACEI-associated angioedema. However, some reports of ARB-induced angioedema have recently been published. The mechanism of how ARBs cause angioedema is unclear. A meta-analysis suggests that for patients who developed angioedema when taking an ACEI, the risk of persistent angioedema when subsequently switched to an ARB is less than 10%. Therefore ARBs may be an alternative only for patients with a high therapeutic need for angiotensin inhibition. ARB treatment should be started with observation. Patients should be educated on the signs of angioedema and provided with proper emergency instructions on how to proceed if angioedema should occur.

The direct renin inhibitor aliskiren (Tekturna) does not alter local or circulating bradykinin and is believed to be an alternative in patients with ACEI- and ARB-related angioedema. However, cases of angioedema have been reported with aliskiren. As with ARBs, renin inhibitors should be used with caution in patients who previously experienced angioedema to ACEIs.

### Aspirin and NSAIDs

Aspirin (ASA) and NSAIDs can cause several types of hypersensitivity reactions. The four most-common types of reactions are based on the drug pathways. Aspirin-exacerbated respiratory disease (AERD) is a serious reaction induced by ASA and NSAIDs

in patients with asthma and chronic rhinosinusitis. AERD does not fit precisely into a specific type of ADR and is often referred to as a type of pseudoallergic reaction. AERD affects up to 20% of adults with asthma. It is more common in women. The usual age of onset is around 30 years. The pathophysiology of AERD is related to aberrant arachidonic acid metabolism. Patients with AERD also have increased respiratory tract expression of cysteinyl leukotriene 1 receptor and heightened responsiveness to inhaled leukotriene E<sub>4</sub>. Administration of aspirin or an NSAID to these patients leads to inhibition of cyclooxygenase 1 (COX-1), resulting in a decrease in prostaglandin E<sub>2</sub> levels. Prostaglandin E<sub>2</sub> normally inhibits 5-lipoxygenase. As a result of decreased prostaglandin E<sub>2</sub> levels, arachidonic acid is preferentially metabolized in the 5-lipoxygenase pathway, leading to increased production of cysteinyl leukotrienes.

Patients with AERD typically have both rhinoconjunctivitis and bronchospasm within minutes of ingestion of a dose of ASA or NSAID. The bronchospasm can be severe and result in respiratory failure, which may require intubation and mechanical ventilation. Management of patients with AERD involves treatment of the patient's asthma and chronic rhinosinusitis and avoidance of aspirin and NSAIDs. Desensitization is available in cases when the patient has a specific therapeutic need for regular ASA or NSAID therapy. Selective COX-2 inhibitors very rarely cause reactions in patients with AERD and can be taken safely.

The second type of ASA and NSAID hypersensitivity reaction is an exacerbation of urticaria or angioedema in patients with chronic idiopathic urticaria. Approximately 20% to 40% of patients with chronic urticaria may have this drug-induced reaction. The mechanism of this reaction is related to COX-1 inhibition. The exacerbating effects are usually dose dependent. All drugs that inhibit COX-1 cross-react to cause this reaction. Selective COX-2 inhibitors are generally considered safe to take in patients with chronic idiopathic urticaria.

The third type of hypersensitivity reaction is an anaphylactic or immediate urticarial reaction or angioedema appearing soon after the intake of a specific NSAID. Other NSAIDs from other groups or even an NSAID from the same group with a slightly different chemical structure is tolerated by the patient. An IgE-mediated mechanism is implicated only in some instances. The diagnosis is made mainly by exclusion. Further research is needed in this topic.

The fourth type of hypersensitivity reaction is urticaria or angioedema caused by ASA or any NSAID that inhibits COX-1 in patients without chronic urticaria. These reactions may be either drug specific or cross-reactive to other NSAIDs. Rarely, patients may have combined respiratory and cutaneous reactions that cannot be classified into one of the four reaction types described.

### Corticosteroids

Corticosteroids are the most frequently used drugs for the treatment of allergic conditions, yet they can also induce hypersensitivity reactions. Most hypersensitivity reactions to steroids can be classified into type I (immediate, IgE-mediated) and type IV (delayed, cell-mediated) mechanisms. Type I reactions are characterized by the presence of urticaria and anaphylaxis. Type IV reactions can be presented as maculopapular exanthema and delayed urticaria.

Allergic contact dermatitis (type IV reaction) caused by topical administration of steroids is the most common type of allergic reaction induced by this class of drugs, occurring at the rate of 3% to 6%. Usually this is seen as a failure to improve or a worsening of an existing dermatitis that is being treated with topical steroid. Keep in mind that the reaction can also be due to other constituents of the creams, such as neomycin or cetostearyl alcohol. The diagnosis can be done using patch testing, which detects more than 90% of allergic patients. The topical steroids most frequently involved are nonfluorinated, such as hydrocortisone and budesonide.

Inhaled and intranasal steroids can induce both local and systemic reactions. Local reactions include contact dermatitis, pruritus, nasal congestion, erythema, and dry cough and are quite

often irritant in nature. Systemic reactions include eczematous lesions, particularly on the face, exanthema, and urticaria. The most frequently involved steroid is budesonide. The actual mechanism of this reaction is not clear, but it may be a T-cell-mediated reaction.

Hypersensitivity reactions to systemically administered steroids seldom occur. Most of the data come from case reports. Both immediate and delayed reactions have been described, ranging from urticaria to sudden cardiovascular collapse and death. Most immediate reactions are caused by intravenous methylprednisolone and hydrocortisone. In a few cases, the reactions can be induced by salts, such as succinate, or rarely by certain diluents such as carboxymethylcellulose or metabisulfite. Non-immediate reactions are mainly mild, such as delayed urticaria or maculopapular exanthema. The drug involved most often is betamethasone.

Cross-reactivity between steroids is difficult to assess. Based on corticosteroid patch test results and their chemical structure, Coopman and colleagues divided the steroids into four groups: A (hydrocortisone type), B (triamcinolone acetonide type), C (betamethasone type), and D (hydrocortisone-17-butyrate type). Group D can be subdivided into D1 and D2 depending on the presence or absence of a C16 methyl substitution and/or halogenations on the C9 of the B ring. Table 3 provides the listing of the four groups. High cross-reactivity exists between corticosteroids in each group, as well as between group D2 and groups A and B, with group D1 exhibiting quite low cross-reactivity with the other groups.

### Local Anesthetics

The most common immunologic reaction to local anesthetic is allergic contact dermatitis (type IV). IgE-mediated reactions (type

I) to local anesthetics are very rare. Most adverse reactions are due to nonallergic factors such as vasovagal response, anxiety, dysrhythmias, and toxic reactions resulting from inadvertent IV epinephrine effects.

Any patient who presents with a history of an allergic reaction to local anesthetics should be carefully evaluated. Skin testing and graded challenge can be performed in patients who present with a history suggestive of a possible IgE-mediated allergic reaction to these drugs. A local anesthetic that does not contain epinephrine or other additives, such as parabens or sulfites, is preferred in this situation.

It is necessary to identify the type of local anesthetics to be used. Local anesthetics are classified as esters or amides based on their chemical structure. Drugs in the esters group include benzocaine (Americaine, Dermoplast, Lanacane, Hurricaine), chloroprocaine, cocaine, procaine (Novocaine), proparacaine (Alcaine, Opthaine), and tetracaine (Tetacaine). Most allergic reactions reported in the literature have been caused by agents in the esters group, which are derivatives of para-aminobenzoic acid (PABA), a known allergen. Cross-reactivity occurs among members of the ester group, but the esters do not cross-react with the amides. Agents in the amides group include bupivacaine (Marcaine), lidocaine, mepivacaine (Polocaine), prilocaine (Citanest), and ropivacaine (Naropin). Amide local anesthetics generally do not cross-react with other amides or with the esters.

### Radiocontrast Media

There are two types of radiocontrast media (RCM): ionic high osmolality and nonionic low osmolality. Both of these agents contain iodine. The nonionic RCMs are much more widely used today than the ionic agents.

Allergic reactions to RCM are common and can range from mild to life threatening. Anaphylactoid reactions and severe life-threatening reactions occur in 1% to 3% and 0.22% of patients who receive ionic RCM, respectively. Less than 0.5% and 0.04% of patients who receive nonionic agents have anaphylactoid reactions and severe reactions, respectively. The fatality rate is approximately 1 to 2 per 100,000 procedures, and it is similar for both ionic and nonionic agents. RCM reactions are typically not mediated by IgE antibodies. RCM acts directly on mast cells and basophils, resulting in the release of histamine and other systemic mediators, which cause the anaphylactoid reactions. Patients at greater risk for more serious anaphylactoid reactions include females; those with asthma, heart disease, and a history of previous anaphylactoid reaction to RCM; and those taking beta-blockers. People who have seafood allergy are not at increased risk for reactions to RCM compared with the general population. The pathogenesis of anaphylactoid reactions is also not related to iodine.

Management of patients with previous RCM reactions include the use of a nonionic, low-osmolality agent and a pretreatment regimen. One common regimen consists of prednisone (50 mg PO at 13, 7, and 1 hour before the procedure), diphenhydramine (50 mg at 1 hour before the procedure), and a histamine H<sub>2</sub>-receptor antagonist (1 hour before the procedure). This will significantly reduce the risk for anaphylactoid reaction with reexposure to RCM.

Delayed reactions to RCM occur 1 hour to 1 week after RCM administration. Approximately 2% of patients have delayed reactions to RCM. These reactions are generally mild, self-limited cutaneous eruptions. The mechanism is usually T-cell mediated. Rarely, more serious and life-threatening delayed reactions such as SJS, TEN, and DRESS syndrome have been reported.

### Chlorhexidine

Chlorhexidine gluconate is an antiseptic agent. It is commonly available in OTC products as a skin and wound disinfectant (e.g., Betasept, Hibiclens). Hypersensitivity reactions to chlorhexidine include contact dermatitis, pruritus, urticaria, dyspnea, and anaphylaxis. Prescription chlorhexidine gluconate mouthwashes and

D2	Hydrocortisone-17-butyrate	Fluticasone (Flonase) Mometasone Prednicarbate (Dermatop) Hydrocortisone 17-butyrate (Locoid) Hydrocortisone 17-propionate* Methylprednisolone aceponate*

\*Not available in the United States. From Torres and Canto (2010).

oral chips used for gum disease contain a warning about the rare but serious allergic reactions in their labels. According to a recent FDA Drug Safety Communication, the number of reports of serious allergic reactions to chlorhexidine-containing products has increased over the last several years. As a result, an anaphylaxis warning is now added to the OTC product labels under Drug Facts.

Several case reports have suggested that some patients with prior exposure to chlorhexidine and patients with chlorhexidine-induced contact dermatitis may be susceptible to anaphylaxis caused by chlorhexidine sensitization. Since chlorhexidine is the standard skin disinfectant used before surgery or invasive procedures, the exposure to the agent becomes more widespread. Even though severe anaphylaxis to chlorhexidine has been estimated to be rare, the actual rate may be higher than reported. Such reports remind clinicians to be vigilant about chlorhexidine as a hidden allergen, especially in surgical patients.

### Herbal Supplements

There is a perception that herbal supplements are “natural” and therefore safe. In fact, severe allergic reactions including asthma and anaphylaxis have been well documented in patients using bee pollen products and echinacea. Echinacea is an herb belonging to a group of flowering plants known as Asteraceae. Asteraceae-derived pollens are an important cause of hay fever and asthma. Asteraceae may cause contact allergic dermatitis. Cross-reactivity exists between members of the Asteraceae family, such as ragweed, dandelion, daisy, chamomile, echinacea, feverfew, and milk thistle.

A lack of quality control has been a major concern in the herbal supplement industry. Chinese herbal products may be adulterated with synthetic medications not listed on the label. Contaminated supplements may be a potential risk for systemic contact dermatitis in nickel- and mercury-allergic patients. Because of the widespread use of herbal supplements and the underreporting of adverse events to herbs, all patients should be questioned about the use of herbal supplements when being evaluated for hypersensitivity reactions.

### Conclusion

Drug hypersensitivity reactions are common; fortunately, severe and often fatal reactions are not. It is important for the clinician to have a working knowledge of common drug-induced hypersensitive reactions as well as the ability to identify and document common dermatologic findings. With that background knowledge, a thorough history and physical examination should enable the clinician to diagnose the majority of these types of reactions. A timely and appropriate management plan can then be implemented. As always, it is important to educate patients regarding their drug hypersensitivity history and the potential for future reactions.

## SERUM SICKNESS

Method of

Amy Robertson, PharmD; and Amanda Rhyne, MD

### CURRENT DIAGNOSIS

- Identified by: fever, rash, joint pain (in combination or isolated)
- 7–14 days after exposure to offending agent
- Most frequently in the adult female population
- There are no disease defining labs, although complement tests may be elevated

### CURRENT THERAPY

- Identify and discontinue offending agent
- Symptomatic relief with analgesics and antihistamines, as needed
- Those with severe disease may be treated with oral or intravenous corticosteroids for 10–14 days
- If symptoms reappear after discontinuation of corticosteroid, reinstitute with a slow taper

### Pathophysiology

Serum sickness is classified as a type III delayed immune-complex-mediated hypersensitivity reaction. It was first noted by Von Pirquet in the early 1900s after administration of equine antiserum. The mechanism consists of exposure to an antigen (often a large protein) that leads to formation of an antigen-antibody complex. The immune complex load becomes too high to be appropriately excreted from the body, causing deposition in joints, tissues, and vascular endothelium. It also leads to activation of the complement pathway, which prompts mast cell and basophil degranulation with vasoactive amine release. The deposition of immune complexes and release of inflammatory mediators (histamine, serotonin) leads to the common symptoms of urticarial rash, joint pain, and fever.

Serum sickness–like reaction is not as well defined as true serum sickness. It is postulated that a non-protein drug binds to a serum protein to make a complete antigen. The newly formed antigen goes on to become an antigen-antibody complex. These complexes mimic the inflammatory cascade and symptomatic response of a true serum sickness reaction.

### Epidemiology

Serum sickness is most common in the adult female population. A systematic review involving 33 cases of rituximab (Rituxan)-induced serum sickness (RISS) showed 76.7% female predominance with a mean age of 39.1 years. The majority of cases occurred in patients with an autoimmune condition, specifically immune thrombocytopenic purpura and Sjogren. Due to a lack of clear diagnostic tools and varying symptoms that can closely mimic a flare of an underlying rheumatologic illness, these reactions are often poorly documented or not identified. A study of Australian snake antivenom showed that the incidence of serum sickness was 29% ( $N = 32/109$ ). Further research will need to be done to determine current incidence with the increasing treatment of rheumatologic disorders with immunologic medications.

### Risk Factors

Risk factors for serum sickness include parenteral and cutaneous administration of chemicals, especially those with large molecular weights (e.g., proteins, serum). Heterologous (animal-derived) proteins, in particular, are associated with a high risk for a delayed immune response. Historically, equine-derived antisera and antitoxins were common causes and now includes murine and chimeric monoclonal antibodies such as rituximab (Rituxan) and infliximab (Remicade). Fewer adverse events have been reported with adalimumab (Humira), a humanized monoclonal antibody. Additional risk factors include administration of large doses, repeated dosing, and longer administration times. Patients with autoimmune disorders, circulating histamine-releasing factors, and atopy are also at an increased risk.

Serum sickness–like reactions are associated with a wider variety of molecules, including non-protein medications (e.g., antibiotics), vaccines, allergy extracts, hormones, and enzymes. See [Table 1](#) for a list of agents commonly associated with serum sickness and serum sickness–like reactions.

### Clinical Manifestations

Common manifestations of serum sickness include fever, pruritic rash (not involving mucosal membranes), and arthralgia of the metacarpophalangeal joints, knees, wrists, ankles, and shoulders. The timing of these symptoms occurs 7 to 14 days after exposure to the offending agent and can happen more promptly if there has been previous exposure. Urticaria has been reported as the most prominent symptom, present in 90% of cases. In a study of 33 cases of RISS: 78.8% presented with fever, 72.7% with arthralgia, and 69.7% with rash. The triad of fever, rash, and arthralgia were present in 48.5% of the cases. There are many less prominent manifestations of serum sickness, including headache, gastrointestinal (GI) bloating, cramps, diarrhea, and nephropathy.

### Diagnosis

Recommended workup includes complete blood count (CBC), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), urinalysis (UA), and comprehensive metabolic panel (CMP). Although lab work can help to differentiate from other causes, diagnosis is made clinically. Attempts have been made to link serum sickness to elevated levels of rheumatoid factor, complement, and antibody levels without success.

### Differential Diagnosis

The differential diagnoses for serum sickness include: serum sickness–like reaction, other hypersensitivity reactions, viral illness, rheumatologic disease, tick-borne disease, reactive arthritis, Stevens-Johnson syndrome, rheumatic fever, and lupus.

**TABLE 1** Medications Associated With Serum Sickness and Serum Sickness–Like Reactions

#### Serum Sickness

Heterologous (animal-derived) proteins:

- Antivenom for snake bites: Crotalidae polyvalent immune fab, North and South American snake antivenom (CroFab)
- Chimeric (murine/human) monoclonal antibodies: rituximab (Rituxan), infliximab (Remicade)
- Equine serum heptavalent botulism antitoxin
- Equine-derived antivenom for spider bites
- Equine-derived diphtheria antitoxin
- Murine monoclonal antibodies
- Polyclonal antibodies: equine or rabbit anti-thymocyte globulin (Atgam, Thymoglobulin)

Homologous (human-derived) proteins:

- Anti-D (Rho[D]) immune globulin (RhoGAM)
- Humanized monoclonal antibodies: adalimumab (Humira), omalizumab (Xolair), natalizumab (Tysabri), alemtuzumab (Lemtrada)
- Intravenous immune globulin (Carimune NF, Gamunex-C)

#### Serum Sickness–like Reactions

- Allopurinol (Zyloprim)
- Antimicrobials
  - Cephalosporins (especially cefaclor [Ceclor])
  - Ciprofloxacin (Cipro)
  - Griseofulvin (Gris-PEG)
  - Isoniazid (Nydrazid, INH)
  - Minocycline (Minocin)
  - Penicillins (Pen-Vee K)
  - Streptomycin (Agri-mycin-17, Agrept)
  - Sulfonamides
- Barbiturates
- Bupropion (Wellbutrin)
- Captopril (Capoten)
- Hydantoins
- Hydralazine (Apresoline)
- Iodides
- Methyl dopa (Aldomet)
- Phenytoin (Dilantin)
- Procainamide (Pronestyl, Procan-SR, Procanbid)
- Quinidine (Cardioquine)
- Thiouracils (e.g., methimazole [Tapazole])

### Treatment

Treatment of serum sickness and serum sickness–like reactions are similar. Discontinuation and avoidance of the offending agent is recommended and usually leads to spontaneous resolution within several weeks. Due to the self-limiting nature and generally mild presentation, treatment is symptom driven. Low-grade fever and/or arthralgias can be treated with analgesics (e.g., acetaminophen [Tylenol]) or nonsteroidal anti-inflammatory drugs. Antihistamines and corticosteroids are commonly used, but there are limited data to support their efficacy. Antihistamines may be used to treat urticarial symptoms. Those with more severe disease (e.g., temperature  $>38.5^{\circ}\text{C}$ , severe arthralgias, extensive rashes) can be treated with a short course of corticosteroids (e.g., prednisone [Deltasone] 40 to 60 mg by mouth daily). Generally oral corticosteroids are sufficient, but intravenous agents may be appropriate for some patients (e.g., methylprednisolone [Solu-Medrol] 1 to 2 mg/kg in one or two divided doses intravenously). A systematic review revealed intravenous methylprednisolone (Solu-Medrol) as the most common treatment of RISS. Other treatment options identified were intravenous betamethasone (Celestone Soluspan), intravenous hydrocortisone (Solu-Cortef), oral prednisone (Deltasone), and oral prednisolone (Millipred). This study demonstrated a mean treatment duration of 9 days with complete resolution of symptoms in all cases. Some studies recommend tapering corticosteroids over 2 weeks to avoid rebound symptoms. There are currently no evidence-based guidelines available to guide dosing or duration of therapy.

Plasmapheresis or plasma exchange is another treatment option used to eliminate immune complexes. One study reports the use of plasmapheresis in five patients post-renal transplant who experienced anti-thymocyte globulin-induced serum sickness with no improvement after administration of oral prednisone (Deltasone) 1 mg/kg/d or intravenous prednisolone (Millipred) 2 mg/kg/d. This treatment method is generally reserved for refractory cases that do not respond to corticosteroid therapy due to limited evidence of its safety and efficacy.

## Cardiovascular System

### ACUTE MYOCARDIAL INFARCTION

Method of

Kuang-Yuh Chyu, MD, PhD; and Prediman Krishan Shah, MD

#### CURRENT DIAGNOSIS

- Patients are encouraged to seek medical evaluation as soon as possible when chest pain or angina-equivalent symptoms occur.
- Early presentation leads to early recognition, diagnosis, and treatment of acute myocardial infarction (MI).
- The diagnosis of acute MI relies on detailed history, ECG changes consistent with myocardial ischemia, and elevation of serum biomarkers.
- Although echocardiogram is not essential to diagnose acute MI, it is useful in diagnosing complications from acute MI and guiding management.

#### CURRENT THERAPY

- Timely reperfusion of occluded coronary artery is essential in managing ST-elevation myocardial infarction (STEMI).
- Early reperfusion therapy (percutaneous coronary intervention [PCI] or coronary artery bypass grafting [CABG]) is beneficial in non-ST-elevation myocardial infarction (NSTEMI) patients with high-risk features such as congestive heart failure, dynamic ECG changes, arrhythmia, and refractory angina.
- Medical therapy and lifestyle modification strategies are important to reduce long-term atherosclerotic cardiovascular events.

Coronary heart disease results from atherosclerotic coronary artery disease (CAD), and its acute manifestation is acute coronary syndrome (ACS). Based on presenting symptoms, characteristic ECG changes, and cardiac biomarkers, ACS can be further subdivided into unstable angina (USA), NSTEMI, or STEMI. Most patients with ACS have similar underlying pathophysiology: atherosclerotic plaque formation leading to narrowing of coronary arteries with plaque rupture or erosion and superimposed thrombus formation resulting in an acute presentation. A small portion of ACS cases can be caused by conditions such as coronary artery spasm, spontaneous coronary artery dissection, coronary embolization, or cocaine use. Stress-induced acute cardiomyopathy without angiographic signs of severely occlusive disease can closely simulate atherothrombotic STEMI.

Although the three ACS entities share similar pathophysiology, their presentations vary widely. The initial recognition, diagnostic testing, and management strategies for these entities are similar and applicable to all patients with ACS. Diagnostically, patients with STEMI, as a whole, reflect a more homogeneous group of

patients when compared with patients with USA or NSTEMI, and patients with STEMI carry the highest risk regarding acute morbidity and mortality. The major difference in managing these three groups of patients lies in the decision for and timing of acute reperfusion of occluded culprit coronary arteries.

In the past three decades, there has been a steady decline in the incidence of STEMI and a significant improvement in the outcomes of patients with STEMI with the introduction of early coronary reperfusion strategies; improved adjunctive pharmacologic therapies; adoption of guideline-directed treatments such as lipid lowering, blood pressure control, and diabetes mellitus control; and cigarette smoking cessation to effectively modify risk factors. Currently, the in-hospital mortality of STEMI has reached as low as 7%.

#### Diagnosis

##### Electrocardiogram

ECG is the most important diagnostic test to detect STEMI because the clinical features, physical examination, and CAD risk factor profile only have modest sensitivity and specificity in diagnosing STEMI. Current guidelines define ST elevation at the J point in at least two continuous leads of 2 mm or greater in men or 1.5 mm or greater in women in leads V2 to V3 and/or 1 mm or greater in other contiguous chest leads or the limb leads in the absence of left ventricular (LV) hypertrophy or left bundle branch block. Other ECG abnormalities such as paced rhythm, drug or electrolyte (hyperkalemia) effects, or Brugada syndrome also reduce the sensitivity and specificity of STEMI ECG interpretation.

Some patients present with ECG changes without typical ST elevation, indicating an equivalent clinical risk to STEMI, and they should be treated as having a true STEMI. These STEMI-equivalent ECG patterns include (1) isolated ST depression in two or more precordial leads (V1 to V4), indicating true posterior wall MI; (2) ST depression in multiple leads with ST-segment elevation in aVR, indicating left main or triple-vessel CAD; (3) Wellens sign with symmetrical deep T-wave inversions in anterior precordial leads; (4) hyperacute T waves; and (5) de Winter sign showing ST depression and peaked T waves in the precordial leads. Occasionally, patients with left circumflex artery occlusion will present with a normal or near-normal ECG.

##### Serum Biomarkers

Serum biomarkers of myocardial necrosis such as cardiac-specific troponins T and I are complementary to diagnosing STEMI. In clinical practice, STEMI is often diagnosed with ECG alone, before the laboratory result of biomarkers is available. The troponin level typically increases 4 to 6 hours after the onset of symptoms and peaks within 12 to 24 hours if reperfusion therapy succeeds in reperfusing the occluded coronary artery and patients present early in the course of STEMI; its level tends to peak after 24 hours if reperfusion therapy fails or in patients who receive no reperfusion therapy. After STEMI, successfully reperfused or not, the troponin level remains elevated for 7 to 10 days. For patients suspected of having recurrent ACS within 1 week after the index STEMI, given that troponin levels remain elevated, creatine kinase (CK) and the MB isoform of CK (CK-MB) levels can be used as biomarkers to establish

additional myocardial necrosis from a recurrent event because CK and CK-MB levels usually return to normal 48 to 72 hours after the initial index event. For patients with symptoms of ACS but without ST elevation on ECG, normal levels of serial high-sensitivity troponin using a 0/3-hour algorithm has a negative predictive value of approximately 99% to exclude ACS. Shorter 0/1-hour or 0/2-hour algorithms have also been validated and included in the 2020 European Society of Cardiology (ESC) NSTEMI guideline.

### Imaging

STEMI is commonly accompanied with wall motion abnormalities on echocardiogram, but echocardiogram is not essential to diagnose STEMI. Echocardiogram is extremely useful in managing patients with STEMI, especially when they present with acute complications from STEMI such as acute congestive heart failure, acute mitral regurgitation, free wall or ventricular septal rupture, pericardial effusion, cardiogenic shock, or LV thrombus.

### Management of STEMI

The principal concept of managing STEMI is “time is muscle”; hence it is important for patients to recognize symptoms for early presentation and for the medical community to administer suitable reperfusion therapy in a timely manner.

#### Prehospital Phase

Current guidelines recommend that patients with STEMI receive reperfusion therapy as soon as possible but within 12 hours of symptom onset to achieve optimal myocardial salvage to reduce mortality and morbidity. In daily clinical practice, a substantial number of patients still present late and miss the golden window of reperfusion. Common reasons for late presentation include (1) patients’ lack of knowledge to recognize symptoms, (2) patients’ inertia to seek medical care, (3) patients’ lack of access to medical care, and (4) atypical symptoms that mislead patients or health-care providers to consider noncardiac problems.

Patients with suspicious myocardial ischemic symptoms are encouraged to call emergency medical services (EMS) immediately for help; this has the following benefits: (1) patients can receive early treatment, (2) patients can receive immediate resuscitation should STEMI complications such as cardiac arrest occur en route to the hospital, and (3) an early prehospital ECG and communication with a hospital capable of percutaneous coronary intervention (PCI) by EMS significantly reduces reperfusion time and improves outcome. A recent Lifeline STEMI Accelerator Study reported that only 55% of STEMI patients were transported via EMS. Improving this requires public education to enhance recognition of symptoms, implementation of an efficient EMS system, and infrastructures with standardized treatment algorithms for STEMI.

Initial management by EMS usually includes pain relief by morphine, administration of nitroglycerin,<sup>1</sup> oxygen, and non-enteric-coated aspirin (162 to 325 mg) unless contraindicated. The role of routine oxygen supplementation to patients with STEMI has been questioned. A randomized clinical trial (Air Versus Oxygen in Myocardial Infarction [AVOID] trial) suggests that supplemental oxygen therapy (8 L/min via face mask) in patients with STEMI without hypoxia (oxygen saturation >94%) may increase early myocardial injury and is associated with larger MI size at 6 months.

Once STEMI is identified by a prehospital ECG performed by EMS, an assessment of candidacy for and availability of reperfusion therapy is an important next step of management to ensure immediate reperfusion and administration of its adjunctive therapy to maintain culprit coronary artery patency, limit infarct size and adverse LV remodeling, and improve outcome. To achieve the most favorable outcome from reperfusion therapy, patients with STEMI should receive suitable reperfusion therapy within 12 hours of symptom onset—the earlier the better. Current reperfusion therapy options for STEMI include primary percutaneous coronary intervention

(PPCI) or fibrinolysis. PPCI is the treatment of choice for STEMI because it confers a beneficial reduction in mortality and recurrent ischemia when compared with fibrinolysis. Hence current guidelines recommend that EMS transport patients to a PCI-capable hospital and PPCI as the preferred method of reperfusion therapy with a system goal of less than 90 minutes from first medical contact (FMC) to device time. Such timely reperfusion is even more important for STEMI patients with cardiogenic shock but without out-of-hospital cardiac arrest. The Feedback Intervention and Treatment Times in ST-Elevation Myocardial Infarction (FITT-STEMI) trial demonstrated that every 10-minute treatment delay between 60 and 180 minutes from the FMC leads to 3.3 additional deaths per 100 PCI-treated patients.

Not every hospital is PCI capable. If a patient is sent to or arrives at a non-PCI-capable hospital, guidelines recommend transferring the patient to a PCI-capable hospital for PPCI with a system goal of less than 120 minutes from FMC to device time. If there is an anticipated delay of FMC to device time of 120 minutes or more, a fibrinolytic agent can be given within 30 minutes of hospital arrival if the patient has no contraindications for fibrinolysis (Box 1). Prehospital fibrinolysis, administered by EMS with physician supervision, has been shown to be feasible and safe, with a shortened reperfusion time and reduced mortality. Such strategy, however, is not used in the United States.

In real world clinical practice, sometimes it is not possible to achieve strict time goals because of uncertainty of the initial diagnosis, necessity to treat concomitant comorbidities or complications, patient preference or consent issues, and local

### BOX 1 Contraindications and Cautions for Fibrinolytic Therapy in STEMI\*

#### Absolute Contraindications

- Any prior ICH
- Known structural cerebral vascular lesion (e.g., arteriovenous malformation)
- Known malignant intracranial neoplasm (primary or metastatic)
- Ischemic stroke within 3 months except acute ischemic stroke within 4.5 h
- Suspected aortic dissection
- Active bleeding or bleeding diathesis (excluding menses)
- Significant closed-head or facial trauma within 3 months
- Intracranial or intraspinal surgery within 2 months
- Severe uncontrolled hypertension (unresponsive to emergency therapy)
- For streptokinase, prior treatment within the previous 6 months

#### Relative Contraindications

- History of chronic, severe, poorly controlled hypertension
- Significant hypertension on presentation (SBP >180 mm Hg or DBP >110 mm Hg)
- History of prior ischemic stroke >3 months
- Dementia
- Known intracranial pathology not covered in absolute contraindications
- Traumatic or prolonged CPR (>10 min)
- Major surgery (<3 weeks)
- Recent (within 2–4 weeks) internal bleeding
- Noncompressible vascular punctures
- Pregnancy
- Active peptic ulcer
- Oral anticoagulant therapy

CPR, Cardiopulmonary resuscitation; DBP, diastolic blood pressure; ICH, intracranial hemorrhage; SBP, systole blood pressure; STEMI, ST-elevation myocardial infarction.  
\* Viewed as advisory for clinical decision making and may not be all-inclusive or definitive.

<sup>1</sup>Not FDA approved for this indication.

factors delaying transport. Therefore, emphasis should be to deliver reperfusion therapy to eligible patients as rapidly as possible.

### In-Hospital Reperfusion Strategy

#### Primary Percutaneous Coronary Intervention

PPCI performed in a high-volume hospital by experienced operators achieves a higher patency rate of infarct-related artery (IRA) and a lower rate of recurrent ischemia, reinfarction, hemorrhagic stroke, and death when compared with fibrinolysis. In particular, PPCI has the greatest benefit in high-risk patients such as those with cardiogenic shock. Hence PPCI is the preferred method of reperfusion whenever possible with a system goal of 90 to 120 minutes.

The reperfusion technique used in PPCI has evolved greatly in the past few decades, from balloon angioplasty, bare-metal stent (BMS), and drug-eluting stent (DES) to bioresorbable vascular scaffold (BVS). Compared with balloon angioplasty, BMS used in PPCI confers reduced risk for subsequent target-vessel revascularization but does not reduce the mortality rate. Compared with BMS, DES used in PPCI decreases the restenosis rate and need for reintervention without reduction in reinfarction and death. BVS is a new stent technology, with a hope of better restoration of vasomotion, less lumen loss, and reduction of target lesion revascularization in the stented vessels when compared with metallic DES. However, polymer-based ABSORB BVS failed to demonstrate such benefits; instead it caused a concerning hazard of device thrombosis. A newer generation of metallic BVS (Magmaris; Biotronik, Lake Oswego, OR) also increased late lumen loss and target lesion revascularization in STEMI patients when compared with sirolimus-eluting stent placement in the recently published Magnesium-Based Bioresorbable Scaffold in ST-Segment Elevation Myocardial Infarction (MAGSTEMI) trial.

#### Fibrinolysis

The currently available intravenous fibrinolytic agents are tenecteplase (TNKase), reteplase (Retavase), and alteplase (Activase) (Table 1). A fibrinolytic agent should be administered to eligible patients without contraindication within 30 minutes of arrival at the emergency department. It is important to evaluate the risk-to-benefit ratio for each individual patient before administering fibrinolytic therapy because it carries a small but fatal risk of hemorrhage stroke (about 1%). The ideal patient to receive a fibrinolytic agent would be with symptom onset within 1 to 2 hours, low bleeding risk, and age younger than 65 years.

Although fibrinolysis achieves a reasonable patency rate of IRA (see Table 1), a substantial portion of patients fail to achieve successful reperfusion as defined by the following clinical criteria: (1) resolution of chest pain, (2) reduction of greater than 50% of the initial ST-segment elevation pattern on follow-up ECG 60 to 90

minutes after initiation of fibrinolysis, and (3) occurrence of reperfusion arrhythmia (accelerated idioventricular rhythm [AIVR]). If fibrinolysis does not achieve resolution of ST elevation by at least 50% in the worst lead at 60 to 90 minutes, rescue PCI (or transfer to a PCI-capable hospital if necessary) should be strongly considered.

#### Percutaneous Intervention After Fibrinolysis

Approximately 40% of STEMI patients who receive fibrinolysis fail to achieve successful reperfusion and require emergent rescue PCI. Other indications for rescue PCI include severe heart failure, cardiogenic shock, persistent chest pain, or electrical instability. Hence these patients should be transferred to a PCI-capable hospital immediately if fibrinolysis has been administered in a non-PCI capable hospital.

Otherwise, stable patients after successful fibrinolysis can undergo coronary angiography with an intent to revascularize as soon as logistically feasible, ideally between 3 and 24 hours after fibrinolysis (so-called *pharmaco-invasive strategy*). In patients older than 75 years of age, if a pharmaco-invasive strategy is chosen as the reperfusion strategy, a fibrinolytic agent at half dose (such as the half dose of tenecteplase used in the STREAM trial) should be used to reduce bleeding risks because patients will receive concomitant antiplatelets and anticoagulants for PCI. The Early Routine Catheterization After Alteplase Fibrinolysis Versus Primary PCI in Acute ST-Segment-Elevation Myocardial Infarction (EARLY-MYO) trial confirmed that the efficacy of a pharmaco-invasive strategy using half-dose alteplase followed by PCI within 3 to 24 hours was not inferior to primary PCI in 30-day rates of total death, reinfarction, heart failure, or major bleeding, but with a higher rate of minor bleeding. Very early PCI after successful fibrinolysis (<2 to 3 hours) is not recommended.

#### Facilitated Percutaneous Intervention

This strategy refers to a full dose or partial dose of fibrinolysis plus a glycoprotein (GP) IIb/IIIa antagonist or antithrombotic followed by immediate PCI if there is no evidence of reperfusion failure. Current guidelines do not recommend this strategy because of potential harms such as an increase in ischemic events, bleeding, and mortality.

#### Patients with STEMI and Multivessel

##### Coronary Artery Disease

About 40% to 65% of patients with STEMI undergoing PPCI for culprit IRA have multivessel CAD. Significant multivessel CAD, if left unrevascularized, is associated with a poorer clinical prognosis. For patients with STEMI with cardiogenic shock, conventional paradigm deemed it reasonable to perform multivessel PPCI (or emergency CABG in selected patients) to achieve as complete a revascularization as possible. However, the Culprit Lesion Only PCI versus Multivessel PCI in Cardiogenic Shock (CULPRIT-SHOCK) trial showed that initial revascularization of

Modified from 2013 American College of Cardiology/American Heart Association (ACCF/AHA) STEMI guideline.

the culprit vessel only by PCI in patients with acute MI and multivessel CAD with cardiogenic shock resulted in a lower 30-day risk of death or renal-replacement therapy when compared with a strategy of immediate multivessel PCI.

For stable patients, randomized clinical trials have demonstrated the feasibility of performing multivessel PPCI in acute settings. This approach has the following advantages: complete revascularization leading to improved LV function and prognosis, decreased vascular complications from repeated procedures, and reduced length of stay and medical costs. However, the procedure will be longer with potentially higher radiation exposure, higher risk for contrast nephropathy resulting from a higher contrast load, risk of compromising viable myocardium supplied by the nonculprit coronary artery as a result of procedure complications, and unnecessary stenting to the nonculprit artery without objective evidence of ischemia. Many guidelines published by professional cardiology societies in North America and Europe support multivessel PCI, either at the time of PCI to the STEMI culprit vessel or as a staged procedure in selected hemodynamically stable patients. The recent Complete Revascularization with Multivessel PCI for Myocardial Infarction (COMPLETE) trial further confirmed the efficacy of reducing new MI or ischemia-driven revascularization in the complete revascularization group than in the culprit lesion PCI group, but without mortality benefit. Interventional cardiologists should integrate clinical data, characteristics of lesions and procedures, clinical risks, and complications from procedures to determine the best timing and strategy to achieve the optimal benefit.

#### *Patients with STEMI Older Than 75 Years*

Patients older than 75 years of age are usually underrepresented in STEMI clinical trials; however, revascularization with PCI still confers beneficial clinical outcomes compared with no revascularization despite age, frailty, and comorbidities. Hence PCI as a revascularization strategy for STEMI in older adults is encouraged whenever the patient's condition allows. In the United States, utilization of PCI for patients with STEMI older than 70 years has increased from 11% in 1998 to 35.7% in 2013 based on data from the National Inpatient Sample Database. When caring for this group of patients, cardiologists must pay particular attention to minimize bleeding complications (such as using radial access); monitoring patients' nonverbal responses, as many patients have difficulty communicating with caregivers effectively; and identifying and treating comorbid conditions early, as many older adult patients lack functional reserves in many organ systems and are prone to adverse effects of drug interactions.

#### *Patients with STEMI Who Present Later Than 12 Hours After Symptom Onset*

Irrespective of time of presentation, patients with STEMI who present with hemodynamic or electrical instability should undergo coronary angiography with an intent to revascularize the jeopardized myocardium as soon as possible.

Patients with STEMI who present between 12 hours and 2 days after symptom onset without unstable symptoms or signs are no longer eligible for fibrinolysis but are still eligible for PPCI to salvage myocardium, which confers the benefit of reduced infarct size when compared with conventional therapy guided by a pre-discharge symptom-limited exercise test or unplanned PCI guided by clinical instability, as demonstrated in the Beyond 12 Hours Reperfusion Alternative Evaluation (BRAVE-2) trial. For patients with STEMI who present more than 48 hours after symptom onset without clinical instability, a strategy of symptom-limited stress test first or coronary angiography first to delineate high-risk features of coronary anatomy is reasonable with an intent to revascularize high-risk coronary anatomy. If patients are clinically stable without high-risk coronary anatomy noted by angiography and present between 3 and 28 days after symptom onset, PCI to open the occluded IRA does not confer a clinical benefit in reducing mortality, congestive heart failure, or nonfatal MI when compared with medical therapy, as demonstrated in the Occluded Artery Trial (OAT).

Figure 1 summarizes current pathways of managing patients with STEMI based on their time of presentation, their clinical status, and availability of reperfusion therapy.

### **Adjunct Therapy**

#### **Antiplatelet Therapy**

##### *Aspirin*

Unless contraindicated, 162 to 325 mg of aspirin should be administered as a loading dose immediately followed by at least 81 to 325 mg daily in all patients with STEMI, with 81 mg being the preferred maintenance dose. Patients with a history of aspirin allergy can be given clopidogrel (Plavix) instead.

##### *P2Y<sub>12</sub> Receptor Inhibitors*

Clopidogrel is a second-generation thienopyridine and irreversibly blocks the platelet P2Y<sub>12</sub> receptor to inhibit platelet activation and aggregation. Current guidelines support the use of clopidogrel during fibrinolysis or PPCI. For patients undergoing fibrinolytic therapy, a loading dose of 300 mg followed by a maintenance dose of 75 mg daily has been recommended for patients younger than 75 years of age. For patients older than 75 years of age, only the maintenance dose of 75 mg should be given. Prasugrel (Effient) and ticagrelor (Brilinta) have not been studied and hence are not recommended in the setting of fibrinolysis as reperfusion therapy. For patients undergoing PPCI, depending on whether they are receiving a fibrinolytic agent and the timing of subsequent PCI, a different dosing regimen of clopidogrel may be recommended (Figure 2).

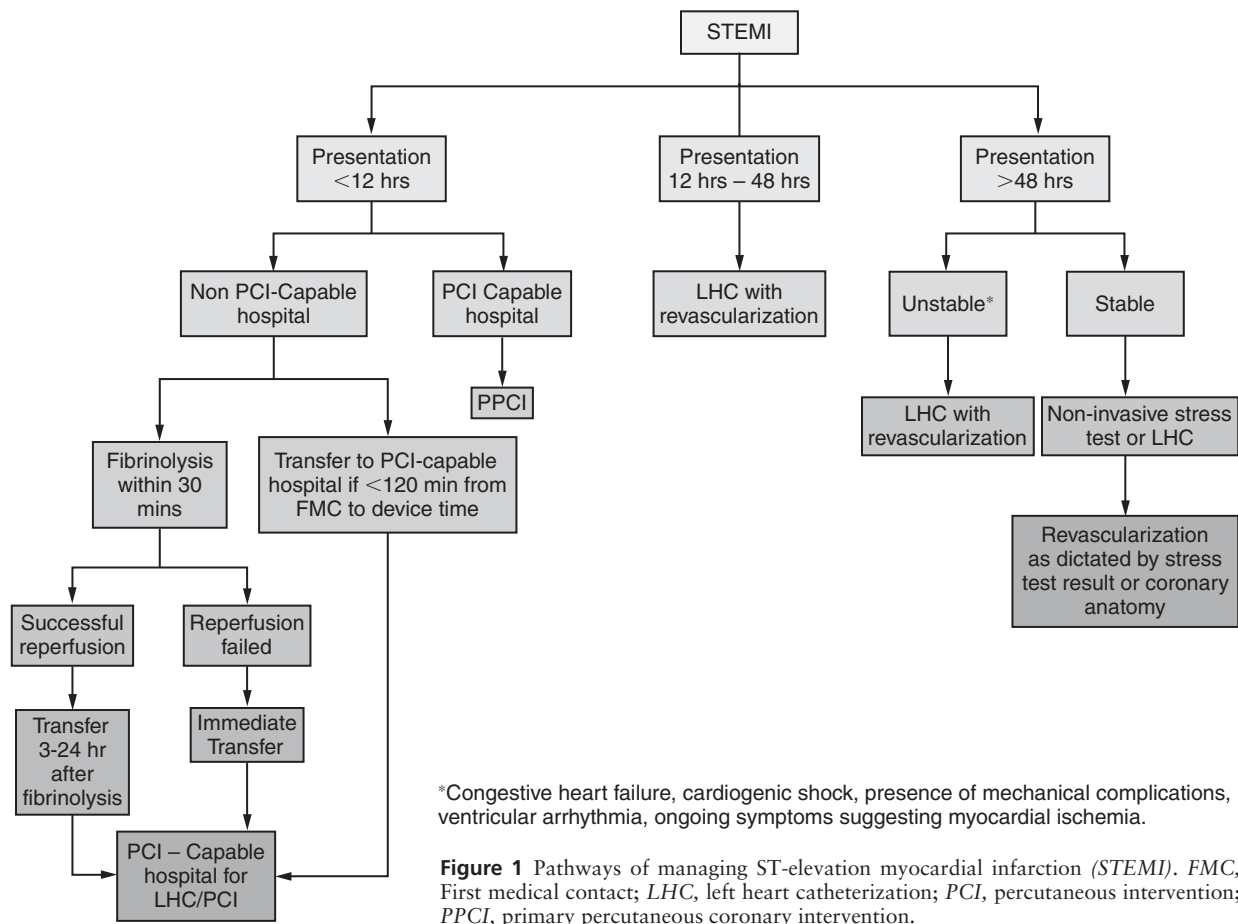

Prasugrel is a third-generation thienopyridine P2Y<sub>12</sub> receptor inhibitor. It is metabolized to its active form more quickly than clopidogrel and hence confers a more potent effect. In a subset of patients with STEMI in the Trial to Assess Improvement in Therapeutic Outcomes by Optimizing Platelet Inhibition with Prasugrel–Thrombolysis in Myocardial Infarction (TRITON-TIMI 38), prasugrel was more efficacious in preventing composite endpoints of cardiovascular death, MI, and stroke when compared with clopidogrel, but with a higher major bleeding rate. Prasugrel is also contraindicated in patients older than 75 years of age, patients with body weight less than 60 kg, or those with a prior history of stroke or transient ischemic attack.

Ticagrelor is a direct reversible P2Y<sub>12</sub> receptor inhibitor with a more potent, faster-acting property when compared with clopidogrel or prasugrel. In the pivotal Platelet Inhibition and Patient Outcomes (PLATO) trial, ticagrelor lowered composite cardiovascular death, MI, and stroke when compared with clopidogrel, but with an increase in non–procedure-related bleeding.

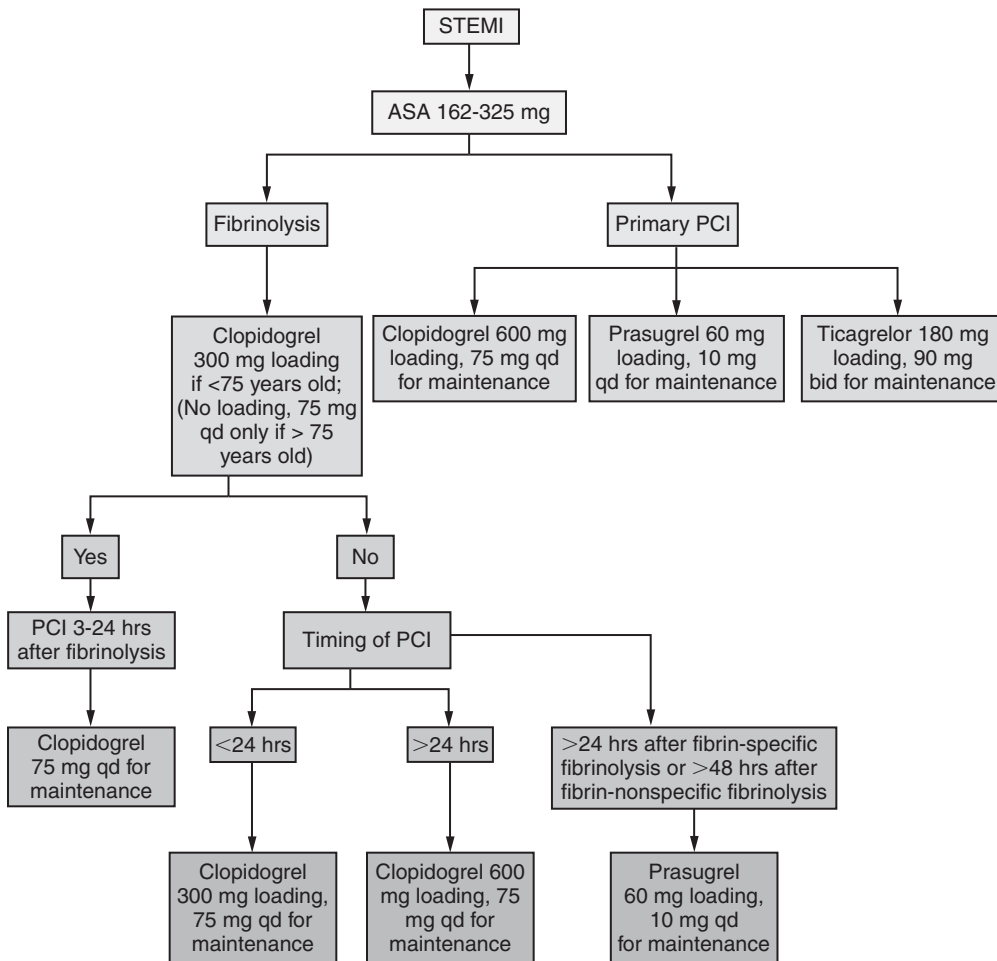

Biotransformation of clopidogrel into active metabolites requires CYP2C19, whereas prasugrel mainly relies on CYP3A4 and CYP2B6, and to a lesser extent, CYP2C19 to form active metabolites. Ticagrelor is an active P2Y<sub>12</sub> receptor inhibitor, and its metabolite via CYP3A4 carries equal antiplatelet potency. About 30% of the U.S. population carries one or two CYP2C19 loss-of-function alleles, rendering them less responsive to the antiplatelet effect of clopidogrel. Hence genotyping CYP2C19 polymorphism could potentially affect the selection of P2Y<sub>12</sub> receptor inhibitor. In STEMI populations, a recent study demonstrated that genotype-guided strategy, that is, patients without loss-of-function of CYP2C19 were treated with clopidogrel, whereas patients with loss of function received ticagrelor or prasugrel, is not inferior to standard treatment with ticagrelor or prasugrel in the control group with respect to thrombotic events at 12 months. However, genotype-guided strategy was associated with a lower risk of bleeding.

Clopidogrel, prasugrel, and ticagrelor require several hours to achieve maximal platelet inhibition. Additionally, in the setting of STEMI, the bioavailability of these oral agents may be hampered by clinical factors such as nausea, vomiting, and cardiogenic shock, leading to poor gastrointestinal absorption and leaving patients not adequately protected by platelet inhibition during immediate PPCI. Cangrelor (Kengreal) is a fast-acting, reversible adenosine

<sup>1</sup>Not FDA approved for this indication.

**Figure 1** Pathways of managing ST-elevation myocardial infarction (STEMI). FMC, First medical contact; LHC, left heart catheterization; PCI, percutaneous intervention; PPCI, primary percutaneous coronary intervention.

**Figure 2** Oral regimen of different P2Y<sub>12</sub> receptor inhibitors based on reperfusion strategies. PCI, Percutaneous intervention. Modified from 2013 ACCF/AHA STEMI guideline.

diphosphate (ADP) receptor inhibitor that is administered intravenously to achieve P2Y<sub>12</sub> receptor inhibition within 2 minutes. Its plasma half-life is 3 to 6 minutes, and platelet function returns to normal within 60 minutes after discontinuation of infusion. The U.S. Food and Drug Administration (FDA) has approved cangrelor to be used as an adjunct therapy during PCI to reduce repeat coronary revascularization and stent thrombosis in patients who have not been pretreated with an oral P2Y<sub>12</sub> receptor inhibitor and are not receiving a GP IIb/IIIa receptor antagonist. How to transition from cangrelor to an oral P2Y<sub>12</sub> receptor inhibitor after PCI depends on which oral P2Y<sub>12</sub> receptor inhibitor a patient is being transitioned to. Based on the Cangrelor Versus Standard Therapy to Achieve Optimal Management of Platelet Inhibition (CHAMPION PHOENIX) trial, to transition to clopidogrel, 600 mg clopidogrel loading is necessary immediately after discontinuation of cangrelor infusion. Based on pharmacodynamic data, prasugrel 60 mg should be administered immediately after discontinuing cangrelor infusion, whereas ticagrelor 180 mg can be given any time during cangrelor infusion or immediately after infusion ends.

#### Use and Duration of Antiplatelet Therapy

Current guidelines recommend administering aspirin and one of the potent P2Y<sub>12</sub> receptor inhibitors (ticagrelor or prasugrel) before primary PCI for STEMI patients. When potent P2Y<sub>12</sub> receptor inhibitors are not available or contraindicated, clopidogrel can be given instead. Routine administration of P2Y<sub>12</sub> receptor inhibitors is not recommended in NSTEMI patients in whom coronary artery anatomy is not known and early invasive management is planned. This recommendation is based on the aggregated results from several clinical trials and registries including ACCOAST, ISAR-REACT 5, DUBIUS, the ARIAM-Andalucia registry, and SCAAR. Once coronary anatomy is defined and PCI deemed necessary, a P2Y<sub>12</sub> receptor inhibitor can be administered. This approach has the benefit of reducing unnecessary bleeding risk in patients whose NSTEMI diagnosis is disproved by coronary angiogram, reducing the wait time for patients with suitable coronary anatomy for bypass surgery.

Current guidelines recommend 12 months of dual antiplatelet therapy (DAPT) in patients with ACS (STEMI or NSTEMI) after stent implantation. The duration of DAPT can be shortened to 6 months followed by discontinuation of the P2Y<sub>12</sub> receptor inhibitor if bleeding risk is high (e.g., PRECISE DAPT >25). Recent trials suggest that an even shorter duration of DAPT (3 months) followed by monotherapy (aspirin or P2Y<sub>12</sub> receptor inhibitor) may be considered in patients with high bleeding risk. Continuation of DAPT beyond 12 months is reasonable in patients who tolerate DAPT, do not have bleeding complications, and are not at high bleeding risk (prior bleeding on DAPT, coagulopathy, or oral anticoagulant use).

The use and duration of DAPT becomes more complicated in patients taking oral anticoagulation therapy for a variety of reasons. Guidelines and consensus documents from North America recommend the default approach of administering triple therapy (DAPT + anticoagulation) during a PCI procedure and in the hospital for up to 1 week followed by clopidogrel and an oral anticoagulant for 12 months. If patients have a high risk for an ischemic event, the default approach is modified to use triple therapy (aspirin + clopidogrel or ticagrelor + oral anticoagulant) for 1 month and discontinue the aspirin afterward. If patients have a high bleeding risk, the default approach is modified to use clopidogrel for only 6 months. A novel oral anticoagulant (NOAC) is preferred to a vitamin K antagonist as the oral anticoagulant unless the patient's clinical condition prohibits the use of a NOAC. An oral anticoagulant alone can be used after 12 months of treatment with a single additional antiplatelet agent based on individual clinical circumstances. Other strategies include use of the radial artery approach for vascular access, use of proton pump inhibitors, avoidance of GP IIb/IIIa inhibitors unless for periprocedural complications, and avoidance of NSAIDs.

#### Glycoprotein IIb/IIIa Receptor Antagonists

GP IIb/IIIa receptor antagonists include abciximab (ReoPro, a chimeric monoclonal antibody), eptifibatid (Integrilin, a synthetic

peptidic inhibitor), and tirofiban (Aggrastat, a nonpeptidic inhibitor). The benefit of intravenous GP IIb/IIIa receptor antagonists in patients with STEMI was largely established before the era of oral DAPT. With current use of DAPT, contemporary trials fail to show benefit with upstream administration of GP IIb/IIIa receptor antagonists before PPCI with either unfractionated heparin (UFH)<sup>1</sup> or bivalirudin (Angiomax). Current U.S. and European guidelines recommend using GP IIb/IIIa receptor antagonists for bailout situations after a large thrombus burden, no reflow or slow flow, or inadequate P2Y<sub>12</sub> receptor antagonist loading during PCI.

#### Anticoagulants

Unfractionated heparin (UFH)<sup>1</sup>, low-molecular-weight heparin with enoxaparin (Lovenox) as prototype, fondaparinux (Arixtra)<sup>1</sup>, and bivalirudin (Angiomax) are widely used in reperfusion therapy to limit thrombus propagation, reduce reocclusion and reinfarction, and improve vessel patency unless contraindicated. The choice of individual agent and its dose and duration of use depend on the choice of reperfusion therapy, concomitant use of other antiplatelet agents, and renal function (Table 2).

Given that PPCI is the preferred method of reperfusion and occurs early after presentation, and given physicians' familiarity with UFH, intravenous UFH is the preferred anticoagulant agent for PPCI. In patients with high bleeding risk, bivalirudin with DAPT is a reasonable alternative to UFH (whether the patient was pretreated with UFH) when avoidance of GP IIb/IIIa receptor antagonists is desired during PPCI.

For patients with STEMI who receive fibrinolysis as initial reperfusion therapy, UFH, enoxaparin, and fondaparinux<sup>1</sup> all receive a class I recommendation based on American College of Cardiology/American Heart Association (ACC/AHA) guidelines. UFH is preferred because a pharmaco-invasive strategy is common or for patients who may need rescue PCI. Bivalirudin may be used after fibrinolysis in patients who develop heparin-induced thrombocytopenia and require continued anticoagulation.

#### Guideline-Directed Medical Therapy

##### Beta Blocker

Beta-blocker therapy decreases myocardial oxygen demand and improves myocardial remodeling with the benefits of reducing angina, infarct size, and mortality. Current guidelines recommend initiating oral beta blockers in the first 24 hours in patients with STEMI who are without contraindications such as congestive heart failure, evidence of a low output state, increased risk for cardiogenic shock, heart block, or reactive airway disease. If not given in the first 24 hours because of contraindications, physicians must reevaluate patients to determine their subsequent eligibility. Oral beta blockers should be continued for 3 years after MI as recommended by the ACC/AHA secondary prevention guideline, and longer if there are other indications (such as systolic LV dysfunction). Commonly used beta-blocker regimens are (1) metoprolol tartrate (Lopressor) 25 to 50 mg every 6 to 12 hours orally, transitioned over the next 2 to 3 days to twice-daily dosing of metoprolol tartrate or to daily metoprolol succinate (Toprol XL), and then titrated to a daily dose of 200 mg as tolerated, and (2) carvedilol (Coreg)<sup>1</sup> 6.25 mg twice daily, titrated to 25 mg twice daily as tolerated.

Current guidelines recommend an intravenous beta blocker only for patients with refractory hypertension or ongoing ischemia without contraindications. Several small randomized clinical trials have suggested that early use of intravenous metoprolol tartrate in selected patients with STEMI with Killip class I to II and no atrioventricular (AV) block before PPCI may reduce infarct size with a higher left ventricular ejection fraction (LVEF) or reduce the incidence of malignant arrhythmia in the acute phase without an excess of adverse events.

<sup>1</sup>Not FDA approved for this indication.

**TABLE 2** Dosage of Anticoagulants in Reperfusion Therapy for STEMI

REPERFUSION THERAPY		
	FIBRINOLYSIS	PRIMARY PCI
Unfractionated heparin <sup>1</sup>	<ul style="list-style-type: none"> <li>• IV bolus of 60 U/kg (maximum 4000 U) followed by an initial infusion of 12 U/kg/h (maximum 1000 U), adjusted to maintain aPTT at 1.5–2.0 times control (approximately 50–70 s) for 48 h or until revascularization</li> </ul>	<ul style="list-style-type: none"> <li>• With GPI planned, 50–70 U/kg IV bolus, to achieve ACT 200–250 s</li> <li>• Without GPI planned, 70–100 U/kg IV bolus to achieve ACT 250–300 s with HemoTec or 300–350 s with Hemochron</li> </ul>

Modified from 2013 American College of Cardiology/American Heart Association (ACC/AHA) STEMI guideline.

### Angiotensin-Converting Enzyme Inhibitors or Angiotensin II Receptor Blockers

Angiotensin-converting enzyme inhibitors (ACEIs) and angiotensin II receptor blockers (ARBs) reduce afterload and decrease myocardial remodeling. Either ACEIs or ARBs should be started within 24 hours if there are no contraindications such as worsening renal function, advanced kidney disease, bilateral renal artery stenosis, hyperkalemia, or hypotension. These agents have the largest benefit in patients with anterior STEMI, congestive heart failure, or LVEF less than 40%. ACEIs may be given routinely to all patients without contraindication, whereas ARBs are an alternative for patients who are intolerant to ACEIs. There is no additional benefit, only more harm if ACEIs and ARBs are given concomitantly.

Commonly used ACEI regimens are (1) captopril 6.25 to 12.5 mg three times per day to start, titrated to 25 to 50 mg three times per day as tolerated; (2) lisinopril (Prinivil) 2.5 to 5 mg/day to start, titrated to 10 mg/day or higher as tolerated; (3) ramipril (Altace) 2.5 mg twice daily to start, titrated to 5 mg twice daily as tolerated; and (4) trandolapril (Mavik) test dose 0.5 mg, titrated up to 4 mg daily as tolerated. A commonly used ARB regimen is valsartan (Diovan) 20 mg twice daily to start, titrated to 160 mg twice daily as tolerated.

### HMG CoA Reductase Inhibitors (Statins)

Treatment with statins after ACS lowers the risk of cardiovascular mortality, recurrent MI, stroke, and the need for coronary revascularization. Without contraindications, all patients should receive high-intensity statins as early as possible to improve compliance. Although current guidelines do not endorse a specific low-density lipoprotein (LDL) level as a treatment goal, it is recommended to obtain a fasting lipid panel within 24 hours of presentation. A commonly used high-intensity statin regimen is atorvastatin (Lipitor)<sup>1</sup> 40 to 80 mg or rosuvastatin (Crestor)<sup>1</sup>

20 to 40 mg daily as tolerated. Statins must be used cautiously with drugs metabolized via CYP3A4 and fibrates, with frequent monitoring for myopathy and hepatic toxicity. Statin use must be combined with diet and therapeutic lifestyle therapies. In patients who cannot achieve an LDL cholesterol level less than 70 mg/dL on adequate statin treatment, addition of a PCSK9 antibody such as alirocumab (Praluent) or evolocumab (Repatha) to the statin can further reduce LDL cholesterol level and risk of recurrent cardiovascular events.

### Aldosterone Antagonists

Eplerenone (Inspra) improves myocardial remodeling and may reduce all-cause and cardiovascular mortality and rehospitalization. The 2013 ACC/AHA STEMI guideline recommends starting this medication 3 to 14 days after STEMI in eligible patients (creatinine ≤2.5 mg/dL in men and ≤2.0 mg/dL in women, potassium ≤5.0 mEq/L) with heart failure, with LVEF less than 35% to 40%, and already on adequate doses of beta blockers and ACEIs or ARBs. However, earlier administration (<7 days) is preferable to achieve mortality and rehospitalization benefits as suggested by a post hoc analysis of the Eplerenone Post-Acute Myocardial Infarction Heart Failure Efficacy and Survival Study (EPHESUS) trial.

### Implantable Cardioverter-Defibrillator

Patients who develop ventricular tachycardia (VT) or fibrillation more than 48 hours after STEMI have the highest risk of sudden cardiac death (SCD) and hence are eligible for an implantable cardioverter-defibrillator (ICD) as a secondary prevention measure for SCD. For primary prevention, multiple trials have established the efficacy of prevention of SCD by ICD implantation in patients with an LVEF less than 35% and New York Heart Association (NYHA) class II or III symptoms (or LVEF <30% with NYHA class I symptoms) despite optimal medical therapy 40 days after index STEMI and expectation of at least 1-year survival.

<sup>1</sup>Not FDA approved for this indication.

## Other Medical Therapy

### Morphine

Morphine is a time-honored medication used to reduce pain and anxiety, especially in patients with pulmonary edema during acute presentation of STEMI. However, analysis of results from several clinical trials and a large meta-analysis involving more than 69,000 ACS patients suggests that a morphine/P2Y<sub>12</sub> receptor inhibitor interaction exists, which could lead to adverse clinical consequences. Several pharmacokinetic studies in healthy volunteers have shown that intravenous morphine administration can reduce the level of active metabolites of clopidogrel and delay the maximal inhibition of platelet aggregation. A similar effect of morphine on ticagrelor was also reported. Given the current trend of using oral P2Y<sub>12</sub> receptor inhibitors before PPCI for STEMI, careful selection of patients and judicious administration of morphine with P2Y<sub>12</sub> receptor inhibitors deserves careful consideration.

### Nitrate

Nitroglycerin reduces LV preload, increases coronary blood flow, and relieves chest pain symptoms. However, it plays no role in decreasing myocardial injury from coronary artery occlusion in STEMI. Its use in STEMI is mostly for congestive heart failure, hypertension, or rare cases of coronary spasm. It is contraindicated in patients with hypotension (systolic blood pressure [SBP] <90 mm Hg or SBP >30 mm Hg below baseline), right ventricular infarction from right coronary artery occlusion, or use of phosphodiesterase-5 inhibitors within 24 to 48 hours.

## Complications of STEMI

### Cardiogenic Shock

Cardiogenic shock is defined as an SBP less than 90 mm Hg for longer than 30 min that is (1) not responsive to fluid administration alone, (2) secondary to cardiac dysfunction, or (3) associated with signs of hypoperfusion or cardiac index less than 2.2 L/min per m<sup>2</sup> and pulmonary capillary wedge pressure greater than 15 mm Hg. It occurs in fewer than 10% of STEMI patients: 2.4% in the 1986 Gruppo Italiano per lo Studio della Streptochinasi nell'Infarto (GISSI-1) trial and 6.5% in the German Arbeitsgemeinschaft Leitende Kardiologische Krankenhausärzte (ALKK) PCI registry as reported in 2013.

Almost 75% to 80% of cases of cardiogenic shock are caused by severe LV systolic dysfunction; right ventricular infarction, mechanical complications from ventricular septal rupture, acute mitral regurgitation, and free wall rupture leading to tamponade account for the rest. Other uncommon causes of shock from non-cardiac etiology after STEMI are bleeding, systemic inflammatory response syndrome, infection, bowel ischemia, or iatrogenic causes (e.g., medication).

Cardiogenic shock resulting from mechanical complications after STEMI occurs in a bimodal fashion, with most cases occurring within 24 hours. Risk factors for mechanical complication include female gender, old age, and late or no reperfusion in the infarcted territory. An early echocardiogram is extremely helpful to delineate the etiology of cardiogenic shock to guide subsequent definitive treatment. Cardiogenic shock carries a high in-hospital mortality (approaching 50%) and is higher in patients older than 75 years of age. These high-mortality patients require immediate stabilization to prevent end-stage organ damage followed by emergency coronary angiography and revascularization (Box 2).

### Electrical Complications

#### Ventricular Arrhythmia

Lethal ventricular arrhythmia (VT or ventricular fibrillation [VF]) is the most common cause of out-of-hospital cardiac arrest in STEMI. For hospitalized patients, VT/VF occurs in fewer than 10% of cases in the era of reperfusion therapy, and most cases occur within 48 hours of presentation. VT/VF is often associated with congestive heart failure, cardiogenic shock, or failed reperfusion of an occluded coronary

## BOX 2 Management Measures for Cardiogenic Shock

### Immediate Stabilization of Patients to Prevent End-Stage Organ Damage

- Maintain adequate mean arterial blood pressure with norepinephrine (Levophed), dopamine, or dobutamine with intraarterial pressure monitoring; norepinephrine preferred over dopamine for less arrhythmogenic effect
- Hemodynamic monitoring with Swan-Ganz catheter to guide inotrope or fluid management
- Selective use of mechanical circulatory support\* if patient cannot be stabilized by previous measures
- Early echocardiography to define etiology of cardiogenic shock
- Early mechanical ventilation
- Management of hemodynamically significant arrhythmia
- Fibrinolysis in STEMI if delay to PCI >2 h

### Early Coronary Angiography and Revascularization

- Early transfer to regional tertiary care hospital for revascularization
- Prophylactic IABP placement before transfer
- PCI often the treatment of choice
- CABG (with correction of mechanical complications if present) in cardiogenic shock if feasible

CABG, Coronary artery bypass grafting; IABP, intraaortic balloon pump; LV, left ventricular; PCI, percutaneous coronary intervention; STEMI, ST-elevation myocardial infarction.

\* IABP is more readily available; limited experience with other LV assist devices such as Impella and TandemHeart device

artery. Hence correction of electrolyte and acid-base disturbance, adequate reperfusion to reduce myocardial ischemia, and treatment of heart failure or shock are important preventive measures. Early administration of beta blockers within 24 hours to patients without contraindications reduces the incidence of VF. If VT/VF occurs, treatment includes immediate defibrillation or cardioversion and an antiarrhythmic agent such as amiodarone (Cordarone). Isolated premature ventricular contractions, nonsustained VT without hemodynamic instability, and AIVR do not generally require specific treatment.

### Supraventricular Arrhythmia

Common supraventricular arrhythmias after STEMI include atrial fibrillation, atrial flutter, and sinus tachycardia. They are usually the consequence of or triggered by congestive heart failure, atrial infarction, pericarditis, hypoxia, or other underlying systemic problems (such as chronic obstructive pulmonary disease, bleeding, anemia, or infection). Treatment is directed to the underlying causes. For atrial fibrillation/flutter, physicians should pay special attention to anticoagulation use given the frequent concomitant use of DAPT and antithrombotics and the rate versus rhythm control strategy.

### Bradycardia and Heart Block

Sinus bradycardia may occur after inferior STEMI. Because it is generally mediated through increased vagal tone, close monitoring usually suffices. High-grade AV block (second or third degree) can occur after inferior or anterior STEMI, with a poorer prognosis after anterior STEMI resulting from a greater degree of myocardial injury. High-grade AV block after inferior STEMI usually is transient and with a narrow complex escape rhythm, which subsides within 2 weeks. Occasionally, temporary pacemaker placement may be necessary if bradycardia causes hemodynamic instability. High-grade AV block from anterior STEMI usually requires placement of a prophylactic temporary pacing system because it is commonly associated with hemodynamic instability.

## ANGINA PECTORIS

Method of

Kenneth Tobin, DO; and Kim Eagle, MD

### CURRENT DIAGNOSIS

- The clinical diagnosis of angina depends largely on the accurate assessment of a patient's risk factor profile for coronary artery disease and the typicality of the symptom complex.
- The most common symptom of angina pectoris is left-sided chest pain or pressure, with or without associated radiation of pain or pressure to the jaw or left arm, occurring with exertion and relieved with rest or sublingual nitroglycerin.
- Women may present with atypical symptoms such as sharp, nonexertional chest pain, generalized fatigue, shortness of breath, or right-sided chest pain.
- Basic screening tests (e.g., 12-lead electrocardiogram, laboratory data, chest radiograph) are normal in most cases.
- For an initial diagnosis, appropriate noninvasive testing or coronary angiography, or both, is important to define the amount of ischemic myocardium and an overall treatment plan.
- Even when invasive procedures are clinically indicated, aggressive medical therapy with high-dose statins, attainment of appropriate blood pressure levels, smoking cessation, and use of antiplatelet therapy is of paramount importance.
- Patients who have clinical evidence of unstable angina and laboratory evidence of myocardial ischemia most often benefit from early invasive treatment strategies.

### CURRENT THERAPY

#### Stable Angina Pectoris

- Treatment includes  $\beta$ -blockers, nitrates, and calcium channel blockers for symptom control.
- Consider the addition of ranolazine (Ranexa) if symptoms are not adequately controlled.

#### Aggressive Cholesterol Treatment Based on the American College of Cardiology (ACC)-American Heart Association (AHA) Blood Cholesterol Guidelines

- Blood pressure management
- Antiplatelet therapy
- Lifestyle modifications:
  - Smoking cessation
  - Exercise prescription
  - Mediterranean, plant-based diet
  - Depression assessment

#### Unstable Angina

- With positive biomarkers for myocardial ischemia, consider coronary angiography.
- With negative biomarkers for myocardial ischemia, consider noninvasive assessment once symptoms are controlled.
- With a substantial ischemic burden identified, consider coronary angiography.
- With no or minimal ischemia identified, consider increasing medical therapy.
- With persistent symptoms, consider other treatment modalities.

Angina pectoris is defined as cardiac-induced pain that is a direct result of a mismatch between myocardial oxygen supply and demand. The initial presentation of ischemic heart disease is chronic stable angina in approximately 50% of patients; it is estimated that 16.5 million Americans are being diagnosed with this condition. Ischemic heart disease is the leading cause of death in the United States.

Stable angina refers to predictable chest discomfort during various levels of exertional activity that is predictably resolved with rest or administration of sublingual nitroglycerin (Nitrostat). Unstable angina is an acute ischemic event; this diagnosis includes patients with new-onset cardiac chest pain, angina at rest, postmyocardial infarction angina, or an accelerating pattern of previously stable angina. The terms unstable angina and non-Q wave myocardial infarction are often used interchangeably and should be further defined on the basis of myocardial necrosis as measured by serum biomarkers.

The clinical sensation of angina pectoris is caused by stimulation of chemosensitive and mechanosensitive receptors of unmyelinated nerve cells found within cardiac muscle fibers and around the coronary vessels. This stimulation cascade is thought to occur when lactate, serotonin, bradykinin, histamine, reactive oxygen species, and adenosine are released into the coronary circulation during periods of lactic acidosis. Nerve stimulation via the sympathetic ganglia occurs most commonly between the seventh cervical and fourth thoracic portions of the spinal cord. This explains from an anatomic standpoint why the most commonly recognized pain patterns for angina pectoris involve discomfort in the chest, neck, jaw, and left arm.

The most common cause of angina pectoris is coronary atherosclerosis. As plaque is initially deposited within a coronary vessel, there may be no significant internal luminal compromise during the early positive remodeling phase. However, at the point at which this compensatory mechanism fails, internal luminal compromise ensues. As long as the coronary artery segment distal to the stenosis retains the ability to vasodilate in response to increasing blood flow demands, coronary homeostasis is maintained. Once the critical threshold is passed, the blood supply cannot accommodate this demand, and angina may occur. The four major factors that determine myocardial oxygen demand are heart rate, systolic blood pressure, myocardial wall tension, and myocardial contractility.

### Clinical Features

For patients with documented coronary artery disease (CAD) who have predictable episodes of classic symptoms, the diagnosis of angina pectoris is straightforward. Most patients are aware of the levels of exertion that typically induce angina symptoms. Most describe a pain or heaviness across their middle chest that may or may not radiate to the jaw or left arm. Some patients deny chest pain symptoms altogether and instead complain of exertional dyspnea or diaphoresis. Environmental situations such as cold exposure, emotional stress, or heavy meals can induce angina. The Canadian Cardiovascular Society and the New York Heart Association classification systems are used to define angina severity. Both systems use a I through IV scale, with mild angina (class I) referring to episodes that occur with extreme exertion and severe angina (class IV) to episodes that occur with minimal or no exertion. These classification systems are useful for risk stratification and for assessing medical therapy efficacy.

There are clear gender differences in the clinical presentations of angina. Pleuritic, musculoskeletal-type pain, nonexertional pain, and nocturnal pains have been reported as anginal equivalents in women. Fatigue is one of the most common presenting symptoms for CAD in women. The key to the diagnosis in men and women lies in a thorough history, which should always include the quality, location, provoking activities, and duration of pain and factors that relieve the pain. Based on a detailed clinical history, the many diagnoses that can masquerade as angina may be eliminated (Table 1).

**TABLE 1** Differential Diagnosis of Chest Pain

Cardiac ischemia
Angina
Myocardial infarction
Vasospastic angina
Pericarditis
Aortic dissection (new-onset chest pain and new aortic insufficiency noted on auscultation is an aortic dissection until proven otherwise)
Pulmonary embolism
Esophageal spasm
Gastroesophageal reflux disease
Musculoskeletal pain
Biliary colic
Acute pneumonia

### Diagnostic Testing

A baseline electrocardiogram (ECG) is often one of the initial tests obtained in a patient with the complaint of chest pain. A normal tracing does not exclude the diagnosis of ischemic heart disease. More than 50% of patients with diagnosed angina have a normal ECG at rest. The baseline ECG may, however, show evidence of pathologic Q waves or left ventricular hypertrophy, either of which increases the statistical probability of significant CAD. Baseline laboratory data should include a fasting lipid panel to help define the patient's risk factor profile.

Stress testing is an appropriate screening tool for the initial diagnosis of CAD, risk stratification after acute ischemic syndrome, and assessment of treatment efficacy. Whenever feasible, it is more advantageous to obtain an exercise stress test rather than a pharmacologically based study. The additional prognostic data obtained through exercise include blood pressure response, heart rate response, heart rate recovery, metabolic equivalent level attained, and ECG assessment of the ST segment. There are several validated exercise protocols that provide additional risk stratification measures to the test results.

The predictive value of exercise treadmill stress testing ranges from 40% for single-vessel disease to 90% for three-vessel disease. A baseline left bundle branch block, paced rhythm, poorly controlled atrial arrhythmia, or left ventricular hypertrophy with secondary ischemic changes often renders the test inconclusive when assessing for ischemic changes. However, if stress testing is being performed for attainment of hemodynamic responses and achievable metabolic equivalent levels, these baseline ECG abnormalities may be overlooked.

Stress test accuracy is markedly improved by the addition of an imaging modality such as echocardiography or nuclear perfusion scanning. The sensitivity and specificity of stress echocardiography and stress nuclear imaging are 85% to 90%. Stress echocardiography is believed to be more specific, and stress nuclear imaging is thought to be more sensitive. A stress echocardiogram also allows assessment of left ventricular systolic function and valvular function and prediction of right ventricular pressure. In deciding on which stress test to perform, one should rely on the expertise of the testing facility and the individual patient's circumstance.

### Risk Factor Management

#### Hypertension

Hypertension is a commonly occurring, well-established, major cardiovascular risk factor. Initial treatment of hypertension in patients with ischemic heart disease should always include lifestyle management. Appropriate weight loss with a goal of achieving a

body mass index  $<25 \text{ kg/m}^2$  can improve hypertension control. A reduction in dietary salt intake can also have positive effects on a patient's blood pressure. Following a heart healthy diet and increased physical activity with a structured exercise program are also very important.

Discord has resulted from the publication of several recent hypertension guidelines by various medical societies, as well as the 2014 Evidence-Based Guideline for the Management of High Blood Pressure in Adults Report from the Panel Members Appointed to the Eighth Joint National Committee. It has been shown that cardiovascular risk progressively increases at blood pressures greater than 115/75 mm Hg. A meta-analysis of 61 prospective observational trials of hypertension involving 1 million adults with no known vascular disease at baseline revealed several interesting findings. Patient outcomes were related per decade of age to the usual blood pressure at the start of that decade. For example, from ages 40 to 69 years, for each increase in 20 mm Hg systolic blood pressure, a twofold increase in cardiovascular death rate occurred. These findings were much more pronounced in patients who were between 80 and 89 years old than in the youngest cohort, 40 to 49 years old. Although the relative risk was much higher in the younger group, the absolute risk was greatest among the octogenarians. These increased cardiovascular risks were not confined to subjects with blood pressures greater than 140/90 mm Hg; rather, there was a threshold of risk shown all the way down to 115/75 mm Hg. Even small reductions in blood pressure can have a significant positive impact on cardiovascular disease. Blood pressure reductions of 4 mm Hg systolic and 3 mm Hg diastolic were shown to reduce cardiovascular events by 15% in a cohort of 20,888 patients.

The Heart Outcomes Prevention Evaluation study asked the question whether all patients with atherosclerosis, regardless of blood pressure, should be treated with an angiotensin-converting enzyme inhibitor. Although many subsequent editorials implied that all patients with CAD could benefit from this therapy, a closer look at the data suggests a different interpretation. The mean blood pressure was 139/79 mm Hg, suggesting that a significant portion of the 9297 participants had a baseline blood pressure higher than this value. Compared with placebo, the treatment group had a 22% reduction in the primary outcome composite of myocardial infarction, stroke, or cardiovascular death. A small substudy using 24-hour ambulatory blood pressure monitoring showed blood pressure differences of 11 mm Hg systolic and 4 mm Hg diastolic in the treatment group compared with the placebo group, which may explain the cardiovascular event reductions reported.

The Systolic Blood Pressure Intervention Trial (SPRINT) studied cardiovascular outcomes in patients with increased cardiovascular risk (excluding diabetes) and randomized the more than 9000 participants to either intensive blood pressure control of  $<120$  mm Hg or a standard blood pressure goal of  $<140$  mm Hg. The trial was halted early because of the significant benefits seen in the intensive blood pressure arm. The intensive group had a 25% relative risk reduction for the primary composite endpoint compared to the standard care group. The blood pressure goal for treatment of hypertension in patients at high cardiovascular risk should be  $<130/80$  mm Hg. High cardiovascular risk is defined as a history of clinical cardiovascular (CV) disease (established coronary artery disease, heart failure, or stroke), or an estimated 10-year atherosclerosis CV disease of  $\geq 10\%$ . (One must be careful with aggressive diastolic blood pressure management, as some studies have shown a J-shaped curve relationship between diastolic blood pressures and coronary events.)

### Hyperlipidemia

Dyslipidemia is an important risk factor for atherosclerotic cardiovascular disease, and the lowering of low density lipoprotein (LDL)-cholesterol has been shown to correlate with reductions in cardiovascular disease event rates. Previously published cholesterol treatment guidelines recommended achieving less than 70 mg/dL LDL-cholesterol levels in CAD patients.

The current guidelines published by the ACC-AHA depart from these specific values, and instead recommend using high-intensity 3-hydroxy-3-methylglutaryl coenzyme reductase inhibitors (statins) to reduce the LDL-cholesterol levels by more than 50%. These agents have been shown to be well tolerated and have positive nonlipid pleiotropic effects, as well as the ability to dramatically lower LDL levels.

Observational evidence suggests that regardless of how cholesterol is lowered, a reduction in atherosclerotic cardiovascular disease will result. However, to achieve meaningful reductions in cardiovascular mortality, the recommended choice for lowering LDL-cholesterol levels among the currently available pharmacology are the statins. These agents have been studied exclusively using fixed-dose combinations and not dose-titrated to achieve various LDL-C levels; therefore currently available data do not support specific LDL target goals.

The Cholesterol Treatment Trialists' meta-analysis, including 90,056 subjects from 14 trials, showed a 12% reduction in all-cause mortality per 38.6 mg/dL (1 mmol/L) reduction in LDL-cholesterol, with a 19% reduction in coronary mortality, a 24% reduction in need for revascularization, a 17% reduction in stroke incidence, and a 21% reduction in any major vascular event during a mean follow-up period of 5 years. These benefits were observed in different age groups, across genders, at different baseline cholesterol levels, and equally among those with and without prior CAD and cardiovascular risk factors.

The Heart Protection Study showed that in patients with established CAD, other atherosclerotic vascular disease, or diabetes, statin therapy reduced cardiovascular events regardless of the baseline LDL-cholesterol level. The trial, which enrolled 20,536 patients aged 40 to 80 years, showed a 24% reduction in major cardiovascular events, a 25% reduction in stroke, and a 13% reduction in overall mortality with statin therapy.

Patients with a recent acute ischemic syndrome were enrolled in the Pravastatin or Atorvastatin Evaluation and Infection Therapy trial, known as Thrombolysis in Myocardial Infarction 22, which compared 80 mg atorvastatin (Lipitor) with 40 mg of pravastatin (Pravachol). The atorvastatin group achieved a median LDL level of 62 mg/dL, compared with 96 mg/dL in the pravastatin group. The relative risk reduction for this reduced LDL level was 16%. A substudy looking at the LDL-cholesterol levels achieved with atorvastatin showed that those subjects achieving a level of 40 to 60 mg/dL had a 22% reduction in events, compared with those achieving a level of 80 to 100 mg/dL. Therefore, it appears that high-dose statin therapy and aggressive LDL-lowering in this patient population lead to reduced cardiovascular events.

The Treating to New Targets trial was the first to compare a more intensely treated group with a less intensely treated group using the same agent. The design of this 10,000-patient study eliminated concerns that outcome differences were induced by dissimilar statin preparations. The mean LDL level achieved was 101 mg/dL with 10 mg atorvastatin, and 77 mg/dL with the 80 mg dose. This LDL reduction was associated with a relative risk reduction of 27% for the primary endpoint of the first major cardiovascular event.

There is an increased risk of myopathy and rhabdomyolysis in patients taking 80 mg simvastatin (Zocor), according to the Study of the Effectiveness of Additional Reductions in Cholesterol and Homocysteine (SEARCH). The US Food and Drug Administration (FDA) has subsequently restricted high-dose simvastatin to patients who have been on this dose for longer than 12 months without evidence of myopathy, and the agency has recommended that new patients should not be started on this particular dose.

To effectively achieve a greater than 50% LDL-cholesterol reduction in CAD patients utilizing currently available pharmacologic agents, the most recent treatment guidelines suggest either atorvastatin 40 to 80 mg or rosuvastatin (Crestor) 20 to 40 mg. In other patient populations that require moderate-intensity statin therapy, there are several statin choices. Because there is no currently available evidence to suggest that nonstatin lipid-altering agents effectively reduce cardiovascular mortality, these medications should not be routinely prescribed.

It is apparent from both primary and secondary prevention lipid trials that achieving lower LDL levels reduces cardiovascular event rates. Because there is no high-quality clinical evidence to support achieving specific LDL levels in patients with diagnosed CAD, high-dose statin therapy should be the mainstay of pharmacologically based therapy, if tolerated.

Although statins are the standard pharmacologic approach for primary and secondary prevention of atherosclerotic cardiovascular disease, as many as 20% of patients may be intolerant. The numbers may be even higher if medication adherence is included. For secondary prevention in patients whose cholesterol levels are not adequately achieved on a statin or other cholesterol-lowering medication, a proprotein convertase subtilisin kexin type 9 (PCSK9) inhibitor is an FDA-approved option. PCSK9 inhibitors can also be considered for those with familial hypercholesterolemia and can be prescribed with or without a statin. The FOURIER Cardiovascular Outcomes trial studied more than 27,000 patients with stable atherosclerotic cardiovascular disease and showed that evolocumab (Repatha) reduced the primary endpoint of atherosclerotic events by 15%, without significant safety differences between treatment groups. Subgroup analyses suggested that greater benefits were seen in patients with longer exposure to evolocumab, recent acute coronary syndrome, multiple myocardial infarctions, multivessel coronary artery disease, peripheral arterial disease, as well as the subgroup who achieved very low low-density lipoprotein-cholesterol levels of below 0.3 mmol/L (10 mg/dL).

#### **Omega-3 Fatty Acids**

Omega-3 polyunsaturated fatty acids (PUFAs) are a well known part of a heart healthy diet, and are also an effective treatment for patients with elevated triglyceride levels. The Reduce-it trial studied a prescription strength omega-3 PUFA in well-controlled statin-treated patients with elevated triglycerides and either documented coronary artery disease, diabetes mellitus, or other cardiovascular risk factors. Seventy percent of the 8179 patients enrolled had a previous diagnosis of ischemic heart disease.

Patients were randomly assigned to receive 2 g of icosapent ethyl twice daily or placebo. The primary end point included cardiovascular death, nonfatal myocardial infarction, nonfatal stroke, coronary revascularization, or unstable angina. Patients treated with icosapent ethyl had a 25% risk reduction in cardiovascular events, and a 20% reduction in death due to cardiovascular causes.

This preparation of omega PUFA, icosapent ethyl (Vascepa), is pure eicosapentaenoic acid (EPA) which differs from agents used in other similar trials that contain both EPA and docosahexaenoic acid (DHA). This may explain the strongly positive outcomes that have not been shown in other similar trials.

#### **Metabolic Syndrome**

The combined presence of insulin resistance, hypertension, dyslipidemia, and abdominal obesity define metabolic syndrome. There is debate about whether this is a true syndrome or simply a clustering of cardiovascular risk factors in a particular individual. The key concept is that the concomitant presence of these particular cardiovascular risk factors markedly increases a patient's chances of developing diabetes mellitus and coronary atherosclerosis. The approach to treatment for this syndrome is no different from that for the individual components. Recognition of the components is key to the treatment of this disorder.

#### **Smoking**

Cigarette smoking is probably the most important of the identified modifiable cardiovascular risk factors. The incidence of CAD is two to four times higher in smokers than in nonsmokers. The pathophysiologic process that leads to atherosclerosis from smoking stems from induced platelet dysfunction, endothelial dysfunction, smooth muscle cell proliferation, and attenuated high-density lipoprotein cholesterol levels. Smoking cessation must be sought for every CAD patient.

#### **Diet**

Lifestyle changes for patients with CAD must incorporate healthy eating habits. The Mediterranean diet has been shown to positively affect cardiovascular disease, and conversely, a diet high in saturated fats has been shown to negatively influence multiple cardiac risk factors. Patients should be encouraged to incorporate high proportions of fruits and vegetables into their diet, along with olive oil and regular servings of fish coupled with a reduced amount of red meats and excess sugar.

#### **Other Lifestyle Changes**

Exercise should be encouraged in patients with stable angina, once all appropriate invasive and noninvasive tests have been completed and a stable medical regimen has been established.

Increasing a patient's aerobic capacity can lower the body's oxygen requirement for a given workload, which can lead to increased exercise tolerance and reduced anginal symptoms. Aerobic exercise can improve endothelial function and positively affect baroreflex sensitivity and heart rate variability in patients with CAD.

Endorphins released during exercise are thought to be mood enhancers, as well as effective muscle relaxants. Exercise itself improves sleep patterns. Cortisol levels are reduced with regular exercise, which may attenuate the body's sensation of stress and anxiety. For these reasons, appropriate exercise programs for patients with stable angina have far-reaching positive benefits. Exercise guidelines for CAD patients have been published and should be reviewed before patients begin aggressive secondary prevention efforts.

Major depression affects approximately 25% of people recovering from a myocardial infarction, and another 40% suffer from mild depression. In any given year, one of every three long-term acute ischemic syndrome survivors will develop depression. The Heart and Soul Study examined 1017 patients with stable CAD over a period of 4.8 years. Patients identified with depression were twice as likely to experience recurrent cardiovascular events. Physical inactivity was associated with a 44% greater rate of cardiovascular events. Patients with symptoms of depression were less likely to follow dietary, exercise, and medication recommendations.

#### **Approach to Treatment**

##### **Medical Therapy**

Medications used to treat angina pectoris and typical dosages are listed in [Table 2](#).

##### **Nitrates**

Nitrates provide an exogenous source of nitric oxide, which serves to relax smooth muscle and inhibit platelet aggregation. Nitrates exert their antianginal effect by reducing myocardial oxygen demand through coronary and systemic vasodilation. Nitrates are strong venodilators, and in higher doses they can also induce arterial dilation. Reducing the preload through venodilation reduces myocardial oxygen demand. Coronary artery dilatation of stenotic vessels and intracoronary collaterals directly increases myocardial oxygen delivery. Through these mechanisms, nitrates have been shown to prevent recurrent episodes of angina and to increase exercise tolerance.

There are several nitrate preparations; they differ mainly in route of administration, onset of action, and effective half-life. Nitrate tolerance can occur with long-term use of any nitrate preparation and can be avoided by providing a 10- to 12-hour nitrate-free interval. Nitrates should be used with caution in patients with a diagnosis of hypertrophic obstructive cardiomyopathy.

##### **$\beta$ -Blockers**

$\beta$ -Blockers competitively inhibit catecholamines from binding to  $\beta$ -receptors. Over time,  $\beta$ -blocker therapy leads to an increase in  $\beta$ -receptor density. Because of receptor upregulation, acute  $\beta$ -blocker withdrawal may lead to a transient supersensitivity to catecholamines and subsequent angina or even myocardial

**TABLE 2** Medications Used for the Treatment of Angina Pectoris

NAME	DOSAGE
<b>β-Blockers</b>	
Atenolol (Tenormin)	25–200 mg PO qd
Metoprolol tartrate (Lopressor)	25–200 mg bid
Metoprolol succinate (Toprol XL)	25–200 mg qd
Carvedilol (Coreg) <sup>1</sup>	6.25–25 mg PO bid
Carvedilol phosphate (Coreg CR) <sup>1</sup>	20–80 mg PO qd
Propranolol (Inderal)	80–320 mg/d, divided bid or tid
Propranolol (Inderal LA)	80–160 mg PO qd
Labetalol (Trandate, Normodyne) <sup>1</sup>	200–800 mg bid
<b>Nitrates</b>	
Isosorbide dinitrate (Isordil)	10–40 mg PO bid or tid
Isosorbide mononitrate (Imdur)	30–240 mg PO qd
Nitroglycerin (Nitrostat)	0.4 mg SL q5min
Nitroglycerin transdermal (Nitro-Dur)	0.2–0.8 mg/h 12–14 h patch
<b>Calcium Channel Blockers</b>	
<b>Dihydropyridines</b>	
Amlodipine (Norvasc)	2.5–10 mg PO qd
Felodipine (Plendil) <sup>1</sup>	2.5–10 mg PO qd
Nifedipine (Procardia XL)	30–90 mg PO qd
<b>Nondihydropyridines</b>	
Verapamil (Calan)	80–120 mg PO tid
Verapamil (Calan SR)	120–480 mg PO qd
Diltiazem (Cardizem)	360 mg/d PO, divided tid or qid
Diltiazem (Cardizem LA)	180–360 mg PO qd
<b>Other</b>	
Ranolazine (Ranexa)	500 mg twice daily and increase to 1000 mg twice daily as needed, based on clinical symptoms

<sup>1</sup>Not FDA approved for this indication.

infarction. There are three classes of β-receptors. Some β-blockers are receptor specific, and some exert an effect over all three receptors. However, at higher doses, even β-selective agents have cross-reactivity for all β-receptors. β-Blockers reduce myocardial oxygen demand through a negative inotropic effect, a chronotropic effect, and a reduction in left ventricular wall stress.

Several cardioselective β-blockers, including atenolol (Tenormin) and metoprolol (Lopressor), have been shown to be effective antianginals that are fairly well tolerated in patients with underlying bronchospastic disease. Dosing is important for β-blocker efficacy. A study comparing atenolol with placebo showed that all doses from 25 through 200 mg/day were effective in reducing angina, but only the two highest doses led to an increase in exercise tolerance. Certain β-blockers have intrinsic sympathomimetic activity, including pindolol (Visken)<sup>1</sup> and acebutolol (Sectral).<sup>1</sup>

<sup>1</sup>Not FDA approved for this indication.

Although they may be effective in reducing angina, they should be used with caution in patients with a prior history of myocardial infarction and in those with left ventricular dysfunction, because they may not reduce heart rate or blood pressure at rest.

When β-blockers are used to treat angina, a goal resting heart rate should be between 55 and 60 beats/min. Caution should be used in patients with resting bradycardia and in those with known reactive airway disease. Atenolol is renally excreted and should be used with caution in the elderly and in those with known renal dysfunction.

#### Calcium Channel Blockers

Calcium channel blockers are classified as either dihydropyridines or nondihydropyridines. The former group includes amlodipine (Norvasc), felodipine (Plendil)<sup>1</sup>, nifedipine (Procardia), and nifedipine (Cardene); the latter includes diltiazem (Cardizem) and verapamil (Calan). There are differences among the two subclasses in terms of chronotropic, dromotropic, and inotropic effects.

Calcium channel blockers positively alter myocardial oxygen supply and demand, mainly through direct arterial vasodilatation. The nondihydropyridines also exhibit negative chronotropic and inotropic effects, thus further lowering myocardial oxygen demands.

One of the early quick-release preparations of a dihydropyridine calcium channel blocker, nifedipine, was reported to potentially induce myocardial infarction when used to treat angina. This was most likely due to a rapid drop in afterload leading to reflex adrenergic activation. Sustained-release preparations of nifedipine (Procardia XL), as well as the other dihydropyridines, have been proven safe and effective in patients with cardiovascular disease. Although amlodipine and felodipine are tolerated in patients with left ventricular systolic dysfunction, other calcium channel blockers should be avoided in this patient subset.

#### Ranolazine (Ranexa)

Ranolazine (Ranexa) is a new and unique antianginal drug approved for the treatment of stable angina. It is a sustained-release preparation that has been approved for patients who remain symptomatic while on standard angina pharmacotherapy. Its mechanism of action may be through reduction of fatty acid oxidation or effects on sodium shifts and intracellular calcium levels. QT prolongation has been reported, but a significant increase in arrhythmias has not been seen. Side effects include dizziness, constipation, and nausea. Dosing is 500 or 1000 mg twice daily, and the major route of metabolism is the cytochrome P 450 system. Ranolazine should be used cautiously in patients who are taking other pharmacologic agents that have the potential to prolong the QT interval, and in patients with liver cirrhosis.

#### Ivabradine (Corlanor)<sup>1</sup>

Heart rate has a profound effect on diastolic perfusion time and subsequent myocardial oxygen supply. Ninety percent of coronary blood flow occurs in diastole. Therefore, an elevated heart rate may result in myocardial ischemia and angina. Ivabradine (Corlanor) selectively reduces heart rate without affecting inotropic function or coronary vasomotor tone. Ivabradine does not affect central aortic pressure or ventricular repolarization.

Ivabradine is a selective and specific inhibitor of the cardiac pacemaker current (I<sub>f</sub>) that controls the spontaneous diastolic depolarization in the sinus node and regulates heart rate. It is metabolized by both the liver and the gut by oxidation through the cytochrome P450 3A4 (CYP3A4). Although ivabradine has a low affinity for CYP3A4, potent inhibitors and inducers of CYP3A4 may affect its plasma levels. Although nondihydropyridine calcium channel blockers should not be co-administered, other first-line coronary artery disease medications such as β-blockers, renin-angiotensin-aldosterone system inhibitors, aspirin, and HMG-CoA reductase inhibitors can be safely combined. Starting dosage is 5 mg twice daily in patients <75 years old, and

<sup>1</sup>Not FDA approved for this indication.

2.5 mg twice daily for patients  $\geq 75$  years old. No dosage adjustments are necessary in patients with renal impairment or creatinine clearance  $>15$  mL/min. In patients with moderate hepatic impairment, caution is advised, and ivabradine is contraindicated in patients with severe liver impairment. The maintenance dose is  $\leq 7.5$  mg twice daily, with up titration possible after 4 weeks if initial dose is well tolerated, symptoms persist, and heart rate is  $>60$  bpm. Ivabradine is contraindicated in patients with a pre-treatment resting heart rate  $<70$  bpm.

Heart rate reduction triggered by ivabradine appears to be greatest in those patients with highest pre-treatment baseline heart rates. Borer et al. showed that ivabradine improved exercise stress testing variables in a dose-dependent fashion. In this study, ivabradine improved time to 1 mm ST-segment depression as compared to placebo ( $P = .016$ ). In a pooled analysis of 5 randomized, double blind, parallel-group studies of patients with stable angina, ivabradine  $\geq 5$  mg/day (maximum dose 7.5 mg/day) resulted in a 14.5% heart rate reduction, a  $-59.4\%$  change in the number of angina attacks per week, and a  $-53.7\%$  change in the consumption of nitrates.

There is mounting clinical evidence that ivabradine improves angina symptoms and quality of life (QOL) regardless of age, gender, and pre-treatment angina class. It also appears to improve prognosis and reduce hospitalizations in angina patients with left ventricular systolic dysfunction.

### Medication Combinations

Many patients with chronic stable angina require more than one antianginal medication to control their symptoms. Current guidelines recommend  $\beta$ -blockers or calcium channel blockers as initial therapy unless otherwise contraindicated, with the addition of nitrates as symptoms dictate. Further medications may be added and individualized to each patient based on their degree of angina and overall clinical response.

However, it is important to recognize medication side effects when deciding which agents to combine.  $\beta$ -Blockers block the atrioventricular (AV) node and exert a portion of their effectiveness through this mechanism. The nondihydropyridine calcium channel blockers also have AV-nodal blocking properties and therefore should be used cautiously with  $\beta$ -blockers, especially in patients with preexisting conduction system disease. The dihydropyridine agents do not have AV-nodal blocking effects and may be a safer choice when used in combination with  $\beta$ -blockers. Nitrates do not have a side-effect profile that raises concerns when they are used with  $\beta$ -blockers or with calcium channel blockers.

### Antiplatelet Therapy

The common etiology leading to an acute ischemic syndrome is a platelet-rich clot occurring at the site of a significant coronary artery stenosis, often after a plaque rupture. Antiplatelet medications have been shown to consistently decrease morbidity and mortality in a wide array of cardiovascular disease patients. A meta-analysis suggested that for patients with stable cardiovascular disease, low-dose aspirin therapy (50 to 100 mg daily) is as effective as higher doses ( $>300$  mg). In this patient population, aspirin therapy resulted in a 26% reduction in myocardial infarction; the number of patients needed to treat to prevent a myocardial infarction was 83.

The Antiplatelet Trialists' Collaboration study demonstrated a reduction in myocardial infarction, stroke, and death in high-risk cardiovascular patients treated with antiplatelet therapy. Consensus guidelines recommend indefinite oral aspirin for the secondary prevention of cardiovascular events in all angina patients.

Clopidogrel (Plavix)<sup>1</sup> is an effective alternative to aspirin for the treatment of stable cardiovascular disease in those patients with a true aspirin allergy. However, there are no compelling data to indicate that clopidogrel (or newer agents, such as prasugrel [Effient]<sup>1</sup> and ticagrelor [Brilinta]<sup>1</sup>) are superior to aspirin

in this particular patient population. In patients with unstable angina, dual antiplatelet therapy with aspirin and clopidogrel is recommended.

### Oral Anticoagulation

The use of vitamin K antagonists to reduce cardiac events in patients with stable ischemic heart disease has been shown to be beneficial, with results tempered by the cost of a substantial increased risk of bleeding. With the advent of newer anti-thrombotic agents, also referred to as direct oral anticoagulants (DOACs), there has been renewed interest in further modulating the coagulation cascade to positively affect clinical outcomes.

The recent Rivaroxaban for the Prevention of Major Cardiovascular Events in Coronary or Peripheral Artery Disease (COMPASS) study evaluated the use of a factor Xa inhibitor, rivaroxaban (Xarelto), with or without aspirin vs. aspirin monotherapy in patients with stable atherosclerotic vascular disease. Rivaroxaban (Xarelto) dosing was 5 mg twice daily as monotherapy, 2.5 mg twice daily (referred to as a vascular dose) with 100 mg ASA, or 100mg ASA.

Although the primary combined endpoint revealed positive results in the rivaroxaban plus aspirin group, this was at the cost of a significant increase in overall bleeding events. If these events are separated into fatal or critical organ bleeding only, the findings favor a vascular dose of rivaroxaban plus aspirin for treatment of stable atherosclerotic vascular disease patients. Unfortunately, these results are equivocal when all bleeding events are taken into consideration. Moreover, the positive findings of this trial are driven mainly by a reduction in ischemic stroke and not myocardial infarction (49% RRR for ischemic stroke and 14% RRR for myocardial infarction). Although atrial fibrillation and/or prior use of systemic anticoagulation were exclusion criteria, certainly the percentage of this patient population with subclinical atrial fibrillation cannot be discounted.

Therefore, at this time there is no convincing evidence that adding antithrombotic therapy to aspirin or antithrombotic monotherapy should replace goal directed medical therapy of appropriate antiplatelet medications.

### Invasive Assessment

The decision to pursue an invasive treatment approach differs significantly in patients with chronic stable angina and in those with acute coronary syndromes. Within both groups, accurate risk stratification is the key consideration in choosing who will benefit from coronary angiography and subsequent percutaneous coronary intervention. An invasive strategy in unstable angina patients has been shown to reduce recurrent acute coronary syndrome events consistently in many trials. A routine invasive strategy is recommended for patients with non-ST-segment acute ischemic syndromes who have refractory ischemia, elevated cardiac biomarkers suggesting myocardial necrosis, or new ST-segment depression on ECG monitoring.

In patients with unstable angina, there are significant gender differences in outcomes related to the use of invasive therapy. Both men and women with elevated biomarkers from myocardial necrosis have comparable reductions in rates of death, myocardial infarction, and rehospitalization with invasive treatment strategies. However, in the absence of positive biomarkers, women appear to have potentially negative outcomes with an invasive approach. The current American College of Cardiology and American Heart Association guidelines recommend a conservative approach in such women.

Patients diagnosed with stable angina comprise a vast array of clinical presentations. The two most heated debates in this arena concern the initial choice of medical therapy versus an invasive approach, and when to cross over from a medical treatment plan to an invasive one. The Atorvastatin Versus Revascularization Treatment (AVERT) trial studied the effects of intensive lipid-lowering therapy on ischemic events in a relatively low-risk population of patients with single- or two-vessel disease compared

<sup>1</sup>Not FDA approved for this indication.

with percutaneous transluminal coronary angioplasty. AVERT randomized 341 patients to medical therapy plus atorvastatin 80 mg or to angioplasty followed by usual medical care (which included the option of statin therapy at the choice of the treating physician). The medical treatment group experienced a 36% reduction in the composite endpoint of ischemic events compared with the angioplasty group. This difference was due primarily to repeated angioplasty, coronary artery bypass grafting, or hospitalization for worsening angina. The primary outcome of this trial from a practical standpoint was that high-dose statin therapy was safe in this patient population and did not increase cardiovascular events, compared with an angioplasty-based treatment plan.

One of the keys in interpreting the available data is recognizing that by the time many of these trials are published, the percutaneous treatment choices are often outdated. Early trials used mainly balloon angioplasty; later trials used early-generation bare metal stents. Equally as important is to determine what the background medical treatment plans were for any particular trial on this subject. Often, lipid therapy was not aggressive, hypertension management was not confirmed to be adequate, and intravenous glycoprotein IIb/IIIa antagonists were either not available or not used as a standard protocol when indicated.

The Clinical Outcomes Utilizing Revascularization and Aggressive Drug Evaluation (COURAGE) trial was designed to address the potential advantages of current medical therapy over a percutaneous approach in patients with demonstrable ischemia but stable CAD. Of the 35,000 patients screened, only 2287 met the study inclusion criteria. All participants of the COURAGE trial underwent a coronary angiography, and patients with high-risk anatomic findings such as severe left main coronary artery stenosis were excluded. The biggest difference in this trial compared with previous studies was that strict guideline-based medical therapy was followed in both groups. In the entire cohort, 85% of subjects were taking a  $\beta$ -blocker, 93% were taking a statin, and 85% were taking aspirin. The final interpretation of the COURAGE trial results was not that medical therapy is superior for all patients with CAD, but that in selected cohorts, aggressive medical therapy is an appropriate first step in the treatment of ischemic heart disease.

It is well accepted that a coronary artery lesion  $\geq 70\%$  is clinically significant. Historically, the interventional cardiologist has relied on visually estimating this value during coronary angiography to determine when a percutaneous intervention is appropriate. However, physiology-guided revascularization has become an established practice in the management of patients with coronary artery disease. Both instantaneous wave free ratio (iFR) and fractional flow reserve (FFR) are well-studied techniques that allow assessment of the pressure differences across a coronary artery stenosis.

iFR isolates a specific period in diastole where pressure and flow are linearly related, which is referred to as the wave-free period. During this time, competing forces (waves) that affect period diverge; an iFR value below 0.9 suggests flow restriction (normal value is 1.0). iFR is measured at rest, without the need for pharmacologic vasodilators or stressors.

FFR utilizes a guidewire that is passed through a coronary lesion and allows for measurement of both blood flow and pressure. After direct administration of the hyperemic agent adenosine (Adenocard)<sup>1</sup>, the pressure difference across a stenosis is determined. An FFR of  $\leq 0.80$  is considered clinically significant.

Physiologic assessment of obstructive coronary artery disease adds clarity to the visual angiogram interpretation, thereby leading to more appropriate coronary interventions.

The ORBITA trial was a 200-patient placebo-controlled randomized trial assessing the efficacy of percutaneous coronary intervention (PCI) compared with a placebo sham procedure for the relief of angina in patients with severe ( $>70\%$ ) single-vessel coronary artery disease. Patients were randomized in a 1:1

fashion, and all patients had assessment of their coronary lesion by both FFR and iFR. All patients were assessed by cardiopulmonary exercise testing, symptom questionnaires, and dobutamine stress echocardiography before and six weeks after the procedure.

Compared with placebo, PCI reduced ischemia as assessed by stress echocardiography. However, there was no difference in the primary endpoint of exercise time between the two arms, or statistically significant differences between the two groups with respect to angina frequency. Changes in the Duke treadmill score and exercise time were both numerically higher in the PCI arm, which poses the question of small sample size effects on these outcomes.

Within the spectrum of stable ischemic heart disease, a portion of patients have coronary arteries that have chronic total occlusions (CTO). Some of these ischemic heart disease patients may suffer from coronary reserve insufficiency and develop recurrent angina.

Since a CTO lesion cannot contribute to collateral blood flow, development of further CAD is often poorly tolerated. CTO lesions are encountered in clinical practice at a frequency of 16%–18%, but only intervened upon in 5%–10% of cases. We suspect this discrepancy in prevalence and treatment is based on the combination of a high rate of technical difficulty coupled with the uncertainty of clinical benefit.

Unfortunately, successful treatment of CTO lesions does not appear to benefit all patients with chronic ischemic heart disease. Patients with underlying diabetes have a reduction in major adverse cardiac events (MACE) when compared to standard medical therapy. This same finding, however, is not seen in non-diabetic patients with CTO lesions.

## Novel Therapies

### External Counterpulsation

External counterpulsation is a noninvasive method of increasing coronary blood flow through diastolic augmentation. Large blood pressure cuffs are placed on both legs and thighs and are inflated to a pressure of 300 mm Hg in early diastole (triggered by the patient's ECG), promoting venous return to the heart. The mechanism is unclear but may be related to enhanced endothelial function, improved myocardial perfusion, and possibly placebo effect. Several small studies have suggested a clinical reduction in angina episodes, but no positive mortality benefit has yet been published. A meta-analysis that included 13 observational studies and followed 949 patients with stable angina. Using the CCS classification scheme, there was at least a one-class improvement in 86% of the study population. Contraindications to this treatment include certain aortic valvular diseases, aortic aneurysm, and peripheral vascular disease.

### Spinal Cord Stimulation

For patients whose angina is refractory to medical therapy and who are not candidates for revascularization, spinal cord stimulation may be considered. Little intermediate or long-term data are available, but many short-term studies suggest reduced angina episodes. Placement of the device and subsequent stimulation at the C7-T1 level suggests that the mechanism of action is reduced pain sensation.

### Acupuncture

Acupuncture has been shown to be of benefit for the relief of both acute and chronic pain in various medical conditions. With respect to patients with documented CAD and symptomatic angina, there are only limited data currently available to recommend this modality.

A recently published randomized trial of treating chronic stable angina patients with acupuncture as an adjunct to standard medical therapy was undertaken in China. It was a small study of 398 relatively healthy angina patients. Those with prior myocardial infarction or a history of congestive heart failure were excluded. Patients were randomized to the following groups; disease-affected meridian (DAM), nonaffected meridian (NAM), sham acupuncture group, and a wait-list group. Treatment was 3

<sup>1</sup>Not FDA approved for this indication.

times per week for 4 weeks; each session was for 30 minutes. The greatest reduction of angina episodes occurred in the DAM group as compared to each of the other 3 groups.

This is the largest published clinical trial showing evidence that adding acupuncture to goal-directed medical therapy reduces angina frequency. There were some study limitations that are worth mentioning that may soften the results. Namely, the operators were not blinded to their treatment plans, angina episodes were reduced in the sham and wait-list groups (suggesting a strong placebo-associated effect), and the study population was small.

### Other Causes of Angina Syndrome X

The cardiac syndrome X refers to patients who have normal or near-normal epicardial coronary arteries and episodic chest pain. This disorder is much more common in women and is often seen in patients younger than 50 years of age. The chest pain episodes may last longer than 30 minutes and may have a variable response to sublingual nitrates. Patients with syndrome X often describe typical stress-induced angina. Risk factors include hypertension, diabetes, and hyperlipidemia. Female patients are typically postmenopausal and frequently have stress-induced symptoms and ischemia on stress imaging. They often respond to standard angina medications and typically have a better prognosis than patients with significant epicardial plaque.

### Vasospastic or Prinzmetal Angina

The classic definition of Prinzmetal angina is chest pain with documented ST-segment elevation during symptoms or during exercise in the face of angiographically normal or near-normal coronary arteries. Over the years, the definition has expanded to include patients who have classic angina symptoms commonly relieved with nitrates or calcium channel blockers and minimal or no CAD. It has been shown that patients with nonobstructive CAD may be prone to focal artery spasm at the stenosis site; therefore, the previous requirement of normal coronary arteries is not an absolute necessity. Other disease states (e.g., Raynaud phenomenon) can increase a patient's development of coronary artery spasm, as can illicit drug usage (e.g., cocaine). Vasospasm is more common in active smokers.  $\beta$ -Blockers should be used cautiously in these patients because they may exacerbate coronary spasm. Patients with angiographically documented intramyocardial bridging may be prone to focal coronary spasm and subsequent angina pectoris.

### Newer Imaging Techniques Calcium Scoring

Coronary artery calcium scoring is a well-studied imaging modality used to assess a patient's pretest probability of CAD. With respect to evaluation for angina, one must remember that electron-beam computed tomographic (CT) scanning does not offer physiologic data and therefore does not allow determination of myocardial ischemia. This study is most useful in the workup of a low-risk patient with an atypical chest pain syndrome. If such a patient has an elevated calcium score, other studies may be reasonable and further assessment of the patient's cholesterol values should be performed.

### Computed Tomographic Coronary Angiography

CT coronary angiography is a noninvasive way to image the coronary arteries. Similar to electron-beam CT, it does not provide physiologic data regarding coronary artery perfusion, but it does provide anatomic information such as the presence and percentage of coronary artery stenosis. Although selected patients with stable or unstable angina may be considered candidates for CT angiography, its main utility is to evaluate patients for chest pain who are otherwise at low risk and have a low pretest probability. Because of the volume of intravenous contrast required by CT angiography, the risk of contrast nephropathy must be considered when contemplating this study.

### Summary

The approach to the patient with angina should be based on a global assessment and intensive treatment of all identified cardiovascular risk factors. It is recommended that all patients receive the appropriate dose of statin and antiplatelet therapy. Noninvasive testing is helpful for an initial diagnosis and to guide the decision for a more invasive approach. Familiarity and adherence to current treatment guidelines is of paramount importance. There are important gender differences that should not be overlooked in the clinical presentation of angina and in the approach to optimal therapy.

## AORTIC DISEASE: ANEURYSM AND DISSECTION

Method of  
David G. Neschis, MD

### CURRENT DIAGNOSIS

- Because the majority of patients with abdominal aortic aneurysms are asymptomatic, the majority of abdominal aortic aneurysms are detected on imaging studies performed for other indications.
- Patients older than 50 years who present with abdominal or back pain of unclear etiology should be considered for evaluation of possible abdominal aortic aneurysm.
- Asymptomatic men older than 65 years who have ever smoked are eligible for abdominal aortic aneurysm screening.
- All patients older than 60 years who have a strong family history of abdominal aortic aneurysms should be considered for screening.
- Patients presenting with sudden onset of chest or back pain without clear etiology should be evaluated for dissection.
- Dissection can mimic numerous other conditions.

### CURRENT THERAPY

#### Indications for Repair of Aneurysm

- Fusiform abdominal aortic aneurysms greater than 5.5 cm in maximum diameter
- Most saccular aneurysms and pseudoaneurysms
- Thoracic and thoracoabdominal aortic aneurysms of greater than 6 cm in maximal diameter
- Aneurysms that are symptomatic or are rapidly enlarging

#### Indications for Repair of Aortic Dissection

- Dissections involving the ascending aorta
- Dissections involving only the descending aorta are usually managed medically unless complicated by the following: unremitting pain, end organ ischemia, or significant aneurysmal degeneration to greater than 6 cm in maximal diameter

## Abdominal Aortic Aneurysms

### Epidemiology

A ruptured abdominal aortic aneurysm is a devastating event leading to approximately 15,000 deaths per year, and it is the 13th leading cause of death in the United States. It is the 10th leading cause of death in men. Once rupture occurs, there is an 85% chance of death overall and approximately 50% mortality in the patients who make it to the hospital alive. Clearly, the goal is to identify this life-threatening lesion and repair prior to rupture. Abdominal aortic aneurysms are approximately four times more prevalent in men than in women. The overall incidence in persons older than 60 years is approximately 3% to 4%, with incidence as high as 10% to 12% in an elderly hypertensive population.

### Risk Factors

Men are approximately 4 times more likely than women to develop an abdominal aortic aneurysm. Clearly, older persons, particularly those older than 60 years, are at higher risk. Tobacco use is probably the strongest preventable risk factor, with tobacco users being approximately eight times more likely to be affected than nonsmokers. Hypertension is present in approximately 40% of patients with abdominal aortic aneurysms. Family history also plays a significant role. In fact, men who have first-degree female relatives who had aneurysms are approximately 18 times more likely than the general population to develop an abdominal aortic aneurysm. There is also a strong correlation between abdominal aortic aneurysms and other peripheral artery aneurysms. Patients with bilateral popliteal artery aneurysms have an approximately 50% to 60% risk of having an abdominal aortic aneurysm.

### Pathophysiology

An aneurysm is a dilatation of a blood vessel that could occur in any blood vessel in the body, even in the veins. Most commonly it is defined as a dilatation of approximately 1.5 to 2 times at that diameter of the adjacent normal vessel.

The definition of a pseudoaneurysm is often misunderstood. The attempt to describe a pseudoaneurysm in terms of the number of layers of the artery wall involved does nothing to help resolve this confusion. A pseudoaneurysm is a walled-off defect in the artery wall. A circular shell of adventitial and surrounding connective tissue contains the blood, preventing free hemorrhage. However, there remains continued flow out and back into the arterial lumen, resulting in a classic to-and-fro pattern on duplex ultrasound. The most common cause of a pseudoaneurysm is iatrogenic, from needle puncture, but it also can be caused by trauma or focal rupture of the artery at the site of an atherosclerotic ulcer.

The etiology of true aneurysms is not clear, although in the past these have been attributed to atherosclerosis. However, it is well known that the majority of patients with abdominal aortic aneurysms do not have associated significant occlusive disease. Biochemical studies have demonstrated decreased quantities of elastin and collagen in the walls of aneurysmal aortas. It is believed that a family of enzymes known as matrix metalloproteinase (MMP), particularly those that have collagenase and elastase activity, are likely involved in development of arterial aneurysms. The propensity for growth and rupture is based on Laplace's law,  $T = PR$ , where T represents wall tension (or in other words the propensity to rupture), P is the transmitted pressure, and R is the radius. This explains why patients with hypertension and those with larger aneurysms are at higher risk for aortic rupture.

### Prevention

Currently the most effective means to prevent aneurysm rupture is early detection and elective repair. Avoidance of smoking and aggressive control of blood pressure would likely be helpful in preventing aneurysmal development and growth. Patients with known abdominal aortic aneurysms that are relatively small and at low risk for rupture are generally serially followed with imaging studies over time. These patients are advised to avoid straining (e.g., heavy lifting), avoid smoking, and keep their blood pressure well controlled.

Investigation is ongoing in efforts to develop a medication that may be helpful in slowing the growth of abdominal aortic aneurysms. It has been known since 1985 that tetracycline antibiotics have activity against MMPs. There had been several animal studies and at least one small human study suggesting that doxycycline (Vibramycin)<sup>1</sup> may be effective at slowing the growth of abdominal aortic aneurysms. Currently, larger human studies are ongoing. At this point, there are no formal recommendations regarding the use of doxycycline for the purpose of slowing aneurysmal growth.

### Clinical Manifestations

Approximately 75% of abdominal aortic aneurysms are asymptomatic and discovered incidentally. Unfortunately, physical examination is an unreliable method for detecting aneurysms or determining aneurysm size. In heavier patients it may be simply impossible to adequately palpate the aorta. The majority of aneurysms are incidental findings identified on imaging studies performed for other reasons. Occasionally, an aneurysm is first detected upon operation for another condition.

Unfortunately, when an aneurysm becomes symptomatic, this is usually a sign of impending rupture. Symptoms related to abdominal aortic aneurysms can include abdominal or back pain. The classic triad of findings in the setting of abdominal aortic aneurysm rupture includes abdominal pain, hypotension, and a pulsatile abdominal mass. This triad, however, occurs in only approximately 20% of the patients. Often a high index of suspicion needs to be maintained.

The episode of hypotension associated with aneurysm rupture may be manifested as an episode of syncope or near-syncope before the patient arrives at the hospital. It is quite possible for the patient to have a contained rupture of the abdominal aorta and appear quite stable with a normal blood pressure in the emergency department. Although uncommon, a primary fistula between the aneurysm and gastrointestinal tract can occur and manifest as gastrointestinal bleeding.

### Diagnosis

Several imaging modalities are available that can accurately diagnose and measure abdominal aortic aneurysms. Real-time B-mode ultrasound scanning has the advantage of being almost universally available, relatively inexpensive, and essentially risk free. The major disadvantage, however, is that it is technician dependent. Computed tomography (CT) scans can provide a very accurate representation of the aorta in a very short study time (Figures 1 and 2). The use of iodinated contrast is not necessary to obtain a gross size measurement of the aorta. The contrast, however, helps delineate the flow lumen more clearly, and it is quite valuable in planning repair. Disadvantages include the use of ionizing radiation and the use of iodinated contrast material. MRI is also accurate in determining the size of the aneurysm; however, study times are longer, equipment is less widely available, and the expense is considerable. Angiography, while excellent for evaluating the status of important aortic branches and for evaluating occlusive disease, is not an accurate study for the purpose of determining maximal diameter of the aneurysm. Often aneurysms are filled with laminated thrombus, and the flow lumen, which was seen on aortography, is not representative of the true aneurysm size.

### Treatment

The decision on when to intervene in an abdominal aortic aneurysm is based on a careful analysis of the patient's risk for rupture versus the risk of operative repair. Historically, open repair can be performed with less than 5% in-hospital mortality. Based on historical studies it was estimated that the risk of rupture for an approximately 5-cm aneurysm was about 1% per year, which increased dramatically to 6.6% for aneurysms between 6 and 7 cm. It has been fairly well established for years that aneurysms larger than 5.5 cm are generally recommended for repair and those less

**Figure 1** Large abdominal aortic aneurysm. Notice how the majority of this aneurysm is filled with laminated thrombus. The flow lumen is only mildly dilated, and this aneurysm could be missed on angiography alone.

**Figure 2** Classic image of a ruptured abdominal aortic aneurysm, which in this case can be seen even without the use of intravascular contrast. Note the lack of symmetry and obliteration of tissue planes in the retroperitoneum on the left.

than 4 cm are generally observed over time. There remains a gray area for moderate aneurysms in the 4- to 5.5-cm category.

Two large prospective randomized trials were developed to answer this question. These include the United Kingdom Small Aneurysm Trial and the Department of Veterans Affairs Aneurysm Detection and Management (ADAM) trial. Both these studies randomized patients with moderately sized aneurysms to observation versus open repair. Results of both trials were fairly similar. The rupture rate for aneurysms under observation was 0.5% to 1% per year, and neither trial showed a difference in long-term survival. Both studies concluded that it was relatively safe to observe patients with aneurysms less than 5.5 cm in diameter, particularly in men who would be compliant with the follow-up regimen. The diameter of the aneurysm, however, should not be the only data point used for a decision on whether to repair.

Women seem to have a higher rupture rate for a particular aneurysm diameter than men, perhaps because they are starting with smaller aortas to begin with. Patients with COPD may be at higher risk for rupture as well. Saccular or eccentric-shaped aneurysms may also have a higher propensity to rupture and should not be subject to diameter recommendations for fusiform aneurysms (Figures 3 and 4). Additionally, rapidly growing aneurysms—growing at a rate faster than approximately 0.5 cm per year—should be considered for repair.

<sup>1</sup>Not FDA approved for this indication.

**Figure 3** Axial CT slice and reconstructed images of a sacular abdominal aortic aneurysm. This lesion could also be described as a pseudoaneurysm. For these, treatment is recommended because it is thought that the risk of rupture is higher than for a similarly sized fusiform abdominal aortic aneurysm.

**Figure 4** Angiogram of patient in [Figure 3](#), demonstrating aneurysm before and after deployment of an endograft, which successfully excluded the lesion from the circulation.

Once it has been determined that repair is indicated, a number of options are available. Traditional open repair involves a relatively large abdominal incision, cross clamping of the aorta, and replacement of the aneurysmal segment with a graft of polyethylene terephthalate (Dacron) or polytetrafluoroethylene (PTFE; Teflon). Often the iliac arteries are involved, and in these cases a bifurcated graft is placed. Open repair is quite durable and very effective at preventing aneurysm-related deaths. Long-term complications are rare, and patients following open repair generally enjoy 95% freedom from issues related to the repair over the course of their lifetime. Disadvantages, however, include the

large incision and an approximate 1-week hospital stay. Recovery to a relatively normal level of function occasionally takes months. In the past, many patients were deemed too old or frail to be expected to undergo open surgery.

Endograft repair has revolutionized the practice of vascular surgery. Using small incisions placed at the groin and performing the procedure under fluoroscopic guidance, devices can now be advanced into the aorta from the femoral artery. Using angiography as a guide, the graft typically is deployed below the renal arteries and effectively excludes the aneurysm from the circulation. Advantages include small incisions and very short hospital

stays. Patients are typically discharged on the first or second day after aneurysm repair. Recovery to normal activity is also quite rapid, taking approximately 1 to 2 weeks. Use of this modality has allowed treatment of older and frailer patients who previously were denied treatment due to concerns of operative risk.

Endograft repair, however, is clearly not without its disadvantages. Currently, the durability of endograft repair is unknown, and these patients are subject to frequent serial imaging. Also, there is a higher incidence of graft-related complications, which can occur in up to 35% of patients. These include the development of leaks of blood into the aneurysm sac outside the graft device, issues related to graft failure and migration, and graft limb thrombosis. These grafts are also quite expensive.

Two major prospective randomized trials studying traditional open versus endograft repair are often cited. These include the United Kingdom-based EVAR-1 trial (first Endovascular Aneurysm Repair trial) and the Dutch-based DREAM trial (Diabetes REduction Assessment with ramipril and rosiglitazone Medication trial). Both studies randomized patients who were believed to be good risks for open repair to endograft versus traditional open repair. The results of both of these studies were relatively similar in that both studies demonstrated a clear early survival benefit for patients in the endograft group. However, this came at a cost of an increased incidence of graft-related complications in the endograft group and a higher cost for the endograft group. Additionally, at 2 to 4 years, there was no clear difference in long-term survival in either group.

Ultimately, the decision about whether to proceed with open or endograft repair is a decision between surgeon and patient based on the patient's aortic anatomy, overall health, and the patient's and physician's preference. It would appear, however, that older and frail patients with good anatomy should be strongly considered for endograft repair.

### Monitoring

Patients with abdominal aortic aneurysms should be evaluated for the presence of femoral and popliteal aneurysms (particularly in men) and for thoracic aortic aneurysms. After open repair, a follow-up CT scan with contrast should be considered approximately 5 years out to evaluate for the integrity of the graft (i.e., pseudoaneurysms), as well as development of new aneurysms. Patients who have undergone endograft repair require more-intensive monitoring. Typical regimens include a contrast-enhanced CT scan approximately 2 weeks after repair, then 6 months after repair, and then based on the perceived stability of the graft, approximately yearly thereafter. Some centers have used duplex ultrasonography for evaluating patients after endograft repair in efforts to reduce the amount of ionizing radiation the patients receive. However, it should be remembered that duplex ultrasound is highly technician dependent, and follow-up of patients with endograft repairs using only duplex ultrasound should be performed in experienced centers.

### Thoracic Aortic Aneurysms

Thoracic aortic aneurysms (TAAs) are limited to the chest cavity. Although they are less common than infrarenal abdominal aortic aneurysms, they share similar risk factors. The male-to-female ratio incidence of the TAA is approximately 1:1.

In the past, the threshold for repair was at a diameter greater than 6 cm. This threshold was chosen due to the higher operative risks associated with repair of the thoracic aorta. Now with the availability of endograft, patients with good anatomy are generally recommended for repair at a diameter similar to those for the infrarenal aorta.

Open repair involves performing a thoracotomy and cross-clamping the aorta. Repair in this location is often performed with the addition of extracorporeal bypass to maintain perfusion to the viscera and spinal cord drain performance of the repair. Although the risk of paraplegia in the treatment of infrarenal aortic is exceedingly low, the risk of paraplegia from a repair of an isolated TAA is approximately 6%. Endograft devices for repair

of TAA are now widely available and have reduced the incidence of paraplegia to approximately 3%.

### Thoracoabdominal Aortic Aneurysms

By definition, thoracoabdominal aortic aneurysms require entrance to both the thoracic and abdominal cavity to perform repair. These lesions are usually true aneurysms of the aorta and should not be confused with dissection. Repair of thoracoabdominal aortic aneurysms is quite complex and carries risks of death and paraplegia as high as 20% in some settings. These procedures are generally performed at larger institutions with considerable experience with this condition. Unfortunately, endograft devices for the repair of thoracoabdominal aortic aneurysms are limited to a handful of centers in the United States.

### Thoracic Aortic Dissection

Thoracic aortic dissection is the most common aortic emergency, even more common than ruptured abdominal aortic aneurysm. This potentially fatal condition is rare in patients younger than 50 years and is approximately two times more common in men than women. Patients at risk include patients with a history of connective tissue disorders and patients with severe, poorly controlled hypertension.

An aortic dissection occurs when there is loss of integrity of the intima and blood dissects into the media. Once in the media, there is a natural plane through which dissection is quite easy.

Although there are various classification systems for aortic dissection, the Stanford classification is perhaps the most widely used and the most useful. In this classification, any dissection that involves the ascending aorta, whether it involves the ascending aorta alone or both the ascending and descending thoracoabdominal aorta, are classified as type A. Dissections that do not involve the ascending aorta are classified as type B. This classification is useful because type A dissections require urgent surgery. Type B dissections are typically managed medically unless they are associated with complications such as unremitting pain, aneurysmal expansion, and end-organ ischemia. By convention, aortic dissections that are evaluated within 14 days after the onset of symptoms are considered acute, and those evaluated beyond 14 days are considered chronic.

Helical CAT scanners with the use of contrast are excellent at defining the location and extent of aortic dissection. However, being alert to the potential for this diagnosis requires a high index of suspicion. Aortic dissection can mimic a variety of common conditions based on the extent of the dissection and the aortic branches involved (Table 1). Uncomplicated type B dissections are typically managed medically. This is usually performed in an

**TABLE 1** Dissection: The Great Mimic

TERRITORY INVOLVED OR AFFECTED BY DISSECTION	MIMICS
Rupture into pericardial sac	Cardiac tamponade
Dissection through aortic valve	Acute aortic insufficiency
Dissection occluding coronary arteries	Myocardial infarction
Involvement of cerebral vessels	Stroke
Involvement of subclavian arteries	Upper extremity ischemia (cold arm)
Dissection running down descending thoracic aorta	Severe back pain and paralysis
Mesenteric artery obstruction	Mesenteric ischemia
Renal artery obstruction	Oliguria and acute renal failure
Iliac artery occlusion	Lower extremity ischemia (cold leg)

intensive care setting with the use of intravenous medications to control contractility and, if necessary, hypertension.

In the past, due to the friability of dissected aortic tissue, the results of operative repair for type B dissections have been particularly poor. Currently, endograft repair with the purpose of excluding the entry point of dissection and reestablishing flow to the true lumen is gaining popularity in the treatment of complex dissection. This at times may be supplemented by stenting of affected aortic side branches and fenestration to establish a connection between the true and false lumen to restore perfusion to certain organs. Once the acute phase has passed and medically treated patients are under good hypertensive control, these patients are then converted to an oral medication regimen and transferred out of the intensive care setting. Patients need to be followed up with serial CT imaging after discharge to evaluate for aneurysmal degeneration of the false lumen. This evaluation should occur every 6 months until the patient is stable and then yearly thereafter.

In cases where the total aortic diameter grows to greater than 6 cm, repair for the purpose of preventing rupture is indicated, although this is often technically more complicated than treating a fusiform aneurysm in the absence of a previous dissection. Patients should strictly adhere to their blood pressure medication regimen for life.

## ATRIAL FIBRILLATION

Method of

Lin Yee Chen, MBBS, MS; and Samuel C. Dudley Jr., MD, PhD

## CURRENT DIAGNOSIS

- History taking and physical examination for atrial fibrillation (AF) should focus on determining symptom severity (to decide on treatment strategy), risk of thromboembolic stroke, and associated cardiovascular risk factors.
- Symptoms include palpitations, chest discomfort, shortness of breath, and reduced exercise capacity. Some patients have no symptoms.
- Investigations include a 12-lead electrocardiogram (ECG) for confirmation; transthoracic echocardiogram to evaluate left atrial size, left ventricular ejection fraction, and rule out valvular abnormalities; and blood tests for thyroid, renal, and hepatic function.

## CURRENT THERAPY

- Rate control: Achieve average ventricular rate of less than 110 beats/min by using atrioventricular node (AVN) blockers or catheter ablation of AVN
- Rhythm control: Prevent AF recurrence by using antiarrhythmic drugs or catheter ablation (pulmonary vein isolation)
- Stroke prophylaxis: Risk stratification and stroke prevention by oral anticoagulation or left atrial appendage closure
- Risk-factor management or lifestyle modification: Prevent AF by weight management, intensive blood pressure lowering, and exercise training

## Epidemiology

AF is the most common sustained arrhythmia in the adult general population. Globally, the estimated number of individuals with AF in 2010 was 33.5 million. Between 1990 and 2010, the global estimated age-adjusted prevalence rate of AF increased from 569.5 to 596.2 per 100,000 men and from 359.9 to 373.1 per 100,000 women. This increase in prevalence was accompanied by a substantial increase in health burden: disability-adjusted life-years increased by 18.8% in men and 18.9% in women from 1990 to 2010. Finally, the lifetime risk for development of AF in adults at age 40 is 1 in 4.

## Risk Factors and Pathophysiology

Table 1 shows the known risk factors of AF; many of these are also risk factors for atherosclerotic disease. Traditional cardiovascular risk factors such as diabetes, hypertension, and obesity can lead to AF via the following pathway: cardiovascular risk factors → left ventricular diastolic dysfunction → structural and functional alterations in the atria (enlargement, impaired function, fibrosis, etc.) → AF. The aforementioned pathway creates the substrate for AF; premature atrial contractions and supraventricular ectopic beats are the trigger for AF. Other pathophysiologic pathways include inflammation and increased oxidative stress, leading to electrical remodeling and, consequently, AF.

## Clinical Manifestations

Common symptoms of AF include palpitations, irregular heartbeat sensation, lightheadedness, dyspnea, chest discomfort, and fatigue. Some patients may have no symptoms at rest but report poor stamina or easy fatigability with physical activity. Other patients, particularly among the elderly, may be asymptomatic.

## Diagnosis

The absence of distinct P waves with irregularly irregular RR interval on the ECG are the sine qua non for diagnosing AF. Rhythm documentation can be obtained via the standard 12-lead ECG, Holter monitors that can record up to 48 hours, leadless patch monitors that can record up to 2 weeks, or implantable loop recorders. Newer wearable technologies that can diagnose AF include smartwatches and smartphones with specialized apps.

Paroxysmal AF is defined as AF that terminates spontaneously typically in less than 24 hours and in all cases in less than 7 days. AF that continues for more than 7 days and requires cardioversion for conversion to sinus rhythm is termed persistent AF. Long-standing persistent AF is AF that has been continuous for more than 1 year. Permanent AF exists when both patient and physician have decided not to pursue further attempts to maintain sinus rhythm.

## Differential Diagnosis

These include other supraventricular arrhythmias such as atrial tachycardia, atrial flutter, long runs of premature atrial contractions, and multifocal atrial tachycardia.

## Treatment

### Rate Control

The goal of rate control is to prevent excessive ventricular rate response. This is a reasonable treatment strategy given data from randomized controlled trials (RCTs) that did not show any difference in cardiovascular outcomes between rate-control and rhythm-control strategy.

**TABLE 1** Risk Factors of Atrial Fibrillation

Cardiovascular risk factors
Older age
Male sex
Diabetes mellitus
Overweight and obesity
Hypertension
Chronic kidney disease
Structural heart disease
Valvular heart disease
Cardiomyopathy (dilated, restrictive, and hypertrophic)
Congenital heart disease
Coronary heart disease
Left ventricular diastolic dysfunction
Left atrial enlargement
Family history
Genetics (polygenic and monogenic inheritance)
Inflammation
Low serum magnesium
Heavy alcohol consumption
Poor cardiorespiratory fitness
Low physical activity
Premature atrial contractions or supraventricular ectopy

The AFFIRM (Atrial Fibrillation Follow-up Investigation of Rhythm Management) trial found no difference in mortality or stroke rates between patients assigned to rhythm-control and ventricular rate-control strategies. Similarly, the RACE (Rate Control versus Electrical Cardioversion for Persistent Atrial Fibrillation) trial found that rate control was not inferior to rhythm control for prevention of death.

The RACE II study showed that lenient ventricular rate control targeting a heart rate of lower than 110 beats/min was not inferior to stricter rate control of less than 80 beats/min. Lenient rate control is more convenient and requires fewer outpatient visits and fewer medications.

Other than pharmacologic agents (Table 2), catheter ablation of the AVN is effective in controlling ventricular rate in patients with AF. AVN ablation is indicated if patients fail to achieve adequate ventricular rate control despite maximum doses of AVN blockers.

### Rhythm Control

Although AF is associated with an increased risk of stroke and mortality, current evidence indicates that there is no difference in the rates of these cardiovascular outcomes between rhythm- and rate-control strategies. In the CABANA (Catheter Ablation vs Antiarrhythmic Drug Therapy for Atrial Fibrillation) trial, based on intention-to-treat analysis, there was no significant difference between catheter ablation and drug therapy with respect to a primary composite outcome of death, disabling stroke, serious bleeding, or cardiac arrest. However, in selected younger patients with paroxysmal AF, rhythm control may be a better approach. Additionally, catheter ablation to maintain sinus rhythm in selected patients with symptomatic AF and heart failure with reduced left ventricular ejection fraction may reduce mortality rate and hospitalization for heart failure. Finally, in patients who continue to have symptoms despite an adequately controlled ventricular rate, rhythm control is an appropriate next step.

Rhythm control can be achieved by the use of antiarrhythmic drugs (Table 3) or catheter ablation. In patients with paroxysmal and persistent AF who have failed at least one antiarrhythmic drug, catheter ablation by pulmonary vein isolation is indicated to maintain sinus rhythm. In persistent AF, the STAR AF II (Substrate and Trigger Ablation for Reduction of Atrial Fibrillation Trial Part II) showed that performing additional linear ablation

**TABLE 2** Pharmacologic Agents for Rate Control

DRUG	INTRAVENOUS ADMINISTRATION	USUAL ORAL MAINTENANCE DOSE	MAJOR SIDE EFFECTS
<b>β Blockers</b>			
Metoprolol (Lopressor) <sup>1</sup>	2.5–5 mg IV bolus; up to 3 doses	100–200 mg (long acting) daily	Bradycardia, hypotension, heart block, asthma, heart failure
Atenolol (Tenormin) <sup>1</sup>	N/A	25–100 mg qd	
Esmolol (Brevibloc)	50–200 μg/kg/min IV	N/A	
Propranolol (Inderal)	1–3 mg IV	10–40 mg tid	
Carvedilol (Coreg) <sup>1</sup>	N/A	3.125–25 mg bid	
<b>Nondihydropyridine Calcium Channel Antagonists</b>			
Verapamil (Calan)	5–10 mg bolus	80 mg tid or up to 360 mg (long acting) daily	Hypotension, heart block, heart failure
Diltiazem (Cardizem)	0.25–0.35 mg/kg	60 mg tid or up to 360 mg (long acting) daily	
<b>Digitalis Glycosides</b>			
Digoxin (Lanoxin)	0.25–0.5 mg	0.125–0.25 mg qd	Digitalis toxicity, bradycardia, heart block

<sup>1</sup>Not FDA approved for this indication.  
IV, Intravenous.

or ablation targeting complex fractionated electrograms does not improve rhythm control compared with pulmonary vein isolation alone. The optimal approach to ablate persistent AF remains to be defined.

### Stroke Prophylaxis

Stroke prevention is a two-stage process: determination of thromboembolic stroke risk and selection of prevention strategy. The most commonly used risk-stratification scheme for stroke prevention is the CHA<sub>2</sub>DS<sub>2</sub>-VASc score (<https://www.mdcalc.com/cha2ds2-vasc-score-atrial-fibrillation-stroke-risk>) (Table 4). Oral anticoagulation is recommended for CHA<sub>2</sub>DS<sub>2</sub>-VASc score of 2 or greater in men or 3 or greater in women. Aspirin should not be used for stroke prevention in AF.<sup>1</sup>

### Oral Anticoagulants

These include vitamin K antagonists (warfarin [Coumadin]) and non-vitamin K oral anticoagulants or novel or direct oral anticoagulants (DOAC) (Table 5). Compared with warfarin, DOACs are as effective in preventing thromboembolic stroke in AF. The risk of intracranial hemorrhage from the use of DOACs is 33% to 60% less than that with warfarin. Other advantages of DOACs over warfarin include the facts that there are fewer interactions with food and there is no need for monitoring the international normalized ratio.

### Left Atrial Appendage Closure

The Watchman device is approved by the US Food and Drug Administration (FDA) for stroke prevention in AF patients with a contraindication to long-term oral anticoagulation and who are at risk of thromboembolic stroke. Patients, however, must be able to take oral anticoagulants for at least 6 weeks after implantation of the device.

### Risk Factor Management and Lifestyle Modification

Recent compelling evidence underscores the importance of a fourth pillar of AF management: risk-factor and lifestyle modifications.

### Weight Loss

An RCT has shown that weight reduction with intensive risk-factor management results in a reduction of AF symptom burden and severity and reversal of cardiac remodeling.

### Intensive Blood Pressure Lowering

Blood pressure lowering targeting a systolic blood pressure of 120 mm Hg is associated with lower incidence of AF compared with 140 mm Hg.

### Exercise Training

A small RCT showed that, compared with nonexercise control patients, high-intensity interval training reduced AF burden and

**TABLE 3** Pharmacologic Agents for Rhythm Control

DRUG	USUAL ORAL MAINTENANCE DOSE	MAJOR SIDE EFFECTS
Flecainide (Tambocor)	50–200 mg bid	Hypotension, atrial flutter with high ventricular rate
Propafenone (Rythmol)	150–300 mg tid	
Propafenone Extended Release (Rythmol SR)	225–425 mg bid	
Sotalol (Betapace)	80–160 mg bid	Bradycardia, hypotension, QT prolongation, torsades de pointes
Dofetilide (Tikosyn)	125–500 µg bid	QT prolongation, torsades de pointes

<sup>1</sup>Not FDA-approved for this indication.

improved atrial contractile function. This time-efficient form of exercise can potentially overcome the lack-of-time problem—an oft-quoted reason for poor compliance with regular aerobic exercise.

### Complications

Other than thromboembolic stroke, heart failure, and death, AF is also associated with greater cognitive decline and risk of dementia. More recently, AF has been reported to be associated with a higher risk of sudden cardiac death in the general population. Apart from stroke prevention and rate and rhythm control to prevent heart failure, we currently lack effective prevention strategies for dementia and sudden cardiac death.

### Special Considerations

#### Subclinical Atrial Fibrillation

Subclinical AF is commonly detected from interrogation of cardiac implantable electronic devices. Whether subclinical AF poses the same health risks as clinical AF is the subject of much debate and active investigation.

#### Atrial Fibrillation Burden

A corollary to the problem of subclinical AF is that of AF burden—the amount of AF that a patient has. Studies based on cardiac implantable electronic devices suggest that a higher AF burden is associated with a higher risk of thromboembolic stroke, but it is unclear whether the risk increases continuously or whether a threshold exists.

## CONGENITAL HEART DISEASE

Method of

Richard A. Lange, MD, MBA; and Joaquin E. Cigarroa, MD

### CURRENT DIAGNOSIS

- Examine blood pressures in arms and legs, pulse oximetry, mucous membranes and nail beds, respiratory rate, and peripheral pulses.
- In addition to listening over the precordium for heart sounds and murmurs, palpate for thrills and evidence of right or left chamber enlargement.
- Ancillary testing should include chest radiography, electrocardiography, and echocardiography.
- Consult a cardiologist if the physical examination or ancillary tests suggest congenital heart disease.

### CURRENT THERAPY

- All congenital heart disease patients should have long-term follow-up for possible complications.
- Endocarditis prophylaxis is recommended for subjects with:
  - Unrepaired cyanotic congenital heart disease
  - Recently repaired congenital heart disease (<6 months after surgical or percutaneous repair)
  - Repaired congenital heart disease with residual defects
- Closure of defects with large left-to-right shunts (i.e., atrial septal defect, ventricular septal defect, atrioventricular canal, or patent ductus arteriosus) is recommended unless pulmonary vascular obstructive disease is far advanced.
- Patients with bicuspid aortic valves should be monitored for aortic root dilation.
- Pregnancy should be avoided in women with cyanotic congenital heart disease because of high maternal and fetal morbidity and mortality rates.

Congenital heart disease affects 0.4% to 0.9% of live births. Nowadays, most survive to adulthood because of improved diagnosis and treatment. Congenital cardiac defects can be categorized according to the presence or absence of cyanosis (due to right-to-left shunting) and the amount of pulmonary blood flow (Box 1).

### Acyanotic Conditions

#### Atrial Septal Defect

Atrial septal defect (ASD) occurs in female patients two to three times as often as in male patients. Although most result from spontaneous genetic mutations, some are inherited.

The physiological consequences of ASD result from the shunting of blood from one atrium to the other; the direction and magnitude of shunting are determined by the size of the defect and the relative compliances of the ventricles. A small defect (<0.5 cm in diameter) is associated with a small shunt and no hemodynamic sequelae, whereas a sizable defect (>2 cm in diameter) usually is associated with a large shunt and substantial hemodynamic consequences. In most patients with ASD, the right ventricle is more compliant than the left; as a result, left atrial blood is shunted to the right atrium, causing increased pulmonary blood flow and dilation of the atria, right ventricle, and pulmonary arteries (Figure 1). Eventually, if the right ventricle fails or its compliance declines, the magnitude of left-to-right shunting diminishes.

In a patient with a large ASD, a right ventricular or pulmonary arterial impulse may be palpable, and wide, fixed splitting of the second heart sound is present. A systolic ejection murmur, audible in the second left intercostal space, is caused by increased

blood flow across the pulmonic valve; flow across the ASD itself does not produce a murmur.

Because ASDs initially produce no symptoms or striking physical examination findings, they are often undetected for years. Small defects with minimal left-to-right shunting cause no symptoms or hemodynamic abnormalities, so they do not require closure. Even patients with moderate or large ASDs (characterized by a ratio of pulmonary to systemic blood flow of 1.5 or more) often have no symptoms until the third or fourth decade of life. Over the years, the increased blood volume flowing through the right heart chambers usually causes right ventricular dilation and failure. Obstructive pulmonary vascular disease (Eisenmenger syndrome) occurs uncommonly in adults with ASD.

The symptomatic patient with an ASD typically reports fatigue or dyspnea on exertion. Alternatively, the development of supraventricular tachyarrhythmias, right heart failure, paradoxical embolism, or recurrent pulmonary infections might prompt the patient to seek medical attention. Although an occasional patient with an unrepaired ASD survives to an advanced age, those with

sizable shunts often die of right ventricular failure or arrhythmias in their 30s or 40s.

Echocardiography can reveal atrial and right ventricular dilation and identify the ASD's location. The sensitivity of echocardiography may be enhanced by injecting microbubbles in solution into a peripheral vein, after which the movement of some of them across the defect into the left atrium can be visualized.

An ASD with a pulmonary-to-systemic flow ratio of 1.5 or more should be closed (surgically or percutaneously) to prevent worsening right ventricular dysfunction. Prophylaxis against infective endocarditis is not recommended for patients with ASD (repaired or unrepaired) unless a concomitant valvular abnormality is present.

### Ventricular Septal Defect

Ventricular septal defect (VSD) is the most common congenital cardiac abnormality, with similar incidence in boys and girls. Approximately 25% to 40% of them close spontaneously by 2 years of age.

The physiological consequences of a VSD are determined by the size of the defect and the relative resistances in the systemic and pulmonary vascular beds. A small defect causes little or no functional disturbance, because pulmonary blood flow is only minimally increased. In contrast, a large defect causes substantial left-to-right shunting, because systemic vascular resistance exceeds pulmonary vascular resistance (Figure 2). Over time, however, the pulmonary vascular resistance usually increases, and the magnitude of left-to-right shunting declines. Eventually, the pulmonary vascular resistance equals or exceeds the systemic resistance; the shunting of blood from left to right ceases; and right-to-left shunting begins (e.g., Eisenmenger physiology).

A small, muscular VSD can produce a high-frequency systolic ejection murmur that terminates before the end of systole (when the defect is occluded by contracting heart muscle). With a moderate or large VSD and substantial left-to-right shunting, a holosystolic murmur, loudest at the left sternal border, is audible and is usually accompanied by a palpable thrill. If pulmonary hypertension develops, the holosystolic murmur and thrill diminish in magnitude and eventually disappear as flow through the defect decreases.

### BOX 1 Categorization of Congenital Heart Disease

#### Acyanotic Cardiac Defects

Increased pulmonary blood flow

- Atrial septal defect
- Ventricular septal defect
- Atrioventricular canal defect
- Patent ductus arteriosus

Normal pulmonary blood flow

- Aortic stenosis
- Pulmonic stenosis
- Aortic coarctation

#### Cyanotic Cardiac Defects

Normal pulmonary blood flow

- Ebstein's anomaly

Decreased pulmonary blood flow

- Tetralogy of Fallot
- Eisenmenger syndrome

**Figure 1** Atrial septal defect. Blood from the pulmonary veins enters the left atrium, after which some of it crosses the atrial septal defect into the right atrium and ventricle (*longer arrow*). Thus left-to-right shunting occurs. (Reprinted with permission from Brickner ME, Hillis LD, Lange RA: Congenital heart disease in adults. First of two parts. N Engl J Med 2000;342:256–263.)

**Figure 2** Ventricular septal defect. When the left ventricle contracts, it ejects some blood into the aorta and some across the ventricular septal defect into the right ventricle and pulmonary artery (*arrow*), resulting in left-to-right shunting. (Reprinted with permission from Brickner ME, Hillis LD, Lange RA: Congenital heart disease in adults. First of two parts. N Engl J Med 2000;342:256–263.)

Echocardiography is usually performed to confirm the presence and location of the VSD and to delineate the magnitude and direction of shunting. With catheterization, one can determine the magnitude of shunting and the pulmonary vascular resistance.

The natural history of VSD depends on the size of the defect and the pulmonary vascular resistance. Adults with small defects and normal pulmonary arterial pressure are generally asymptomatic, and pulmonary vascular disease is unlikely to develop. In contrast, patients with large defects who survive to adulthood usually have left ventricular failure or pulmonary hypertension (or both) with associated right ventricular failure.

Closure of VSDs (surgically or percutaneously) is recommended if the pulmonary vascular obstructive disease is not severe. Prophylaxis against infective endocarditis is recommended for patients with unrepaired VSD and those with a residual shunt despite surgical or percutaneous closure.

### Atrioventricular Canal Defect

The endocardial cushions normally fuse to form the tricuspid and mitral valves, as well as the atrial and ventricular septa. Atrioventricular (AV) canal defects are caused by incomplete fusion of the endocardial cushions during embryonic development. They are the most common congenital cardiac abnormality in patients with Down syndrome. Such cushion defects include a spectrum of abnormalities, ranging from ASD with a cleft anterior mitral valve leaflet to a common AV canal defect in which a single AV valve in association with a large ASD and VSD is present.

A common AV canal defect permits substantial left-to-right shunting at both the atrial and ventricular levels, which leads to excessive pulmonary blood flow and resultant pulmonary congestion within months of birth. Eventually, the excessive pulmonary blood flow leads to irreversible pulmonary vascular obstruction (e.g., Eisenmenger physiology).

In the patient with an AV canal defect and left-to-right intracardiac shunting, the physical examination reveals a loud holosystolic murmur audible throughout the precordium. As pulmonary vascular resistance increases, the holosystolic murmur diminishes in intensity and duration, eventually disappearing as flow through the defect decreases.

AV canal defects require surgical repair if the magnitude of pulmonary vascular obstructive disease is not prohibitive. Although such patients might initially benefit from medical treatment with diuretics and afterload reduction, the onset of heart failure symptoms is generally the point at which surgery is considered. Prophylaxis against infective endocarditis is recommended for patients with repaired and unrepaired AV canal defects.

### Patent Ductus Arteriosus

The ductus arteriosus connects the descending aorta (just distal to the left subclavian artery) and the left pulmonary artery. In the fetus, it permits pulmonary arterial blood to bypass the unexpanded lungs and to enter the descending aorta for oxygenation in the placenta. Although it normally closes spontaneously soon after birth, it fails to do so in some infants, so that continuous flow from the aorta to the pulmonary artery (i.e., left-to-right shunting) occurs (Figure 3). The incidence of patent ductus arteriosus (PDA) is increased in pregnancies complicated by persistent perinatal hypoxemia or maternal rubella infection as well as among infants born prematurely or at high altitude.

A patient with PDA and a moderate or large shunt has bounding peripheral arterial pulses and a widened pulse pressure. A continuous “machinery” murmur, audible in the second left intercostal space, begins shortly after the first heart sound, peaks in intensity at or immediately after the second heart sound (thereby obscuring it), and diminishes in intensity during diastole. If pulmonary vascular obstruction and hypertension develop, the murmur decreases in duration and intensity and eventually disappears.

With echocardiography, the PDA can usually be visualized, and Doppler studies demonstrate continuous flow in the pulmonary trunk. Catheterization and angiography allow one to quantify the

**Figure 3** Patent ductus arteriosus. Some of the blood from the aorta crosses the ductus arteriosus into the pulmonary artery (arrows), with resultant left-to-right shunting. (Reprinted with permission from Brickner ME, Hillis LD, Lange RA: Congenital heart disease in adults. First of two parts. *N Engl J Med* 2000;342:256–263.)

magnitude of shunting and the pulmonary vascular resistance and to visualize the PDA.

The subject with a small PDA has no symptoms attributable to it and a normal life expectancy. However, it is associated with an elevated risk of infective endarteritis. A PDA of moderate size might cause no symptoms during infancy; during childhood or adulthood, fatigue, dyspnea, or palpitations can appear. Additionally, the PDA can become aneurysmal and calcified, with subsequent rupture. Larger shunts can precipitate left ventricular failure. Eventually, pulmonary vascular obstruction can develop; when the pulmonary vascular resistance equals or exceeds the systemic vascular resistance, the direction of shunting reverses.

One third of patients with an unrepaired moderate or large PDA die of heart failure, pulmonary hypertension, or endarteritis by 40 years of age, and two thirds die by 60 years of age. Because of the risk of endarteritis associated with unrepaired PDA (about 0.45% annually after the second decade of life) and the safety of surgical ligation (generally accomplished without cardiopulmonary bypass) or percutaneous closure, even a small PDA should be ligated surgically or occluded percutaneously. Once severe pulmonary vascular obstructive disease develops, ligation or closure is contraindicated.

### Aortic Stenosis

A bicuspid aortic valve is found in 2% to 3% of the population and is four times more common in males than in females. The bicuspid valve has a single fused commissure and an eccentrically oriented orifice. Although the deformed valve is not typically stenotic at birth, it is subjected to abnormal hemodynamic stress, which can lead to leaflet thickening and calcification. In many patients, an abnormality of the ascending aortic media is present, predisposing the patient to aortic root dilation. Twenty percent of patients with a bicuspid aortic valve have an associated cardiovascular abnormality, such as PDA or aortic coarctation.

In patients with severe aortic stenosis (AS), the carotid upstroke is usually delayed and diminished. The aortic component of the second heart sound is diminished or absent. A systolic crescendo-decrescendo murmur is audible over the aortic area and often radiates to the neck. As the magnitude of AS worsens, the murmur peaks progressively later in systole.

In most patients, echocardiography with Doppler flow permits an assessment of the severity of AS and of left ventricular systolic

**Figure 4** Coarctation of the aorta. Coarctation causes obstruction to blood flow in the descending thoracic aorta; the lower body is perfused by collateral vessels from the axillary and internal thoracic arteries through the intercostal arteries. (Reprinted with permission from Brickner ME, Hillis LD, Lange RA: Congenital heart disease in adults. First of two parts. *N Engl J Med* 2000;342:256–263.)

function. Cardiac catheterization is performed to assess the severity of AS and to determine if concomitant coronary artery disease is present.

The symptoms of AS are angina pectoris, syncope or near syncope, and those of heart failure (dyspnea). Asymptomatic adults with AS have a normal life expectancy. Once symptoms appear, survival is limited. The median survival is 5 years once angina develops, 3 years once syncope occurs, and 2 years once symptoms of heart failure appear. Therefore patients with symptomatic AS should undergo surgical or percutaneous valve replacement.

#### Pulmonic Stenosis

Pulmonic stenosis (PS) is the second most common congenital cardiac malformation (after VSD). Although typically an isolated abnormality, it can occur in association with VSD.

The patient with PS is usually asymptomatic, and the condition is identified by auscultation of a loud systolic murmur. When it is severe, dyspnea on exertion or fatigue can occur; less often, patients have retrosternal chest pain or syncope with exertion. Eventually, right ventricular failure can develop, with resultant peripheral edema and abdominal swelling.

In patients with moderate or severe PS, the second heart sound is widely split, with its pulmonic component soft and delayed. A crescendo-decrescendo systolic murmur that increases in intensity with inspiration is audible along the left sternal border. If the valve is pliable, an ejection click often precedes the murmur. On echocardiography, right ventricular hypertrophy is evident; the severity of PS can usually be assessed with measurement of Doppler flow.

Adults with mild PS are usually asymptomatic and do not require a corrective procedure. In contrast, patients with moderate or severe PS should undergo percutaneous balloon dilation.

#### Aortic Coarctation

Aortic coarctation typically consists of a diaphragm-like ridge extending into the aortic lumen just distal to the left subclavian artery (Figure 4), resulting in an elevated arterial pressure in both arms. Less commonly, the coarctation is located immediately

proximal to the left subclavian artery, in which case a difference in arterial pressure is noted between the arms. Extensive collateral arterial circulation to the lower body through the internal thoracic, intercostal, subclavian, and scapular arteries often develops in patients with aortic coarctation. Aortic coarctation, which is two to five times as common in males as in females, can occur in conjunction with gonadal dysgenesis (e.g., Turner's syndrome), bicuspid aortic valve, VSD, or PDA.

On physical examination, the arterial pressure is higher in the arms than in the legs, and the femoral arterial pulses are weak and delayed. A harsh systolic ejection murmur may be audible along the left sternal border and in the back, particularly over the coarctation. A systolic murmur, caused by flow through collateral vessels, may be heard in the back.

On chest radiography, increased collateral flow through the intercostal arteries causes notching of the posterior third through eighth ribs. The coarctation may be visible as an indentation of the aorta, and one may see prestenotic and poststenotic aortic dilation, producing the "reversed E" or "3" sign. Computed tomography, magnetic resonance imaging, and contrast aortography provide precise anatomic delineation of the coarctation's location and length.

Most adults with aortic coarctation are asymptomatic. When symptoms are present, they are usually those of hypertension: headache, epistaxis, dizziness, and palpitations. Complications of aortic coarctation include hypertension, left ventricular failure, aortic dissection, premature coronary artery disease, infective endocarditis, and cerebrovascular accidents (due to rupture of an intracerebral aneurysm). Two thirds of patients older than 40 years who have uncorrected aortic coarctation have symptoms of heart failure. Three fourths die by the age of 50 years and 90% by the age of 60 years.

Surgical repair or intraluminal stenting should be considered for patients with a transcoarctation pressure gradient greater than 30 mm Hg, with the choice of procedure influenced by the age of the patient, anatomic considerations of the coarctation, and the presence of concomitant cardiac abnormalities. Persistent hypertension is common despite surgical or percutaneous intervention, and recurrent coarctation or aneurysm formation at the repair site may occur.

### Cyanotic Conditions

#### Ebstein's Anomaly

With Ebstein's anomaly, the tricuspid valve's septal leaflet and often its posterior leaflet are displaced into the right ventricle, and the anterior leaflet is usually malformed and abnormally attached or adherent to the right ventricular free wall. As a result, a portion of the right ventricle is atrialized, in that it is located on the atrial side of the tricuspid valve, and the remaining functional right ventricle is small (Figure 5). The tricuspid valve is usually regurgitant, but it may be stenotic. Eighty percent of patients with Ebstein's anomaly have an interatrial communication (ASD or patent foramen ovale) through which right-to-left shunting of blood can occur.

The severity of the hemodynamic derangements in patients with Ebstein's anomaly depends on the magnitude of displacement and the functional status of the tricuspid valve leaflets. On the one extreme, patients with mild apical displacement of the tricuspid valve leaflets have normal valvular function; on the other extreme, those with severe leaflet displacement or abnormal anterior leaflet attachment, with resultant valvular dysfunction, have an elevated right atrial pressure and right-to-left shunting if an interatrial communication is present.

The clinical presentation of subjects with Ebstein's anomaly ranges from severe right heart failure in the neonate to the absence of symptoms in the adult in whom it is discovered incidentally. Older children with Ebstein's anomaly often come to medical attention because of an incidental murmur, whereas adolescents and adults may be identified because of a supraventricular arrhythmia.

On physical examination, the severity of cyanosis depends on the magnitude of right-to-left shunting. The first and second heart sounds are both widely split, and a third or fourth heart sound is often present, resulting in triple or even quadruple heart sounds. A systolic murmur caused by tricuspid regurgitation is usually present at the left lower sternal border.

**Figure 5** Ebstein's anomaly. With Ebstein's anomaly, the tricuspid valve is displaced apically, a portion of the right ventricle is atrialized (i.e., located on the atrial side of the tricuspid valve), and the functional right ventricle is small. (Reprinted with permission from Brickner ME, Hillis LD, Lange RA: Congenital heart disease in adults. Second of two parts. *N Engl J Med* 2000;342:334–342.)

Echocardiography is used to assess the presence and magnitude of right atrial dilation, anatomic displacement and distortion of the tricuspid valve leaflets, and the severity of tricuspid regurgitation or stenosis.

Prophylaxis against infective endocarditis is recommended. Patients with symptomatic right heart failure should receive diuretics. Tricuspid valve repair or replacement in conjunction with closure of the interatrial communication is recommended for older patients with severe symptoms despite medical therapy and those with less severe symptoms who have cardiac enlargement.

### Tetralogy of Fallot

Tetralogy of Fallot is characterized by a large VSD, an aorta that overrides both ventricles, obstruction to right ventricular outflow (subvalvular, valvular, supra-valvular, or in the pulmonary arterial branches), and right ventricular hypertrophy (Figure 6).

Most patients with tetralogy of Fallot have substantial right-to-left shunting through the large VSD because of increased resistance to flow in the right ventricular outflow tract; the magnitude of right ventricular outflow tract obstruction determines the magnitude of shunting. Because the resistance to flow across the right ventricular outflow tract is relatively fixed, changes in systemic vascular resistance affect the magnitude of right-to-left shunting: A decrease in systemic vascular resistance increases right-to-left shunting, whereas an increase in systemic resistance decreases it.

Patients with tetralogy of Fallot typically have cyanosis from birth or beginning in the first year of life. In childhood, they might have sudden hypoxic spells, characterized by tachypnea and hyperpnea, followed by worsening cyanosis and, in some cases, loss of consciousness, seizures, cerebrovascular accidents, and even death. Such spells do not occur in adolescents or adults. Without surgical intervention, most patients die in childhood.

On physical examination, patients with tetralogy of Fallot have cyanosis and digital clubbing. A right ventricular lift or tap is palpable. The second heart sound is single, because its pulmonic component is inaudible. A systolic ejection murmur, audible along the left sternal border, is caused by the obstruction to right ventricular outflow. The intensity and duration of the murmur are inversely related to the severity of right ventricular outflow

**Figure 6** Tetralogy of Fallot. Tetralogy of Fallot is characterized by a large ventricular septal defect, obstruction of the right ventricular outflow tract, right ventricular hypertrophy, and an aorta that overrides the left and right ventricles. With right ventricular outflow tract obstruction, blood is shunted through the ventricular septal defect from right to left (arrow). (Reprinted with permission from Brickner ME, Hillis LD, Lange RA: Congenital heart disease in adults. Second of two parts. *N Engl J Med* 2000;342:334–342.)

obstruction; a soft, short murmur suggests that severe obstruction is present.

Laboratory examination reveals arterial oxygen desaturation and compensatory erythrocytosis. Echocardiography can be used to establish the diagnosis and to assess the location and severity of right ventricular outflow tract obstruction.

Complete surgical repair (closure of the VSD and relief of right ventricular outflow tract obstruction) is recommended to relieve symptoms and to improve survival; it should be performed when patients are very young. Those with tetralogy of Fallot (repaired or unrepaired) are at risk for endocarditis and therefore should receive antibiotic prophylaxis before dental or elective surgical procedures.

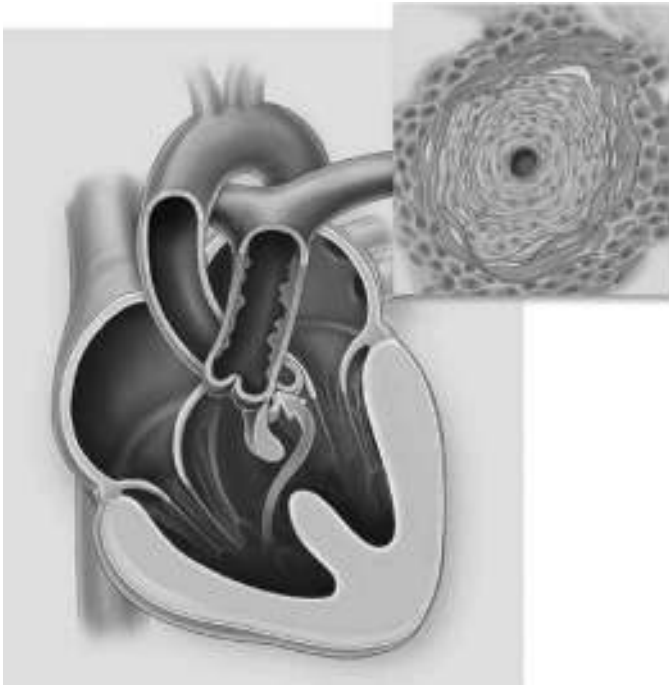

Patients with repaired tetralogy of Fallot require careful follow-up, because they can subsequently develop atrial or ventricular arrhythmias, pulmonic regurgitation, right ventricular dysfunction, or recurrent obstruction of the right ventricular outflow tract.

### Eisenmenger Syndrome

With substantial left-to-right shunting, the pulmonary vasculature is exposed to increased blood flow under increased pressure, often resulting in pulmonary vascular obstructive disease. As the pulmonary vascular resistance approaches or exceeds systemic resistance, the shunt is reversed (right-to-left shunting develops), and cyanosis appears (Figure 7).

Most patients with Eisenmenger syndrome have impaired exercise tolerance and exertional dyspnea. Palpitations are common and most often result from atrial fibrillation or flutter. As erythrocytosis (due to arterial desaturation) develops, symptoms of hyperviscosity (visual disturbances, fatigue, headache, dizziness, and paresthesias) can appear. Patients with Eisenmenger syndrome can experience hemoptysis, bleeding complications, cerebrovascular accidents, brain abscess, syncope, and sudden death.

Eisenmenger syndrome patients typically have digital clubbing and cyanosis, a right parasternal heave (due to right ventricular hypertrophy), and a prominent pulmonic component of the second heart sound. The murmur caused by a VSD, PDA, or ASD disappears when Eisenmenger syndrome develops.

**Figure 7** Eisenmenger syndrome. In response to substantial left-to-right shunting, morphologic alterations occur in the small pulmonary arteries and arterioles (*inset*), leading to pulmonary hypertension and the resultant reversal of the intracardiac shunt (*arrow*). In the small pulmonary arteries and arterioles, medial hypertrophy, intimal cellular proliferation, and fibrosis lead to narrowing or closure of the vessel lumina. With sustained pulmonary hypertension, extensive atherosclerosis and calcification often develop in the large pulmonary arteries. (Reprinted with permission from Brickner ME, Hillis LD, Lange RA: Congenital heart disease in adults. Second of two parts. *N Engl J Med* 2000;342:334–42.)

The chest x-ray reveals normal heart size, prominent central pulmonary arteries, and diminished vascular markings (pruning) of the peripheral vessels. On transthoracic echocardiography, evidence of right ventricular pressure overload and pulmonary hypertension is present. The underlying cardiac defect can usually be visualized, although shunting across the defect may be difficult to demonstrate by Doppler because of the low jet velocity.

Even though patients with Eisenmenger syndrome have severe pulmonary hypertension, they have a favorable long-term survival: 80% at 10 years after diagnosis, 77% at 15 years, and 42% at 25 years. Death is usually sudden, presumably caused by arrhythmias, but some patients die of heart failure, hemoptysis, brain abscess, or stroke.

Phlebotomy with isovolumic replacement should be performed in patients with moderate or severe symptoms of hyperviscosity; it should not be performed in asymptomatic or mildly symptomatic patients regardless of the hematocrit. Repeated phlebotomy can result in iron deficiency, which can worsen the symptoms of hyperviscosity, because iron-deficient erythrocytes are less deformable than iron-replete ones. Anticoagulants and antiplatelet agents should be avoided, because they exacerbate the hemorrhagic diathesis.

Patients with Eisenmenger syndrome should avoid intravascular volume depletion, high altitude, and the use of systemic vasodilators. Because of high maternal and fetal morbidity and mortality, pregnancy should be avoided. Patients with Eisenmenger syndrome who are undergoing noncardiac surgery require meticulous management of anesthesia, with attention to maintenance of systemic vascular resistance, minimization of blood loss and intravascular volume depletion, and prevention of iatrogenic paradoxical embolization. In preparation for noncardiac surgery, prophylactic phlebotomy (usually of 1 to 2 units of blood, with isovolumic replacement) is recommended for patients with a hematocrit greater than 65% to reduce the likelihood of perioperative hemorrhagic and thrombotic complications.

Lung transplantation with repair of the cardiac defect or combined heart–lung transplantation are options for patients with Eisenmenger syndrome who are deemed to have a poor prognosis (as reflected by the presence of syncope, refractory right heart failure, a high New York Heart Association [NYHA] functional class, or severe hypoxemia). Because of the somewhat limited success of transplantation and the reasonably good survival among patients treated medically, careful selection of patients for transplantation is imperative. Although pulmonary vasodilators improve exercise capacity, they have not been proved to improve survival.

## CONGESTIVE HEART FAILURE

Method of

Alex Schevchuck, MD, MS; and Mark E. Garcia, MD

### CURRENT DIAGNOSIS

- Recognize clinical symptoms and signs of congestive heart failure (HF).
- Determine left ventricular ejection fraction (EF) using imaging modalities.
- Identify the potential etiologies.
- Evaluate hemodynamic status.

### CURRENT THERAPY

- Current therapies differ for heart failure with preserved (HFpEF) and reduced EF (HFrEF).
- Angiotensin converting enzyme inhibitors (ACEIs), angiotensin-receptor blockers (ARBs), angiotensin receptor-neprilysin inhibitor (ARNI), and mineralocorticoid receptor antagonists (MRAs) play a pivotal role in reducing morbidity and mortality in patients with HFrEF.
- Diuretics are useful in both HFrEF and HFpEF patients to treat congestion and fluid volume removal. A patient with decompensated heart failure may need intravenous diuretic treatment for decongestion caused by intestinal edema and malabsorption of oral diuretics. High-dose IV diuretic is important for treatment of decompensated HF.
- There are limited treatment options for HFpEF. The mainstay of therapy in HFpEF is using diuretics to relieve congestion and treatment of coexisting diseases.
- In advanced heart failure, identification of high-risk features and early referral for consultation with an advanced heart failure specialist are important.

### Heart Failure Definition

The definition of heart failure has been variable in part caused by a wide spectrum of etiologies and pathologic processes resulting in this disease.

Heart failure is a clinical syndrome that includes a variety of signs and symptoms of systemic and/or pulmonic congestion from cardiac dysfunction. Specifically, systolic insufficiency and/or elevated ventricular filling pressures result in decreased perfusion and congestion. The symptoms of heart failure commonly include shortness of breath with exertion or at rest, fatigue, limited exercise capacity, and edema. **Figure 1** shows the new proposed universal definition of heart failure.

Heart failure can sometimes be confused for a cardiomyopathy and/or a low EF. A cardiomyopathy is a disease state of the myocardium, such as ischemic heart disease or hypertrophic cardiomyopathy. This may lead to the heart failure syndrome but is not necessarily needed to develop heart failure. Thus these terms are not synonymous or interchangeable. Likewise, a low EF does not automatically imply the diagnosis of heart failure in absence of the clinical syndrome.

There are four stages of clinical development and progression of heart failure (**Table 1**).

### Epidemiology

Based on 2013 to 2016 NHANES data, there were 6.2 million adults with congestive heart failure in the United States, and this number has increased from 5.7 million from 2009 to 2012. This represented about 2% of the U.S. population. Projections now show that by the year 2030, the prevalence of HF may increase to nearly 3%, or >8 million adults. The prevalence of HF increases with age, approaching >12% of the population in the age group of 80 and older.

In the ARIC study, the incidence of HF in subjects ≥55 years-old was 1 million cases in 2014 and was slightly higher among women comparatively to men and among African Americans comparatively to whites.

The lifetime risk of developing heart failure is 20% to 45% in subjects ≥45 years of age. HF mortality depends on the type of heart failure, demographics, and history of hospitalizations. Although HF survival has improved with the development of contemporary therapies, 1-year mortality remains substantial,

nearing 30%. The overall cost of HF care was ~30 billion dollars in 2012. By 2030, the cost is projected to increase by 127%, to nearly 70 billion a year.

### Heart Failure Classification Based on Left Ventricular Ejection Fraction (LVEF)

HF classification based on LVEF has been updated in the 2021 Universal Definition of Heart Failure document and is summarized in **Table 2**.

EF-based classification further implies prognostic and therapeutic differences. Thus patients with EF ≤40 benefit from specific treatments for heart failure with a reduced LVEF. HF with a mildly reduced ejection fraction has been a controversial topic and generally represents heterogeneous phenotypes that may benefit from treatments for a reduced EF and also may have a worse prognosis than patients with a preserved EF. If a patient has had heart failure with low EF that has improved to ≥40% as a result of treatment or a natural cause, the patient is subcategorized into the “HF with preserved Ejection Fraction, improved” class. Clinicians have to keep in mind the limitations of the LV assessment methods. For example, echocardiography may have variability in EF quantification based on a quantification method, reader experience/style, and image quality. An EF decrease from 41% to 39% may not necessarily represent a clinical change or deterioration from HFmrEF to HFpEF but rather be attributed to a measurement variability. Verification tests, such as cardiac magnetic resonance imaging (MRI) or multiple-gated acquisition (MUGA) scan, may be used to validate if the change is true before major therapeutic changes are made.

### Functional Capacity

New York Heart Association (NYHA) Functional Class is commonly accepted classification of functional capacity in symptomatic and advanced (stages C and D) heart failure patients. Functional class has prognostic and therapeutic implications. Four NYHA functional classes (FC) are listed in **Table 3**.

NYFA functional class should be assessed at the time of heart failure diagnosis and then reassessed during subsequent encounters to track progress of heart failure treatment and for monitoring of disease progression.

### Left Ventricular Physiology and Hemodynamic Profile

Left ventricular performance depends on three major components: preload, afterload, and contractility. The preload is the maximum amount of myocardial stretch prior to onset of ventricular systole. A clinically accepted measure of preload is the left ventricular end-diastolic pressure (LVEDP), which can be measured directly using cardiac catheterization techniques or indirectly using transthoracic echocardiography. The relationship between cardiac output (CO) and preload is described by Frank-Starling mechanism (**Figure 2**, Panel A). CO will continue to increase in response to increasing preload, until the LV stretch reaches the point when actin and

**Figure 1** Universal definition of heart failure. BNP: Brain natriuretic peptide

**TABLE 1** Stages of Development and Progression of HF

Stage	A AT RISK FOR HF	B PRE-HF	C HF	D ADVANCED HF
Symptoms	No prior or current symptoms of HF	No prior or current symptoms of HF	Prior or current symptoms of HF	Severe symptoms of congestion, dyspnea at rest, recurrent hospitalization despite GDMT
Clinical features	Presence of HTN, CVD, DM, obesity, exposure to cardiotoxins, family history of familial cardiomyopathy	Presence of one of the following: Structural heart disease Abnormal cardiac function Elevated BNP or troponin level in case of cardiotoxins	Symptoms are caused by structural or functional heart abnormality (i.e., systolic dysfunction or elevated filling pressures)	Requires advanced therapies (VAD, transplant) or palliative care

CVD, cardiovascular disease; DM, diabetes mellitus; HTN, hypertension; GDMT: guideline-directed medical therapy; VAD: ventricular assist-device.

myosin fibers lose interlink. Any further increase in preload past this point will result in decrease in CO.

Afterload, on the other hand, has a hyperbolic relationship with the stroke volume (see Figure 2, Panel B). Any reduction in afterload results in an increase in CO and vice versa.

The contractility is a highly debated term in the myocardial physiology world and sometimes is referred to as *inotropy*. This generally implies an intrinsic force or an intensity of a myocardial contraction that is affected by positive and negative inotropic agents. Many conditions that affect the myocardium may also adversely affect the contractility.

The preload-CO relationship determines four hemodynamic profiles (Table 4).

### Neurohormone and Sympathetic Nervous System Activation

Heart failure leads to a decreased cardiac output, and in this disease state multiple detrimental physiologic pathways are activated. This includes the renin-angiotensin-aldosterone system (RAAS) and the sympathetic nervous system (SNS). The RAAS is activated in this low perfusion state where the kidney senses the decreased perfusion pressure stimulating the release of renin. Renin is responsible for activating angiotensin-I, which is then further activated to its more potent form angiotensin-II by the angiotensin converting enzyme. Angiotensin-II binds to the AT1 receptor and this process triggers multiple cardiovascular and renal effects including vasoconstriction, triggering of sodium and water absorption in the renal tubules, stimulating aldosterone release, and several direct detrimental myocardium effects including hypertrophy and fibrosis.

Activation of the sympathetic nervous system during heart failure is a complex pathway that is associated with increased catecholamine levels and increased sympathetic tone. Activation of the SNS initially can be considered beneficial in early HF because this has a

wide range of effects including increased heart rate and cardiac contractility, but long-term activation has significant detrimental effects leading to further cardiac remodeling and arrhythmias.

Activation of these systems directly contributes to cardiac remodeling and worsening of HF. These pathways allow for multiple different therapeutic interventions that have been proven to improve survival, decrease hospitalizations, decrease symptoms, and potentially improve cardiac function.

### Diagnosis

Clinical diagnostic criteria for HF are listed in Box 1. For establishing a definite diagnosis of heart failure in this study, two major or one major and two minor criteria have to be present concurrently.

Echocardiography plays a key role in diagnosis of heart failure. Transthoracic echo (TTE) provides information about the left and right ventricular systolic function, chamber sizes, structural disease such as ventricular hypertrophy, valve structure and function, relaxation function, presence of the intracardiac shunts, and ventricular filling pressures and pulmonary artery pressure. TEE may be helpful to clarify details on cardiac structure, such as anatomy of shunts or mechanism of valve dysfunction.

Cardiac CT may provide information on cardiac and vascular structure. Cardiac MRI is excellent at the evaluation of cardiac structure, function and chamber size, as well as assessing and

Figure 2 Effects of preload and afterload on cardiac output.

TABLE 2 Classification of Heart Failure Based on LVEF

HF CLASS ACCORDING TO LVEF (MUST HAVE SIGNS AND SYMPTOMS)	ACRONYM	LVEF, %
HF with reduced Ejection Fraction	HFrEF	≤40
HF with mildly reduced Ejection Fraction	HFmrEF	41–49
HF with preserved Ejection Fraction	HFpEF	≥50
HF with preserved Ejection Fraction, improved	HFpEF, improved	Prior <40, now ≥40

TABLE 3 NYHA Functional Classification

NYHA FC	FUNCTIONAL CAPACITY
I	No limitations. Can perform high level of activity without symptoms (for example, running, cycling, weightlifting).
II	Slight limitations. Tolerate lower or moderate level activities well, may have limitations with higher level activities (for example, regular walking causes no symptoms, but a run may cause shortness of breath).
III	Significant limitations. Symptoms with low-level activities such as with daily activities such as walking, household chores, etc.
IV	Symptoms at rest, dyspnea with any physical activity.

TABLE 4 Heart Failure Hemodynamic Profiles

	NORMAL LVEDP	ELEVATED LVEDP
Normal CO	A “warm and dry”	B “warm and wet”
Decreased CO	L “lethal, cold, and dry”	C “cold and wet”

BOX 1 Clinical Criteria for CHF Diagnosis

#### Major Criteria

- Paroxysmal nocturnal dyspnea or orthopnea
- Neck-vein distention
- Rales
- Cardiomegaly
- Acute pulmonary edema
- S<sub>3</sub> gallop
- Increased venous pressure (≥16 cm of water)
- Circulation time ≥25 sec
- Hepatojugular reflux

#### Minor Criteria

- Ankle edema
- Night cough
- Dyspnea on exertion
- Hepatomegaly
- Pleural effusion
- Vital capacity ↓ 1/3 from maximum.
- Tachycardia (rate of ≥120/min)

#### Major or Minor Criterion

- Weight loss ≥4.5 kg in 5 days in response to treatment

diagnosing myocardial disease, such as tumors, fibrosis, thrombi, and inflammatory and infiltrative processes.

Nuclear radiology offers a MUGA scan that is considered a superior EF evaluation method and a myocardial perfusion viability testing, which is an important tool for evaluation of ischemic heart disease.

Left heart catheterization (a percutaneous catheter placement into the left ventricle) allows for a direct measurement of the LVEDP but is rarely performed as a standalone test because of associated risks. This is generally reserved for cases involving other percutaneous cardiac procedures, such as a coronary angiogram. A right heart catheterization (sometimes referred to as a Swan-Ganz catheter or pulmonary artery [PA] catheter) offers a lower complication risk profile and is our favorite method of invasive hemodynamic assessment.

A 12-lead electrocardiography (ECG) is an important test for HF patients. It may diagnose cardiac arrhythmias or ischemic disease, or can be suggestive of other myocardial diseases (i.e., amyloid) providing a clue to the etiology of HF.

### Laboratory and Diagnostic Tests

In the newly decompensated HF patient, several laboratory tests should be obtained including serum creatinine, blood urea nitrogen, serum electrolytes, complete blood counts, urinalysis, liver function tests, thyroid stimulating hormone, and fasting lipid panel. In patients with a new HF diagnosis, it is reasonable to screen for hemochromatosis and HIV and to obtain diagnostic tests if there is a clinic concern for systemic disease such as rheumatologic diseases, amyloidosis, or pheochromocytoma.

Natriuretic peptide biomarkers include B-type natriuretic peptide (BNP) and N-terminal pro-B-type natriuretic peptide (NT-proBNP). Natriuretic peptides are released from the heart tissues when stretching (increased intracardiac volume and/or pressure). Circulating natriuretic peptides have a vasodilation and natriuretic response. BNP is the biologically active form and is inactivated by the enzyme neprilysin. Inhibition of the neprilysin enzyme is a target for sacubitril-valsartan. Natriuretic peptide levels can be useful in the ambulatory setting when the evaluation of dyspnea is unclear, assisting with the diagnosis of new onset HF, and in the emergency setting when normal natriuretic peptide levels can help rule out HF. There is no role of serial natriuretic testing in the hospitalized or ambulatory setting but it can be useful when assessing changes in symptoms and upon hospital discharge because the level can help in establishing disease severity and be a predictor of worse outcomes.

Troponin levels can be elevated in decompensated HF. Troponin elevations in HF are not diagnostic to HF but provide information on prognosis in HF and should be obtained on hospital admission.

### Therapy for HFrEF

#### Diuretics (High Dose IV Diuretic Is Important)

Loop diuretics are the mainstay of therapy to relieve congestion in HFrEF and HFpEF. In hospitalized patients already on loop diuretic therapy, the IV dose should exceed the outpatient oral dose and should be given as intermittent boluses or infusion. Consider dosing the IV loop diuretic at 2.5 times the home oral dose. If resistant to initial IV loop diuretic dose, then consider doubling the initial dose. If resistance to IV diuretic continues then consider adding a thiazide diuretic. We prefer IV chlorothiazide, 500 mg  $\times$  1, 30 minutes before infusion of a loop diuretic. IV or PO metolazone (2.5–5 mg  $\times$  1) or HCTZ 25 mg PO  $\times$  1 can also be used. Chronic oral loop diuretics should be adjusted to maintain euolemia.

### Renin-Angiotensin-Aldosterone System Inhibitors

#### Angiotensin-Converting Enzyme Inhibitor (ACEI)

In patients with HFrEF, ACEIs are indicated and can reduce morbidity and mortality. ACEIs are now considered a class effect in HFrEF. ACEI block the conversion of angiotensin-I to angiotensin-II, thus avoiding vasoconstriction and other direct myocardial detrimental effects of angiotensin.

#### Angiotensin Receptor Blocker (ARB)

In similar fashion to ACEIs, ARBs are indicated in HFrEF to reduce morbidity and mortality. ARBs block angiotensin II from binding to the AT1 receptor and avoid the vasoconstriction and other direct myocardial detrimental effects of angiotensin.

#### Angiotensin Receptor–Neprilysin Inhibitor (ARNI)

ARNI is a combination drug with ARB effect and added neprilysin inhibition (Sacubitril/Valsartan [Entresto]). Neprilysin is an enzyme responsible for the degradation of BNP, and by inhibiting neprilysin circulating BNP is available for further vasodilation and natriuretic effects. ARNI provided further morbidity and mortality benefit compared with ACEI. When possible, patients should be transitioned from an ACEI or ARB to an ANRI. If already on an ACEI, then an ARNI should not be taken within 36 hours of the ACEI to avoid drug interactions. ARNI can cause hypotension, renal insufficiency, and angioedema.

#### Aldosterone Antagonists

Aldosterone antagonists include spironolactone (Aldactone) or eplerenone (Inspra).<sup>1</sup> They can further reduce morbidity and mortality in HFrEF when added to a background of ACEI/ARB/ARNI and beta blocker. In HFpEF, aldosterone antagonist can be considered to decrease hospitalization. But be aware of the risk of hyperkalemia.

#### Sympathetic Nervous System

There are three appropriate beta blockers for HFrEF that reduce morbidity and mortality. These include metoprolol succinate (Toprol XL), carvedilol (Coreg), and bisoprolol (Zebeta).<sup>1</sup> When initiating a beta blocker for HFrEF, the patient should have resolution of congestive symptoms and typically will already be on ACEI/ARB/ARNI. Beta blockers are contraindicated in cardiogenic shock.

#### Hydralazine and Isosorbide Dinitrate Combination

Hydralazine in combination with isosorbide dinitrate is a vasodilator. Hydralazine-isosorbide dinitrate (ISDN) combination (BiDil) or hydralazine and isosorbide dinitrate as a separate combination is indicated for patients self-described as African American and with persistent significant symptoms (NHYA III-IV) while on a background of maximal tolerated ACEI/ARB/ARNI, beta blocker, and aldosterone antagonist. Hydralazine-isosorbide dinitrate combination can also be beneficial in those patients that cannot tolerate an ACEI/ARB/ARNI but not as a replacement for those that are able to tolerate.

#### Sodium-Glucose Cotransporter-2 Inhibitors (SGLT2 Inhibitors)

SGLT2 inhibitors are a newer therapy that is an adjunctive therapy to the existing guideline-directed medical therapy (GDMT). SGLT2 inhibitors can be considered in HFrEF patients with or without diabetes and are associated with reduced cardiovascular events.

#### Ivabradine

Lower heart rates in HFrEF are associated with better outcomes. Ivabradine (Corlanor, Lancora) is an adjunctive medication to the existing GDMT and can further reduce heart rate. Ivabradine can be considered in HFrEF (LVEF  $\leq$ 35%) for those in sinus rhythm and on maximal tolerated beta blocker dose when the resting heart rate  $\geq$ 70 beats per minute.

#### Digoxin

Digoxin (Lanoxin) can be added as an adjunctive medication in HFrEF and is associated with reduced hospitalizations. Digoxin should be used with caution in the elderly and those with renal dysfunction.

Treatment strategies for acute decompensated heart failure based on hemodynamic profile are described in [Table 5](#). Treatment pathways for HFrEF stage C are shown on [Figure 3](#).

<sup>1</sup>Not FDA approved for this indication.

### Device Therapies

Medicine therapy is the cornerstone of HF treatment, but there are several other therapeutic options that need to be incorporated to further improve survival and decrease symptoms in

patients that have demonstrated a lack of response to initial management and through intensification of that therapy. For patients with HFrEF, device therapy including implantable cardioverter-defibrillator (ICD) and cardiac resynchronization therapy (CRT) are proven modalities that further improve survival, and referral to an electrophysiologist and/or heart failure specialist is indicated. ICD can help prevent sudden cardiac death (SCD) in patients with ischemic or nonischemic cardiomyopathies at least 40 days post-MI with LVEF of  $\leq 35\%$  and NYHA II or III symptoms on GDMT or NYHA I with LVEF  $\leq 30\%$ . CRT is indicated in patients with an LVEF of  $\leq 35\%$  and LBBB with persistent symptoms. Transcatheter mitral valve repair (TMVR) using MitraClip™ (Abbott, IL, USA) is another device option in HF patients that decreases mitral regurgitation severity in secondary mitral regurgitation and improves survival in persistent HF.

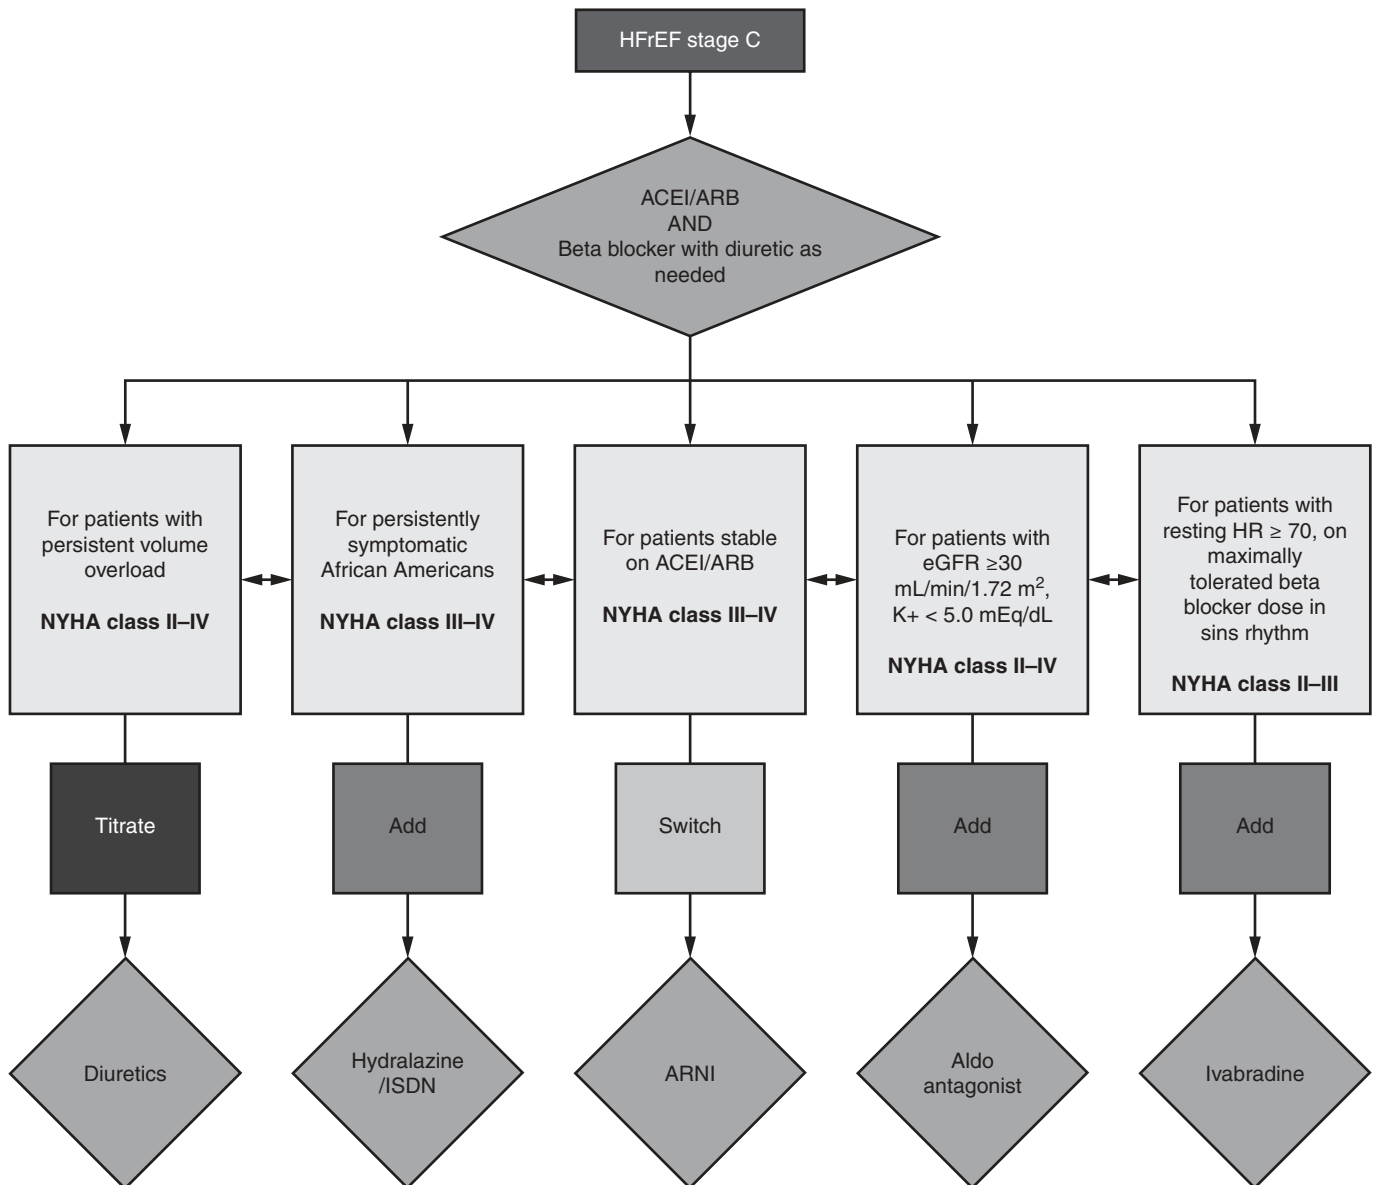

**TABLE 5** Acute Decompensated HF Therapies Based on the Hemodynamic Profile

	NORMAL LVEDP	ELEVATED LVEDP
Normal CO	A “warm and dry” GDMT	B “warm and wet” IV diuretic GDMT
Decreased CO	L “lethal, cold, and dry” Cardiac replacement therapy (circulatory assist devices, cardiac transplant) Palliative care	C “cold and wet” IV inotropes IV diuretics

GDMT, Guideline-Directed Medical Therapy.

### Therapy for HFpEF

HFpEF is a complex heterogeneous disease where the mortality and morbidity parallel that of HFrEF. Drug therapies have

**Figure 3** GDMT treatment algorithm for HFrEF stage C. Adapted from 2017 ACC Expert Consensus Decision Pathway for Optimization of Heart Failure Treatment: Answers to 10 Pivotal Issues About Heart Failure With Reduced Ejection Fraction: A Report of the American College of Cardiology Task Force on Expert Consensus Decision Pathways.

**TABLE 6** I-NEED-HELP: Identifying Patients Needing Referral to an HF Specialist or an Advanced Therapy

I	Intravenous inotropes
N	New York Heart Association (NYHA) class IIIB/IV or persistently elevated Natriuretic peptides
E	End organ dysfunction
E	EF $\leq$ 35%
D	Defibrillator shocks
H	Hospitalizations $\geq$ 2
E	Edema despite escalating diuretics
L	Low systolic blood pressure ( $\leq$ 90), tachycardia
P	Prognostic medications; Progressive intolerance or down-titration of guideline-directed medical therapy

From Maddox, Thomas. M., et al. 2021 "Update to the 2017 ACC Expert Consensus Decision Pathway for Optimization of Heart Failure Treatment: Answers to 10 Pivotal Issues About Heart Failure With Reduced Ejection Fraction." *Journal of the American College of Cardiology* 77.6 (2021): 772-810.

fallen short in being able to significantly impact this disease. A few medical therapies can have impact on this disease including diuretics, which are the mainstay of therapy in relieving congestion; aldosterone antagonists have potential benefit by decreasing hospitalizations, and exercise training can be used to improve symptoms. Treatment of coexisting diseases that drive HFpEF are equally important in the management. This includes addressing coexisting systemic diseases including hypertension, diabetes, obesity, sleep apnea, ischemic heart disease, and chronic kidney disease.

### Advanced Heart Failure

Stage D HF or advanced HF are those patients with symptoms at rest or with minimal exertion, recurrent hospitalizations, or refractory symptoms despite appropriate medical therapy. An important key factor in HF management is early identification of high-risk patients for consideration of advanced HF therapies. Early referral to a HF specialist or HF program is key and needs to be considered especially when there is a new onset of HF with unclear etiology, needing assistance with GDMT management, comorbid conditions that increase complexity of management, a persistent reduced LV function despite GDMT, needing referrals for possible device therapies, or having high-risk features (Table 6). These situations could potentially have a significant benefit from an HF specialist consultation. Using the acronym I NEED HELP (see Table 6) is helpful in identifying those potentially needing consideration for referral to an HF specialist for advanced therapies including transplant and mechanical circulatory support (MCS).

## HEART BLOCK

Method of

Kelley P. Anderson, MD

### CURRENT DIAGNOSIS

- Assess risk for heart block in the absence of symptoms or heart block on electrocardiogram (ECG).
- Review cardiac or systemic disorders associated with cardiac conduction disease (CCD), ECG pattern, family history, maternal antibodies, cardiac interventions, and surgery.
- Evaluate documented asystole or bradycardia due to heart block.
  - Classify heart block: transient, recurrent, progressive, permanent.
  - Grade signs and symptoms: none, mild, severe.
- Evaluate signs or symptoms of possible transient heart block with no documentation.
  - Establish temporal pattern: recent versus remote onset, solitary versus recurrent, daily, weekly, monthly, yearly.
  - Grade signs and symptoms: none, mild, severe.
  - Document rhythm during symptoms: telemetry monitoring, Holter monitor, external loop recorder, implantable recorder.

## CURRENT THERAPY

- Methods of heart rate support:
  - Immediate: intravenous catecholamines, atropine, or aminophylline<sup>1</sup>; transcutaneous pacing
  - Short term: transvenous temporary pacing
  - Long term: permanent pacemakers
- Pacemaker configuration:
  - Number of leads: 1, 2, 3, 4
  - Lead locations: right atrial appendage, Bachman's bundle, right ventricular apex, outflow tract, left ventricle, coronary sinus
  - Programming to minimize ventricular pacing: manufacturer dependent

<sup>1</sup>Not FDA approved for this indication.

Heart block refers to block or delay of electrical propagation between the atria and ventricles. It is a form of cardiac conduction disease (CCD), which applies more generally to disorders of electrical impulse formation or propagation anywhere along the cardiac conduction system from the sinus node to the ventricular myocardium. Heart block or CCD may present as a syndrome, as an electrocardiographic (ECG) pattern, or as a mechanism of serious signs and symptoms such as sudden death or syncope. Pacemaker therapy is an effective treatment, but it is associated with significant short- and long-term complications. This underscores the importance of recognizing preventable and reversible causes of heart block for accurate targeting of permanent pacing. Risk stratification of patients with heart block, assessment of the benefits and risks of the therapeutic options, and patient education and guidance are largely in the domain of heart rhythm specialists. However, heart block may be encountered unexpectedly in any patient during any clinical encounter. Furthermore, some patients may require evaluation in the absence of known cardiac disease because of increased risk of CCD, or increased risk of CCD in family members or future children. A basic understanding of heart block may be useful to initiate emergency treatment and to recognize patients who warrant further evaluation or specialist referral.

### Epidemiology

The prevalence and incidence of heart block are difficult to establish because they are strongly dependent on the demographic and clinical characteristics of the population sample. The prevalence is higher among the elderly and those with cardiovascular disease. First-degree heart block, defined as prolongation of the PR interval >200 ms on ECG, occurs in the population setting with prevalence of 0.7% to 2% in the young and up to 14% in the elderly. Higher degrees of heart block can be expected to be less common but similarly associated with age and underlying cardiovascular disease. In a study of the Framingham population, the prevalence of first-degree heart block was 1.6% and was associated with an incidence of pacemaker implantation of 59 per 10,000 person-years in persons with a PR interval >200 ms compared to 6 per 10,000 person-years in persons with a PR interval <200 ms. Approximately 36% of the pacemakers were for high-grade atrioventricular (AV) block.

### Risk Factors

Patients with genetic or acquired CCD and patients subject to trauma or surgical procedures that can damage the conduction system are at increased risk for developing symptomatic advanced heart block. In the Framingham population, subjects with first-degree AV block had an increased risk of mortality, atrial fibrillation, and pacemaker implantation. However, the vast majority with risk factors never develop symptomatic heart block and have not been shown to benefit from intense monitoring or prophylactic pacemaker placement. The few possible exceptions are discussed below.

**TABLE 1** Mechanisms of Conduction Disturbances (Examples)

- Prolonged refractory period (vagal activity, drugs, ischemia)
- Sarcolemmal ion gradient disturbances (hyperkalemia, hypokalemia)
- Sodium channel dysfunction (SCN5A mutations, sodium channel blocking drugs such as lidocaine, procainamide, flecainide [Tambacor], amiodarone [Cordarone], and imipramine [Tofranil])
- Calcium channel dysfunction (verapamil [Isoptin], diltiazem [Cardizem], mutations)
- Energy deprivation (ischemia, cyanide)
- Cell dysfunction (inflammation, barotrauma, thermal injury)
- Cell death (apoptosis, ischemic necrosis, inflammatory necrosis, surgical trauma, ablation)
- Congenital structural defects (endocardial cushion defects)
- Gap junction disturbances (fibrosis, edema, inflammation, genetic defects)
- Genetic defects (SCN5A and NKX2.5 mutations)

### Pathophysiology

The function of the cardiac conduction system is to initiate and coordinate cardiac contraction to circulate blood according to physiological needs. Electrical activation is initiated by pacemaker cells of the sinus node regulated by the autonomic nervous system. Unlike conduction in common electrical circuits in which electrons flow along a conductor according to the voltage gradient, electrical activity in cardiac cells propagates from segment to segment of the cell membrane in cardiac myocytes (myocardial cells) and in specialized cardiac conduction cells. Energy-requiring ion pumps maintain an electrochemical gradient across the insulating cell membrane. Electrical activity opens voltage-sensitive ion channels causing regenerative electrical activity as ions shift along their electrochemical gradient. Electrical activity in a single cell excites several adjacent cells via gap junctions. This cascade effect makes it possible for a single cell impulse to spread rapidly throughout the myocardium to enhance synchronous contraction. This also provides a safety mechanism in that each myocardial cell can be activated by many electrical paths. In addition, specialized conduction cells exhibit automaticity (impulse formation). Although normally latent because normal activation inhibits spontaneous discharge, when the normal impulse is blocked, discharges from these subsidiary physiological pacemakers provide vital heart rate support.

Block of electrical activation can occur due to failure of any step in the process, for example, lack of metabolic energy, electrolyte imbalance, inflammatory disruption of the membrane, block of ion channels by drugs, or interference with gap junction function due to infiltration of fibrous tissue (Table 1). Because of the extensive redundancy and interconnectivity and because of the capacity to compensate for injury by electrical and anatomic remodeling, there may be extensive damage before signs or symptoms of heart block occur. Regions of the heart where there are fewer alternative paths for electrical activation, such as proximal portions of the His-Purkinje system where all conducting fibers are confined to a relatively small area, are more vulnerable to complete block. Subsidiary pacemakers sometimes fail to provide adequate rate support when heart block occurs because of pre-existing injury. If the patient survives an episode of heart block, there is a possibility for recovery due to remodeling. However, remodeling can be maladaptive and result in an adverse long-term outcome by further conduction system damage, by left ventricular dysfunction, and by bradycardia-induced ventricular tachyarrhythmias (VTAs). The mechanisms of bradycardia-induced VTAs are not known, but bradyarrhythmias precipitate torsades de pointes, a specific form of VTA, in the presence of drugs that block potassium channels, electrolyte disturbances, certain genetic abnormalities of ion channel function, heart failure, and

**TABLE 2** Etiologies of Heart Block

- Frequently permanent or progressive (examples)
  - Alcohol septal ablation (acute, delayed)
  - Cardiomyopathies (hypertrophic, idiopathic, mitochondrial)
  - Catheter ablation (atrioventricular nodal reentry, accessory atrioventricular connections)
  - Congenital heart block (neonatal lupus)
  - Congenital heart disease (endocardial cushion defects)
  - Genetic disorders (SCN5A sodium channel mutations, gap junction gene mutations, fatty acid oxidation disorders, PRKAG2 mutations, LMNA gene mutations)
  - Hypertension
  - Idiopathic fibrosis and calcification (Lev's disease, Lenegre's disease)
  - Infectious disorders—destructive (endocarditis)
  - Infiltrative disorders (amyloidosis)
  - Myocardial infarction
  - Neuromyopathic disorders (myotonic dystrophy, Erb's dystrophy, peroneal muscular atrophy)
  - Noninfectious inflammatory disorders (HLA-B27–associated disorder, sarcoidosis)
  - Tumors (mesothelioma, metastatic cancer)
  - Valvular heart disease
- Frequently transient or reversible (examples)
  - Blunt trauma (baseball)
  - Cardiac surgery (valve replacement)
  - Cardiac transplant rejection
  - Central nervous system
  - Drugs (antiarrhythmics, digoxin [Lanoxin], edrophonium [Enlon])
  - Electrolyte disturbances (hyperkalemia)
  - Metabolic disturbances (hypothermia, hypothyroidism)
  - Increased vagal activity
  - Infectious disorders—nondestructive (Lyme disease)
  - Myocardial ischemia
  - Myocarditis (Chagas disease, giant cell myocarditis)
  - Rheumatic fever

myocardial hypertrophy. A comprehensive list of drugs that may account for bradyarrhythmia-related ventricular arrhythmias is available at [www.torsades.org](http://www.torsades.org).

Although there are many potential causes of heart block, the pathophysiology is not known for the vast majority of cases because there are no tests that allow detailed structural or functional examination in patients. By the time of death, morphologic examination may reveal only nonspecific changes such as fibrosis. Instead, most etiologies are inferred by history of recent or past exposures (e.g., trauma or radiation), concomitant disorders (e.g., muscular dystrophy, cardiac sarcoidosis), abnormal test results (e.g., Lyme disease) or family history (e.g., SCN5A sodium channel mutations) (Table 2). Because most etiologies cannot be verified, the clinician must remain open to alternative explanations and accept the likelihood of multiple contributors.

Some patients, usually young, otherwise healthy individuals, present with prolonged asystole due to heart block but have no other detectable abnormalities and have excellent outcomes in the absence of intervention beyond counseling. This suggests that autonomic influences alone can cause prolonged heart block and suppression of subsidiary pacemakers. It is not known whether such responses result from an abnormality or an exaggerated normal reflex. However, the identification of such patients is important because most can be managed without pacemakers.

### Prevention

Prevention of heart block is a challenge for the future. Some instances can be prevented by treatment of inflammatory disorders that cause heart block, such as Lyme disease or cardiac sarcoid. Other individuals who should be identified are those with conditions that place them, their relatives, or their unborn children at risk for heart block. This includes patients and family members with genetic disorders associated with heart block. Genetic testing and counseling may be appropriate in some patients with a

family history of CCD. Neonatal lupus syndrome is a rare disorder with a high mortality rate and risk of permanent complete heart block in survivors. This occurs in pregnant women with anti-Ro/SSA or anti-La/SSB antibodies. Some such women have autoimmune disorders such as systemic lupus erythematosus and Sjögren's syndrome, but many are symptom free. Members of this group may benefit from counseling and anticipatory evaluation and treatment of offspring. Although controversial, fetal monitoring of pregnant women with anti-Ro/SSA and/or anti-La/SSB antibodies and treatment of those with signs of fetal conduction system involvement have been recommended. It should be recognized that with current methods the vast majority of heart block events cannot be predicted or prevented, and the vast majority of persons with risk factors never develop symptomatic heart block.

### Clinical Manifestations

Most of the symptoms experienced by patients with heart block are common and nonspecific, including syncope, lightheadedness, fatigue, and dyspnea. Asystole or profound bradycardia may cause syncope, death, or other manifestations of hypoperfusion. Rarely, first-degree AV block results in significant symptoms (e.g., fatigue, palpitations, chest fullness), probably due to atrial contraction against a partially closed mitral valve.

### Diagnosis

Because various arrhythmias and other cardiac and noncardiac disorders may be responsible for similar symptoms, it is important to identify the cause. An ECG recording of asystole or bradycardia due to heart block at the time of symptoms strongly suggests a causal relationship, but this is usually difficult to accomplish because the symptoms are often transient and infrequent. Absence of arrhythmias at the time of symptoms is also helpful in excluding heart block as the cause. Asymptomatic heart block is not infrequent. Cardiac conduction disturbances are classified by the pattern of ECG complexes. A normal 12-lead ECG lessens the probability of conduction disturbances due to structural changes but it does not eliminate the possibility of transient third-degree block due to reversible functional effects such as intense vagal activity or ischemia. Significant disease of the His bundle may be electrocardiographically silent, but more often concomitant distal disease is evident in the form of fascicular or bundle branch block or a nonspecific intraventricular conduction delay. In a patient with syncope, the presence of bifascicular block raises the possibility of transient third-degree block as the mechanism and of progression to permanent complete block. Most patients with conduction disorders are not symptomatic and do not progress to complete block. However, the combination of right bundle branch block (RBBB) and left posterior fascicle block has a greater tendency to progress to complete block than the more common RBBB and left anterior fascicle block. Nevertheless, conduction disturbances of the His-Purkinje system should not be assumed to be responsible for syncope or cardiac arrest because they are relatively common in patients with cardiovascular disorders that cause syncope or cardiac arrest due to other mechanisms. Conduction disturbances can cause dyssynchronous contraction and result in adverse remodeling. In addition, they can mask or mimic the ECG signs of myocardial infarction. Alternating bundle branch block refers to a changing ECG pattern in which both RBBB and left bundle branch block are observed or when the bifascicular block pattern switches between the anterior and posterior fascicle involvement. This pattern is considered a harbinger of complete block and warrants continuous monitoring and evaluation for permanent pacemaker implantation.

### Differential Diagnosis

The challenge in second- and transient third-degree AV block is distinguishing between block in the AV node, which is often functional and reversible, and infranodal block, which often progresses to permanent complete heart block. ECG clues that block is in the AV node include normal QRS duration (<100 ms), type I

(Wenckebach) pattern, PR prolongation before blocked impulses and PR shortening after pauses, occurrence during enhanced vagal activity (e.g., sleep), narrow QRS escape complexes, and no factors favoring infranodal block. ECG clues for infranodal block include prolonged QRS duration ( $\geq 120$  ms), type II pattern, and escape QRS complexes broader than intrinsic complexes. Type II second-degree AV block is almost always due to block in the His-Purkinje system. Other second-degree AV block ECG patterns have poor sensitivity and specificity for site of block.

Unsustained polymorphic ventricular tachycardia is an ominous sign in any context and may result from a variety of cardiac, metabolic, and autonomic abnormalities. However, in the presence of heart block it suggests that heart rate support may be necessary to prevent sustained VTA. QT prolongation and post-pause U-wave accentuation should be sought as other harbingers of bradycardia-related VTA.

The importance and value of ECG documentation of heart block cannot be overemphasized. ECGs are subject to artifact and may be misleading when standards for acquisition and analysis are not followed. Multiple tracings of suspicious events should be obtained in multiple leads when possible. A 12-lead simultaneous rhythm recording mode is available on most modern ECG machines and should be used when continuous recordings are obtained to document arrhythmias.

Clinicians encounter heart block in three general contexts. For the patient with documented heart block, the clinician selects therapy based, in part, on whether the arrhythmia is permanent or likely to recur. There are currently no tests that provide direct information about the pathologic state of the AV conduction system. Instead, these outcomes must be inferred from functional assessment, that is, from the ECG or electrophysiological testing. Other indirect sources such as coronary angiography, magnetic resonance imaging, nuclear imaging, and myocardial biopsy, as well as a large number of specific laboratory tests, are often helpful for identifying disorders that may be causative or associated with heart block and that may affect the choice of treatment.

Another common context is the patient with symptoms for whom the objective is to verify or exclude heart block as the mechanism by correlating the cardiac rhythm with symptoms. Real-time monitoring (e.g., in-patient telemetry) is used for patients who might require immediate access to drugs or pacing devices to prevent or terminate asystole or bradycardia-dependent VTA. Holter monitoring is useful for patients who have very frequent events (at least 1 every 24 hours), and they are useful for capturing asymptomatic rhythm disturbances. External recorders are applied for a month or longer and are very helpful to associate rhythm abnormalities with symptoms and to rule out a rhythm disorder as the cause of symptoms in patients with at least one event per month. Patients with infrequent events may be candidates for implantable loop recorders, which monitor for greater than a year. Modern monitors will provide a permanent record of arrhythmias on activation by the patient or by a detection algorithm.

Electrophysiological studies allow precise measurements of AV node and His-Purkinje system function and can provide definitive information regarding the site of block if the conduction disturbance occurs during the study. Additional tests have been developed that “stress” the AV conduction system, including rapid atrial and ventricular pacing and administration of drugs such as procainamide and disopyramide (Norpace). The provocation of heart block is assumed to indicate a propensity for spontaneous AV block. Unfortunately, the sensitivity is low and a negative test does not imply a low risk of future episodes. Electrophysiological studies have the additional advantage of providing immediate test results, as well as providing the results of programmed stimulation for provocation of supraventricular and VTAs, which may be included in the differential diagnosis.

## Therapy

The object of the evaluation and management for heart block is to prevent death and morbidity by (1) heart rate support in

patients with poorly tolerated bradycardia; (2) monitoring and standby heart rate support in patients at high risk for asystole or severe bradycardia; (3) identifying and treating reversible causes of heart block; (4) identifying patients at high risk for sudden death, syncope, or recurrent symptoms; and (5) selecting and implanting the appropriate rate support system as soon as safety permits.

Advanced cardiac life-support guidelines apply to the patient who is unresponsive or severely compromised by heart block. However, heart block is rarely the primary problem. Therefore evaluation and treatment of other disorders should continue while efforts to obtain the appropriate heart rate are underway.

The initial evaluation should include a detailed history and physical examination and review of current and previous ECGs and rhythm strips to determine whether heart block is present or occurred in the past and whether there were symptoms or other evidence of hemodynamic compromise. Basic laboratory tests (electrolytes, metabolic panel, cardiac biomarkers, thyroid function, blood count, and coagulation studies) and basic imaging (chest x-ray and echocardiography) are usually appropriate. The patient should then be stratified for the appropriate level of care: (1) the unstable patient who requires ongoing evaluation and treatment in an intensive care setting, (2) the stable patient at high risk for asystole or complications who needs temporary transvenous pacing or other invasive procedures, (3) the patient at moderate risk who requires continuous monitoring and standby noninvasive heart rate support measures, (4) the patient at low risk who requires rapid but not immediate access to heart rate support measures that hospital monitoring provides, and (5) the patient at low risk who can be evaluated and managed as an outpatient. Additional testing and procedures may be necessary to determine the etiology of heart block and to determine whether there is a significant risk of future adverse events.

Determination of the need for long-term heart rate support, as well as other issues that may affect implantable device selection (e.g., risk for VTAs), should be accomplished as soon as possible because the risk of complications and anxiety associated with temporary heart rate support measures increases over time. Major societies have developed guidelines for implantable rhythm management devices (<http://www.cardiosource.org/Science-And-Quality/Practice-Guidelines-and-Quality-Standards.aspx>; <http://www.escardio.org/guidelines-surveys/esc-guidelines/Pages/GuidelinesList.aspx>). The reasons for the selected therapy, including the rationale for any deviation from established guidelines, should be documented and provided to the patient. This will reduce future confusion or misunderstanding about the original rationale for implantation that can affect management of patients with device complications, recalls (safety alerts), and those with a compelling need for device upgrade or explantation.

Patients with acute coronary syndromes require special consideration. The incidence of heart block in patients with myocardial infarction based on creatine phosphokinase as the marker of necrosis is approximately 10%. Although the incidence is probably lower using more sensitive markers such as troponin, heart block is still likely to be associated with increased in-hospital mortality due to larger infarct size. Tachycardia and high blood pressure increase myocardial oxygen consumption. Therefore overcorrection of heart rate and blood pressure should be avoided and ischemia should be relieved by reperfusion as soon as possible. Studies in the prethrombolytic era did not demonstrate a benefit in mortality with prophylactic temporary transvenous pacing, and complications were frequent. The risks of transvenous insertion may be higher in patients requiring administration of thrombolytics and other anticoagulants. Catheter-based revascularization methods should be given strong consideration because of established effectiveness, the possible avoidance of thrombolytic drugs, and because transvenous temporary pacing, if needed, is readily and safely accomplished during the procedure. Suggestions for standby temporary pacing (Table 3) should take into consideration the risks of transvenous pacing based on

**TABLE 3** Suggestions for Temporary Pacing in Acute Myocardial Infarction

- Transvenous pacing
  - Asystole or poorly tolerated bradycardia unresponsive to atropine or aminophylline
  - Persistent third-degree AV block
  - Alternating RBBB and LBBB, or RBBB and alternating LAFB and LPFB
  - Bifascicular block, new
  - Second-degree AV block (any type) and QRS >110ms
  - Any indication listed below at time of cardiac catheterization if performed
- Standby transcutaneous pacing
  - Any indication listed above until transvenous pacing system inserted
  - Transient asystole or poorly tolerated bradycardia
  - Bifascicular block, uncertain time of onset, or old
  - Second-degree AV block (any type) and QRS <110ms
  - New first-degree AV block

Abbreviations: AV = atrioventricular; LAFB, LPFB=left anterior, left posterior fascicle block; LBBB, RBBB=left, right bundle branch block.

local circumstances (experience, fluoroscopic guidance, insertion site, use of anticoagulants, etc.). Most conduction disturbances associated with myocardial ischemia or infarction resolve quickly but can persist for days or weeks. The need for permanent pacemaker implantation as a consequence of myocardial infarction is rare, and prophylactic pacemaker implantation in high-risk subsets has not been shown to reduce mortality. Guidelines for temporary and permanent pacing in acute myocardial infarction have been published (<http://www.cardiosource.org/Science-And-Quality-Practice-Guidelines-and-Quality-Standards.aspx>; <http://www.escardio.org/guidelines-surveys/esc-guidelines/Pages/GuidelinesList.aspx>).

Selection of the correct therapeutic approach balances the risks and benefits of therapy against the risks of heart block for both immediate and long-term management. Catecholamines (dobutamine, dopamine, epinephrine, isoproterenol [Isuprel]) are useful for emergency, temporary, and standby heart rate support. The standby mode is accomplished by a prepared infusion at the bedside. To avoid underdoses or overdoses at the time of sudden symptomatic heart block, the optimal dose can be established in advance by test doses starting at low infusion rates. Atropine (0.5 mg every 3–5 minutes, with a maximum dose of 0.04 mg/kg or total of 3 mg) may be useful for treatment or pre-treatment of patients who develop heart block at the level of the AV node in the context of elevated vagal tone (e.g., in association with nausea or endotracheal tube suction). Atropine should be avoided in patients with infranodal AV block because prolonged asystole sometimes occurs due to more frequent His-Purkinje system depolarization from increased sinus rate. Vagal activity inhibits sympathetic activity; therefore, reduction of vagal tone by atropine disinhibits sympathetic activity and may account for the unpredictable effects of atropine on heart rate. Elevations in heart rate after atropine can persist for hours and cannot be readily reversed. Aminophylline<sup>1</sup> (2.5–6.3 mg/kg IV) is reported to reverse heart block resistant to atropine and epinephrine by antagonizing adenosine. Stimulation of  $\beta$ -adrenergic receptors increases sinus node and subsidiary pacemaker rates, AV node and His-Purkinje system conduction velocities, and myocardial contractility. The effective refractory period shortens in most tissue but this effect varies with dose and specific tissue type. Dobutamine<sup>1</sup> (2–40  $\mu$ g/kg/min) is a useful  $\beta$ -receptor agonist because it increases cardiac output and lowers filling pressures without excessive rise or fall of blood pressure. Dopamine<sup>1</sup> (2–20  $\mu$ g/kg/

min IV) stimulates  $\beta_1$ -adrenergic receptors and increases heart rate by enhancing impulse formation and conduction, as well as myocardial contractility. At higher doses (10–20  $\mu$ g/kg/min) dopamine causes vasoconstriction by  $\alpha_1$ -receptor stimulation. Isoproterenol (0.02–0.06 mg IV bolus, 0.5–10.0  $\mu$ g/min IV infusion) stimulates  $\beta_1$ - and  $\beta_2$ -adrenergic receptors and enhances vasodilation more than the other catecholamines. This can result in unwanted hypotension in some circumstances but it is also less likely to cause a reflex increase in vagal tone than drugs that cause vasoconstriction. Epinephrine (1 mg IV boluses for cardiac arrest, 0.2–1 mg subcutaneously, 0.5–10  $\mu$ g/min IV) stimulates both  $\alpha$ - and  $\beta$ -adrenergic receptors. It is recommended for asystolic cardiac arrest in part because it increases myocardial and cerebral flow. However, the increase of systemic vascular resistance may be detrimental by augmenting metabolic acidosis and decreasing cardiac performance in patients with poor left ventricular function. The suggested dose ranges are broad because the response to  $\beta$ -adrenergic stimulants such as improved AV conduction varies widely and may be affected by  $\beta$ -adrenergic receptor down-regulation in patients with chronic elevations in sympathetic activity such as patients with long-standing heart failure.

Temporary pacing includes primarily transcutaneous and transvenous approaches. Transthoracic, transesophageal, and transgastric approaches are rarely used. Transcutaneous pacing provides noninvasive heart rate support, as well as immediate access to countershock, but it is often so painful that most patients require sedation. For these reasons its principal uses are for short-term pacing during cardiopulmonary resuscitation and standby pacing in patients at risk for bradyarrhythmias. Capture is not achieved in some patients. Therefore users should be ready to continue mechanical cardiopulmonary support and seek alternative methods. If used in standby applications, ventricular capture should be verified in advance. Capture is often difficult to ascertain because transcutaneous stimuli cause large deflections on the ECG, and pectoral muscle stimulation can be confused with a pulse. Capture should be verified by careful ECG analysis at subthreshold and suprathreshold stimulus amplitudes and confirmed by appropriately timed femoral artery pulses, Korotkoff sounds, or arterial pressure waveforms.

Transvenous insertion of an electrode catheter is the method of choice for most patients who require temporary pacing. This approach is reliable and safe when performed by competent staff with strict aseptic technique, fluoroscopic guidance, and appropriate catheters. Small studies suggest that long-term (>5 days) temporary pacing can be accomplished with active-fixation permanent pacemaker leads attached to an external pulse generator (not approved by the US Food and Drug Administration [FDA]). Tunneling the lead may enhance stability and reduce the risk of infection.

### Monitoring

Patients with high-grade or symptomatic heart block require close monitoring until the process is reversed by treatment or a pacemaker is implanted. All patients who receive pacemakers require lifelong follow-up by a trained team of physicians, nurses, and ancillary personnel using standard procedures guided by practice guidelines and manufacturer recommendations.

### Complications

Catecholamines used to increase heart rate may precipitate tachyarrhythmias by electrophysiological effects mediated by adrenergic receptors or by myocardial ischemia, and they may worsen hemodynamic status. The adverse effects of catecholamines increase with duration of exposure. Ischemia and receptor-mediated electrophysiologic effects occur immediately after administration; changes in gene expression of ion channels begin as early as several hours; and long-term changes such as myocardial hypertrophy, apoptosis, and fibrosis occur

<sup>1</sup>Not FDA approved for this indication.

within 24 hours and may progress over much longer periods. This suggests that the duration and dose of catecholamine infusions should be minimized. Complications of temporary transvenous pacing include inadequate pacing or sensing thresholds, vascular complications, pneumothorax, myocardial perforation, infection, and dislodgment. Permanent pacemakers are highly effective, safe, and cost-effective with few contraindications. Although the complications are rarely life threatening, they should be carefully considered and acknowledged. Septicemia or endocarditis has been reported in 0.5% of patients. In patients with pacemaker-related endocarditis, the in-hospital mortality rate is reported to be over 7% with a 20-month mortality rate over 25%. The rate of significant complications has been reported to be 3.5%. About 10% of pacemakers will become infected or develop some other type of failure that may require extraction. In a recent series the rate of major complications associated with extraction was 1.4%. There is a long-term continuous risk of infection, thrombosis, and erosion. In young persons there is a periodic need to replace generators and leads. Abandoned leads block venous access and extractions are associated with significant risks. Perhaps of greater consequence is the constant inconvenience of lifelong follow-up, electromagnetic interference, and false alarms from electronic surveillance devices, as well as exclusion from important procedures, such as magnetic resonance imaging of the thorax. Conventional pacing, that is, from the right ventricular apex, is now known to be detrimental and may cause adverse ventricular remodeling, atrial fibrillation, heart failure, and premature death. Although it has been shown that patients with reduced left ventricular function are at greater risk for adverse effects, it is not known how to identify other patients at risk. Strategies for reducing the adverse effects of conventional pacing are under study, and recommendations are evolving. Because the decision for pacemaker implantation includes selection of lead configuration, lead locations, and pacing mode, patient guidance and education are complex.

## Conclusions

Heart block remains a challenge because the cellular mechanisms responsible are poorly understood, prediction of symptomatic heart block (who and when) is unreliable, treatments that restore normal conduction do not exist for most conditions, and pacemaker therapy can have significant long-term adverse consequences. Fortunately, current devices and leads are much more reliable than in the past, and remote monitoring has enhanced early detection of problems and has substantially reduced the inconvenience of device monitoring. The newest generation of devices will allow many patients with pacemakers to safely undergo magnetic resonance imaging. Ongoing clinical trials will provide guidance in pacemaker configurations and programming that will minimize adverse effects. In the future, achievements in molecular biology will elucidate mechanisms and produce treatments that will relegate artificial pacemakers to museum pieces.

## HYPERTENSION

Method of

Timothy P. Graham, MD

### CURRENT DIAGNOSIS

- Screening should begin at 18 years of age for the general population per U.S. Preventive Services Task Force (USPSTF) recommendations. The screening interval for those 18 to 39 years of age without other risk factors is every 3 to 5 years. For those older than 40 years of age or those with risk factors, annual screening is recommended.
- Stage 1 hypertension is established at blood pressures of 140 mm Hg systolic and 90 mm Hg diastolic if measured in the office, but 135 mm Hg systolic and 85 mm Hg diastolic if based on ambulatory monitoring per Eighth Joint National Committee (JNC 8) and International Society of Hypertension (ISH) guidelines. The AHA/ACC defines stage I hypertension as at or above 130 mm Hg systolic and at or above 80 mm Hg diastolic.
- Stage 2 hypertension is established at blood pressures of 160 mm Hg systolic and 100 mm Hg diastolic per JNC 8 and ISH guidelines. The American College of Cardiology/American Heart Association (ACC/AHA) defines stage 2 hypertension as at or above 140 mm Hg systolic and at or above 90 diastolic.
- Secondary causes of hypertension should be explored and identified to optimize treatment when there is suboptimal response to treatment, worsening hypertension control, no family history of hypertension, onset of hypertension in patients less than 20 years or older than 50 years.

### CURRENT THERAPY

- Initial interventions, regardless of stage, should include lifestyle modifications, including low-sodium diet and exercise.
- Optimal pharmacologic therapy should be tailored to account for age, race, and the presence or absence of chronic kidney disease.
- For individuals 60 years of age and older, consider initiation of pharmacotherapy when systolic blood pressure is 150 mm Hg and diastolic blood pressure is 90 mm Hg.
- For individuals younger than 60 years of age but at least 18 years of age, pharmacotherapy should be initiated when systolic blood pressure is 140 mm Hg and diastolic blood pressure is 90 mm Hg.
- First-line agents for nonblack individuals should include thiazide-type diuretics, calcium channel blockers, angiotensin-converting enzyme inhibitors (ACEIs), or angiotensin receptor blockers (ARBs).
- First-line agents for black individuals should include thiazide-type diuretics or calcium channel blockers.
- Individuals with chronic kidney disease should have therapy that includes ACEIs or ARBs.

### Epidemiology

Hypertension is one of the most common conditions encountered in primary care offices. According to the AHA/ACC definition of hypertension, hypertension affects 47% of adults in the United States, which represents approximately 116 million people ([cdc.gov](http://cdc.gov)). The most commonly affected individuals are black adults, with approximately 56% affected.

In the pediatric population, the prevalence of hypertension in the United States is approximately 2.6% (representing nearly 800,000 children), with nearly one-half of this number being classified as obese (body mass index [BMI] >95%).

## Risk Factors

### Diet and Sodium Intake

Diet is a clear target for nonpharmacologic management of hypertension. Diets that are high in sodium and fat can put individuals at risk for suboptimal blood pressure control. Limiting sodium to less than 2400 mg per day confers some health benefit to individuals at risk for hypertension. Limiting sodium even further to 1500 mg or less is more ideal and typically results in a significant improvement in both systolic and diastolic blood pressure. Additionally, putting limits on the consumption of sweets, red meat, and soda as well as other sugar-sweetened beverages can help weight reduction and overall health.

### Sedentary Lifestyle and Obesity

Lack of physical activity is another important risk factor contributing to poor overall health and obesity. Current recommendations endorse engaging in at least 150 minutes of moderate-intensity activity per week. If patients are unable or unwilling to commit to that level of physical activity, then encouraging any physical activity is prudent, as it will convey at least some health benefit. Participation in physical activity results in absolute reduction in chronic comorbidities including hypertension, stroke, heart disease, diabetes, and metabolic syndrome. Resultant weight loss also results in significant improvement in blood pressure. It is noted that a weight loss of 22 pounds has the potential to reduce systolic blood pressure by 5 to 20 mm Hg.

For children and adolescents, elevated BMI is the greatest risk factor for the development of hypertension.

### Alcohol Intake

Although moderate alcohol intake is thought to actually reduce cardiovascular risk, heavier consumption is a risk factor for hypertension. Limiting alcohol intake to no more than two drinks per day (with a *drink* defined as 12 oz. of beer, 5 oz. of wine, or 1 oz. of liquor) for men and no more than one drink per day for women (or lightweight men) is beneficial for overall health.

### Smoking

Along with the myriad other reasons that tobacco smoking is not a good choice (e.g., cancer risk, chronic obstructive pulmonary disease, stroke, coronary artery disease), it is also a risk factor for hypertension. This is believed to be at least in part caused by a resultant increase in sympathetic nervous system activity, which leads to an increase in myocardial oxygen demand. Additionally, smoking is the leading modifiable cause of death in the United States.

Of note, the use of marijuana results in an increased risk of hypertension-related death. The magnitude of this increase is estimated to be 3.42-fold higher in marijuana users than in nonusers. Risk also further increases with each year of use.

### Sleep Apnea

Obstructive sleep apnea is a well-known secondary cause of and independent risk factor for hypertension. Statistically, at least one-half of individuals with sleep apnea also have hypertension.

### Age

Age is a nonmodifiable risk factor for cardiovascular disease. Risk is higher in men 55 years of age or older and women 65 years of age or older.

### Gender

Gender is another nonmodifiable risk factor. Men are at greater risk for hypertension before 45 years of age. After 45 years of age and until 64 years of age, the risk for men and women is approximately equivalent. At 65 years of age and older, women have a higher hypertensive risk than men.

### Race

Black individuals have a prevalence of hypertension than nonblack individuals. Statistics from 2019 demonstrated

that approximately 56.8% of black men and 57.6% of black women have hypertension compared with approximately 52.7% of white men and 45.4% of white women. Asians had a lower prevalence, at approximately 49.4% of men and 43.6% of women. Hispanic/Latino individuals had an even lower prevalence than white individuals at 46% of men and 35.4% of women.

### Family History

Family history is another nonmodifiable risk factor for cardiovascular disease. Individuals with family history of premature cardiovascular disease (men younger than 45 years of age and women younger than 55 years of age) are at increased risk themselves.

### Pathophysiology

The pathophysiology of hypertension is a matter of debate. *Essential hypertension*, which is defined as hypertension without a clear secondary cause, makes up the majority of cases. Two primary mechanisms have been proposed for essential hypertension: neurogenic and renogenic (or nephrogenic). The neurogenic model suggests that hypertension is the result of a chronic increase in sympathetic nervous system activity. This is in contrast with the renogenic model, which attributes blood pressure increase to renal origins either through decreased renal blood flow or through renal parenchymal disease.

### Prevention

Prevention of hypertension involves optimization of modifiable risk factors. Maintaining a healthy body weight, avoiding smoking, and moderating alcohol use are all key factors in minimizing risk. Additionally, engaging in regular, moderate-intensity cardiovascular exercise and eating a healthy diet without excessive sodium or fat can help significantly reduce cardiovascular risk and optimize health. These risk factors were discussed in detail in the preceding section.

### Clinical Manifestations

Hypertension may have very few symptoms or none at all. If symptoms are present, they can include headaches, visual changes, dizziness, nausea, or chest pain. Oftentimes, however, there are no symptoms, and individuals can function for years without being diagnosed.

### Diagnosis

#### Screening

As noted previously, hypertension is oftentimes an asymptomatic condition. As such, screening plays a critical role in early detection to minimize the end-organ damage that could result from untreated, long-standing hypertension. The U.S. Preventive Services Task Force (USPSTF) recommends screening for hypertension in adults who are 18 years of age or older (grade A recommendation). Adults 40 years of age and older and those with increased risk of hypertension should be screened annually. A review of the existing evidence demonstrated minimal harm in screening and a significant resultant benefit in the form of a reduction in cardiovascular disease-related events. Adults 18 to 39 years of age with no additional risk factors should be screened every 3 to 5 years. Recommended screening techniques include measurement of blood pressure in the office setting with either a manual or automatic cuff and ambulatory or home blood pressure measurement. Office measurement should be done with the patient seated and after at least 5 minutes of the patient arriving in the room. Home measurement may be beneficial after the initial screening for confirmation purposes.

For children and adolescents, the USPSTF indicates that the current evidence is insufficient to assess the risk versus benefit of screening in asymptomatic individuals (grade I evidence). The predictive value of childhood hypertension for adult hypertension is modest, with a risk for false-positive readings.

## Clinical Diagnosis

Hypertension is classified into two stages based on degree of elevation. In stage 1 hypertension, systolic blood pressure is greater than or equal to 140 mm Hg to 159 mm Hg, and diastolic blood pressure is greater than or equal to 90 mm Hg to 99 mm Hg. Stage 2 hypertension is reached when systolic blood pressure is 160 mm Hg or greater and diastolic blood pressure is 100 mm Hg or greater. Per the 2021 International Society of Hypertension (ISH) guidelines, the setting where the blood pressure is measured affects the threshold for the diagnosis of hypertension. According to the ISH, the above threshold of 140/90 mm Hg applies to the office setting, whereas for home readings, 135/85 should be used. If relying on 24-hour ambulatory monitoring, the thresholds are 130/80 mm Hg when looking at 24-hour average readings, 135/85 mm Hg for daytime average, and 120/70 mm Hg for nighttime average. Also of note, the AHA released a statement in 2017 recommending a change in definition for stage 1 hypertension to greater than or equal to 130/80 mm Hg. The classification and definition is important as the approach to treatment differs for each category, as will be discussed later.

## Primary (Essential) Hypertension

Primary hypertension encompasses persistent blood pressure elevation without a discernible cause (idiopathic or of unknown cause). The majority of cases of hypertension will have no discernible cause and fall into this category.

## Secondary Hypertension

Secondary hypertension is persistent blood pressure elevation that is the result of some other underlying cause. About 10% of all cases of hypertension will fall into this category. If another cause can be identified, in many cases it may be correctable.

## Looking for Secondary Causes

Identifying these underlying causes can be a challenge. Using a systematic method of investigating potential etiologies can simplify this process and improve the chances of identifying a source that with treatment can improve outcomes. One such approach is the *ABCDE* mnemonic. The letter *A* in this mnemonic stands for *accuracy* (making sure the reading is correct—such as checking the cuff for appropriate sizing and measurement technique—and repeating readings that are obtained on automatic cuffs manually). Readings on home monitors may be different from office-based readings for a variety of reasons, such as the effects of “white coat hypertension,” *apnea* (considering the presence of obstructive sleep apnea, which is a known contributor to difficult-to-control hypertension), and *aldosteronism* (investigating for the presence of primary hyperaldosteronism through urinary potassium excretion and an elevation in plasma aldosterone level to plasma renin activity). The letter *B* stands for *bruits* (looking for renovascular sources of hypertension/renal artery stenosis, which often presents with renal bruits upon auscultation) and *bad kidneys* (hypertension resulting from renal parenchymal disease). The letter *C* stands for *catecholamines* (elevation that can contribute to “white coat” hypertension as well as overproduction with pheochromocytoma or associated with other conditions such as obstructive sleep apnea and acute stress reactions), *coarctation* (of the aorta), and *Cushing syndrome* (with mineralocorticoid effects of excess glucocorticoids in this setting). The letter *D* represents both *drugs* (including nonsteroidal antiinflammatory drugs, decongestants, estrogens, immunosuppressive agents, as well as nicotine and alcohol) and *diet* (particularly excess sodium intake). The final letter in the mnemonic, *E*, stands for *erythropoietin* (high endogenous levels—such as in chronic obstructive pulmonary disease—or exogenous levels) and *endocrine disorders* (hypothyroidism or hyperparathyroidism). Utilizing a methodical and organized approach to considering potential causes of hypertension can assist with maximizing the chances of optimally controlling blood pressure.

## Differential Diagnosis

The differential diagnosis for hypertension coincides with the array of potential secondary causes that were noted earlier (see

the “Looking for Secondary Causes” section earlier in this chapter). It is important to rule out potentially treatable secondary causes in the initial phases of hypertension management.

## Treatment Approaches

Approaching treatment of a patient with hypertension can be challenging. Many factors must be considered when making these decisions, including reflection on patient age, race, gender, and comorbidities. Each of these factors can influence what the optimal treatment strategy might be. [Figure 1](#) provides a stepwise strategy to blood pressure management.

Initial treatment should always include lifestyle modification as discussed previously, and this modification must be continued throughout the remainder of any management strategies.

## JNC 8 Guidelines

In 2014, the Eighth Joint National Committee (JNC 8) released recommendations regarding the treatment of hypertension. These guidelines were a divergence from the prior JNC 7 recommendations, effectively loosening the goals and the levels at which treatment is initiated. The following is a summary of the eight treatment recommendations from JNC 8. (Please note that the strength of recommendation that is referenced corresponds to the following: grade A—strong recommendation based on evidence; grade B—moderate recommendation based on evidence; grade C—weak recommendation with moderate certainty of a small benefit; grade D—recommendation against; grade E—expert opinion with insufficient or conflicting evidence; grade N—no recommendation for or against).

### Recommendation 1

Individuals 60 years of age or older in the general population should have pharmacologic treatment initiated at a systolic blood pressure level of 150 mm Hg or a diastolic blood pressure of 90 mm Hg with treatment goals of less than 150 mm Hg systolic and less than 90 mm Hg diastolic. (Strength of recommendation: grade A.)

An additional aspect of this recommendation is that if the pharmacologic treatment results in adequate blood pressure reduction and there is no adverse effect on quality of life or patient health, then the treatment can be continued without alteration. (Strength of recommendation: grade E.)

### Recommendation 2

Individuals younger than 60 years of age in the general population should have pharmacologic treatment initiated at a diastolic blood pressure of 90 mm Hg with a treatment goal of less than 90 mm Hg. (Strength of recommendation: grade A for 30 to 59 years of age, grade E for 18 to 29 years of age.)

### Recommendation 3

Individuals younger than 60 years of age in the general population should have pharmacologic treatment initiated at a systolic blood pressure of 140 mm Hg with a treatment goal of less than 140 mm Hg. (Strength of recommendation: grade E.)

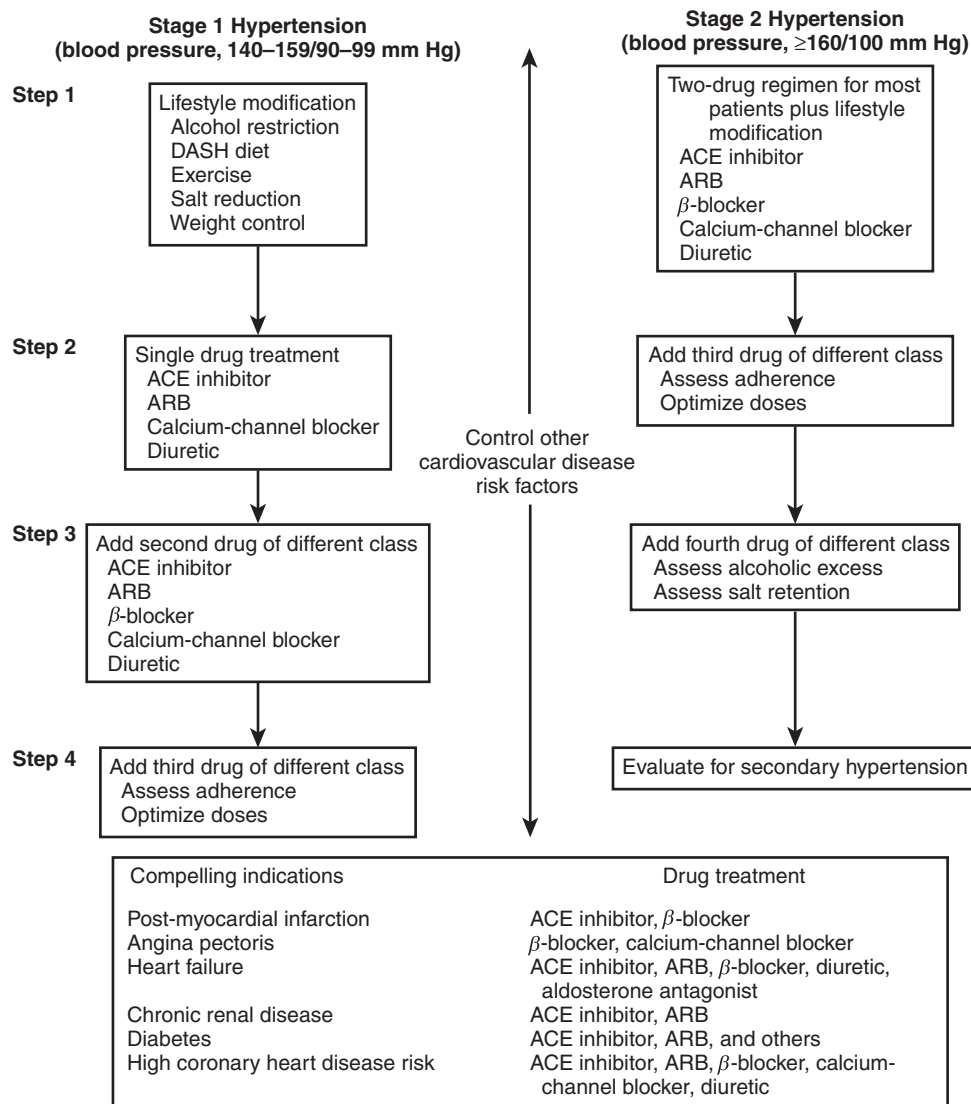

### Recommendation 4

Individuals 18 years of age or older with chronic kidney disease should have pharmacologic treatment initiated at a systolic blood pressure of 140 mm Hg or a diastolic blood pressure of 90 mm Hg with a treatment goal of less than 140 mm Hg systolic and less than 90 mm Hg diastolic. (Strength of recommendation: grade E.)

### Recommendation 5

Individuals older than 18 years of age with diabetes should have pharmacologic treatment initiated at a systolic blood pressure of 140 mm Hg or a diastolic blood pressure of 90 mm Hg with a treatment goal of less than 140 mm Hg systolic and less than 90 mm Hg diastolic. (Strength of recommendation: grade E.)

**Figure 1** Algorithm for management of hypertension. ACE, Angiotensin-converting enzyme; ARB, angiotensin receptor blocker; DASH, Dietary Approaches to Stop Hypertension. (From Chobanian AV. Shattuck Lecture. The hypertension paradox—More uncontrolled disease despite improved therapy. *N Engl J Med* 2009;361:878–887.)

### Recommendation 6

The treatment of nonblack individuals in the general population (including those with diabetes) who require pharmacologic treatment should include thiazide-type diuretics, calcium channel blockers, angiotensin-converting enzyme inhibitors (ACEIs), or angiotensin receptor blockers (ARBs). (Strength of recommendation: grade B.)

### Recommendation 7

The treatment of black individuals (including those with diabetes) should include thiazide-type diuretics or calcium channel blockers. (Strength of recommendation: grade B for the general population, grade C for patients with diabetes.)

### Recommendation 8

The treatment of individuals older than 18 years of age with chronic kidney disease should include, either as initial or add-on treatment, ACEIs or ARBs to improve renal outcomes. (Strength of recommendation: grade B.)

### Recommendation 9

The goal of hypertension treatment is to reach and maintain blood pressure goals consistent with the previous recommendations. If goals are not reached within 1 month of starting pharmacologic treatment, the dose of the initial agent should be increased, or a second agent from recommendation 6 should be added. Blood pressure should continue to be assessed until the goal blood

pressure is achieved. If blood pressure goals are not achieved with two agents, a third agent should be added.

- ACEIs and ARBs should not be used together.
- If necessary, other classes of agents can be used if more than three agents are required or if there are contraindications to the agents in recommendation 6.
- Referral to a hypertension specialist should be considered for patients whose blood pressure goals cannot be met with the previous strategies or patients who are more complicated. (Strength of recommendation: grade E.)

### ACC/AHA 2017 Hypertension Guidelines

In late 2017, the ACC/AHA released an updated hypertension guideline. This guideline provided a different approach to hypertension management, particularly around blood pressure goals. Hypertension stages have tighter cut points than under the JNC 8 guidelines. Under the ACC/AHA guidelines, normal blood pressure is defined as less than 120/80 mm Hg. Blood pressure is considered elevated when systolic blood pressure is in the 120 to 129 mm Hg range and when diastolic blood pressure remains under 80 mm Hg. Stage 1 hypertension is defined as systolic blood pressure between 130 and 139 mm Hg and diastolic blood pressure between 80 and 90 mm Hg. Stage 2 hypertension is defined as blood pressures that are greater than 140/90. This classification is a deviation from the set points within the JNC 8 recommendations.

**TABLE 1** Effect of Lifestyle and Diet Modifications on Systolic Blood Pressure

MODIFICATION	AMOUNT	REDUCTION IN SBP (mm Hg)
Dietary sodium restriction	< 30–50 mmol/day	2–8
Moderation of daily alcohol intake	150–200 mL	2–4
Increased physical activity	30 min 3 × per week	4–9
Reduction in body weight	10 kg or 22 lb	5–10
Adoption of DASH eating plan (high potassium)		8–14

DASH, Dietary Approaches to Stop Hypertension; SBP, systolic blood pressure.

### Nonpharmacologic

For stage 1 hypertension (140 to 159 mm Hg systolic/90 to 99 mm Hg diastolic), the first treatment step is aggressive lifestyle modification. This includes targeting both diet and exercise. These nonpharmacologic strategies should continue, even if pharmacologic treatment is found to be necessary. The relative effects of lifestyle modification on systolic blood pressure reduction are noted in Table 1. ACC/AHA guidelines also recommend lifestyle changes as initial intervention for individuals with stage 1 hypertension without other cardiovascular risk factors and with an atherosclerotic cardiovascular disease (ASCVD) risk of less than 10%; however, as noted earlier, the definition of stage 1 hypertension is at a lower blood pressure level (130 to 139 mm Hg systolic/80 to 90 mm Hg diastolic).

**Diet.** Dietary modifications include salt restriction to a level of less than 2400 mg per day, but ideally less than 1500 mg per day. Suggested dietary interventions also include the use of the DASH (Dietary Approaches to Stop Hypertension) framework. This nutritional framework includes recommendations such as increased consumption of fruits and vegetables, preferential use of complex carbohydrates, and consumption of low-fat dairy products. The DASH diet emphasizes the intake of whole grains, fish, poultry, legumes, nuts, and nontropical vegetable oils. This diet also endorses decreasing higher-fat foods.

**Exercise.** Current exercise recommendations suggest that engaging in a minimum of 150 minutes of moderate-intensity exercise on a weekly basis confers the greatest health benefits. Exercise at this level of intensity reduces the risk of multiple chronic conditions including cardiovascular disease and type 2 diabetes as well as overall all-cause mortality.

**Other Lifestyle Modifications.** In addition to diet and exercise, other lifestyle interventions can optimize health. Smoking cessation is an important modifiable risk factor and is the single leading cause of preventable death in the United States. Smoking increases the risk of cardiovascular morbidity and mortality, including myocardial infarction.

Alcohol consumption is another important lifestyle modification that can have a significant impact on overall health. The effects of alcohol consumption, unlike smoking, depend on quantity. It has been shown that at moderate levels of consumption, alcohol can actually decrease blood pressure (defined as no more than two drinks per day for men and no more than one drink per day for women). However, when consumed in greater quantity, alcohol can increase blood pressure, contributing to hypertension. It is emphasized that alcohol consumption should not be promoted in nondrinkers simply for the purpose of decreasing blood pressure.

Stress reduction is another lifestyle change that can have effects on blood pressure control. The mechanism of this reduction is not clear, but it is hypothesized that it may be related to decreasing autonomic nervous system output. Studies suggest that activities such as transcendental meditation can lead to modest blood pressure reduction. As such, inclusion of these activities in patient treatment plans may provide additional nonpharmacologic options.

Patients frequently ask about the utility of dietary supplements or other natural alternatives for blood pressure management. There is some evidence for select supplements in the management of hypertension, although such effects appear to be small.

Examples of natural substances that may convey a small benefit include garlic and cocoa. Evidence is lacking for other agents including vitamin C, coenzyme Q10, omega-3 fatty acids, and magnesium.

### Pharmacologic

In cases in which hypertension is more significant or nonpharmacologic methods have failed to adequately reduce blood pressure, initiation of medications is indicated (Table 2). The selection of an agent or agents is based on a number of factors including race and comorbidities. As noted earlier, the JNC 8 guidelines provide a stepwise, evidence-based approach to blood pressure management including recommended cut points where pharmacologic intervention is appropriate.

One of the points of emphasis of the JNC 8 guidelines is that the point of intervention for individuals 60 years of age or older is higher than for those younger than 60 years of age. One should also balance the side effects or risks of medications with the benefits of intervention in this age group. The cut points for individuals with chronic kidney disease and diabetes do not differ from the general population. The choice of agent according to JNC 8 recommendations does not differ based on the presence or absence of diabetes, but it does differ based on race (see recommendations 6 and 7 earlier in this chapter). Individuals with chronic kidney disease also should have an ACEI or ARB included in their treatment regimen (either as a lone agent or an add-on). In practice, decisions will need to be tailored to individual patient needs and also should consider other factors including whether or not the patient is a reproductive-age female (as ACEIs and ARBs are contraindicated in pregnancy). This is where our role as family physicians becomes increasingly important—embracing our ability to look at the whole patient when making treatment decisions.

The ACC/AHA recommends initiation of pharmacologic therapy in adults with high cardiovascular risk or preexisting cardiovascular disease and stage 1 or greater hypertension. Patients with both diabetes and hypertension are also assumed to fall into the high-risk category. Again, the defined level of blood pressure classified as stage 1 hypertension under the ACC/AHA guidelines (130 to 139 mm Hg systolic/80 to 90 mm Hg diastolic) is lower than the JNC 8 criteria, as noted earlier. The ACC/AHA recommendations also emphasize the need to balance comorbidities as well as preferences, life expectancy, and clinical judgment when making decisions regarding antihypertensive initiation and titration in older adults (65 years of age and older).

A recent trial (Hygia Chronotherapy Trial) published in 2019 investigated whether timing of antihypertensive medication administration affected blood pressure control and overall outcomes. This study demonstrated that for patients on one or more antihypertensive medications, administration of at least one agent at bedtime rather than upon awakening resulted in better ambulatory blood pressure readings as well as an overall decrease in cardiovascular disease-related events. The results of this study are strongly suggestive that prioritizing bedtime dosing of antihypertensive agents for hypertensive patients leads to greater net benefit.

**TABLE 2** Antihypertensive Classes

DIURETICS				
GENERIC	BRAND NAME	CLASSIFICATION	MECHANISM OF ACTION	DOSING
Chlorthalidone	Thalitone	Thiazide	Inhibits sodium and chloride reabsorption in distal tubules	25 mg by mouth once daily. May increase to a maximum of 100 mg once daily.
Hydrochlorothiazide	Microzide	Thiazide	Inhibits sodium and chloride reabsorption in distal tubules	25 mg by mouth once daily to a maximum of 50 mg in single or divided doses.
Metolazone	Zaroxolyn	Thiazide	Inhibits sodium and chloride reabsorption in distal tubules	Individualize. 2.5–5 mg once daily.
Triamterene/hydrochlorothiazide	Dyazide	Potassium-sparing/thiazide	Inhibits sodium reabsorption in distal tubules	1–2 capsules by mouth once daily (37.5-/25-mg capsules).
Furosemide	Lasix	Loop	Inhibits sodium and chloride reabsorption in ascending loop of Henle	40 mg twice daily by mouth initially. If adding to another antihypertensive, reduce the other agent's dose by 50%
Torsemide	Demadex	Loop	Inhibits sodium and chloride reabsorption in ascending loop of Henle	5 mg once daily by mouth initially. May increase to 10 mg once daily after 4–6 weeks.

**Angiotensin-Converting Enzyme (ACE) Inhibitors**

Mechanism of action: Suppress the renin-angiotensin-aldosterone system

GENERIC	BRAND NAME	CLASSIFICATION	SPECIAL NOTE	DOSING
Fosinopril	Monopril	ACE inhibitor	Only ACE excreted by both renal and hepatic routes	Initially 10 mg once daily. Usual maintenance is 20–40 mg daily in single or 2 divided doses. Max 80 mg per day. If on a diuretic, suspend diuretic for 2–3 days before starting if possible and resume diuretic if pressure is not controlled with fosinopril alone. If diuretic cannot be discontinued, give 10 mg and monitor carefully.
Captopril	Capoten	ACE inhibitor		Take 1 hour before meals. 25 mg two to three times daily by mouth. May increase to 50 mg two to three times daily by mouth. Maximum 450 mg per day.
Ramipril	Altace	ACE inhibitor		2.5 mg once daily by mouth. May increase to a maximum of 20 mg in 1–2 divided doses by mouth.
Enalapril	Vasotec	ACE inhibitor		2.5 mg daily by mouth initially. Typical dose range is 10–40 mg by mouth daily (may be divided doses).
Lisinopril	Prinivil, Zestril	ACE inhibitor		10 mg by mouth daily initial dose. Usual dose range 20–40 mg daily. Doses above 40 mg are not shown to have greater effect. If on diuretics, start 5 mg once daily.
Quinapril	Accupril	ACE inhibitor		10–20 mg daily by mouth initial dose if not on diuretics. Usual maintenance 20–80 mg daily in 1–2 divided doses. If on diuretics, suspend diuretics if possible for 2–3 days before starting and resume if blood pressure not controlled on quinapril alone. Initial dose if on diuretics and CrCl 30–60 mL/min 5 mg. If CrCl 10–30 mL/min, then initially 2.5 mg. If elderly, start 10 mg once daily.

**TABLE 2** Antihypertensive Classes—cont'd**BETA BLOCKERS**

GENERIC	BRAND NAME	CLASSIFICATION	MECHANISM OF ACTION	DOSING
Labetalol	Trandate	Alpha and beta antagonist		100 mg twice daily by mouth initially. May titrate in 2–3 days by 100-mg twice-daily increments. Maximum dose 2400 mg per day. Usual maintenance dose 200–400 mg twice daily.

**CALCIUM CHANNEL BLOCKERS**

GENERIC	BRAND NAME	CLASSIFICATION	MECHANISM OF ACTION	DOSING
Nifedipine, extended release	Adalat CC, Procardia XL	Dihydropyridine	Binds to <i>L</i> -type calcium channels in sinoatrial (SA) and atrioventricular (AV) node, as well as myocardium and vasculature	30–60 mg by mouth once daily initially. Titrate over 7–14 days. Maximum 120 mg daily. Swallow whole.
Diltiazem, extended release	Cardizem CD, Cardizem LA, Cartia XT, Dilacor XR	Nondihydropyridine	Binds to <i>L</i> -type calcium channels in SA and AV node (primarily), as well as myocardium and vasculature	180 mg by mouth per day initially. May titrate at 1–2 week intervals. Maximum dose 360 mg per day.
Verapamil	Calan, Calan SR	Nondihydropyridine	Binds to <i>L</i> -type calcium channels in SA and AV node, as well as myocardium and vasculature	80 mg by mouth every 8 hours initially. Usual max 360 mg/day in divided doses. If elderly or small, start at 40 mg 3 times daily.
Amlodipine	Norvasc	Dihydropyridine	Binds to <i>L</i> -type calcium channels in smooth muscle (vasculature)	5 mg by mouth daily initially. May increase by 2.5 mg every 1–2 weeks. Maximum 10 mg per day. For small, elderly, fragile, or hepatic impaired patients and patients on other antihypertensives, start at 2.5 mg daily.
Felodipine	Plendil	Dihydropyridine	Binds to <i>L</i> -type calcium channels in smooth muscle (vasculature)	5 mg by mouth once daily initially without food or with a light meal. May increase to a maximum dose of 10 mg by mouth once daily.* Adjust at 2 week intervals. For elderly patients or hepatic impairment, start at 2.5 mg once daily.

**ALDOSTERONE ANTAGONISTS**

GENERIC	BRAND NAME	CLASSIFICATION	MECHANISM OF ACTION	DOSING
Spironolactone	Aldactone	Selective aldosterone antagonist	Competes with aldosterone receptor sites. Reduces sodium reabsorption	25–100 mg by mouth once daily or divided twice daily. Titrate at 2 week intervals.
Eplerenone	Inspra	Selective aldosterone antagonist	Competes with aldosterone receptor sites. Reduces sodium reabsorption	50 mg by mouth once daily initially. May increase after 4 weeks to twice daily if needed. (May cause hyperkalemia if doses exceed 100 mg per day.) If on concomitant moderate CYP3A inhibitors such as erythromycin, verapamil, saquinavir, fluconazole, then initially start 25 mg daily with a max of 25 mg twice daily.

**Alpha-2 Agonists**

Mechanism of action: Stimulate presynaptic aldosterone receptors, decreasing sympathetic nervous activity

**TABLE 2** Antihypertensive Classes—cont'd

GENERIC	BRAND NAME	CLASSIFICATION	MECHANISM OF ACTION	DOSING
Clonidine	Catapres, Catapres-TTS	Centrally acting alpha-2 agonist	Stimulation of alpha-2 adrenoreceptors, reducing sympathetic nervous system output	0.1 mg every 12 hours by mouth. Maximum 2.4 mg per 24 hours. (Usual dose range 0.1–0.2 mg every 12 hours.) If using transdermal formulation, 0.1-mg patch applied once every 7 days. May increase by 0.1 mg /day after 1–2 weeks. Maximum 0.6 mg/day.
Methyldopa		Centrally acting alpha-2 agonist	Directly affects peripheral sympathetic nerves through stimulation of central alpha-adrenergic receptors	250 mg by mouth every 8–12 hours initially, then can increase every 2 days. (maximum 3 g per day). Typical maintenance dose is 500–2000 mg/day by mouth divided every 6–12 hours. If also on other antihypertensives (other than thiazides), initial max 500 mg/day.

**Alpha Blockers**

Mechanism of action: Selectively block postsynaptic alpha-1 adrenergic receptors

GENERIC	BRAND NAME	CLASSIFICATION	MECHANISM OF ACTION	DOSING
Prazosin	Minipress	Alpha-1 blocker	Competitive antagonist, reduces vascular resistance	1 mg by mouth every 8–12 hours initially. Give first dose at bedtime. Maintenance dose typically 6–15 mg divided every 6–8 hours. Typical maximum 20 mg per day in divided doses (although may increase to 40 mg per day in divided doses in some patients). When adding other antihypertensives, reduce dose to 1–2 mg 3 times daily and retitrate.
Terazosin	Hytrin		Selective competitive inhibitor, decreases vascular resistance	1 mg by mouth at bedtime initially. Typical maintenance 1–5 mg daily or in divided dose every 12 hours. Maximum 20 mg per day.
Doxazosin	Cardura		Selective postsynaptic alpha-1 receptor inhibitor, vasodilation	1 mg once daily initially, titrate gradually at 2 week intervals (based on standing BP at 2–6 hours and 24 hours post-dose) to a maximum of 16 mg/day.

\*Exceeds dosage recommended by the manufacturer.

Modified from Medscape. Hypertension Medication. Available at: <http://www.emedicine.medscape.com/article/241381-medication>.

**Monitoring**

Clinical practice guidelines vary in their recommendations regarding optimal monitoring. It is clear that monitoring in the early stage or during periods of treatment change should be more frequent than during times of stability, somewhere between monthly and every 6 weeks. Once the patient is stabilized, periodic monitoring can occur either every 3 to 6 months for everyone or in a more risk-stratified manner, with lower-risk patients being seen every 6 months and higher-risk patients every 3 months. Monitoring can also be done through home blood pressure monitoring and through the use of telehealth. This method has become more common and is both convenient and easily accessible to patients. There is evidence to support the use of telehealth for hypertension management, particularly in those individuals with difficult-to-treat hypertension and those with medication compliance issues. Ongoing studies work to support the generalizability to other hypertensive patient populations.

JNC 8 recommendations, as previously discussed, suggest that patients with hypertension be monitored on at least a monthly basis until goal blood pressure is achieved, with any necessary adjustments being made at these visits.

**Complications**

Hypertension is often referred to as *the silent killer*. This menacing name refers to the fact that this condition often presents without any discernible symptoms, which at times can make treatment compliance challenging. One of the greatest concerns with uncontrolled hypertension is the risk of end-organ damage, which is far-reaching.

Uncontrolled hypertension can lead to serious complications including myocardial infarction, stroke, peripheral artery disease, retinopathy, and renal failure. Given that hypertension is at the same time the most common condition we treat as primary care physicians, the opportunities to circumvent these sources of morbidity and mortality present themselves on a daily basis.

## HYPERTROPHIC CARDIOMYOPATHY

Method of

Sandeep Sangodkar, DO

### CURRENT DIAGNOSIS

- Echocardiography is a mainstay of clinical diagnosis.
- Cardiac magnetic resonance imaging (MRI) can provide important prognostic information.
- Left ventricular outflow tract pressure and flow measurements have a classic dynamic pattern.
- Left ventricular wall thickness of at least 15 mm.

### CURRENT THERAPY

#### Asymptomatic Disease

- Periodic follow-up to assess symptoms and risk for sudden cardiac death.
- Important to counsel patients regarding potential genetic transmission.
- Patients with concurrent atrial fibrillation should be anticoagulated.

#### Symptomatic Disease

- $\beta$ -Blockade or calcium channel blockers are drugs of choice.
- Implantable defibrillator is indicated if the patient has risk factors for sudden cardiac death.
- Surgical myectomy may be undertaken in patients who do not respond to pharmacologic therapy.
- Alcohol ablation may be used in patients who are not candidates for surgery.

### Definition

Many names, terms, and acronyms (more than 80) have been used to describe hypertrophic cardiomyopathy (HCM). Common names such as *idiopathic hypertrophic*, *subaortic stenosis*, and *hypertrophic obstructive cardiomyopathy*, popular in the literature in the 1960s and 1970s, imply that left ventricular outflow tract (LVOT) obstruction is a required component of the disease, whereas one-third of patients have no obstruction at rest or exertion. The term *HCM*, first used in 1979, encompasses both the obstructive and nonobstructive hemodynamic variants of this disease and is now considered the formal name.

### Epidemiology

Although once thought of as a rare entity, HCM is now recognized as a common inherited cardiovascular disease. Epidemiologic studies from various parts of the world report a similar prevalence, thought of as 1 in 200 to 1 in 500 people, which occurs equally among sexes and ethnic groups. This may, in fact, be underreported because many people with HCM are not clinically diagnosed and achieve normal life expectancy without any HCM-related complications.

### Risk Factors

HCM is caused by mutations in genes coding for thin and thick filament proteins of the sarcomere. These mutations are inherited in an autosomal dominant pattern with variable penetrance and expression. At least 11 genes have been identified as responsible for causing HCM, with 70% of successfully genotyped patients found to have mutations in the two most-common genes:  $\beta$ -myosin heavy chain and myosin binding protein C. More than 1500 individual gene variants have been identified, which complicates predicting prognosis for individual patients.

### Clinical Manifestations

HCM is seen from pediatric to geriatric populations. A classic description of a murmur suggestive of HCM is a harsh crescendo-decrescendo systolic ejection murmur that increases in intensity with Valsalva or standing from a squatting position. Most patients with HCM are asymptomatic or only mildly symptomatic, with the most common presenting complaints being dyspnea or chest pain. The most worrisome manifestation is sudden cardiac death owing to ventricular tachyarrhythmia, seen more commonly in younger symptom-free patients. Systolic anterior motion of the mitral valve can

cause significant mitral regurgitation. Heart failure with preserved ejection fraction is another manifestation of HCM; however, systolic dysfunction can be present owing to myocardial scarring. In addition, atrial fibrillation is associated with an increased risk of thromboembolism in patients with HCM and anticoagulation must be considered. Most patients with HCM have normal life expectancy without a need for major intervention.

### Pathogenesis

The pathophysiology of HCM stems from multiple abnormalities, including LVOT obstruction, diastolic dysfunction, mitral regurgitation, myocardial ischemia, and arrhythmias. The peak LV outflow gradient is an important factor in determining treatment options. The obstruction was originally thought to be caused by a hypertrophied basal septum that caused ventricular outflow obstruction during systolic contraction. More recently, it is thought mitral valve systolic anterior motion and mitral-septal contact caused by venturi forces on the mitral leaflets and displacement into the outflow tract cause obstruction of LVOT. The increased LV systolic pressure in turn results in elevated diastolic pressures, mitral regurgitation, and, ultimately, decreased cardiac output.

### Diagnosis

Clinically, HCM is defined as maximal end diastolic LV wall thickness of at least 15 mm based on echocardiography or cardiac MRI. Patients should have a comprehensive physical and three-generation family history as part of their initial evaluation. A distinction between HCM and physiologic LV hypertrophy from athletic conditioning must be recognized because the athletic hearts may demonstrate enlargement of the cardiac chambers and thickened septum. The likelihood of clinically significant HCM is determined by identification of sarcomere mutations, marked LV thickness (more than 25 mm), and LVOT obstruction with systolic anterior motion and mitral-septal contact. Provocative testing (exercise or pharmacologic) may elucidate the diagnosis of HCM in symptomatic patients presenting with a normal LVOT gradient at rest. Measurement of outflow gradients by echocardiography and invasive pressures by cardiac catheterization show a characteristic dynamic pattern that can be enhanced by loading conditions.

### Imaging

The mainstay of imaging has been held by echocardiography. Transthoracic echocardiography is recommended in the initial evaluation of all patients with suspected HCM and family members of those diagnosed with HCM. Transesophageal echocardiography is used for diagnosis and intraprocedural guidance of surgical myectomy and alcohol septal ablation.

In recent years, cardiac magnetic resonance imaging (MRI; CMR) has proven to be an increasingly useful modality in the diagnosis and treatment of HCM. Contrast-enhanced CMR allows imaging of presumed myocardial fibrosis. Late gadolinium enhancement (LGE) is commonly seen in HCM; an extensive percentage of left ventricular mass involvement is associated with higher risk of sudden cardiac death. Consequently, an absence of LGE is associated with a lower risk of sudden cardiac death and can often provide reassurance.

### Treatment

#### Asymptomatic Disease

Given that a large subset of HCM patients are symptom free and will achieve normal life expectancy, it is important to educate patients about the disease process, screen family members, and advise them to avoid strenuous activity. Coronary artery disease has an impact on survival, and thus aggressive modification

of risk factors contributing to atherosclerosis (diabetes, hyperlipidemia, and obesity) is recommended. Low-intensity aerobic exercise is reasonable to allow the patient to maintain fitness. Adequate hydration and avoidance of situations leading to vasodilation are encouraged to minimize exacerbation of an existing LVOT obstruction.

Septal reduction therapy is not indicated in a symptom-free patient with any degree of obstruction.

### Symptomatic Disease

#### Pharmacologic Management

$\beta$ -Blockade is the mainstay of treatment owing to negative inotropic and negative chronotropic effect. Verapamil (Calan)<sup>1</sup> or diltiazem (Cardizem)<sup>1</sup> are reasonable alternatives to  $\beta$ -blockade. Disopyramide (Norpace)<sup>1</sup> may be added if symptomatic despite these medications (Table 1). An important role in management is to discontinue medications that promote outflow tract obstruction via vasodilatory effects such as dihydropyridine calcium channel blocking agents, angiotensin converting enzyme inhibitors, and angiotensin receptor blockers. Low-dose diuretics may provide symptomatic relief; however, high-dose diuretics should be avoided. Digitalis is potentially harmful in patients without atrial fibrillation. Phenylephrine (Neo-Synephrine)<sup>1</sup> is useful when treating acute hypotension in these patients.

For the treatment of atrial fibrillation in HCM, it is recommended to keep a low threshold for initiating prophylactic anticoagulation with a direct-acting oral anticoagulant or vitamin K antagonist caused by a higher risk of thromboembolic stroke.

#### Invasive Therapies

The major septal reduction therapies are surgical myectomy and alcohol ablation. These should be performed by experienced operators at comprehensive centers in patients with refractory symptoms.

**TABLE 1** Pharmacologic Management of Patients With Obstructive HCM

		INITIAL DOSE	TITRATE TO MAX DOSE
<b>Symptoms Attributable to LV Outflow Tract Obstruction</b>			
Non-Vasodilating Beta Blockers	Metoprolol	50 mg/day	400 mg/day
	Atenolol	25 mg/day	100 mg/day
	Propranolol	60 mg/day	240 mg/day
<b>Beta Blocker Ineffective or Not Tolerated</b>			
Nondihydropyridine Calcium Channel Blockers	Verapamil	120 mg/day	480 mg/day
	Diltiazem	120 mg/day	360 mg/day
<b>Severe Symptoms Despite Beta Blocker or Nondihydropyridine CCB</b>			
	Disopyramide	200 mg BID	300 mg BID

<sup>1</sup>Not FDA approved for this indication.

Surgical septal myectomy is considered the most appropriate therapy for eligible patients unresponsive to optimal medical therapy. The most common procedure is a Morrow procedure in which a rectangular trough is created in the basal septum below the aortic valve, which abolishes or reduces the LVOT gradient. Eligible patients include those with severe dyspnea, chest pain, or exertional syncope despite maximal medical therapy. Hemodynamic considerations that determine eligibility consist of an LVOT gradient of at least 50 mm Hg associated with septal hypertrophy and mitral valve systolic anterior motion. Studies have shown that surgical myectomy can reverse heart failure symptoms owing to the fact it permanently removes LVOT obstruction and can reduce mitral regurgitation.

Alcohol septal ablation can benefit adult patients with HCM and LVOT obstruction. This percutaneous procedure involves injection of ethanol into a major septal perforator coronary artery, with the intent of inducing infarction of the basal septal wall near the anterior leaflet contact point. The effectiveness of alcohol septal ablation is not clear in patients with more than 30 mm of septal hypertrophy, and it should not be performed in patients with disease (coronary artery disease, mitral valve repair) that would need surgical correction regardless. Other downsides of septal ablation include an increased risk of complete heart block requiring pacemaker implantation and an undefined risk of arrhythmogenicity owing to scar tissue.

#### Role of Implantable Devices

Determining which patients with HCM should receive an implantable cardiac defibrillator (ICD) is challenging given the unpredictability of the disease. ICDs are the only treatment to have proven to decrease mortality given their ability to reliably abort life-threatening arrhythmias. All patients with HCM need comprehensive sudden cardiac death risk stratification, with strong consideration for ICD implantation in those with personal history of ventricular fibrillation, sustained ventricular tachycardia, family history of sudden cardiac

death, unexplained syncope, abnormal exercise blood pressure response, LGE >15% of LV mass, massive left ventricular hypertrophy (LVH) (>30 mm), or documented nonsustained ventricular tachycardia on Holter monitor. Device-related complications and issues such as inappropriate shocks and multiple generator changes for patients receiving a device at a young age must also be weighed when considering implantation of ICD. Risk scores can be helpful in the processes of shared decision making.

#### Participation in Sports

HCM has been reported as one of the most common causes of sudden death among competitive athletes; however, SCD is overall a rare event in young people. In the United States, there have been cardiovascular screening initiatives, including history and physical in addition to 12 lead electrocardiograms (ECGs), with limited success. The American College of Cardiology and American Heart Association do not currently recommend a national mandatory cardiovascular screening program.

It is reasonable for most HCM patients to engage in low-intensity competitive sports (golf, bowling) and recreational sporting activities. Participation in competitive sports is a modifiable risk factor, and it is recommended that HCM patients avoid participation in intense competitive sports regardless of age, sex, LVOT obstruction, prior septal reduction, or ICD. In addition, ICD placement should not be implanted for the sole purpose of participating in competitive athletics. For most HCM patients, mild-moderate intensity recreational exercise is beneficial for cardiovascular fitness and overall health.

#### Monitoring

The unpredictability of HCM disease makes regular surveillance a necessity. Patient age has been seen as a predictor of HCM-related events, with sudden death events more common in young patients. With a family history of sudden cardiac death, periodic screening by transthoracic echocardiography (every 12–18

**Figure 1** A, Gross anatomy section of heart demonstrating septal hypertrophy and LVOT obstruction. B, Microscopic section demonstrating myocyte hypertrophy and disarray.

**Figure 2** Cardiac MRI demonstrating septal hypertrophy (A,B) and late gadolinium enhancement (C).

months) is recommended in children by the age of 12 (or younger if the child has signs of early puberty) or if there are plans for intense sports competition. Repeat transthoracic echocardiography is recommended for any change in clinical status or new cardiovascular event. As recognition of the genetic basis of this disease has improved over time, genetic screening and counseling of all first-degree family members of patients with HCM are now recommended.

### Future Research

The perception of HCM has evolved from a rare and deadly condition to a more common and treatable disease. Effective use of ICDs for primary prevention and advances in surgical treatment of obstruction now allow most HCM patients to achieve normal life expectancy. Although significant progress has been made in elucidating the etiology and pathophysiology of HCM, there is much room for advancement. In addition, the relationship between genetics and environmental influences, as well as the management of family members of genotype positive–phenotype negative patients, is still unclear. Although rapid genetic testing to identify those at risk has become more widespread, further understanding of pathogenic mutations is required. Furthermore, advancement in technology will hopefully lead to therapies that can specifically target these pathways.

## INFECTIVE ENDOCARDITIS

Samuel Mathis, MD; and Oyetokunbo Ibadapo-Obe, MD

### CURRENT DIAGNOSIS

- Infective endocarditis (IE) should be a diagnostic consideration in patients with fever and heart murmur.
- Healthcare related infections account for 25% to 30% of newly diagnosed cases.
- Positive blood cultures are present in approximately 90% of cases. Multiple sets should be obtained prior to initiating antibiotic therapy to improve diagnostic yield.
- Transesophageal echocardiography has the highest sensitivity and specificity in native heart evaluations while alternative imaging techniques can be used in patients with implanted heart valves.
- Complications of disease include heart failure, valvular incompetence, and structural defects such as abscess, perforation, and fistulas.

### CURRENT THERAPY

- Empiric therapy for *Staphylococcus aureus* should be initiated after blood cultures have been drawn and before the results are available.
- Antibiotic choice is complex and dependent on culture results and sensitivities of organisms identified.
- Best practices propose a multidisciplinary approach to care for patients with IE and should include specialties such as cardiology, infectious disease/microbiology, and cardiothoracic surgery in cases of complicated IE or if prosthetic valves or a cardiac device is present.
- Neurology or neurosurgery consults should be accessible as up to 30% of patients will experience symptomatic neurologic events during their disease.
- Increasing numbers of patients with IE will require surgical intervention due to complications from disease such as heart failure, embolism, intracardiac abscess, or failure to control infection.
- Outpatient parenteral antibiotic therapy can be considered in a subset of patients based on their culture results and with close follow-up.

## Definition

Infective endocarditis (IE) is a microbial infection of the valves or endocardium of the heart.

## Epidemiology and Risk Factors

IE remains a rare disease in Western countries with incidence varying by geographic location, predisposing risk factors, and preexisting conditions.

IE has an annual incidence of 3 to 10/100,000 of the North American population with a mortality of about 30% at 30 days and 40% at 1 year.

Over the years, the epidemiology of IE has shifted with a steady increase in healthcare-associated IE accounting for about 25% to 30% of newly reported cases.

Risk factors include advancing age, prosthetic heart valves, congenital heart disease, intracardiac devices, intravenous/parenteral drug use, indwelling venous access lines, diabetes mellitus, or immunosuppression to name a few.

Developing worlds have rheumatic heart disease as a leading risk factor for IE.

Infection with *Staphylococcus aureus* is presently the most prevalent cause of IE accounting for ~26% and overtaking the Strep group, next is *Streptococcus viridans* group at ~19%, other Streptococci at 17.5% and Enterococci at 10.55. The above listed bacteria jointly account for 80% to 90% of all cases of endocarditis.

## Pathophysiology

IE occurs as a result of endothelial damage, which invariably exposes the basement membrane on the valve causing a structural abnormality that allows bacteria present in the bloodstream to colonize the initially sterile vegetation (nonbacterial thrombotic endocarditis).

Bacterial involvement and growth enlarge the vegetation, impede blood flow, and cause inflammation with multiple systemic symptoms/signs.

Progressive valve dysfunction can quickly lead to heart failure, and bacterial colonization of the vegetation causes septic emboli into the bloodstream, causing sepsis, and can lead to a metastatic septic site outside of initial vegetation area on the valve.

## Prevention

The mainstay of prevention of IE is antimicrobial therapy prior to procedures, which may cause IE. This has been and remains a topic of debate and varies by geographic location worldwide.

The efficacy of antimicrobial therapy as a prophylaxis depends greatly on multiple factors, which include patient's medical conditions in terms of being high risk for IE, the procedure being done, the probability of sending bacteria into the bloodstream as a result of the said procedure, and the evidence backing antibiotic prophylaxis in the patient scenario.

The guidelines have remained dynamic based on review of published literature, most of which seems to favor less use of antibiotics and better patient selection for prophylaxis if needed. See current guidelines in [Box 1](#).

## Clinical Manifestations and Diagnosis

The diagnosis of IE is based on findings of bacteremia from an organism associated with IE along with evidence of endocardial involvement. This allows for highly variable presentations of disease. Due to this variability, it is important to perform a detailed history and physical examination to help lead to the diagnosis. Blood cultures should be obtained as discussed below prior to initiating antibacterial therapy to ensure appropriate management of the causative organism. This is especially important in the setting of predisposing conditions or risk factors for IE, including recent invasive procedures, history of structural heart disease, or injection drug use. Because of the insidious nature of the disease process, many patients will present with symptoms within 2 weeks of the inciting event or infection.

## BOX 1

Antibiotic Regimens for High-Risk Patients and Dental Procedures<sup>1</sup> (Taken 30–60 Minutes Prior to Procedure)

**Oral:** Amoxicillin 2 g (child 50 mg/kg) PO 30–60 minutes before procedure

**Penicillin Allergy:** Cephalexin 2 g (child 50 mg/kg) PO 30–60 minutes before procedure or clindamycin 600 mg (child 20 mg/kg)

or azithromycin or clarithromycin 500 mg (child 15 mg/kg)

**Unable to tolerate oral:** Ampicillin 2 g IM/IV (child 50 mg/kg)

**Unable to tolerate oral and PCN allergy:** Cefazolin or ceftriaxone 1 g IM/IV (child 50 mg/kg) or clindamycin 600 mg IM/IV (child 20 mg/kg)

**Patients that would benefit from antibiotics due to high risk:**

- Acquired valvular heart disease with stenosis or regurgitation
- Valve replacement
- Structural congenital heart disease
- Previous endocarditis
- Hypertrophic cardiomyopathy

**Dental procedures to consider antibiotic prophylaxis:**

- Manipulation of the gingival or periapical region of the teeth
- Perforation of oral mucosa
- Extractions

All these regimens are not approved by the FDA for this indication.

Adapted from Bonow RO, Carabello BA, Kanu C, et al: ACC/AHA 2006 guidelines for the management of patients with valvular heart disease: A report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines (writing committee to revise the 1998 Guidelines for the Management of Patients with Valvular Heart Disease): Developed in collaboration with the Society of Cardiovascular Anesthesiologists: Endorsed by the Society for Cardiovascular Angiography and Interventions and the Society of Thoracic Surgeons. *Circulation* 114(5):e84–e231, 2006.

The most common presentation includes fever in up to 90% of patients, though it may not be present in immunocompromised patients or those who have received previous antibiotic therapy. This can be seen in postoperative patients after valve replacement or intracardiac devices. Night sweats, fatigue, weight loss, and appetite changes are other nonspecific signs that can indicate an infection and will be present in up to half of patients with IE.

A new or changing regurgitant murmur will also be present on physical examination along with evidence of endocardial involvement. The presentation of such involvement can range from tachycardia and hypotension to embolization of the vegetations causing embolic symptoms. Approximately 25% of patients with IE will present with evidence of embolization. If left untreated, symptoms of heart failure, valvular dysfunction, and destruction of cardiac structures can occur. Other physical exam findings of IE include petechia, splinter hemorrhages, Janeway lesions, Osler nodes, and Roth spots. As these findings can occur in other conditions and have low incidence in proven cases of IE, their diagnostic use is limited.

## Differential Diagnosis

There are several conditions that can mimic the symptoms of IE. Consideration of systemic lupus erythematosus, acute rheumatic fever, atrial myxoma, vasculitis, and renal cell carcinoma should be on the differential. Care must be taken to not confuse the complications of IE as the causative etiology for hospitalization. One study found that up to 50% of patients with IE were initially diagnosed with complications of their disease (pneumonia, CNS infection, septic arthritis, heart failure, stroke) before correctly identifying the causative agent. Misdiagnosis was found to significantly increase the risk of comorbidity and in hospital mortality in these patients.

## Laboratory Evaluation and Blood Cultures

Blood cultures are one of the major diagnostic criteria used to diagnose IE. They are of utmost importance due to their use in the treatment of IE by identifying the microorganisms involved as well as their antibiotic sensitivities. The continuous bacteremia present in IE means that fever need not be present before ordering blood cultures. In up to 90% of cases, the etiologic agent is identified in the first two blood cultures. It is recommended that three sets of blood cultures be obtained at least 1 hour apart from separate venipunctures for the most sensitive findings (98% of cases successfully identified). Each vial should have at least 10 mL of blood to increase the chances of obtaining an appropriate amount. Alternatively, two sets of three bottles each (two aerobic, one anaerobic—six bottles total) can be drawn if timing of antibiotic therapy is a concern. Unfortunately, the most common cause of negative culture IE is due to prior administration of antibiotic therapy. This results in prolonged, broad coverage antibiotic therapy and increased uncertainty of the diagnosis.

Other lab findings that may be present in IE but are not specific for the disease include a normocytic, normochromic anemia, thrombocytopenia, leukocytosis, and elevations in erythrocyte sedimentation rate (ERS), C-reactive protein, and procalcitonin.

## Imaging

Cardiac imaging should be considered if there is a strong clinical suspicion of IE. The inclusion of cardiac imaging of IE has increased the sensitivity of diagnosis (see modified Duke Criteria [Box 2]). Transthoracic echocardiogram (TTE) should be performed if there is clinical suspicion for IE. The echocardiogram should be specifically looking for any oscillating intracardiac mass on the valve or supporting structure which would indicate vegetations. It can also be used to detect abscesses, dehiscence of prosthetic valve, or newly identified valvular regurgitations. The sensitivity of detecting vegetations on native valves is approximately 70% with TTE. This is increased to a sensitivity and specificity around 90% if transesophageal echocardiogram (TEE) is used instead. Due to this increased sensitivity, TEE should be used in high-risk patients with a negative TTE. Transesophageal echocardiogram should also be considered in patients with prosthetic valves, those with *S. aureus* bacteremia, and when IE-related complications have occurred such as heart block, cardiac abscess, embolism, or new/worsening murmurs.

Due to the increased number of patients with prosthetic valves or intracardiac devices, TTE and TEE may prove to be unhelpful due to the artifact from these devices. In these cases, additional imaging with F-labeled fluoro-2-deoxyglucose positron emission tomography/computed tomography (F-FDG-PET/CT) or single-photon emission computed tomography-CT (SPECT-CT) should be considered to assess for inflammation around the prosthetic or intracardiac device. These studies have been found to have a sensitivity of 93% in cases of prosthetic valve endocarditis. They have significantly lower sensitivity in cases of native heart disease (22% sensitivity). Thoracic CT scans have significant value in determining presence of perivalvular abscesses, aneurysms, or pseudoaneurysms.

Cerebral magnetic resonance imaging (MRI) should be considered in patients with evidence of embolic neurologic complications as most of these lesions are ischemic in origin.

## Treatment

Treatment should be multidisciplinary and involve cardiology, cardiac surgeon, infectious disease, or microbiology. This approach improves outcomes by optimizing appropriate antibiotic regimens and assessments for surgical interventions. Initiating appropriate antibiotic therapy can improve in-hospital survival by 70% to 80%. Recommended antibiotic regimens against common organisms causing IE are listed in Table 1. These should be adjusted based on the organism and susceptibilities.

Patient with IE will require a prolonged duration of intravenous (IV) antibiotic treatment for up to 6 weeks. This is in order to ensure that all bacteria located in the vegetations are

## BOX 2 Modified Duke Criteria for Infective Endocarditis

### Definite Infective Endocarditis:

- Two major
- or
- One major and three minor
- or
- Five minor

### Possible Infective Endocarditis:

- One major and one minor
- or
- Three minor

### Major Criteria

#### Positive blood cultures:

- Typical microorganisms consistent with IE from two separate blood culture: viridans group streptococci, *Streptococcus bovis* group, HACEK group, *Staphylococcus aureus*; community acquired enterococci with abscess of primary focus or
- Microorganisms consistent with IE from persistently positive blood cultures: at least two positive blood cultures drawn more than 12 hours apart; all of three or a majority of positive blood cultures in more than four drawn; or single positive blood culture for *Coxiella burnetii* or phage IgG antibody titer >1:800

#### Evidence of endocardial involvement:

- Echocardiogram positive for IE showing vegetation, abscess, pseudoaneurysm, intracardiac fistula, valvular perforation or aneurysm, new partial dehiscence of prosthetic valve
- Abnormal activity around site of a prosthetic valve detected by PET/CT assuming >3 months after surgery or radiolabeled leukocyte-SPECT/CT
- Definite paravalvular lesions by cardiac CT

### Minor Criteria

- Predisposition: predisposing heart condition or injection drug use
- Fever, temperature >38°C
- Vascular phenomena (including those detected by imaging alone): arterial emboli, septic pulmonary infarcts, mycotic aneurysm, intracranial hemorrhage, conjunctival hemorrhage, and Janeway lesions
- Immunologic phenomena: glomerulonephritis, Osler's nodes, Roth's spots, and rheumatoid factor
- Microbiological evidence: positive blood cultures not meeting major criteria above or serologic evidence of infection with organism consistent with IE

CT, Computed tomography; HACEK, *Haemophilus* spp, *Aggregatibacter* spp, *Cardiobacterium hominis*, *Eikenella corrodens*, *Kingella* spp; IE, infective endocarditis; IgG, immunoglobulin G; PET, positron emission tomography; SPECT, single-photon emission computed tomography.

completely eradicated. Blood cultures should be repeated every 24 to 48 hours until resolution of bacteremia is confirmed. If surgery is required, a 4- to 6-week course of antibiotics is still recommended to reduce recurrence of IE.

In addition to IV antibiotic therapy, many patients will also be placed on parenteral therapies. In certain cases, patients may be eligible for transition to oral antibiotic to complete the duration of therapy. The criteria for step down therapy are patients who have no indication for surgery, have completed an initial course of IV antibiotics with no bacteremia, have no concerns for absorption of oral therapy in the gastrointestinal tract, have no psychological or socioeconomic concerns that would cause IV therapy to be preferred for adherence, and the organism is susceptible to the prescribed oral regimen. Oral therapy is preferred over IV due to the decreased potential for harm.

**TABLE 1** Antimicrobial Regimens Against Typical Infective Endocarditis Organisms

ORGANISM	SUSCEPTIBILITY	REGIMENT	DOSAGE	DURATION (WEEK)
<b>Native Valve</b> <i>Streptococcus viridans</i> , <i>Streptococcus bovis</i>	Penicillin	Penicillin G	12–18 MU IV per 24 h continuously or in four to six equally divided doses	4
		or ceftriaxone <sup>1</sup>	2 g IV or IM per 24 h	4
		or vancomycin	30 mg/kg IV per 24 h in two divided doses. Max: 2 g/24 h	4
	Penicillin-relative resistance	Penicillin G	24 MU IV per 24 h continuously or in four to six equally divided doses	4
		or ceftriaxone <sup>1</sup>	2 g IV/IM per 24 h 4	4
		plus gentamicin <sup>1</sup>	3 mg/kg IV/IM per 24 h in one dose	2
<i>Enterococcus</i> spp	Penicillin	Ampicillin	12 g IV per 24 h in six divided doses	4–6
		or penicillin G <sup>1</sup>	18–30 MU IV per 24 h continuously or in six equally divided doses	4–6
		Plus gentamicin 3 mg/kg IV or IM per 24 h in three divided doses	2	
	Penicillin Resistant	or ampicillin	12 g IV per 24 h in six divided doses	6
		plus ceftriaxone <sup>1</sup>	2 g IV every 12 h	6
<i>Staphylococcus</i> spp	Oxacillin	Nafcillin <sup>1</sup> or oxacillin <sup>1</sup>	12 g IV per 24 h in four to six divided doses	6
		or cefazolin	100 mg/kg IV/IM per 24 h in three equally divided doses	6
		6 g IV per 24 h in three divided doses	6	
	Oxacillin resistant	Vancomycin plus gentamicin	30 mg/kg IV per 24 h in two divided doses (goal: 1 h peak concentration 30–45 µg/mL and trough 10–15 µg/mL)	6
<b>Prosthetic Valve</b> <i>Staphylococcus</i> spp.	Oxacillin-susceptible	Nafcillin <sup>1</sup> or oxacillin <sup>1</sup>	12 g IV per 24 h in four to six divided doses	6
		plus gentamicin	3 mg/kg IV or IM per 24 h in three divided doses	2
		plus rifampin <sup>1</sup>	900 mg IV or PO per 24 h in three divided doses	6
	Oxacillin-resistant	Vancomycin	30 mg/kg IV per 24 h in two divided doses. Goal: 1 h peak concentration 30–45 µg/mL and trough 10–15 µg/mL	6
		plus gentamicin	3 mg/kg IV or IM per 24 h in three divided doses	2
		plus rifampin <sup>1</sup>	900 mg IV or PO per 24 h in three divided doses	6

<sup>1</sup>Not FDA approved for this indication.

Adapted from Bonow RO, Carabello BA, Kanu C, et al: ACC/AHA 2006 guidelines for the management of patients with valvular heart disease: A report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines (writing committee to revise the 1998 Guidelines for the Management of Patients with Valvular Heart Disease): Developed in collaboration with the Society of Cardiovascular Anesthesiologists: Endorsed by the Society for Cardiovascular Angiography and Interventions and the Society of Thoracic Surgeons. *Circulation* 114(5):e84–e231, 2006.

Due to increasing microorganism resistance, parenteral therapy typically consists of a beta-lactam and aminoglycoside. They should be taken close together to increase the bactericidal effect. Care should be maintained with close observation of renal function.

### Complications and Surgical Indications

Infective endocarditis carries a high in-hospital mortality of up to 30% due to the development of potential complications either prior or during effective treatment. Heart failure or pulmonary edema is common, occurring in up to half of patients with IE, and is the most common indication for urgent surgery. Destruction of the valvular tissues creates significant regurgitation leading to volume overload. Conversely, severe vegetations can cause significant stenosis and lead to the same outcome. In rare cases, this can lead to cardiogenic shock, which is an immediate indication for surgery (within 24 hours). For those with symptoms of heart failure

and worsening hemodynamic response, surgery should be considered within 7 days of identification. Patients with heart failure will typically require surgical intervention as medical therapy alone is insufficient at repairing the damage caused by the infection. It is important to note here that valvular or other surgical interventions for IE may be performed in the acute or active phase of infection as delay can significantly increase the mortality.

Other complications include failure to quickly eradicate infection. This can be due to inability or delays in identifying the causative organism or for severe infections. Severe localized infections can cause paravalvular or aortic root abscesses. These abscess formations usually complicate 30% to 40% of IE cases due to their contiguous spread along the tissue planes. Other risk factors for abscess formation include prosthetic valves or difficult-to-treat organisms such as fungi or multidrug-resistant organisms. For this reason, all IE cases associated with

prosthetic valves should have surgical consideration. These cases are typically identified by persistently positive blood cultures despite appropriate antibiotic regimens. Abscesses are identified via TEE or the aforementioned imaging studies in patients with prosthetic valves. Due to the abscess formation and deep infection, surgical debridement or valve replacement is almost always required. Surgical evaluation and debridement is the gold standard of abscess identification.

The third major complication of IE relates to septic emboli from valvular vegetations. While one-third of patients with IE will have signs and symptoms of embolization, another one-third can be found to have silent emboli. Neurologic embolization is the most frequent site (40%), followed by lungs (20%), spleen (20%), peripheral arteries (~15%), and kidneys (10%). Embolization most often occurs prior to the initiation of antibiotic therapy and the risk of embolization is reduced by approximately 65% after 2 weeks of antibiotic therapy. Risk factors include vegetations greater than 10 mm in size and infections associated with *S. aureus* and *Streptococcus bovis*. These embolic events can further complicate treatment by causing metastatic infection sites. Embolic events are an independent risk factor for in-hospital death in IE and as such require surgical evaluation if the vegetations meet certain criteria. Surgery is indicated in valvular vegetations greater than 10 mm with embolic event while on antibiotics, in vegetations greater than 30 mm, and in those with vegetations greater than 10 mm with severe valvular (native and prosthetic) disease who are low operative risk.

### Conclusion

Infective endocarditis continues to maintain a relatively high mortality rate even with the advances in both surgical and antibiotic treatment. Prompt diagnosis and targeted antimicrobial therapy are vital to improving outcomes in patients with IE. Surgical evaluation and treatment should be considered relatively early in the disease course. Even with high rates of surgical intervention, in-hospital mortality continues to remain between 15% and 20% in native valves and up to 25% in prosthetic valves. Complications associated with disease progression (heart failure, uncontrolled infections, embolic events) also increase the mortality risk. Therefore a multidisciplinary team should be involved in patients identified with IE to provide best possible outcomes. Additionally, close follow-up after hospitalization should be conducted as up to 30% of patients with IE may require surgery in the first 12 months after diagnosis.

## MITRAL VALVE PROLAPSE

Method of

Kurt M. Jacobson, MD; Peter S. Rahko, MD; and Shenil Shah, MD

### CURRENT DIAGNOSIS

- A midsystolic click with or without a middle- to late-peaking crescendo systolic murmur is the classic auscultatory finding of mitral valve prolapse (MVP).
- Key examination maneuvers can help differentiate MVP from other valvular heart diseases.
- Diagnostic echocardiographic findings of MVP are systolic billowing of the mitral valve leaflets 2 mm above the annulus into the left atrium.
- The presence of significant myxomatous thickening of the valve leaflets (>5 mm) is significant for prognosis.

### CURRENT THERAPY

- Patients with physical findings of mitral valve prolapse (MVP) should have an echocardiogram to confirm the diagnosis, determine the severity of prolapse, determine the amount of myxomatous thickening, document the severity (if present) of mitral regurgitation, and determine left ventricular size and function.
- Uncomplicated MVP without significant mitral regurgitation can be evaluated clinically every 3 to 5 years.
- Complicated MVP (associated with significant mitral regurgitation, left ventricular structural changes, pulmonary hypertension, atrial fibrillation, or stroke) should be observed closely with serial clinical evaluation and echocardiography.
- Surgery may be required for complicated MVP associated with severe mitral regurgitation. Repair rather than replacement is the procedure of choice and should be performed at surgical centers experienced with mitral valve repair.
- Recommendations for surgery are the same for MVP as for other forms of chronic severe mitral regurgitation.
- Percutaneous intervention with the MitraClip (Abbott Vascular) is an option in symptomatic patients with moderate to severe or severe mitral regurgitation, prohibitive surgical risk, and acceptable anatomy.

Mitral valve prolapse (MVP) has been known by many names, including floppy valve syndrome, Barlow's syndrome, click/murmur syndrome, myxomatous mitral valve disease, and billowing mitral cusp syndrome. MVP is a common cardiac valvular abnormality characterized by redundant, floppy mitral valve leaflets; it is often detected initially by characteristic non-ejection clicks or a middle- to late-peaking crescendo systolic murmur on physical examination.

### Prevalence

MVP is the most common congenital cause of mitral regurgitation (MR) in adults and the most common indication for mitral valve surgery in the United States today. Previously, it was one of the most overdiagnosed conditions within cardiology, with suggested prevalence rates ranging from 5% to 15%. With the use of current diagnostic standards, rates are much lower; the overestimation was a consequence of diverse and nonuniformly accepted two-dimensional echocardiographic diagnostic criteria. Freed and colleagues, using the Framingham study population and applying consistent and more stringent echocardiographic diagnostic criteria, demonstrated a much lower prevalence of MVP (approximately 2.4%). The incidence appeared to be similar among men and women. Gender differences do exist, however. Women tend to have a more benign course, whereas men tend to have more advanced myxomatous disease resulting in a greater chance of more severe MR.

### Classification

Primary MVP is characterized by idiopathic myxomatous change of the mitral valve leaflets or the chordal structures or both. Secondary MVP is present when underlying conditions such as Marfan's syndrome, Ehlers-Danlos syndrome, osteogenesis imperfecta, or other collagen vascular disorders are evident. Certain congenital cardiac abnormalities, including Ebstein anomaly, aortic coarctation, hypertrophic cardiomyopathy, and ostium secundum atrial septal defects, are also associated with MVP. Familial variants with an autosomal dominant pattern of inheritance have been identified, and work to identify the genes involved is under way. The reported prevalence of MVP in first-degree relatives is between 30% and 50%.

### Pathology

Macroscopic and microscopic changes can involve both the anterior and posterior leaflets as well as the chordal structures of the leaflet apparatus. Macroscopically, the surface area of the leaflet is increased, providing the accentuated, billowing appearance of the valve leaflets. Additional notable changes are thickening of the individual leaflets, increased leaflet length, thinning and stretching of the chordae, and increased circumference of the mitral valve annulus. At the microscopic level (Figure 1), normal mitral valves have three well-defined layers, each containing cells and a characteristic composition and configuration of the extracellular matrix: the fibrosa, composed predominantly of collagen fibers densely packed and arranged parallel to the free edge of the leaflet; the centrally located spongiosa, composed of loosely arranged collagen and proteoglycans; and the atrialis, composed of elastic fibers. In myxomatous mitral valves, the spongiosa layer is expanded by loose, amorphous extracellular matrix that has more proteoglycans but less collagen and more fragmented elastic fibers. What collagen is present appears to be disorganized and fragmented, giving the appearance of a haphazard layering of the spongiosa. It is this thickening that produces the classic macroscopic appearance of the myxomatous valve on two-dimensional echocardiography.

### Clinical Presentation

Most patients with MVP are asymptomatic and will remain so, testifying to the often benign nature of this disease. Previously, various nonspecific symptoms, including fatigue, dyspnea, palpitations, postural orthostasis, anxiety, and panic attacks, were described as an MVP syndrome when present in association with the characteristic nonejection systolic click or middle- to late-peaking crescendo systolic murmur. Other symptoms, including chest discomfort, near-syncope, and syncope, have also been described by patients with MVP. However, in a community-based study, the prevalence of various clinical complaints including chest pain, dyspnea, and syncope was no higher in patients with MVP than in those without evidence of MVP, making such findings nonspecific. In a controlled study that compared symptomatic MVP patients with first-degree relatives with and without echocardiographic evidence of MVP, there also was no association of MVP with atypical chest pain, dyspnea, panic attacks, or anxiety. There was, however, a significant association of MVP with physical findings of systolic clicks, systolic murmurs, thoracic bony abnormalities, low body weight, and low blood pressure. Congestive heart failure, atrial fibrillation, stroke or transient ischemic attack, hypertension, diabetes, and hypercholesterolemia are no more likely in patients with MVP than in those without MVP. However, previous retrospective studies suggested a higher incidence of cerebral embolic events, infectious endocarditis, severe MR, and need for mitral valve replacement in patients with classic (complicated) versus nonclassic MVP. Symptoms of poor cardiac reserve, such as reduced exercise tolerance, dyspnea on exertion, and fatigue, may reflect the presence of significant MR and warrant clinical concern.

### Diagnosis

Symptoms are not predictive of the presence or absence of MVP. Certain physical and auscultatory characteristics on examination do support the diagnosis of MVP. Patients with MVP more often have a lower body mass index, have a lower waist-to-hip ratio, and are taller. Findings of scoliosis, pectus excavatum, and hyperextensibility are also prevalent among patients with MVP. The classic auscultatory findings include a midsystolic click and a middle- to late-peaking crescendo systolic murmur heard best at the apex. The auscultatory findings are best elicited with the diaphragm of the stethoscope, and they change in relation to the first and second heart sounds ( $S_1$  and  $S_2$ ) in response to changes in left ventricular (LV) volume. Therefore the patient should be examined in several positions: supine (including lateral decubitus), sitting, standing, and, if possible, squatting. Changes in LV filling and volume affect the degree of prolapse.

The most important and most specific finding on auscultation is the presence of a nonejection midsystolic click or clicks caused by snapping of the valve apparatus as parts of the valve leaflets billow into the atrium during systole. Although these clicks can be heard over the entire precordium, they are best heard at the apex. The click can be misinterpreted as a split  $S_1$ , a true  $S_1$  with an  $S_4$ , or a true  $S_1$  with an early ejection click from a bicuspid valve. It can be differentiated from an ejection click heard in bicuspid aortic valves by its timing relative to the beginning of the carotid upstroke. Ejection clicks occur as the aortic valve opens and therefore precede the carotid upstroke, whereas the nonejection clicks of MVP occur afterward. Clicks from atrial septal aneurysms are uncommon but can be difficult to distinguish from those of MVP. Ejection clicks and clicks from atrial septal aneurysms are not altered by changes in loading characteristics, allowing them to be differentiated from clicks of MVP. Often, but not always, a middle- to late-peaking crescendo systolic murmur can be appreciated by itself or after a click. The murmur terminates with closure of the aortic valve (A2). This represents MR, and, in general, the duration of the murmur correlates with the

**Figure 1** Morphologic features of normal mitral valves (*left*) and valves with myxomatous degeneration (*right*). Myxomatous valves have an abnormal layered architecture: loose collagen in fibrosa, expanded spongiosa strongly positive for proteoglycans, and disrupted elastin in atrialis (*top*). Movat pentachrome stain (collagen stains yellow, proteoglycans blue-green, and elastin black). Modified from Rabkin E, Aikawa M, Stone JR, et al: Activated interstitial myofibroblasts express catabolic enzymes and mediate matrix remodeling in myxomatous heart valves. *Circulation* 2001;104:2525.)

**Figure 2** Auscultative findings with changes in position in patients with mitral valve prolapse (MVP). Abbreviations: C = click of MVP; S<sub>1</sub>, mitral valve closure; S<sub>2</sub>, aortic valve closure. Modified from Devereux RB, Perloff JK, Reichek N, et al: Mitral valve prolapse. *Circulation* 1976;54[1]:3–14.)

severity of the MR. The earlier in systole the murmur is detected, the more severe the MR. Eventually, with more severe MR, the murmur becomes holosystolic. MVP manifestations on examination vary, and they may not always be reproducible, even in the same patient.

Certain maneuvers can aid in more accurately diagnosing MVP on examination (Figure 2). MVP is very sensitive to LV filling, and subtle changes in auscultatory findings elicited by careful examination maneuvers can be instrumental in separating MVP from other valvular abnormalities. Generally, maneuvers that decrease LV volume or increase contractility produce earlier and more prominent systolic prolapse of the mitral leaflets, causing the systolic click and murmur to move closer to S<sub>1</sub>. For example, in the transition from squatting to standing, LV volume is reduced, and the onset of the click and murmur is moved closer to S<sub>1</sub>. Conversely, anything that increases LV volume, such as leg-raising, squatting, or slowing the heart rate (increased diastolic filling), delays the onset of the click or murmur and usually diminishes its duration and intensity.

### Use of Echocardiography

Two-dimensional echocardiography has proved to be the most accurate noninvasive tool for the diagnosis, assessment, and follow-up of clinically suspected MVP. In fact, physical signs of MVP in an asymptomatic patient are an American College

of Cardiology/American Heart Association (ACC/AHA) class I indication for use of echocardiography to make the diagnosis of MVP and assess the severity of MR, leaflet morphology, and ventricular size and function. Once the diagnosis is made, follow-up is determined by the severity of MVP. Routine echocardiographic follow-up of asymptomatic patients with MVP is not recommended unless there are significant findings of MR or LV structural changes. Frequency of follow-up in patients with prolapse and MR is determined by the severity of MR and should be at least annual in patients with severe MR.

Diagnostic criteria for MVP on two-dimensional echocardiography are:

- Billowing of one or both mitral valve leaflets or their prolapse superiorly across the mitral annular plane in the parasternal long-axis view by greater than 2 mm during systole
- The degree of thickening of the leaflets

Combined leaflet prolapse of greater than 2 mm and leaflet thickness greater than 5 mm are supportive of classic MVP, whereas prolapse in the absence of increased thickness is considered nonclassic MVP. In addition to more often being associated with the auscultative findings of the click and murmur, the classic form is more commonly associated with increased risk of endocarditis, stroke, progressive MR, and need for mitral valve repair or replacement.

**TABLE 1** ACC/AHA Recommendations for Oral Anticoagulation in Patients With Mitral Valve Prolapse

CLASS	RECOMMENDATION
I	ASA therapy (75–325 mg/d) for cerebral TIAs Warfarin (Coumadin) therapy for patients $\geq 65$ years in atrial fibrillation with hypertension, MR, or history of congestive heart failure ASA therapy (75–325 mg/d) for patients $< 65$ years in atrial fibrillation with no history of MR, hypertension, or congestive heart failure Warfarin therapy after stroke for patients with MR, atrial fibrillation, or left atrial thrombus
Ia	ASA therapy is reasonable in patients after stroke who do not have MR, atrial fibrillation, left atrial thrombus, or echocardiographic evidence of thickening $\geq 5$ mm or redundancy of leaflets Warfarin therapy is reasonable after stroke for patients without MR, atrial fibrillation, or left atrial thrombus who have echocardiographic evidence of thickening $\geq 5$ mm or redundancy of leaflets Warfarin therapy is reasonable for TIAs that occur despite ASA therapy ASA therapy (75–325 mg/d) can be beneficial for patients with a history of stroke who have contraindications to anticoagulants
Iib	ASA therapy (75–325 mg/d) may be considered for patients in sinus rhythm with echocardiographic evidence of complicated MVP

Abbreviations: ACC/AHA = American College of Cardiology/American Heart Association; ASA = aspirin; MR = mitral regurgitation; TIA = transient ischemic attack.

Adapted from Bonow RO, Carabello BA, Chatterjee K, et al: 2008 Focused update incorporated into the ACC/AHA 2006 guidelines for the management of patients with valvular heart disease. *Circulation* 118(15):e523–661, 2008.

Because the mitral apparatus is saddle-shaped, certain echocardiographic views are more specific than others for determining leaflet prolapse. Most practitioners agree that the parasternal long-axis and apical two-chamber or apical long-axis views are the most accurate for determining prolapse. A finding of prolapse as determined on other views, particularly the apical four-chamber view, is much less specific and frequently leads to a false-positive diagnosis.

### Medical Management

Most patients with MVP remain asymptomatic and require no additional management aside from careful observation over time. It is appropriate to provide reassurance that uncomplicated (nonclassic) MVP is a non-life-threatening condition and is unlikely to affect longevity. Periodic clinical evaluation every 3 to 5 years is reasonable. Patients who develop palpitations, lightheadedness, dizziness, or syncope should undergo Holter or event monitoring for detection of arrhythmias. Palpitations are frequently controlled with  $\beta$ -blockers or calcium channel blockers, although the presence of specific arrhythmias may mandate additional therapy. Endocarditis prophylaxis is no longer recommended for patients with MVP unless they have a history of endocarditis or valve replacement. Prophylaxis is recommended for patients who have undergone repair if prosthetic material was used (e.g., in ring repairs).

Aspirin or warfarin (Coumadin) therapy may be recommended for certain symptomatic patients with neurologic events who have atrial fibrillation, significant MR, hypertension, or heart failure (Table 1).

Patients with classic (complicated) MVP deserve regular clinical follow-up, particularly if MR is present. These patients are more likely to develop moderate or severe MR over time. Patients with mild to moderate MR and normal LV function should be clinically evaluated at least annually and should undergo echocardiography every second or third year if stable. Patients with severe MR should have an annual echocardiogram and closer clinical follow-up. Those who have severe MR and develop symptoms or impaired LV systolic function require cardiac catheterization and evaluation for mitral valve surgery. Often the valve can be repaired rather than replaced, with a low operative mortality rate and excellent short- and long-term results when performed at experienced centers. Preservation of the native valve allows for lower risks of thrombosis and endocarditis than does prosthetic valve replacement.

### Surgical Management

MVP is the most common cause of adult MR requiring mitral valve surgery. Symptoms of heart failure, severity of MR, presence or absence of atrial fibrillation, LV systolic function, LV end-diastolic and end-systolic volumes, and pulmonary artery pressure (at rest and with exercise) influence the decision to recommend mitral valve surgery. Indications for surgery in patients with MVP and MR mirror those with other forms of nonischemic severe MR. Patient outcomes after mitral valve repair are typically very good, and the surgical risk is lower than for many other forms of cardiac surgery, including mitral valve replacement.

Based on a Cleveland Clinic review of 1072 patients who underwent primary isolated mitral valve repair for MR due to myxomatous disease, the in-hospital mortality rate was 0.3%. The Mayo Clinic reviewed 1173 patients who underwent mitral valve repair for MVP from 1980 to 1999, observing mortality rates of 0.7%, 11.3%, and 29.4% at 30 days, 5 years, and 10 years, respectively.

Because of the remarkably low mortality rates associated with MVP repair, some experts advocate earlier rather than later repair of MVP in asymptomatic patients with severe MR and no evidence of LV dysfunction, pulmonary hypertension, or atrial fibrillation. AHA/ACC recommendations for surgery in patients with chronic primary mitral valve regurgitation are shown in Table 2.

### Percutaneous Management

In 2013 the FDA approved the MitraClip (Abbott Vascular) for patients with symptomatic degenerative MR who are deemed high risk for mitral valve surgery. The MitraClip technology is based on the Alfieri edge-to-edge repair in which the middle segments of the anterior and posterior leaflet are sutured together to create a double-orifice. It is approved for use in patients with New York Heart Association Class III or IV heart failure despite medical therapy, chronic moderate to severe or severe primary MR, favorable anatomy typically involving the middle segments of the anterior and posterior leaflets, reasonable life expectancy, and prohibitive surgical risk. This approval is based on the results of the Endovascular Valve Edge-to-Edge Repair Study (EVEREST II), which randomized 279 patients to either percutaneous repair or conventional surgery for repair or replacement of the mitral valve with a primary endpoint of freedom from death, from surgery for mitral valve dysfunction, and from grade 3+ or 4+ MR

**TABLE 2** ACC/AHA Recommendations for Surgery in Patients With Chronic Primary Mitral Valve Regurgitation

CLASS	RECOMMENDATION
I	<p>Mitral valve (MV) surgery is recommended for symptomatic patients with chronic severe primary MR (stage D) and left ventricular ejection fraction (LVEF) &gt;30%</p> <p>MV surgery is recommended for asymptomatic patients with chronic severe primary MR and left ventricular (LV) dysfunction (LVEF 30%-60% and/or left ventricular end-systolic dimension [LVESD] ≥40 mm, stage C2)</p> <p>MV repair is recommended in preference to mitral valve replacement (MVR) when surgical treatment is indicated for patients with chronic severe primary MR limited to the posterior leaflet</p> <p>MV repair is recommended in preference to MVR when surgical treatment is indicated for patients with chronic severe primary MR involving the anterior leaflet or both leaflets when a successful and durable repair can be accomplished</p> <p>Concomitant MV repair or replacement is indicated in patients with chronic severe primary MR undergoing cardiac surgery for other indications</p>
IIa	<p>MV repair is reasonable in asymptomatic patients with chronic severe primary MR (stage C1) with preserved LV function (LVEF &gt;60% and LVESD &lt;40 mm) in whom the likelihood of a successful and durable repair without residual MR is &gt;95% with an expected mortality rate of &lt;1% when performed at a Heart Valve Center of Excellence</p> <p>MV repair is reasonable for asymptomatic patients with chronic severe primary MR (stage C1) and preserved LV function (LVEF &gt;60% and LVESD &lt;40 mm) in whom there is a high likelihood of a successful and durable repair with 1) new onset of atrial fibrillation or 2) resting pulmonary hypertension (pulmonary artery systolic arterial pressure &gt;50 mm Hg)</p> <p>MV repair is reasonable for asymptomatic patients with chronic severe primary MR (stage C1) and preserved LV function (LVEF &gt;60% and LVESD &lt;40 mm) with progressive increase in LV size or decrease in ejection fraction on serial imaging studies</p> <p>Concomitant MV repair is reasonable in patients with chronic moderate primary MR (stage B) undergoing cardiac surgery for other indications</p>
IIb	<p>MV surgery may be considered in symptomatic patients with chronic severe primary MR and LVEF less than or equal to 30% (stage D)</p> <p>MV repair may be considered in patients with rheumatic mitral valve disease when surgical treatment is indicated if a durable and successful repair is likely or if the reliability of long-term anticoagulation management is questionable</p> <p>Transcatheter MV repair may be considered for severely symptomatic patients (New York Heart Association class III/IV) with chronic severe primary MR (stage D) who have a reasonable life expectancy but a prohibitive surgical risk because of severe comorbidities and remain symptomatic despite optimal goal directed medical therapy for heart failure</p>
III Harm	<p>MVR should not be performed for treatment of isolated severe primary MR limited to less than one half of the posterior leaflet unless MV repair has been attempted and was unsuccessful</p>

Adapted from 2017 AHA/ACC focused update of the 2014 ACC/AHA guidelines for the management of patients with valvular heart disease. *Circulation* 135(25): e1159–e1195, 2017.

at 12 months. The rates of the combined primary endpoints were 55% in the percutaneous group and 73% in the surgery group (p=0.007). Rates of death (6% and 6%, respectively) and 3+ or 4+ MR (21% and 20%, respectively) were similar in each group. Major adverse events occurred in 15% of patients in the percutaneous repair group versus 48% in the surgery group at 30 days (p<0.001). Although the MitraClip was less effective at reducing MR, it was approved on the bases of its superior safety and similar clinical outcomes.

## PERICARDITIS

Method of

Amir Azarbal, MD; and Martin M. LeWinter, MD

### CURRENT DIAGNOSIS

- Acute pericarditis is an inflammatory syndrome thought to be caused by a viral infection in most cases. It is diagnosed when 2 of the following are present: (1) typical anterior pleuritic chest pain, (2) pericardial friction rub, (3) electrocardiography (ECG) changes (widespread ST segment elevation or PR depression, and (4) new or worsening pericardial effusion.
- Leukocytosis and an elevated high-sensitivity C-reactive protein or erythrocyte sedimentation rate (ESR) are present in most cases.
- Echocardiography is routinely used to detect pericardial effusion. Cardiac magnetic resonance imaging or computed tomography can be used to support the diagnosis.

## CURRENT THERAPY

- Limitation of physical activity and high-dose aspirin<sup>1</sup> or other nonsteroidal antiinflammatory drugs such as ibuprofen (Advil)<sup>1</sup> plus colchicine<sup>1</sup> is the treatment of choice for idiopathic (presumed viral) pericarditis.
- Corticosteroids with gradual taper can be added for recurrences.
- Antiinflammatory drugs such as azathioprine (Imuran),<sup>1</sup> anakinra (Kineret),<sup>1</sup> and human intravenous immunoglobulin (Gammagard)<sup>1</sup> have been used in difficult cases of recurrent pericarditis
- Pericardiectomy is reserved for refractory cases and constrictive pericarditis.

<sup>1</sup>Not FDA approved for this indication.

### Anatomy and Functions of the Pericardium

The pericardium consists of 2 layers. A visceral monolayer comprised of mesothelial cells is adherent to the epicardium and reflects over the origin of the great vessels, where it is continuous with the inner layer of the parietal pericardium. The latter is approximately 2 mm thick and comprised mainly of collagen and elastin. The pericardial sac is the space between visceral and parietal layers and normally contains up to 50 mL of serous fluid. The pericardium has several functions, including (1) acting as a barrier to infections, (2) providing a mechanism whereby hydrostatic pressure is exerted on the surface of the heart when gravitational or inertial forces are altered, (3) participating in neuro-humoral responses, and (4) limiting short-term distention and displacement of the heart, facilitating interactions between the cardiac chambers and modulating pressure-volume relationships and cardiac output.

### Acute Pericarditis

The main inflammatory pericardial syndromes include acute and recurrent pericarditis and constrictive and effusive-constrictive pericarditis. These can be isolated to the pericardium or be a component of a systemic disease.

Acute pericarditis is the most common pericardial syndrome and is responsible for approximately 5% of emergency room visits for chest pain and 2% of patients presenting with ST elevations on ECG. An in-hospital mortality rate of approximately 1% has been reported. Acute pericarditis is more common in males. Recurrence occurs in 15% to 20% of patients within 18 months after a first episode. Acute pericarditis can also involve the myocardium and cause myopericarditis, with elevated cardiac injury biomarkers (e.g., troponin I).

### Etiology

Almost any disease that affects the pericardium can cause acute pericarditis. Acute pericarditis can also cause pericardial effusion; the incidence is highly dependent on etiology. Infectious etiologies are considered to be responsible for the majority of cases. In developed countries 80% to 90% of cases are idiopathic, that is, no specific cause is detected on routine evaluation. These cases are assumed to be viral in etiology. Bacterial and rarely fungal infections account for a small percentage of cases in the developed world. However, *Mycobacterium tuberculosis* is the most common cause of pericarditis in developing countries. Very rarely, parasitic diseases such as echinococcus and toxoplasma species can cause acute pericarditis.

Autoimmune diseases are another common cause of acute pericarditis. These include systemic autoimmune diseases such as lupus erythematosus (SLE), rheumatoid arthritis, Sjögren syndrome, and scleroderma, as well as vasculitic diseases such as eosinophilic granulomatosis with polyangiitis or allergic

granulomatosis (previously named *Churg-Strauss syndrome*), Takayasu disease, and Behçet syndrome. Other autoimmune disorders associated with acute pericarditis are sarcoidosis, familial Mediterranean fever, and inflammatory bowel disease.

Malignancies affecting the pericardium also cause acute pericarditis. Almost all neoplastic pericarditis is caused by secondary metastases from extracardiac tumors, especially lung and breast cancer.

Pericarditis can occur after myocardial infarction (MI), both early (i.e., 2 to 4 days after MI) and late (Dressler syndrome, ≈1 week to 2 months after MI), and after heart surgery. The incidence of post-MI pericarditis has markedly declined because of reperfusion therapy. Trauma such as penetrating and non-penetrating thoracic injury, esophageal perforation, and procedural complications of cardiac procedures (coronary stenting, pacemaker lead insertion, radiofrequency ablation) are all reported. Although these can cause acute cardiac tamponade, acute pericarditis occurs as a late complication within 1 to 2 weeks to as late as 3 months after the initial event. These causes are collectively termed *post-cardiac injury syndromes* and are believed to have an autoinflammatory basis. Acute pericarditis has also been reported as an immune-mediated response to various drugs.

### Presentation

The diagnosis of acute pericarditis is made if two of the following are present: (1) typical anterior chest pain, (2) pericardial friction rub, (3) typical ECG changes (widespread ST segment elevation or PR depression, and (4) new or worsening pericardial effusion. In cases with typical chest pain but no other criteria, additional findings that can establish the diagnosis are elevated cardiac injury biomarkers and evidence of pericardial inflammation or thickening based on advanced imaging modalities (cardiac magnetic resonance imaging [cMRI], computed tomography [CT]). An elevation of either high-sensitivity C reactive protein (hsCRP) or the erythrocyte sedimentation (ESR) rate is supportive but not diagnostic.

Chest pain is the most common symptom of acute pericarditis, present in >90% of cases. The pain is typically sharp, located under the sternum or over the left anterior chest, and almost always pleuritic. The trapezius ridge is a classic radiation. The pain is worst supine and improved by sitting forward. Approximately one-third of patients have a pericardial friction rub (a scratchy or squeaking sound at the left sternal border) because of contact between the layers of the pericardium. The friction rub ordinarily has 3 components. Typical ECG changes include ST elevation in all leads except AVR and sometimes V1, as well as PR segment depression. Over time, these changes either simply disappear or go through a phase of ST segment normalization and T-wave inversion before disappearing. Both the friction rub and ECG changes are often evanescent. In cases where it is difficult to establish a diagnosis, repeated auscultation and ECGs can be rewarding. A pericardial effusion has been reported in as many as two-thirds of patients with acute pericarditis. The great majority are small. Sinus tachycardia and low-grade fever are also common. If cardiac tamponade is present, elevated jugular venous pressure, muffled heart sounds, hypotension, and pulsus paradoxus are seen. Other diagnoses that can be confused with acute pericarditis include acute MI, pleuritis, pulmonary embolism, costochondritis, and herpes zoster before appearance of vesicles.

Features accompanying acute pericarditis that indicate an elevated risk (mainly for development of cardiac tamponade) include fever >38.5°C, subacute onset of symptoms, moderate to large pericardial effusion, lack of response to aspirin or nonsteroidal antiinflammatory drugs (NSAIDs), immunosuppression, white blood cell count >13,000/mm<sup>3</sup>, anticoagulant therapy, and suspicion of a non-idiopathic/viral cause such as cancer, SLE, or bacterial infection.

## Diagnostic Evaluation

Routine evaluation is directed toward identifying patients with or at elevated risk for cardiac tamponade or patients with a non-idiopathic/viral cause. In addition to a careful history, physical examination, and ECG, routine evaluation should include a chest radiograph, CBC, hs-CRP, routine blood chemistries, and an echocardiogram. Echocardiography should be performed in all patients to detect pericardial effusion, which can be hemodynamically significant despite a normal radiographic cardiac silhouette, and to assess cardiac function in cases with myopericarditis. In the vast majority of cases myopericarditis has no long-term prognostic significance.

## Clinical Laboratory Data

Leukocytosis and elevated hs-CRP or ESR are present in most cases. The hs-CRP in particular is increased in about 75% of cases and usually normalizes within 1 to 2 weeks. Failure of normalization within this time frame is associated with higher rates of recurrence. In patients with concomitant myocarditis, markers of cardiac injury such as troponin-I are elevated.

## ECG

As discussed earlier, typical ECG changes considered to be hallmarks of acute pericarditis include widespread ST segment elevations or PR segment depression (Figure 1). ECG changes are dynamic, and about 60% of patients have the following evolution over time: stage I (PR depression, ST segment elevation), stage II (ST normalization), stage III (T-wave inversion after ST segment normalization), and stage IV (ST-T normalization). These evolutionary changes have no known prognostic significance.

## Imaging

The chest radiograph is normal in acute pericarditis unless a moderate- to large-size pericardial effusion or associated pulmonary pathology is present. The echocardiogram is usually normal except for the common presence of small pericardial effusions (Figure 2). In cases with associated myopericarditis, the left ventricular ejection fraction is almost always normal.

Cardiac MRI or CT typically shows pericardial thickening and enhanced gadolinium uptake (Figure 3). Advanced imaging modalities can be used to support the diagnosis of pericarditis in difficult cases.

## Treatment

Treatment of common pericardial syndromes is summarized in Table 1. Reliable patients without high-risk features need not be hospitalized. For treatment of an initial episode of acute idiopathic pericarditis, avoidance of physical activity greater than walking at a normal pace is recommended until symptoms resolve and CRP has normalized. Athletes should refrain from competitive sports activities for at least 3 months. NSAIDs plus colchicine<sup>1</sup> is a first-line pharmacologic treatment. We recommend ibuprofen (Advil)<sup>1</sup> 600 to 800 mg by mouth 3 times daily or aspirin<sup>1</sup> 2 to 4 g by mouth daily in divided doses and colchicine<sup>1</sup> 0.6 mg twice daily (0.6 mg once daily for patients <70 kg) until symptoms resolve and CRP normalizes. The NSAID should then be tapered over 1 to 2 weeks and colchicine continued for 3 months from onset of symptoms. All patients should receive a proton pump inhibitor while receiving NSAIDs.

In pregnancy ibuprofen, aspirin >100 mg/day by mouth, and colchicine are contraindicated after 20 weeks' gestation. Corticosteroids are preferred in this circumstance. In addition, colchicine is contraindicated during lactation.

In patients in whom a specific cause for acute pericarditis other than idiopathic/viral has been identified, the treatment should be directed at that cause. Thus, in patients with autoimmune diseases, corticosteroids may be more appropriate as the initial treatment.

**Figure 1** Electrocardiogram demonstrating typical changes of acute pericarditis. Note the widespread ST segment elevations with concomitant PR segment depression.

**Figure 2** Parasternal long-axis view of a transthoracic echocardiogram performed in a patient with acute pericarditis showing small to moderate-sized pericardial effusion (asterisk). Also note a pacemaker lead in the right ventricle (arrow) and associated acoustic shadowing artifact.

**Figure 3** Cardiac MRI image in a patient with acute pericarditis after intravenous gadolinium administration. Note late gadolinium enhancement of the pericardium along with pericardial thickening indicating inflammation (asterisk). Other findings are pericardial fat (arrowhead) and trivalvular pericardial effusion (arrow).

<sup>1</sup>Not FDA approved for this indication.

**TABLE 1** Treatment Summary of Common Pericardial Syndromes

PERICARDIAL SYNDROME	TREATMENT OVERVIEW	SPECIFIC CONSIDERATIONS
Acute pericarditis	Physical activity restriction <i>and</i> NSAIDs <i>plus</i> Colchicine <sup>1</sup>	Restriction of physical activity until resolution of symptoms NSAIDs until symptoms resolve and CRP normalizes Colchicine for 2 to 3 months See text for pregnancy and lactation considerations
Recurrent pericarditis	Acute pericarditis treatment <i>plus</i> Corticosteroids (in refractory cases) <i>or</i> Immunosuppressive therapy (for multiple recurrences) <i>or</i> Pericardiectomy (last resort)	Restriction of physical activity until resolution of symptoms NSAIDs until symptoms resolve and CRP normalizes for 1 to 2 weeks with subsequent taper Colchicine <sup>1</sup> for at least 6 months For multiple recurrences, low to moderate doses of corticosteroids until resolution of symptoms and normalization of CRP followed by slow taper Immunosuppressants (anakinra [Kineret], <sup>1</sup> azathioprine [Imuran], <sup>1</sup> intravenous immunoglobulin <sup>1</sup> ) for multiple recurrences Pericardiectomy in refractory cases (last resort)
Constrictive pericarditis	Treatment of underlying condition (ie, tuberculosis, inflammation) <i>or</i> Pericardiectomy (if chronic and refractory)	In cases of pericardial inflammation, an empiric antiinflammatory regimen may reverse the disease process and obviate the need for pericardiectomy.

<sup>1</sup>Not FDA approved for this indication.

### Recurrent Pericarditis

Recurrent pericarditis is the most common complication of acute pericarditis and is defined as a repeat episode after a symptom-free interval of at least 4 to 6 weeks. The recurrence rate after an initial episode of acute pericarditis is approximately 15% to 20% and may increase to as much as 50% after a first recurrent episode. Patients with recurrent pericarditis can be severely incapacitated. Certain rare conditions such as familial Mediterranean fever, tumor necrosis factor receptor–associated periodic syndrome, and other periodic fever syndromes are often characterized by bouts of recurrent pericarditis. Inadequate treatment of a first episode (e.g., inadequate drug doses, too short a treatment duration or too rapid discontinuation, or tapering of medications) can be responsible for recurrences.

Recurrent pericarditis after an initial bout of idiopathic/viral pericarditis is currently considered to be an autoinflammatory process (as opposed to an autoimmune disease such as SLE). It is hypothesized that, after an initial viral infection, immune system cross-reaction between viral particles and host tissue occurs. A similar mechanism is believed to be operative in the periodic fever syndromes. Of course, pericarditis due to other, specific causes can also recur.

The most feared complication of recurrent pericarditis is constrictive pericarditis. The incidence is high ( $\leq 30\%$ ) in cases of bacterial pericarditis and low to moderate ( $< 5\%$ ) in systemic inflammatory diseases and cancer. In patients with recurrences after an initial bout of viral/idiopathic pericarditis, symptoms almost always eventually resolve, and progression to constrictive pericarditis is very rare ( $< 1\%$ ).

The diagnosis of a recurrence is based on the same criteria as for an initial episode (i.e., history, friction rub, ECG findings, and a new or worsening pericardial effusion). Elevated hs-CRP, ESR, and white blood cell count remain useful for monitoring disease activity and response to treatment. More advanced imaging modalities such as CT or cMRI are rarely required to diagnose a recurrence but are useful if there is a concern about development of constriction.

In general, for patients with a recurrence after an index episode of idiopathic/viral pericarditis we recommend that treatment be the same as for the initial episode (i.e., restriction of physical activity, NSAID, and colchicine<sup>1</sup>) until complete resolution of symptoms and normalization of hs-CRP. Some patients are able to manage recurrences by initiating treatment at the very first sign of symptoms. If the response is prompt, the recurrence is converted to a minor illness.

Use of corticosteroids for treatment of recurrent pericarditis should be reserved for cases where the above-mentioned measures have failed, especially if recurrences are frequent and severe and do not respond well to NSAIDs. Unusual patients with an initial episode who do not respond to first-line therapy are also candidates. Corticosteroids usually provide rapid relief of symptoms, and almost all patients respond favorably initially. However, corticosteroids appear to increase the chance of further recurrences, especially when high initial doses are used with rapid tapering. High doses also have a much higher incidence of adverse effects. If a decision is made to use corticosteroids, we recommend low to moderate doses (e.g., prednisone<sup>1</sup> 0.25 to 0.5 mg/kg/day or equivalent) usually for about 4 to 8 weeks, followed by gradual tapering (assuming symptom resolution and normalization of hs-CRP) in conjunction with colchicine. NSAIDs may also be included or added later as corticosteroids are tapered. Colchicine should ordinarily be continued for 6 months. During tapering, recurrences typically occur with doses  $< 10$  to 15 mg/day dose of prednisone or equivalent. Patients symptom free at this threshold should be treated with smaller subsequent dose decrements at intervals of 2 to 6 weeks. If possible, recurrences occurring during tapering should be treated with NSAID optimization rather than increasing corticosteroids. To prevent side effects of long-term corticosteroid use, specifically bone loss, consideration should be given to supplementary calcium and vitamin D. Bisphosphonates are recommended in all men  $\geq 50$  years and postmenopausal women in whom long-term treatment with corticosteroids at a dose of 5.0 to 7.5 mg/day of prednisone or equivalent is required.

In patients with multiple recurrences ( $\geq 3$  episodes) despite the aforementioned strategies, alternative drugs have been suggested based on case reports, case series, and small randomized trials. These include azathioprine (Imuran),<sup>1</sup> methotrexate (Trexall),<sup>1</sup> and intravenous human immunoglobulin.<sup>1</sup> Recently, the interleukin (IL)-1 $\beta$  antagonist anakinra (Kineret)<sup>1</sup> (1 to 2 mg/kg/day up to 100 mg subcutaneously for several months) has shown considerable promise; other IL-1 $\beta$  antagonists are in development. Finally, as a last resort for refractory cases of recurrent pericarditis, pericardiectomy may be effective.

### Constrictive Pericarditis

#### Etiology

Constrictive pericarditis is a consequence of chronic forms of pericarditis, especially bacterial (20% to 30%), immune-mediated, and neoplastic (2% to 5%) disease. Some cases are idiopathic. Other causes include cardiac injury syndromes, postradiation, uremia, and sarcoidosis. Before the availability

of effective antimicrobial therapy, tuberculous pericarditis was the most important cause, but this is now rare in the developed world. In the third world, tuberculosis remains an important cause of pericardial disease in general and constrictive pericarditis in particular, often in association with HIV/AIDS. It is very rare (<1%) for idiopathic/viral pericarditis to result in constrictive pericarditis.

When tuberculosis was the major cause of constrictive pericarditis, cases typically presented as a very chronic disease with the features described below. Heavy pericardial calcification was a classic feature. In contemporary practice, most cases of constrictive pericarditis occur in conjunction with the syndrome of effusive-constrictive pericarditis, where pericardial effusion and constriction coexist in varying combinations.

### Presentation and Physical Findings

Patients with constrictive pericarditis present with signs and symptoms of right heart failure, with small cardiac volumes and preserved ejection fraction (EF). (In extreme cases EF may be reduced due to severely impaired filling.) Symptoms include fatigue, peripheral edema, dyspnea, hepatomegaly, pleural effusions, and ascites. On physical examination, the venous pressure is markedly elevated, with an M- or W-shaped waveform caused by rapid atrial pressure descents. There is a paradoxical rise in venous pressure with inspiration (Kussmaul's sign), consistent with impaired filling of the right ventricle. A paradoxical pulse is present in as many as one-third of patients. Auscultation may reveal a pericardial knock, an early diastolic, medium-frequency sound (occurring slightly earlier than a usual third heart sound) that reflects abrupt cessation of rapid filling of the ventricles caused by the constricting pericardium. Atrial fibrillation is very common.

By definition, patients with effusive-constrictive pericarditis have pericardial effusions of variable size, which often contain adhesions and fibrous strands and are sometimes large enough to cause cardiac tamponade. In these cases, the diagnosis of constriction is often made after pericardiocentesis, when right heart filling pressures remain elevated and typical hemodynamic features become apparent.

### Diagnostic Tests

The ECG often reveals nonspecific repolarization abnormalities, but there are no specific findings. In effusive-constrictive pericarditis, low-voltage and electrical alternans may be apparent if there is a large effusion. The chest X-ray film may reveal pericardial calcification, but its incidence is now low. Pleural effusions are common.

Major echocardiographic-Doppler findings include small cardiac chambers, a septal "bounce" because of exaggerated septal motion related to increased ventricular interdependence, increased mitral and tricuspid respiratory flow variation, and pericardial thickening and calcification. Interdependence is explained on the basis of a fixed intrapericardial volume, as a result of which when the volume of one ventricle changes (e.g., during respiration), the volume of the other must change reciprocally.

Cardiac catheterization reveals rapid atrial pressure descents, equalization of left- and right-sided filling pressures, increased respiratory variation in LV and RV systolic pressure (also due to ventricular interdependence) and a characteristic "dip and plateau" or "square root" sign evident in the ventricular diastolic pressure.

Cardiac CT and MRI are the best methods for imaging the pericardium. These demonstrate variable increases in pericardial thickness and calcification if present, although rare cases without increased thickness have been reported. Pericardial calcifications can be especially well visualized by cardiac CT and increased ventricular interdependence can be appreciated on real-time cine MR images. Modern cases of constrictive and effusive-constrictive pericarditis often have prominent pericardial inflammation, best imaged by gadolinium uptake during cMRI.

### Treatment

Medical management of constrictive pericarditis is symptomatic and supportive, primarily consisting of diuretics to manage signs of right heart failure. It is important to avoid drugs that slow the heart rate, as these patients are critically dependent on heart rate to maintain cardiac output. Ultimately, these patients become refractory to diuretics.

Pericardiectomy has been considered the most definitive treatment for constrictive pericarditis. However, these are often difficult surgeries with high morbidity and mortality rates and delayed benefit. A number of patients are deemed too debilitated for surgery. Postradiation constriction has been considered a specific contraindication. Before pericardiectomy is undertaken, consideration should be given to a trial of an antiinflammatory regimen, especially in idiopathic cases, cases due to systemic inflammatory diseases, and cases due to post-cardiac injury syndromes. High-intensity gadolinium uptake on cardiac MRI in association with pericardial thickening is a signal that such a regimen may be successful, and apparent cures have been reported. Patients with evidence of intense inflammation often have a subacute course and belong in the subset with effusive-constrictive pericarditis. There have been no formal trials of specific antiinflammatory regimens. We favor a course of intermediate-dose prednisone<sup>1</sup> followed by a gradual taper similar to that recommended for recurrent pericarditis, along with colchicine<sup>1</sup> for at least 6 months. In cases of effusive-constrictive pericarditis presenting with cardiac tamponade, a few days of higher-dose prednisone initially may be reasonable. If an antiinflammatory regimen is to be attempted, we recommend committing to at least 2 to 3 months of prednisone treatment before tapering is begun. Reimaging the pericardium to ensure that inflammation has resolved before tapering is helpful.

## PERIPHERAL ARTERY DISEASE

Method of

William Michael, MD

### Epidemiology and Risk Factors

Peripheral artery disease (PAD), the third leading cause of atherosclerotic morbidity following coronary artery disease and stroke, is estimated to affect 8.5 million Americans older than 40 years of age and more than 230 million people worldwide. The prevalence ranges from ~5% among individuals 40 to 44 years of age up to ~12% among those 70 to 74 years of age. Although PAD is defined as atherosclerotic disease in any arterial vessel outside of the coronary circulation, the most common sites for the development of PAD are the abdominal aorta and vessels of the lower extremities. Patients at increased risk of PAD are those older than

65 years of age and those with diabetes, a history of smoking, hyperlipidemia, and hypertension. Individuals with a family history of PAD or with known atherosclerotic disease in another vascular bed area are also at increased risk.

### Pathophysiology

PAD is related to the development of atherosclerotic plaques of the peripheral arteries that leads to reduction of blood flow to peripheral tissues. Classic claudication involves flow-limiting blockages that present as exertional pain in the lower extremities that is caused by lack of oxygen delivery to the peripheral tissues and improves with rest. More serious manifestations of PAD are termed *critical limb ischemia* (CLI) and involve pain at rest or pain that wakes the patient at night, nonhealing wounds/ulcerations in the distal extremities, or gangrene.

### Prevention and Screening Recommendations

Prevention of PAD involves controlling risk factors associated with the development of atherosclerotic disease (e.g., diabetes mellitus, history of smoking, hyperlipidemia, hypertension) and appropriately managing these conditions. The U.S. Preventive Services Task Force (USPSTF) states that the evidence for screening for PAD as part of cardiovascular risk assessment is inconclusive (I rating). However, the American Heart Association (AHA) recommends screening with ankle-brachial index (ABI) in adults at high risk of having PAD (those older than 65 years of age and those 50 to 64 years of age with risk factors for atherosclerotic disease).

### Clinical Manifestations

PAD can manifest in a number of different ways, and many individuals are asymptomatic (20% to 50%). Classic intermittent claudication presents with exertional leg pain (often in the calf but also in the buttock, hip, thigh, or foot) that resolves within 10 minutes of rest. However, only 10% to 30% of patients present with classic claudication. The remaining 40% to 50% present with “atypical” leg symptoms that include pain that begins at rest, pain that does not cause the patient to stop walking/activity, or discomfort that does not consistently improve with rest. CLI involves pain at rest, nocturnal pain, nonhealing wounds/ulcers that are located distally (e.g., tips of toes, between toes), and gangrene.

### Physical Examination

Physical examination has poor sensitivity in assessing patients with asymptomatic PAD but can be helpful in assessing for and differentiating between claudication and CLI versus presentations that are not related to symptomatic PAD. Lower-extremity pulses should be assessed; pulses are graded on a scale of 0 to 3, with 0 being absent, 1 diminished, 2 normal, and 3 bounding. Absent or diminished pulses are suggestive of PAD and disease at a higher level of the vascular tree than the assessed pulse, making assessment of the dorsal pedal or posterior tibial pulses the most useful. Auscultation for femoral arterial bruit can be helpful but is rare in the primary care setting. Examination of the feet should focus on identification of nonhealing lower-extremity ulceration in a characteristic, well-demarcated, or “punched-out” pattern and lack of granulation tissue at the base, consistent with arterial ulceration. Careful inspection should be paid to the toes, especially between the toes and the webbing of the toes, as these lesions may not be readily noticed by the patient. The anterior lower leg is also a common place for arterial ulcers as they have less collateral circulation. Other examination findings of the lower extremity that suggest a diagnosis of PAD include elevation pallor and dependent rubor.

### Diagnosis

The initial diagnostic workup for patients with suspected PAD involves obtaining a resting ABI or ABI (Table 1). If the resting ABI is normal (1.0 to 1.4 is normal;  $\leq 0.9$  is abnormal) but there remains a high clinical suspicion for PAD, an exercise ABI can be obtained. The ABI is less accurate and can be falsely elevated in

**TABLE 1** Ankle-Brachial Index

ABI	MAGNITUDE OF PERIPHERAL ARTERY DISEASE	TREATMENT CONSIDERATIONS
>1.4	Cannot interpret	Consider TBI
1.0–1.4	Normal	None
0.91–0.99	Borderline	If high concern, consider exercise ABI
0.7–0.90	Mild PAD	Treat risk factors, discuss supervised exercise therapy and/or medication management
0.41–0.69	Moderate PAD	Treat risk factors, refer to vascular surgeon
<0.4	Severe PAD	Treat risk factors, refer to vascular surgeon

ABI, Ankle-brachial index; PAD, peripheral artery disease; TBI, toe-brachial index.

the presence of medial artery calcification that can stiffen arteries in the ankle, an issue most often encountered in patients with diabetes or end-stage kidney disease. This can result in an ABI  $>1.4$ , which is an uninterpretable result. In such cases, a toe-brachial index (TBI) can be considered. An abnormal TBI may predict poor outcomes beyond ABI in such patients (TBI  $\leq 0.7$  is diagnostic of PAD). Arterial duplex ultrasonography is also readily available, low risk, and inexpensive, but it is limited in its ability to detect infrapopliteal stenosis, stenosis that exists in the pelvic or abdominal cavities, or in patients with significant arterial calcifications. More advanced noninvasive studies, such as computed tomography angiography (CTA) and magnetic resonance angiography (MRA) can provide more anatomic detail and is often ordered for patients with PAD who fail medical management and/or are candidates for more invasive interventions. These studies are expensive and come with the added risk of contrast-related complications in certain patient populations. Catheter-based angiography remains the gold standard for diagnosing PAD but is reserved for patients receiving endovascular revascularization.

### Ankle-Brachial Index

The ABI is an inexpensive way to assess for PAD and can be done within 15 minutes in the primary care setting or ordered to be completed in a vascular laboratory. To obtain an ABI in clinic, the patient should be placed in the supine position with the head, hips, and heels fully supported. The ABI averages 0.35 higher in the seated position than in the supine position. A Doppler probe should be used to obtain both the ankle and brachial pressure. After allowing for a 5- to 10-minute rest period, the Doppler probe is used to auscultate flow, and a pneumatic cuff is inflated until flow ceases. The cuff is then slowly deflated until the flow signal reappears, and the corresponding pressure is recorded as the SBP of that limb. The process is then repeated for each limb, and the higher ankle and higher brachial pressures are used for calculation. The ankle pressure is then divided into the brachial pressure to obtain the ABI. A score between 1.0 and 1.4 is considered normal, and a score  $\leq 0.9$  is consistent with mild to moderate PAD. An ABI  $\leq 0.4$  is considered severe PAD. An ABI between 0.91 and 0.99 is considered borderline low, and PAD cannot be ruled out. In such cases, exercise ABI or other noninvasive imaging studies can be helpful to further evaluate for PAD.

### Differential Diagnosis

PAD can present with symptoms that are similar to those for other vascular pathologies, neurologic conditions, and musculoskeletal etiologies. For example, the terms *pseudoclaudication* and *neuro-claudication* are used because of similarities in the presentation of claudication in PAD to conditions such as lumbar spinal stenosis,

sciatica, or structural back disease. Venous claudication, popliteal artery entrapment syndrome, and various arthritides should also be considered in the differential diagnosis. The presence or absence of classic PAD risk factors, the specific location and description of the pain, in addition to the effect of exercise and rest (Table 2) can help differentiate PAD from these other conditions.

## Treatment

### Risk-Factor Control

Control of preexisting risk factors is crucial in the treatment of PAD. Patients with modifiable risk factors such as smoking must be aggressively counseled on the importance of smoking cessation. Patient with diabetes, hypertension, and hyperlipidemia should be treated per the most up-to-date guidelines published by the American College of Endocrinology (ACE) and the American College of Cardiology/American Heart Association (ACC/AHA). The Edinburgh study suggested that a sedentary lifestyle has also been shown to increase the risk for development of PAD by showing that physical activity was inversely proportional to the development of PAD.

### Tobacco Cessation

The risk of developing PAD is double for a smoker compared with a nonsmoker. The risk is related to the number of cigarettes smoked and the age at which an individual started smoking. Although it takes 30 years after quitting for a former smoker's risk for development of PAD to return to that of a nonsmoker, the importance of smoking cessation cannot be overstated. Patients who smoke should be counseled on quitting at every office visit and offered appropriate pharmacotherapy, nicotine replacement, and/or referral to tobacco cessation programs. However, only one-third of patients with PAD receive these therapeutic recommendations from their primary care team. Patients who successfully quit have lower rates of progression of atherosclerosis in their limbs as evidenced by decreasing rates of decline in their ABIs and lower rates of CLI, amputation, and death.

### Glycemic Control

Diabetic patients also carry about double the risk for the development of PAD than do patients without diabetes. Many studies have been designed to look at the role glycemic control should play in reducing both major adverse limb events (MALE) and major adverse cardiovascular events (MACE) in diabetic patients, but the evidence for improved glycemic control in reduction of macrovascular complications for diabetic patients with PAD is lacking, especially in regard to MALE. Multiple studies have demonstrated benefit with sodium glucose transporter 2 inhibitors

(SGLT2i) on MACE, heart failure, and overall mortality but did not show a reduction in MALE. In the Canagliflozin Cardiovascular Study (CANVAS), a subgroup analysis suggested that canagliflozin (Invokana) demonstrated up to a twofold increase in risk of amputation in diabetic patients with PAD compared with older insulin management regimens (sulfonylureas, metformin, insulin). The DECLARE-TIMI 58 trial involving dapagliflozin (Farxiga) redemonstrated the overall positive cardiovascular effects of the SGLT2i medications, but the subgroup analysis also demonstrated an increase in amputation risk in diabetic patients with PAD compared with those without PAD. A subsequent subgroup analysis of a study with canagliflozin, the Canagliflozin and Renal Events in Diabetes with Established Nephropathy Clinical Evaluation (CREDENCE) trial, did not show an increase in amputation risk in diabetic patients with PAD, but the concern remains and would benefit from further direct investigation. Trials looking at glucagon-like protein (GLP)-1 receptor agonists suggest a more direct vascular benefit by their mechanism of action and may provide therapeutic advantage over SGLT2i in diabetic patients with PAD. For example, the Liraglutide Effect and Action in Diabetes: Evaluation of Cardiovascular Outcome Results (LEADER) trial demonstrated benefit for diabetic patients in reduction of MACE and MALE in participants with PAD. It should be noted that the reduction in macrovascular complications related to diabetes, such as MACE, heart failure, and diabetic kidney disease provide distinct overall advantages of both the SGLT2i and GLP-1 receptor agonists over older diabetic medications, even in diabetic patients with PAD, despite the potential for increased amputation risk with SGLT2i. However, for the aforementioned reasons, it may be prudent to start with a GLP-1 receptor agonist before deciding to add an SGLT2i in diabetic patients with PAD.

### Antithrombotic Therapy

The ACC/AHA recommends treatment with once-daily aspirin<sup>1</sup> (81 mg to 325 mg) for patients with PAD based largely on expert opinion. For patients who cannot tolerate aspirin, clopidogrel (Plavix) 75 mg per day is a reasonable alternative. Dual antiplatelet therapy (clopidogrel plus aspirin) may reduce the risk of nonfatal myocardial infarction in patients with PAD and comorbid CAD, but this link is not well established and not generally recommended. However, per the ACC/AHA guidelines, dual antiplatelet therapy may be reasonable to reduce the risk of limb-related events in patients with symptomatic PAD after lower extremity revascularization.

**TABLE 2** Differential Diagnosis for Symptomatic Peripheral Artery Disease

CONDITION	LOCATION	CHARACTERISTIC	EFFECT OF EXERCISE	EFFECT OF REST	OTHER CHARACTERISTICS
Venous claudication	Entire leg, worse in calf	Tight, bursting pain	After walking	Subsides slowly	History of iliofemoral deep vein thrombosis; edema; signs of venous stasis
Popliteal artery entrapment syndrome	Calf muscles	Tight, tearing pain	After moderate to vigorous exercise (jogging)	Subsides slowly	Typically heavy muscular athletes
Spinal stenosis	Often bilateral buttocks, posterior leg	Pain and weakness	May mimic claudication	Variable relief, but can take a long time to recover	Worse with standing and extending spine
Nerve root compression	Radiates down leg	Sharp lancinating pain	Induced by sitting, standing, or walking	Often present at rest	History of back problems; worse with sitting; relief when supine or sitting
Arthritis (hip, foot, or ankle)	Lateral hip, thigh, foot arch, ankle	Aching discomfort	After variable degree of exercise	Not quickly relieved	Symptoms variable; may be related to activity or present at rest

The COMPASS trial looked at patients with symptomatic PAD treated with rivaroxaban (Xarelto) 2.5 mg twice daily and aspirin daily compared with aspirin monotherapy in 7470 patients, and it demonstrated a 46% risk relative risk reduction in MALE and a 24% relative risk reduction in MACE at the expense of a 70% increase in major bleeding events (mainly gastrointestinal), but not a significant difference in fatal bleeding, intracranial bleeding, or bleeding into a critical organ. The VOYAGER trial looked at rivaroxaban 2.5 mg twice daily and aspirin versus aspirin monotherapy in patients who had undergone revascularization for symptomatic PAD and demonstrated similar findings. Based on these trials, rivaroxaban (Xarelto) 2.5 mg twice daily plus aspirin daily is approved by the U.S. Food and Drug Administration (FDA) for the treatment of PAD.

The Warfarin Antiplatelet Vascular Evaluation (WAVE) trial compared warfarin and aspirin to aspirin monotherapy and found no benefit with the combination therapy and a threefold increase in life-threatening and moderate bleed risk compared with aspirin therapy alone. Warfarin is not recommended as part of a PAD treatment plan.

### Lipid-Lowering Therapy

PAD is a coronary artery disease equivalent, and as such, patients should be initiated on a high-intensity statin such as atorvastatin (Lipitor) 80 mg or rosuvastatin (Crestor) 40 mg, per ACC/AHA guidelines. The Reduction of Atherothrombosis for Continued Health (REACH) Registry, an observation investigation for subjects at risk for atherothrombotic events, demonstrated that statin use is associated with a reduction in worsening claudication, new CLI, lower extremity revascularization, or amputation.

In the Further Cardiovascular Outcomes Research with PCSK 9 Inhibition in Subjects with Elevated Risk (FOURIER) trial, patients with atherosclerotic disease (with or without PAD) who were maximized on statin therapy and then treated with the pro-protein convertase subtilisin/kexin type 9 (PCSK 9) inhibitor evolocumab (Repatha) versus placebo were found to have reduced MALE and MACE at an average 2.2-year follow-up. Although all patients should receive statin therapy, patients with difficulty to control low-density lipoprotein and other less commonly used biomarkers such as lipoprotein (a), may help risk-stratify patients who may benefit from therapies such as evolocumab.

### Hypertension Therapy

Hypertension should be treated to a goal of <130/80 per current ACC/AHA guidelines. Systolic blood pressure has more of an impact on the development of PAD than diastolic blood pressure. In the Atherosclerosis Risk in the Community (ARIC) study, an increase in the development of PAD was seen in patients with systolic blood pressure over 140 mm Hg (adjusted hazard ratio of 2.6) and between 120 and 139 mm Hg (adjusted hazard ratio of 1.6). Elevated risk for PAD was only observed in patients with diastolic blood pressure above 90 mm Hg. ACC/AHA guidelines can be followed in regard to initiation and management of blood pressure in patients with PAD similarly as to those who do not have PAD.

### Cilostazol

Cilostazol (Pletal) is a phosphodiesterase III inhibitor that is used to treat intermittent claudication. Cilostazol increases cyclic AMP, which results in vasodilator activity and antiplatelet effects. A 2021 Cochrane review confirmed a 2014 review and found participants taking 100 mg to 300 mg of cilostazol daily had a significant decrease in claudication symptoms and an increase in distance walked compared with those taking a placebo. The main side effects were headache and diarrhea; dizziness and palpitations were also noted, but the medication was generally well tolerated. Of note, there is a black box warning on cilostazol, and it should not be used in patients with congestive heart failure, regardless of class. Although cilostazol did improve symptom-free walking distance in patients with PAD, there is insufficient evidence about the effectiveness on MALE or MACE. The typical dose of cilostazol is 100 mg twice daily, and the medication takes 2 to 4 weeks to have an effect on walking distance. Cilostazol should be discontinued if there is no improvement in intermittent claudication symptoms

after 3 months. Thrombocytopenia and/or leukopenia can occur in patients on cilostazol, and this has the potential to progress to agranulocytosis if the medication is not discontinued immediately.

### Exercise Rehabilitation

Supervised exercise programs have been shown to provide improvements in functional status and quality of life that are similar to endovascular interventions and superior to optimized medical therapy alone. The Supervised Exercise, Stent Revascularization, or Medical Therapy for Claudication Due to Aortoiliac Peripheral Artery Disease : The CLEVER study highlighted both the short-term (6 months) and long-term (18 months) benefits of supervised exercise therapy. A Cochrane review published in 2018 investigated supervised versus unsupervised exercise for intermittent claudication and concluded that although supervised exercise was more effective than unsupervised or home-based exercise programs at improving maximal walking distance, there was no difference in patient-reported quality of life or functional impairment outcomes. This is important to note as not all communities will have access to supervised exercise programs. The structure of most of the programs studied involve walking 30 to 45 minutes three times per week for 12 weeks. Participants would rest when claudication symptoms occur until they resolve and then begin walking again.

### Revascularization/Vascular Interventions

Patients with symptomatic PAD should be considered for revascularization if they have persistent, lifestyle-limiting symptoms despite maximal medical therapy and trial of an exercise rehabilitation program. Patients with CLI should also be considered for urgent revascularization. For patients in whom interventional therapy is indicated, referral to an appropriate specialist, often a vascular surgeon, is warranted, and imaging with CTA or MRA to identify the specific anatomic location of the atherosclerotic lesion should be considered. Endovascular techniques, such as balloon angioplasty and stenting, are often preferred to surgical revascularization. However, patients with challenging anatomy may benefit from surgical revascularization with endarterectomy or surgical bypass.

### Critical Limb Ischemia

Patients with findings consistent with CLI (Table 3) should be managed by an interdisciplinary team that involves vascular surgery, interventionalist (radiology, cardiology), and wound care specialists. The BASIL (Bypass versus Angioplasty in Severe Ischemia of the Leg) trial found that there was no difference in amputation-free survival and overall survival in patients managed with endovascular intervention versus open surgery. The goal in management of such patients is to minimize tissue loss and preserve the function of the foot while also balancing their inherent surgical risk. Although the rate of developing CLI in patients with PAD is low (<10% over 5 years), there is a 20% risk of mortality within 1 year of diagnosis if a patient does develop CLI, and revascularization is generally necessary to avoid amputation.

**TABLE 3** Symptoms Characteristic of Critical Limb Ischemia and Acute Limb Ischemia

	SYMPTOMS	VASCULAR SURGERY REFERRAL URGENCY
Critical limb ischemia	Ischemic pain at rest >2 weeks (especially at night), tissue loss (typically painful “punched out,” sharply demarcated arterial ulcers on toes, foot), gangrene	Urgent
Acute limb ischemia	Paresthesia, Pain, Pallor, Pulselessness, Poikilothermia (cool/cold), and Paralysis (the “6 P’s”)	Emergent

## Acute Limb Ischemia

Acute limb ischemia (ALI) is a medical emergency that requires immediate vascular surgery evaluation. It is characterized by an acute loss of tissue perfusion, as opposed to the more chronically poor limb perfusion characteristic of CLI. Immediate recognition of the signs of ALI (see Table 3) is important as reperfusion may need to occur in <6 hours in some cases to salvage function of the limb and minimize tissue loss. Most commonly, ALI is a result of thromboembolism of a stenotic artery, stent thrombosis, or thrombosis of prior surgical revascularization/bypass graft.

## Monitoring

The majority of patients with PAD can be managed with a combination of risk-factor modification and medical management that includes a supervised exercise rehabilitation program. Although it is important to note that disease severity will remain stable over a 5-year period in most patients, up to 20% will progressively worsen in their disease course, and <10% will go on to develop CLI. Patients with PAD should be seen in follow-up at least once per year and potentially more frequently depending on the severity of PAD and other comorbid health conditions.

## PREMATURE BEATS

Method of

Randell Wexler, MD, MPH; and T.M. Ayodele Adesanya, MD, PhD

## CURRENT DIAGNOSIS

- The cause of a premature beat may be either atrial (premature atrial contractions or PAC) or ventricular (premature ventricular contractions or PVC) in origin.
- PACs are most often benign but are associated with increased risk of atrial fibrillation.
- PVCs may be benign, but underlying ischemia or structural heart disease is not uncommon and must be ruled out with echocardiography.
- PACs and PVCs are most commonly diagnosed by EKG although Holter or event monitoring may be required.
- A heavier PVC burden is associated with increased development of cardiomyopathy and cardiovascular morbidity and mortality.

## CURRENT THERAPY

- PACs are treated if their presence causes the patient symptoms and interferes with daily life.
- Beta blockers are most often used for the treatment of symptomatic PACs.
- In patients with underlying structural heart disease, the treatment of PVCs is directed at the underlying cardiac condition.
- Antiarrhythmics show no benefit in treatment of PVCs in patients with cardiomyopathy and should not be used to suppress their presence post myocardial infarction.
- Patients with a PVC burden of > 15% should see an EPS specialist for evaluation and treatment, as there is an increased risk of a significant cardiac arrhythmia.

It is not uncommon for a patient to present to a primary care physician with the complaint of their “heart pounding,” “skipping beats,” or having “palpitations.” Though often the only symptom, patients may also complain of concomitant dizziness, lightheadedness, or frank syncope. The patient may be young or old, have underlying structural heart disease (or not), or risk factors for heart disease such as hypertension. A patient with such a history may be experiencing one of a number of cardiac arrhythmias, although it is not uncommon to find no underlying etiology at all. No conclusive evidence exists to define the evolving role of wearable devices in assessing such concerns, but abnormal findings may certainly suggest need for further cardiac evaluation.

Normal electrical propagation in the heart begins with the spontaneous electrical discharge at the sinoatrial node, which is then propagated along the right atrial wall to the atrioventricular node and from there to the ventricles via the His-Purkinje System. Disruption anywhere along this pathway may lead to an arrhythmia, which is defined as a rhythm that is not sinus and is accompanied by an abnormal electrical conduction.

If an arrhythmia is present, it is classified by its anatomic location of origin. Common atrial arrhythmias include atrial fibrillation/flutter, paroxysmal supraventricular tachycardia, and premature atrial contractions (PACs). Ventricular arrhythmias are often designated as premature ventricular contractions (PVCs), ventricular tachycardia, and ventricular fibrillation. Other arrhythmias that are often seen include bradycardia, tachycardia, and first-, second-, and third-degree heart block (complex morphology is normal). Age may offer clues as to etiology. As one ages, paroxysmal supraventricular tachycardia and atrial fibrillation/flutter are more likely. This chapter will review arrhythmias commonly referred to as premature beats: PACs, and PVCs.

## Premature Atrial Contractions

### Epidemiology and Risk Factors

PACs are common and are found in both the general population as well as in those with underlying cardiac disease. Research has established that PACs exist in up to 99% of those over the age of 50 with increasing frequency with each decade of life. It has long been believed that atrial ectopy, especially in a patient with no underlying heart disease, is benign and more of a nuisance than a risk. However, it is now understood that PACs do present an increased risk for atrial fibrillation or ischemic stroke, and although most often benign, are not entirely so.

Underlying structural heart disease (such as mitral valve disease or left ventricular dysfunction) is significantly correlated to the risk of developing PACs. Additional risk factors associated with PACs include: 1) height (potentially due to the relationship between body size and left atrial measurements); 2) those with higher levels of B natriuretic peptide (BNP); as well as 3) those with abnormalities of high-density lipoprotein (HDL) lipid metabolism in which a lower HDL is associated with increased risk of PACs. This inverse relationship has also been reported between PACs and physical activity. The difficulty in determining the clinical significance of PACs is owing to their frequent presence in the population at large.

### Pathophysiology

The true etiology of PACs is not well researched and therefore not well understood. Investigation has suggested that normally functioning sino-atrial (SA) and atrio-ventricular (AV) nodes can be impacted by stimuli arising from outside of the atria. It has been proposed that this stimuli leads to reversible nodal remodeling. As a result it has been hypothesized that PACs may occur due to an adversely impacted SA or AV node subsequent to such remodeling. Others have postulated that mechanisms such as reentry and abnormal automaticity initiate PAC transmission but the actual cause is not known.

An electrocardiogram (EKG) provides an electrical account of heart function. Electrical impulses begin in the sinus node and then travel through Bachmann's bundle (the sole specialized atrial conduction system) subsequently diffusing over the atria. The P wave represents atrial electrical activity. A normal P wave as seen on the EKG is smooth and never peaked or sharp. The leads best used to review the P wave are leads II and V1.

A patient may have a left atrial abnormality (LAA), right atrial abnormality (RAA), or both. An LAA abnormality results in prolonged atrial activation times, because left atrial activation is later than right atrial activation. Such abnormalities may result in "notched" P waves because of the spatial separation of the left and right atrial peaks. When a patient has a RAA, the P wave tends to have increased amplitude due to the summation of the two peaks. Whenever possible, P wave abnormalities should be labeled left or right in nature.

A PAC will typically be seen on EKG as an abnormal P wave followed by a normal QRS complex. Morphologically, the P wave will be different than a normal (sinus) P wave. If the site of the PAC origin is near the AV node, it will be inverted, whereas if it is more distal, it will be upright. Should the PAC reach the SA node, the resulting finding on the EKG will be a longer interval between sinus beats, but it is not compensatory in nature. PACs may occur singularly or at regular intervals (every other beat is termed bigeminy) or in a group (two sequential PACs are termed a couplet). In addition, a PAC may be blocked (buried in a T wave) or conducted aberrantly (an atypical electrical configuration).

### Prevention and Clinical Manifestations

The majority of PACs are idiopathic unless there is underlying heart disease. Potential non-cardiac causes include tobacco use, alcohol consumption, substance abuse, and coffee. Reducing and/or eliminating these substances can be helpful in preventing symptoms. Additionally, certain medications, supplements, or substances of abuse may cause PACs, and therefore in any patient

presenting with the complaint of extra beats, a thorough review of all medications, supplements, and illicit substance use should be undertaken.

Although the vast majority of patients who are found to have PACs incidentally will not experience symptoms, patients presenting with the complaint of PACs may state that they feel that their heart is racing, skipping beats, or fluttering, or that they are experiencing palpitations. Though not common, some patients may experience dizziness.

PACs are now known to be precursors to atrial fibrillation or ischemic stroke. Thus the previous belief that atrial ectopy is benign and more of a nuisance has been shown to be incorrect. In fact, some studies suggest that a single PAC on EKG not only predicts atrial fibrillation but may also be a predictor of fatal outcome.

### Diagnosis and Differential Diagnosis

The diagnosis of PACs is often made on EKG, especially if the patient is symptomatic at the time of testing. If the EKG does not demonstrate an etiology, a 24-hour Holter monitor or 30-day event monitor may also be considered. The diagnoses of a PAC can be made if the P wave has a morphology that is different from and occurs earlier in the cardiac cycle than that of a sinus P wave. Many patients experience palpitations in which the EKG evaluation suggests no underlying etiology. Therefore, in addition to electrocardiography, patients with PACs should have baseline labs drawn to include a thyroid stimulating hormone, complete blood count, magnesium and phosphate, and electrolytes. If drug use is a possible etiology, a toxicology screen can be useful.

Differential diagnosis includes other cardiac arrhythmias such as PVCs, atrial fibrillation, atrial flutter, and paroxysmal supraventricular tachycardia. Underlying disorders that may be the cause include underlying anxiety or thyroid and other metabolic disorder, as well as substance abuse.

### Treatment and Monitoring

Echocardiography is helpful in determining if the patient has underlying structural heart disease requiring further evaluation and intervention. If the patient has no underlying structural heart disease, then no treatment is necessary, especially if the individual is asymptomatic and the PACs are found incidentally. If the patient does have symptomatic PACs to a degree that they interfere with the patient's quality of life, interventions include the use of beta blockers, and if they fail, a trial type IA, type IC, or type III antiarrhythmic agents may be considered. If the problem is electrophysiological in nature, catheter ablation or pulmonary vein isolation may be helpful. Elimination of tobacco, alcohol, and caffeine should be recommended.

If the patient has underlying structural heart disease, then treatment is directed at the underlying disorder. Frequent PACs can be associated with an increase in cardiovascular mortality. Patients with PACs should be educated as to the association of atrial fibrillation or stroke with instructions to notify their physician or seek attention immediately should symptoms occur. In case reports, normalization of left ventricular function has been reported following ablation.

## Premature Ventricular Contractions

### Epidemiology and Risk Factors

Premature ventricular contractions (PVCs) are a common cardiac finding, with upward of 40% to 75% of apparently healthy people being affected. As with PACs, they tend to increase with age. Underlying cardiovascular disease, especially ischemic heart disease increases one's risk for PVCs. As such, evaluation should be focused on excluding structural heart disease. Infiltrative cardiomyopathies may be considered, especially if conditions such as sarcoidosis or amyloidosis are present as known comorbidities. It should be noted that PVCs are common in those with inherited channelopathies, so a good family history is important. PVCs are common in well-conditioned athletes due to autonomic tone. Although this may be a normal compensatory mechanism,

structural heart disease still needs to be eliminated. PVCs associated with exercise portend increased cardiac mortality.

### Pathophysiology

After propagation through the atria, the electrical impulse activates the AV node that serves as the sole pathway for electrical transmission between the atria and the ventricles. The terminal portion of the AV junction becomes the bundle of His that propagates the electrical impulse to the bundle branches, which further divide into smaller subdivisions eventually connecting to the Purkinje fibers. From the Purkinje fibers, the electrical impulse diffuses synchronously across the ventricles.

PVCs arise from ectopic foci in the ventricle and occur earlier in the cardiac cycle than expected for a sinus beat. They may be generated by increased automaticity, reentry, or triggered activity. Monomorphic PVCs suggest a triggering component whereas polymorphic PVCs tend to suggest an underlying cardiomyopathy. If the patient has no structural heart disease, the focus is likely to be the right ventricular outflow tract, whereas if the patient has structural heart disease, the left ventricle is most likely to be the site of origin.

PVCs are not preceded by a P wave and demonstrate a prolonged QRS (> 120 ms) with a compensatory pause (as opposed to a non-compensatory pause found with PACs). Conflicting ST and T wave changes are also often seen. ST depression and T-wave inversion tends to occur in R-wave dominant leads, whereas ST elevation and an upright T wave occur in S-wave dominated leads. PVCs may be unifocal or multifocal and their morphology may at times resemble right or left bundle branch blocks. If the PVC occurs with every other beat, it is termed bigeminy (or trigeminy if every third, etc.), or if the PVC is paired with another PVC, it is called a couplet. One may also see an R on T phenomenon whereby the PVC occurs at or near the T wave of the previous QRS complex resulting in the R wave of the PVC blending with the T wave of the preceding beat.

Patients with frequent PVCs will often develop subsequent cardiomyopathy, though the etiology is unknown. There is an increased risk in developing cardiomyopathy the longer one is exposed to PVCs. It is suspected this may be due to a less efficient heartbeat with suboptimal cardiac output similar to bradycardia. Risk factors for progression to cardiomyopathy have been inconsistently identified but likely include increasing age, high body mass index, and male gender.

### Prevention and Clinical Manifestations

Patients with symptoms caused by PVCs often present with palpitations, dizziness, chest pain, syncope, dyspnea, orthopnea, decreased exercise tolerance, and fatigue. If a patient has a cough of unknown etiology, they should be evaluated for PVCs, as PVCs are noted to produce cough as the only symptom. PVCs have also been associated with dysphagia, especially when intermittent, as well as paroxysmal choking or vomiting. As such, PVCs should be considered if a gastroenterological evaluation is normal, or if symptoms persist despite treatment for an underlying gastrointestinal disorder.

PVCs are associated with a multitude of pathologic cardiac processes including heart failure, myocardial ischemia, left ventricular hypertrophy, idiopathic ventricular tachycardia, and right ventricular dysplasia. Non-cardiac diseases with which PVCs are associated include obstructive sleep apnea, chronic obstructive pulmonary disease, and pulmonary hypertension. On exam patients may present with an irregular pulse or canon A wave. PVCs may also be associated with pulmonary or thyroid disease, the consumption of alcohol, caffeine, and the use of beta agonists. Cocaine, amphetamines, or other illicit drugs may precipitate symptoms as well. Syncope is uncommon with PVCs but, if present, represents a red flag for the presence of malignant arrhythmias.

PVCs are found on 40% to 75% of holter monitor evaluations and 1% of EKGs. They are defined as frequent if they are seen on an EKG, or are present at a rate of more than 30 an hour on

event monitoring. In this instance there is a significantly increased cardiovascular risk as well as mortality. In the athlete, sinus bradycardia is common due to enhanced conditioning. This results in a lengthening of the RR interval and is thought to promote the occurrence of PVCs in this population.

The most important prognostic indicator for PVCs is the presence or absence of structural heart disease. Multifocal PVCs are considered to be risk factors for adverse cardiovascular events.

Potential contributors that are amenable to treatment include electrolyte abnormalities, hypoxia, drugs (including prescription as well as illegal), increased adrenergic drive, or ischemia.

### Diagnosis and Differential Diagnosis

A 12-lead EKG is the initial test of choice. Echocardiography is necessary in individuals in which structural heart disease is suspected, or if PVC frequency is high (one or more PVCs on EKG, or more than 30 an hour on event monitoring). This is based on the understanding that the likelihood of underlying structural heart disease increases with PVC burden. In addition, if ischemia is suspected or if PVCs are triggered/evident on exertion, cardiovascular exercise stress testing is recommended. Polymorphic PVCs are more commonly seen in those with underlying cardiomyopathy.

Differential diagnosis includes ventricular arrhythmias such as ventricular tachycardia and ventricular fibrillation. Cardiac conditions include left ventricular hypertrophy in the setting of hypertension, myocarditis, acute coronary syndrome, heart failure, congenital heart disease, and hypertrophic cardiomyopathy.

### Treatment and Monitoring

PVCs have been demonstrated to be an independent risk factor for cardiovascular mortality in heart failure and are associated with ejection fraction and wall motion abnormalities as well. Patients with a family history of frequent PVCs should be evaluated for inherited channelopathies such as catecholamine urgent polymorphic ventricular tachycardia. In patients with PVCs but without underlying coronary artery disease or structural heart disease, the clinical course is generally benign. It should be recalled, however, that patients with a history of PVCs can develop coronary artery disease or underlying structural heart disease, so periodic reevaluation of cardiac status is warranted. A sleep study (or titration of current positive airway pressure therapy) may also be advised, given the high association of PVCs with obstructive sleep apnea, which itself confers independent cardiovascular risk.

Treatment for those with symptomatic PVCs may include beta blockers or non-dihydropyridine calcium channel blockers, but treatment is not necessary in asymptomatic patients. Use of anti-arrhythmic medication to treat PVCs has not been shown to benefit patients with cardiomyopathy. In addition, treatment is not indicated following myocardial infarction to suppress PVCs that may be present. If the patient has a large PVC burden, considered to be greater than 15%, referral to an EPS specialist for consultation and possible radiofrequency ablation should be considered. If the patient has PVC-induced cardiomyopathy, catheter ablation may be considered, especially if the PVCs are monomorphic. There are no randomized controlled trials of radiofrequency ablation and anti-arrhythmic drug therapy, but retrospective studies suggest decreased PVC burden in those with radiofrequency ablation. As with all patients, non-antiarrhythmic medications may have to be adjusted to decrease stimulants, correct electrolyte abnormalities, and reduce cardiovascular risks.

### Premature Junctional Contractions

PJCs are less common than either PACs or PVCs and are rarely seen in the setting of a normal heart. These beats arise from the atrioventricular junction. On EKG they are seen as an aberrant beat with underlying sinus rhythm. The P wave may be absent, inverted, or occur following the associated QRS complex that is morphologically normal. Causes include electrolyte and thyroid abnormalities, underlying lung or cardiac disease, or the use

of excessive amounts of caffeine, nicotine, or alcohol. Medication toxicity may also be a cause, with digitalis toxicity being the classic example. If patients are asymptomatic, no treatment is required, though structural heart disease needs to be ruled out. In addition, the patient should be observed over time, as PJs may be a harbinger of progression to a more serious arrhythmia. In the symptomatic patient, treatment is directed at the underlying cause. Supplemental oxygen may be of benefit.

## TACHYCARDIAS

Method of

Alex Schevchuck, MD, MS; and Paul Andre, MD

## CURRENT DIAGNOSIS

- Tachycardia is defined as cardiac rhythm with heart rate >100 bpm.
- 12-lead ECG and hemodynamic assessment are essential in each patient with tachycardia.
- Sustained arrhythmia is an arrhythmia that lasts for more than 30 seconds.
- Narrow complex rhythm (QRS ≤120 ms) favors supraventricular origin, whereas wide complex (QRS >120 ms) could be either supraventricular (with aberrant conduction) or ventricular.
- Every patient with tachyarrhythmia should be promptly assessed for hemodynamic instability and presence of symptoms (palpitations, angina, shortness of breath, lightheadedness, presyncope, syncope, volume overload).

## CURRENT TREATMENT

- Vagal maneuvers may be useful for diagnosis and treatment of tachyarrhythmia.
- Direct-current (DC) cardioversion should be considered early if hemodynamic instability is present.
- If uncertain whether arrhythmia is ventricular tachycardia (VT) or supraventricular tachycardia (SVT), VT should be presumed and treated.
- Hemodynamic instability implies medical emergency, and culprit tachyarrhythmia should be treated immediately.
- A subspecialty consultation should be considered for each patient with tachyarrhythmia and high-risk features, such as syncope or family history of sudden cardiac death for diagnostic evaluation, treatment recommendations, and risk stratification.

## Definition

Tachycardia is defined as a heart rate greater than 100 beats per min (bpm). This can be a normal response by the heart to the stress on the body (such as sinus tachycardia with exercise or sepsis) or a primary cardiac pathologic condition, such as atrioventricular nodal reentry tachycardia (AVNRT) or ventricular tachycardia (VT). Tachycardia present in the setting of an abnormal cardiac rhythm is defined as tachyarrhythmia.

## Classification

Tachycardias classify into two major categories: wide complex (QRS duration >120 ms) or narrow-complex (QRS duration ≤120 ms). This classification is key, as wide-complex tachycardias are usually caused by an arrhythmia arising from the ventricles, such as monomorphic or polymorphic ventricular tachycardia, which are associated with considerable morbidity and mortality. On the other hand, narrow-complex tachycardias reflect ventricular activation by a competent conduction system below the atrioventricular (AV) node, indicating a source of the arrhythmia above the AV node or within the AV node or bundle of His, and are rarely life threatening.

When the tachyarrhythmia originates in the atria or within the conduction system in the AV node, it is described as a supraventricular tachycardia (SVT).

Wide-complex tachycardias include VT, supraventricular tachycardias with aberrant conduction (i.e., presence of a bundle branch block), and some types of pathway-mediated reciprocating tachycardias discussed separately.

## Epidemiology

Based on the Marshfield Epidemiological Study Area (MESA) data, the incidence of SVT in the general population is 35/100,000 person-years and the prevalence is 2.25 per 1000 persons. The mean age of onset in the study was 37 years old, and the most likely presenting location was the emergency room.

Prevalence of ventricular arrhythmias is higher in men than in women, increases with age, and is strongly linked to the presence of cardiovascular disease. Fifteen percent to 16% of patients with VT have coronary atherosclerosis; and 8% to 9% have hypertension, valvular disease, or nonischemic cardiomyopathy. Only 2% to 3% of patients with VT do not have cardiovascular disease. Five percent to 10% of patients with acute MI demonstrate VT/VF, most of which occurs during the first 48 hours of hospital admission.

## Pathophysiology

There are two major mechanisms of supraventricular tachycardias: automaticity and reentry.

Automaticity involves occurrence of one or multiple ectopic foci of depolarization that are located above or within the AV node. Examples of such tachycardias include focal and multifocal atrial tachycardia and junctional tachycardia.

Reentry mechanism uses a formation of an electrical circuit that may involve the AV node or accessory pathways. These tachyarrhythmias include atrial flutter, AVNRT, and AV-nodal reciprocating tachycardias (AVRT).

Ventricular tachycardias use three major mechanisms: automaticity, triggered activity, and reentry.

Automatic VTs occur from an ectopic focus of depolarization and may originate from either ventricular myocytes or Purkinje fibers. Triggered activity includes early afterdepolarization and delayed afterdepolarization. Early depolarizations occur during the repolarization phase of the membrane, usually in a setting of acquired action potential prolongation (long QT) and serves as a trigger for polymorphic VT or torsades de pointes (Figure 8). Delayed afterdepolarizations occur after a complete cell repolarization and serve as VT triggers in digoxin toxicity, right ventricular outflow tract VT, and catecholaminergic polymorphic VT. Reentry-type VT occurs when an electrical circuit forms around either an anatomic barrier (scar, artificial material in postoperative patients) or an area of a functional block. This mechanism usually results in monomorphic ventricular tachycardia.

### Clinical Presentation

Clinical manifestation of tachyarrhythmias may include palpitations or fluttering sensation in the chest and neck, and signs of decreased perfusion, such as hypotension, dizziness, lightheadedness, syncope, hot flushes, altered mentation, and shock. Ventricular tachyarrhythmias in particular may result in acute loss of circulation and sudden cardiac death (SCD). Effects of tachycardia on cardiac output mostly owe to shortened diastole that affects ventricular filling and decreasing preload leading to decreased cardiac output. VTs, in turn, also result in atrioventricular and intraventricular dyssynchrony that may additionally affect cardiac stroke volume and output.

### Diagnosis

In the acute setting, prompt and accurate diagnosis of the type of tachycardia is paramount. Every patient with suspected tachyarrhythmia should have a 12-lead electrocardiogram (ECG). Because many tachyarrhythmias may cause hemodynamic compromise, an expedited hemodynamic assessment should be performed (vital signs, oxygen saturation, presence of shock that may manifest as altered mentation or evidence of organ system dysfunction). An unstable patient should be treated emergently with an appropriate antiarrhythmic strategy defined by Advanced Cardiac Life Support (ACLS) algorithms.

History plays an important role in diagnosis of tachycardias. Nature and onset of symptoms, frequency of episodes and possible triggers or predisposing conditions, as well as alleviating factors, should be identified. Past medical history may be helpful in differentiation of different types of tachycardia, such as presence of ischemia or a structural heart disease that may favor VT. History of syncope, specifically if suggesting cardiogenic etiology, may help identify high-risk patients. Family history of arrhythmias or sudden cardiac death may yield important information regarding familial arrhythmias, such as Wolff-Parkinson-White (WPW) or long-QT interval syndromes.

If the patient has an implanted cardiac device, such as permanent pacemaker or a defibrillator, the device interrogation is diagnostic in most cases, especially if an AV system is present that is capable of tracking both atrial and ventricular electrical activity.

### Differential Diagnosis for Narrow Complex Tachycardias

Twelve-lead ECG is the first step in differentiating between different types of narrow-complex tachycardia. Analysis of QRS regularity, axis, atrial activity, baseline and relationships between atrial and ventricular activations, and presence of delta-wave (Figure 4) or preexcitation should be performed.

Identification of atrial activity is key in differentiating between subtypes of SVT. When identification of atrial activity is difficult (as during rapid ventricular rate), vagal maneuvers, carotid sinus pressure, or administration of IV adenosine (Adenocard)<sup>1</sup> may assist in diagnosis or potentially terminate the arrhythmia.

Irregular tachyarrhythmia with no identifiable pattern or P waves is diagnostic of atrial fibrillation with rapid ventricular

response. Variable baseline that resembles a sawtooth pattern is suggestive of atrial flutter. AV-nodal reentry usually results in a retrograde P wave that may be hidden within QRS complex or follows QRS immediately (short R-P tachycardia). Atrial tachycardia will have one or more P wave morphologies with 1:1 relationship; however, P wave morphology and axis will be different from sinus P waves. Comparison to prior ECG in sinus rhythm may be particularly helpful in this scenario.

An electrophysiology study is the gold-standard diagnostic approach if the mechanism of tachycardia is unclear from the surface ECG.

### Differential Diagnosis for Wide Complex Tachycardias

Because SVT with aberrancy and some types of AVRT may result in wide QRS complex, differentiation of such arrhythmia from VT may be challenging even for experts. Orthodromic arrhythmia suggests the electrical impulse travels straight down the normal pathway, and antidromic arrhythmia suggests that the impulse travels in the opposite direction.

Atrial activity is typically not affected by the VT (unless retrograde conduction is present), leading to AV disassociation, when P waves have no relationship to the QRS complexes. This may help differentiate VT from SVT with aberrancy. Fusion and capture beats are other hallmarks of monomorphic VT. Fusion beats occur when atrial activity can conduct through the AV node down the His-Purkinje system and “fuse” with ventricular activity. The resulting QRS complex is a hybrid of the sinus rhythm narrow QRS complex and the widened VT QRS complex. Capture beats occur when atrial activity conducts down the His-Purkinje system and creates a narrow QRS complex, followed by ongoing VT. These findings are very specific for VT, but their absence does not rule it out.

Multiple algorithms have been proposed to assist in differentiating SVT from VT. We will discuss the Brugada algorithm that has excellent sensitivity and specificity (0.978 and 0.965, respectively) for diagnosis of VT. If the answer to any of the following questions is yes, subsequent steps are not necessary and the rhythm is VT (Figure 1).

### Specific Tachycardias and Their Treatment

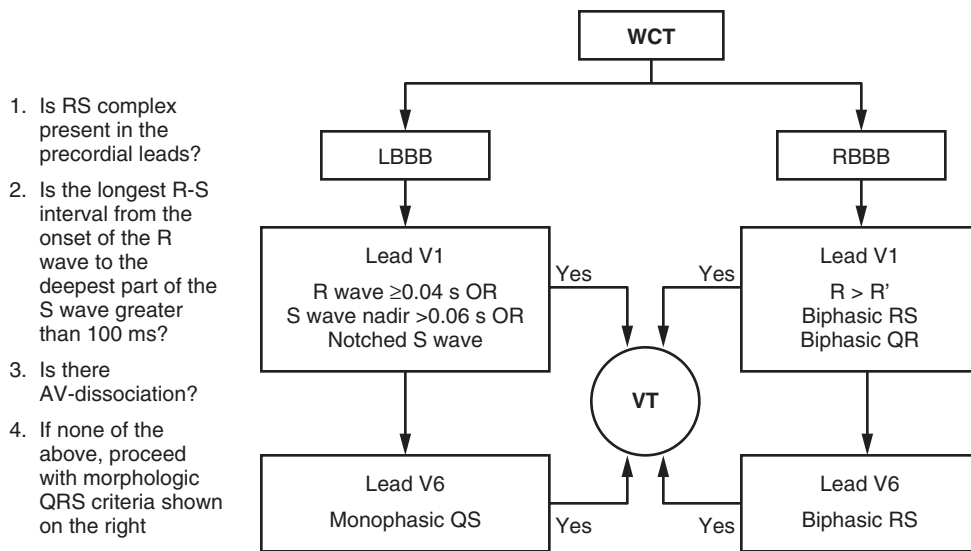

#### Sinus Tachycardia

Sinus tachycardia is a common narrow-complex tachycardia. It can represent a normal response to stress or a disease process (Table 1). Sinus tachycardia on a 12-lead ECG presents with ventricular rate >100 bpm and sinus P waves that are positive in leads I, II, and III, negative in aVR, and biphasic in lead V<sub>1</sub> with a normal PR interval (120–200 ms). Compared with an ECG in normal sinus rhythm, the P wave axis and morphology should be unchanged. A syndrome of inappropriate sinus tachycardia is a diagnosis of exclusion, when average heart rate exceeds 90 bpm over a 24-hour period and no physiologic or medical cause can be identified.

#### Atrioventricular-Nodal Reentry Tachycardia

AV-nodal reentry tachycardia results from activation of a dual-pathway conduit (slow and fast) that includes the AV node. This is the most common type of SVT, with a slightly higher prevalence in women. AVNRT manifests as a regular, usually rapid tachycardia with heart rates that may exceed 250 bpm. The patient will usually experience palpitations and symptoms of decreased perfusion, such as lightheadedness, dizziness, hypotension, flushing, and so forth. Syncope is rare but may occur with very rapid heart rates or in subjects with dehydration or underlying heart disease. A distinguishing symptom of AVNRT is neck palpitations. The mechanism of that is the simultaneous atrial and ventricular systole because of excitation origin located within the AV node, which is located between the atria and ventricles. This results in right atrial contraction against the closed tricuspid valve, forcing blood back into the jugular system that is subjectively perceived as palpitations in the neck. Diagnosis of AVNRT is based on a surface electrocardiogram that will classically demonstrate a rapid narrow complex tachycardia with P waves occurring within

<sup>1</sup>Not FDA approved for this indication.

**TABLE 1** Common Causes of Sinus Tachycardia

PHYSIOLOGIC CAUSES	PATHOLOGIC CONDITIONS	MEDICATIONS AND SUBSTANCES
Exercise Stress (fight or flight response) Anxiety Emotions Pain	Fever Substance withdrawal Hyperthyroidism Pulmonary embolism Sepsis Dehydration Chronic anemia or acute blood loss Pheochromocytoma Heart failure	Caffeine Nicotine Atropine Dobutamine Dopamine Pseudoephedrine Theophylline Cocaine Methamphetamine

**Figure 2** AV-nodal reentry (short R-P) tachycardia. Retrograde P waves are seen (arrows).

the QRS complex; therefore they are not immediately discoverable but may cause subtle deflection at the terminal portion of the QRS or immediately after the QRS (short R-P tachycardia, [Figure 2](#)). Electrophysiology study yields definitive diagnosis by demonstration of a dual-pathway physiology.

In the acute setting, as soon as AVNRT is suspected, termination of the arrhythmia should be attempted. Vagal maneuvers, such as Valsalva, carotid massage, or application of a cold wet towel to the patient's face may be helpful. Adenosine (Adenocard) has been reported to be effective in greater than 95% of patients with AVNRT. If the type of tachyarrhythmia is uncertain, adenosine may also help make a diagnosis by blocking AV conduction and causing ventricular pause that will unmask the underlying atrial activity, and may reveal arrhythmias, such as atrial tachycardia or atrial flutter. It is important to remember that adenosine has a very short half-life and should be administered as a very rapid IV injection followed by a 20 mL fluid bolus. ACLS recommends the initial dose of 6 mg followed by 12 mg

**TABLE 2** Doses of Common AV Blocking Agents Used in Acute Setting for SVT Treatment

AGENT	DOSE
IV Metoprolol (Lopressor) <sup>1</sup>	2.5–5 mg over 2 min, up to 3 doses
IV Diltiazem (Cardizem)	First dose: 0.25 mg/kg over 2 min, average adult dose, 20 mg; second dose (if first dose is ineffective and tolerated): 0.35 mg/kg in 15–30 min over 2 min, average adult dose is 25 mg
IV Verapamil (Calan)	First dose: 0.075–0.15 mg/kg over 2 min; second dose (if first dose is ineffective and tolerated): 10 mg in 15–30 min over 2 min

<sup>1</sup>Not FDA approved for this indication.

if no response. The 12 mg dose can be repeated one more time. Patients taking theophylline (adenosine antagonist) may require a higher initial dose (12 mg), whereas patients with a heart transplant or on carbamazepine (Tegretol) should be given a lower initial dose (3 mg). A 12-lead ECG recording should be performed in a continuous mode while performing this intervention for more accurate rhythm identification. If these measures are ineffective to terminate the arrhythmia, a brief assessment of hemodynamic status must be made. If patient is hemodynamically unstable, a DC cardioversion should be performed, whereas in a stable patient further treatment may include IV beta blockers, IV verapamil (Calan), or IV diltiazem (Cardizem) ([Table 2](#)). IV amiodarone

(Pacerone)<sup>1</sup> is recommended as the next line of treatment if all prior measures are ineffective or not feasible. In a stable patient who is not responding to medications, a DC cardioversion should still be performed to restore the sinus rhythm.

Follow-up management of AVNRT should include a specialty consultation for consideration of slow pathway radiofrequency or cryo catheter ablation. The patient may be started on a maintenance oral beta blocker or a nondihydropyridine calcium channel blocker, such as diltiazem or verapamil. An antiarrhythmic medication, such as flecainide (Tambocor), may also be used to control occurrences of tachyarrhythmia; however, ischemic and structural heart disease has to be ruled out before these agents can be used because of their proarrhythmic effects with these conditions.

### Pathway-Mediated Tachycardias (Orthodromic AVRT, Antidromic AVRT, WPW Syndrome)

Atrioventricular structures (AV valves and annuli) serve as an insulator, and normally there is no electrical communication between atrial and ventricular myocardium outside the normal conduction system. An accessory pathway is defined as an abnormal extranodal electrical communication between atrial and ventricular myocardium. A pathway that causes ventricular preexcitation pattern on a surface ECG (P-R interval <0.12 and presence of a delta-wave) is called a *manifest pathway*. A pathway that is not detectable on a surface ECG is called *concealed*. Accessory pathways can be located anywhere around AV annuli and may be capable of anterograde, retrograde, or bidirectional conduction. They are responsible for two types of reentry tachycardias: *ORT* that uses the normal conduction system for anterograde conduction and the accessory pathway for retrograde conduction and *ART* that uses the accessory pathway for anterograde conduction and AV node for retrograde conduction.

ORT is the most common type of pathway-mediated SVT and accounts for more than 90% of AVRT cases. Because ORT uses the normal conduction system for ventricular activation, it will demonstrate a normal, narrow QRS morphology, whereas ART leads to direct ventricular activation from pathway-conducting anterograde, which results in a wide-complex QRS morphology (Figure 3).

A WPW syndrome is a bundle of a manifest accessory pathway on a surface ECG in sinus rhythm (preexcitation pattern, Figure 4) and presence of supraventricular tachyarrhythmias.

If a patient with an accessory pathway capable of rapid anterograde conduction develops atrial fibrillation, it may result in a very rapid ventricular response rate and sudden cardiac death. AV blocking agents, such as beta blockers, or calcium channel blockers (CCBs), are contraindicated for treatment of atrial fibrillation in WPW patients, as they suppress the AV node (that competes with accessory pathway for atrioventricular conduction and serves as a rate-control “gate keeper”) and further facilitates the conduction down the pathway, increasing the ventricular rate. Instead, procainamide (Pronestyl)<sup>1</sup> should be used to suppress voltage-gated sodium channels of the accessory pathway.

Acute management of AVRT should include assessment of the 12-lead ECG for presence of preexcitation. If no preexcitation is present (ORT), the management is similar to AVNRT, as discussed previously. If preexcitation is detected (ART, WPW), AV blocking agents should be avoided or used with caution. DC cardioversion should be considered early, regardless of hemodynamic status.

For ongoing management, all patients with AVRT should undergo a subspecialty consultation for consideration of a catheter ablation procedure. Patients with a manifest accessory (e.g., WPW) pathway should also undergo risk stratification for sudden cardiac death as soon as diagnosis is made.

### Atrial Tachycardias

Atrial tachycardias can be focal or multifocal. Focal atrial tachycardia is usually regular and is characterized by the presence of distinct uniform P waves on the surface ECG. Morphology of these P waves differs from those in sinus rhythm. Multifocal atrial tachycardia will contain three or more different P wave

**Figure 3** Antidromic reciprocating tachycardia. Wide QRS morphology results from ventricular activation via the accessory pathway. P wave is preceding the QRS complex (long R-P).

**Figure 4** Manifest accessory pathway in a patient with Wolff-Parkinson-White syndrome. A short PR interval and delta-wave (arrow).

morphologies and is associated with structural heart disease, pulmonary disease, and pulmonary hypertension.

Treatment of atrial tachycardias may be challenging, with limited utility for antiarrhythmic medications and cardioversion that is often ineffective. AV-nodal blockers and ablation procedures have the most established role in treatment of these conditions.

### Junctional Tachycardia

Junctional tachycardia is a rapid narrow QRS complex tachyarrhythmia with rates up to 220 bpm that originates within the AV junction and may be regular or irregular. It is more commonly seen in pediatric populations and occurs rarely in adults. In the acute setting, IV beta blockers, nondihydropyridine CCBs, or procainamide<sup>1</sup> can be used. For chronic suppression, oral beta-blockers, verapamil<sup>1</sup>, diltiazem<sup>1</sup>, or antiarrhythmic drugs may be effective.

### Atrial Flutter

Atrial flutter, also known as *macroreentrant atrial tachycardia*, is a reentry arrhythmia that propagates around the tricuspid valve annulus. It most commonly involves the cavotricuspid isthmus (isthmus-dependent) and may be typical, when the signal travels up the intraatrial septum and down the lateral right atrial wall in a counterclockwise fashion around the annulus when observed from the RV apex (Figure 5, panel A), or reverse typical, or clockwise, traveling down the septum and up the atrial wall (see Figure 5, panel B).

Flutter that does not involve the cavotricuspid isthmus is called *atypical*, or *isthmus independent*.

Macroreentrant arrhythmias create a characteristic pattern on the ECG that resembles the “sawtooth” appearance of the electrical baseline, best seen in the inferior leads (Figure 6).

Counterclockwise activation creates positive deflection in lead V<sub>1</sub> (signal travels up the septum toward the lead) and negative deflection in the inferior leads, whereas clockwise demonstrates the opposite. Because the reentrant circle uses a fairly consistent anatomic path, the cycle length of reentry is around 220 ms, resulting in an atrial waveform rate around

<sup>1</sup>Not FDA approved for this indication.

**Figure 5** (Panel A) Direction of a typical, counter-clockwise activation in atrial flutter. (Panel B) Direction of a reverse typical, clockwise activation in atrial flutter. IAS, Intraatrial septum; IVC, inferior vena cava; SVC, superior vena cava; TV, tricuspid valve.

**Figure 6** Macroreentrant atrial tachycardia: typical atrial flutter with 2:1 AV-nodal conduction. A variable baseline is seen that resembles a sawtooth pattern. Positive deflections in lead V<sub>1</sub> and negative in lead III (arrows) indicate counterclockwise signal propagation around the tricuspid annulus.

300 bpm. The AV node will attempt to block the portion of atrial activations, resulting in slower ventricular rates. Two-to-one conduction commonly results in a ventricular rate around 150 bpm, whereas variable conduction may lead to an irregular ventricular response, which, however, usually follows identifiable patterns with R-R intervals multiple to the flutter cycle length, or 220 ms (440 ms, 660 ms, etc.). If the tricuspid annulus is dilated or the patient is receiving an antiarrhythmic medication that slows myocardial conduction (for example, flecainide), it may increase the flutter cycle length, decreasing the flutter rate. This may have an important negative implication. Usually, AV node is able to block fast flutter, decreasing the ventricular response to 2:1. However, when the flutter rate is decreased, it allows the AV node to conduct in 1:1 fashion, leading to very rapid ventricular responses that may result in syncope and ventricular fibrillation. If flecainide is chosen as an antiarrhythmic therapy to control atrial flutter, it is important to always use it in a combination with an AV blocking agent to avoid 1:1 conduction in case of a relapse.

Medical treatment of atrial flutter may be challenging because of weaker ventricular rate responses to AV blocking agents that result in notorious difficulty with the rate-control strategy. One-to-one response should be treated as a medical emergency with a prompt DC cardioversion. For typical flutter, an EP consultation for a radiofrequency catheter ablation procedure should always be considered because of a high success rate and relative simplicity of the procedure. Atypical flutter ablations, however, may be more technically challenging with lower success rates.

### Ventricular Tachycardias

Ventricular tachycardia is defined as a cardiac arrhythmia of three or greater beats at a rate of >100 bpm that originates in the ventricles. Sustained VT, just as SVT, is a VT that sustains for >30 seconds. Nonsustained VT terminates spontaneously within 30 seconds after onset.

VT that manifests with uniform beat-to-beat QRS morphology is called *monomorphic* (Figure 7). This type of morphology is more likely to represent structural or functional electrical reentry as the leading mechanism. A common substrate for such arrhythmia is a myocardial scar resulting from chronic ischemic or structural heart disease.

Polymorphic ventricular tachycardia is characterized by the presence of multiform QRS complexes and likely represents unstable myocyte membranes. Such arrhythmia may be seen in multiple conditions, including long-QT syndromes (congenital and acquired). QT should always be assessed as soon as sinus rhythm is restored. When QT prolongation is detected, a reversible cause, such as medication effect or electrolyte abnormality, should be considered and treated. If no cause can be identified, a congenital condition may be suspected.

If polymorphic VT occurs without QT prolongation, acute myocardial ischemia should be considered and promptly evaluated and treated.

Torsades de pointes represents a subtype of polymorphic VT that is usually associated with long-QT syndromes and demonstrates a characteristic ECG pattern with rotating QRS axis appearance (Figure 8).

Of all the arrhythmias seen in clinical practice, ventricular tachycardias are of most concern to practitioners because of the high morbidity and mortality associated with these disorders. Although both subtypes require emergent medical attention, polymorphic VT poses particular danger because of the often rapid deterioration of hemodynamics, loss of circulation, and death. Sustained polymorphic VT should be treated immediately with an unsynchronized DC cardioversion.

The approach to monomorphic VT starts with assessment of hemodynamic stability. Faster ventricular rates (>150 bpm) and underlying structural heart disease may be associated with more rapid hemodynamic decline. ACLS algorithms for specific types of VT must be implemented. Each patient with ventricular tachycardia should undergo a prompt specialty consultation and risk stratification for sudden cardiac death.

### Artifact

All providers should be aware of telemetry and ECG artifacts that may masquerade as ventricular arrhythmias. If multilead recording is available, all leads should be examined. If sinus rhythm can be found in one or more leads, that indicates the recording is an artifact (Figure 9).

Figure 7 Onset of monomorphic ventricular tachycardia.

Figure 8 Polymorphic ventricular tachycardia: a premature ventricular complex (PVC, arrow), occurring during relative refractory period (“R on T” phenomenon) triggers the arrhythmia. The QT interval duration in the current R-R cycle is determined by the duration of preceding R-R cycle. A PVC that triggers VT occurs during a prolonged QT interval after a long previous R-R cycle and creates a distinctive “long-short R-R” ECG pattern.

Figure 9 Artifact masquerading as ventricular tachycardia. A diagnosis of wide-complex tachycardia is dismissed by presence of sinus rhythm in lead III.

## VALVULAR HEART DISEASE

Method of

Carlos E. Sanchez, MD; Steven J. Yakubov, MD; and Arash Arshi, MD

### CURRENT DIAGNOSIS

- The diagnosis of severe aortic valve stenosis is based on an integration of clinical symptoms and hemodynamic echocardiographic criteria.
- Classic symptoms of severe aortic stenosis include fatigue, dyspnea on exertion, angina, near syncope or syncope, and congestive heart failure.
- Chronic mitral regurgitation tends to be a slowly progressive disease and symptoms may not be apparent.
- Cardiac imaging, especially echocardiography, is crucial to the management of patients with valvular heart disease.
- Diagnostic echocardiographic findings of severe aortic stenosis are peak aortic valve velocity of greater than or equal to 4 m/s, transaortic mean gradient of greater than or equal to 40 mm Hg, and aortic valve area less than or equal to 1 cm<sup>2</sup> or aortic valve area index of less than or equal to 0.6 cm<sup>2</sup>/m<sup>2</sup>.
- Echocardiography should be performed to determine the etiology of and characterize the severity of mitral regurgitation.
- Left ventricular size and function should be assessed in patients with mitral regurgitation.

### CURRENT THERAPY

- Medical therapy has not been shown to change hemodynamic progression or clinical outcomes in patients with aortic stenosis.
- Reevaluation for early symptoms and transthoracic echocardiography should be performed every 6–12 months in asymptomatic patients with severe aortic stenosis and normal left ventricular systolic function.
- Transcatheter aortic valve replacement is currently approved in patients with severe symptomatic aortic stenosis with any level of surgical risk.
- The etiology of mitral regurgitation dictates its treatment.
- Primary (degenerative) mitral regurgitation typically requires surgical repair or replacement.
- The management of secondary (functional) mitral regurgitation requires treatment of the underlying cardiomyopathy.
- Mitral transcatheter edge-to-edge repair with MitraClip (Abbott Laboratories, Abbott Park, IL) is currently indicated in secondary mitral regurgitation patients with left ventricular dysfunction who remain symptomatic despite guideline-directed medical therapy.
- The decision-making process in the management of patients with severe aortic stenosis or severe mitral regurgitation is best achieved by a multidisciplinary heart valve team and should include a systematic risk assessment of the patient's comorbidities and estimation of the 30-day cardiac surgical mortality using the Society of Thoracic Surgeons' Predicted Risk of Mortality (STS-PROM) score.

### Aortic Stenosis

Aortic stenosis (AS) is the most common form of adult valvular heart disease, becoming more prevalent in the aging population. It is estimated that more than 4% of the U.S. population over age 75 have AS. Aortic valve stenosis is the most common cause of left ventricular (LV) outflow tract obstruction, while less

common causes of obstruction may also occur above (supravalvular) or below (subvalvular) the level of the aortic valve and will not be discussed in this chapter.

### Etiology

There are three main causes of valvular AS: congenital in origin (which is usually a bicuspid aortic valve), rheumatic valve disease, and degenerative calcification of a normal aortic valve. Congenitally affected aortic valves may be unicuspid or bicuspid and may become stenotic during childhood. In the majority of cases, a congenital bicuspid valve will develop significant calcific stenosis later in life, usually presenting after the fifth decade.

Rheumatic AS is an important cause of aortic valve disease worldwide; however, with the decline of rheumatic fever in developed countries, it is now a rare cause of AS in the United States. Rheumatic valve disease is characterized by commissural fusion, fibrosis, and calcification. Rheumatic AS is also commonly associated with rheumatic involvement of the mitral valve.

Degenerative or calcific AS is now the most common cause of AS in adults in North America. It has been associated with the same risk factors as vascular atherosclerosis including age, smoking, hypertension, diabetes, and hyperlipidemia. Histopathologic data suggest that calcific aortic valve disease is a chronic inflammatory process with lipid deposition and active leaflet calcification leading to restriction of the cusps.

### Pathophysiology

In adults with AS, the gradual obstruction of the LV outflow produces a systolic pressure gradient between the left ventricle and aorta. The average time interval of disease progression from nonobstructive valve thickening (aortic sclerosis) to severe AS is 8 years. However, only 16% of individuals with aortic sclerosis will develop any grade of valve obstruction. The average rate of hemodynamic progression once moderate AS is present is an increase in aortic jet velocity of 0.3 m/s per year and mean pressure gradient of 7 mm Hg per year with a decrease in aortic valve area of 0.1 cm<sup>2</sup>/year. LV response to chronic pressure overload ultimately leads to concentric wall hypertrophy. This compensatory mechanism helps maintain normal LV contractile function to counteract the gradual increase in afterload at the expense of decreased LV compliance and delayed relaxation resulting in diastolic dysfunction.

### Clinical Presentation

The cardinal symptoms of severe AS are angina, syncope, and congestive heart failure. Because symptoms in severe AS may not occur until late in the disease process, usually in the sixth to ninth decades of life, clinicians should obtain a careful history of symptoms during the patient's initial assessment. Particular attention must be directed at early symptoms of fatigue or decreased exercise tolerance as elderly patients may minimize and attribute these symptoms to aging.

Dyspnea on exertion occurs once the pulmonary capillary pressure increases as a result of excessive elevation in LV end-diastolic pressure in a poorly compliant ventricle. Symptoms of angina pectoris in severe AS may occur in a similar manner as in coronary artery disease, with symptoms precipitated by exertion and relieved by rest even in the absence of obstructive epicardial coronary artery disease. Syncope may result from the inability of the heart to increase cardiac output from the stenotic valve in the setting of transient vasodilatation during physical activity, resulting in decreased cerebral perfusion. Other causes of syncope may also be attributable to arrhythmias, either advanced forms of atrioventricular blocks from calcification impinging on the conduction system or tachyarrhythmias causing a sudden decline in cardiac output such as in atrial fibrillation.

### Diagnosis and Management

Diagnosis of AS is usually suspected after a systolic ejection murmur is heard during cardiac auscultation. The classic physical findings in patients with severe AS are a loud, late-peaking

**TABLE 1** Echocardiographic Stages of Aortic Valve Stenosis and Frequency of Echocardiograms in Asymptomatic Patients With Aortic Stenosis and Normal Left Ventricular Ejection Fraction

	MAXIMUM AORTIC VELOCITY	MEAN PRESSURE GRADIENT	AORTIC VALVE AREA	TTE FOLLOW-UP IN ASYMPTOMATIC PATIENTS
Mild aortic stenosis	2.0–2.9 m/s	<20 mm Hg	>1.5 cm <sup>2</sup>	Every 3–5 years
Moderate aortic stenosis	3.0–3.9 m/s	20–30 mm Hg	1.0–1.5 cm <sup>2</sup>	Every 1–2 years
Severe aortic stenosis	≥4.0 m/s	≥40 mm Hg	≤1.0 cm <sup>2</sup>	Every 6–12 months
Very severe aortic stenosis	≥5 m/s	≥60 mm Hg	≤1.0 cm <sup>2</sup>	

TTE, Transthoracic echocardiogram.

systolic murmur at the base of the heart radiating to the carotid arteries with a delayed and diminished carotid upstroke (*pulsus parvus et tardus*). The latter physical finding may be masked in elderly patients with stiff, inelastic arterial walls. Distinctively, a normally split-second heart sound is the only reliable physical finding to help exclude the diagnosis of severe AS.

A transthoracic echocardiogram (TTE) is recommended as the initial diagnostic test in the evaluation of patients with aortic valve stenosis to determine hemodynamic severity, LV size and function, and prognosis, and to evaluate timing of valve intervention. Echocardiographic valve hemodynamics define the severity of AS (Table 1). Severe AS is characterized by a peak aortic valve velocity of 4 m/s or higher, transaortic mean gradient of 40 mm Hg or higher, and aortic valve area of less than or equal to 1 cm<sup>2</sup> or aortic valve area index of less than or equal to 0.6 cm<sup>2</sup>/m<sup>2</sup>. In severe symptomatic patients with low-flow, low-gradient severe AS and abnormal LV function (<50%), a dobutamine stress echocardiogram can be used to differentiate between true severe AS and pseudo-severe AS. Low-flow, low-gradient true severe AS is characterized by a severely calcified valve with aortic valve area less than or equal to 1 cm<sup>2</sup> and peak aortic valve velocity less than 4 m/s that increases to 4 m/s or higher with low-dose dobutamine administration. Conversely, in pseudo-severe AS the aortic valve area increases to more than 1 cm<sup>2</sup> and flow normalizes during dobutamine stress echocardiogram.

Patients with asymptomatic AS require frequent monitoring owing to the progressive nature of the disease. The frequency of echocardiograms in asymptomatic patients with AS and normal LV systolic function should be performed every 6 to 12 months for reevaluation in severe AS, every 1 to 2 years for moderate AS, and every 3 to 5 years for mild AS (see Table 1). In seemingly asymptomatic patients with severe AS, exercise testing is safe and helpful to expose symptoms, arrhythmias, or abnormal blood pressure response, defined as an exercise-associated decrease of greater than or equal to 10 mm Hg in systolic blood pressure. Exercise testing should not be performed in symptomatic patients.

### Treatment

Indication for intervention in patients with severe AS is dependent on the presence or absence of symptoms, the severity of AS, and LV function. Routine aortic valve replacement in asymptomatic AS is currently not recommended. Importantly, event-free survival at 2 years in asymptomatic patients with severe AS (jet velocity ≥ 4.0 m/s) is 30% to 50%, and as low as 21% in those with very severe AS (jet velocity ≥ 5.0 m/s). Close clinical follow-up to evaluate for early-onset AS symptoms and education regarding the disease course should be performed routinely. Intervention should be considered among asymptomatic patients with very severe AS ( $V_{\max} \geq 5.0$  m/s), serum B-type natriuretic peptide (BNP) >3 times normal, or progression of  $V_{\max} \geq 0.3$  m/s per year.

Medical therapy has not been shown to change hemodynamic progression or clinical outcomes in patients with AS. Clinical data have failed to support the use of statins specifically for the prevention of progression of AS. However, all patients with concomitant coronary artery disease or hypercholesterolemia should be treated per established guidelines. Likewise, concurrent hypertension in

patients with severe AS is common and should receive appropriate treatment per standard guidelines starting at a low dose and slowly titrating upward with frequent blood pressure monitoring. Although indicated in the treatment of acute heart failure, diuretics should be used with caution to avoid volume depletion, which may result in marked reduction in cardiac output.

### Invasive Treatment

Transcatheter aortic valve replacement (TAVR) has expanded rapidly as an alternative to surgical aortic valve replacement (SAVR) since its approval in 2011, with approximately 50,000 patients treated annually in the United States alone since 2017. It is currently approved for use in patients with severe symptomatic AS with any level of surgical risk. Recent published clinical trials in low-surgical-risk candidates showed that the risk of death or disabling stroke and new onset atrial fibrillation was lower among the TAVR treated patients compared to SAVR. Additionally, rehospitalization and hospital length of stay was shorter with TAVR.

Recommendations and timing of intervention for aortic valve stenosis by either SAVR or TAVR are summarized in Table 2. Once the patient with AS is considered to meet an indication for aortic valve replacement, an important component when choosing between SAVR and TAVR is the underlying risk assessment for SAVR. In the United States, the Society of Thoracic Surgeons' Predicted Risk of Mortality (STS-PROM) risk score calculator is the initial step in predicting 30-day mortality for SAVR, with three categories: low risk defined as less than 4%, intermediate risk defined as 4% to 8%, and high risk defined as greater than 8% STS mortality risk. This risk calculator, however, does not include certain comorbid conditions that would also increase the surgical mortality risk such as frailty, porcelain aorta, liver cirrhosis, severe pulmonary hypertension, chest wall abnormalities, and hostile mediastinum. If three or more major organ systems are compromised, with severe frailty, or the morbidity and mortality risk is greater than 50%, the patient is considered prohibitive risk for SAVR. In patients with severe AS and a life expectancy less than 1 year, TAVR or SAVR is considered futile despite successful procedure and it is appropriate to avoid any intervention for severe AS. Hence the risk assessment is a combination of the STS-PROM score, frailty, disability, and major cardiovascular and noncardiovascular comorbidities.

The final treatment decision should be individualized with a risk-benefit assessment by a multidisciplinary heart team (including structural interventional cardiologists, imaging specialists, cardiovascular surgeons, and nursing professionals). The heart team assesses potential procedural outcomes based on the patient's individual procedural risk, anatomic considerations, comorbidities, life expectancy, and potential quality-of-life improvement with SAVR or TAVR. The importance of a collaborative and multidisciplinary heart team approach to the evaluation and management of patients with complex AS has been endorsed by professional guidelines to maximize appropriate outcomes.

Once the patient is considered to be a suitable candidate for TAVR, the evaluation of all patients undergoing the procedure should include (1) coronary angiography to determine the

(E) Left subclavian view with measurement obtained (left of image).

presence of coronary artery disease; and (2) computed tomography of the chest, abdomen, and pelvis to determine preferred vascular access or contraindications to it and aortic annulus dimension for prosthesis sizing (Figure 1).

The currently available TAVR valves approved by the United States Food and Drug Administration (FDA) include the balloon-expandable Edwards Sapien XT and Sapien 3 (Edwards Lifesciences, Irvine, CA), the self-expandable Medtronic Evolut systems (Medtronic, Minneapolis, MN), and the self-expandable Portico valve (Abbott, Santa Clara, CA). The choice of valve mostly depends on anatomic considerations and operator preference and experience.

A series of major procedural cardiovascular complications have been described after TAVR, including paravalvular aortic regurgitation, ischemic strokes, conduction disturbances, cardiac perforation, coronary occlusion, and vascular access complications. With the advancement of valve technology and increase in operator experience, the frequency of procedural complications has reduced since the arrival of TAVR procedures. Cerebral embolic protection has become increasingly common, but its role remains unclear in terms of reducing clinically significant strokes. Preprocedure planning by an expert heart team is essential to recognizing and preventing expected complications during and after transcatheter valve implantation.

**Figure 2** (A) Transthoracic echocardiogram of a patient with a dilated cardiomyopathy with annular dilation resulting in incomplete coaptation of the mitral valve leaflets and severe functional (secondary) mitral regurgitation. The regurgitant jet is central. (B) Transesophageal echocardiogram reveals a markedly myxomatous mitral valve with a large flail segment of the posterior leaflet resulting in severe degenerative (primary) mitral regurgitation. This jet is extremely eccentric. LA, Left atrium; LV, left ventricle; MV, mitral valve.

Currently the optimal antithrombotic regimen following TAVR is daily clopidogrel (Plavix)<sup>1</sup> 75 mg and aspirin<sup>1</sup> 75 to 100 mg for 3 to 6 months followed by daily aspirin alone for life. If there is an indication for chronic anticoagulation, it should follow current guidelines' recommendations for each individual condition (e.g., atrial fibrillation, deep venous thrombosis). The safety of antiplatelet therapy use in conjunction with oral anticoagulation should be individualized based on the patient's bleeding risk.

### Mitral Regurgitation

Mitral regurgitation (MR) is a common valvular disease, and pathology in any of the structures of the mitral valve apparatus may lead to dysfunction of the valve. The base of the leaflets of the mitral valve are attached to the annulus, and the leaflets themselves are attached to the papillary muscles of the left ventricle by the chordae tendineae. The mitral valve is an integral part of both the left atrium and left ventricle, and disorders of these structures affect mitral valve function; likewise, disorders of the mitral valve lead to abnormalities of the left atrium and left ventricle.

### Etiology

MR can be divided into primary (degenerative) MR and secondary (functional) MR (Figure 2). Primary MR refers to pathology of the mitral valve leaflets and chordae tendineae that results in valve dysfunction. The most common etiology is mitral valve prolapse, where the underlying pathology is myxomatous mitral valve degeneration that results in redundant leaflets, causing prolapse of the leaflets. A myxomatous mitral valve is also prone to rupture of the chordae tendineae, leading to a flail leaflet or segment of a leaflet. Other common etiologies of MR include rheumatic heart disease and endocarditis. Mitral annular calcification may cause mild to moderate MR, but severe regurgitation is uncommon.

In contrast, in secondary MR, the mitral valve itself has a relatively normal structure. Instead, the pathology is an abnormality of the left ventricle. This most commonly occurs after myocardial infarction, with focal wall motion abnormalities and displacement of the papillary muscle causing tethering of the chordae and leaflets, along with dilatation of the mitral valve annulus, resulting in incomplete coaptation of the mitral valve leaflets during systole. Secondary MR may also occur in a dilated cardiomyopathy.

### Clinical Manifestations

The clinical presentation of MR is extremely variable and depends largely on the severity of the regurgitation and its acuity. MR

<sup>1</sup>Not FDA approved for this indication.

tends to be asymptomatic when mild to moderate, but severe MR frequently results in symptoms. Acute MR occurring from papillary muscle rupture complicating an acute myocardial infarction leads to rapid hemodynamic collapse and carries a high risk of mortality. These patients experience pulmonary edema due to the acute volume overload of the left ventricle and left atrium. In contrast, chronic severe MR may have a relatively indolent course, with some patients reporting few symptoms. While chronic MR typically manifests as congestive heart failure, with exertional dyspnea, orthopnea, and lower extremity edema as the hallmark symptoms, owing to the insidious nature of the disease, patients may not always recognize their symptoms. A detailed history with a specific focus on symptoms of congestive heart failure in addition to fatigue and effort intolerance must be elicited. Atrial fibrillation is a common complication of MR and is associated with worse outcomes.

### Diagnosis

Physical examination classically may reveal a soft S1 and a holosystolic murmur at the apex that radiates to the left sternal border or to the axilla. However, the intensity of the murmur does not correlate to the severity of disease, nor does the absence of a murmur reliably rule out severe MR. Physical examination is important to assess the patient's volume status, with pulmonary rales and lower extremity edema suggesting congestive heart failure, and an irregularly irregular rhythm indicative of atrial fibrillation.

Cardiac imaging, in particular echocardiography, is crucial in the evaluation of suspected MR. Transthoracic echocardiography can reveal abnormalities of the mitral valve and provide important information on LV size and function and estimation of pulmonary arterial pressure. Given the orientation of the mitral valve and the limits of transthoracic echocardiography, the severity of MR can be grossly underestimated, particularly if the regurgitant jet is eccentric. Transesophageal echocardiography, especially with the availability of three-dimensional imaging, provides higher-quality images of the mitral valve and allows more precise evaluation of the severity and etiology of MR, and has become the gold-standard test in the evaluation of patients with clinically significant MR. Echocardiography with color Doppler can be used to provide a visual estimate of the severity of regurgitation. The presence of reversal of flow into the pulmonary veins during systole suggests severe regurgitation. Quantitative analysis can also be performed to determine the volume of regurgitation and the orifice of the regurgitant jet. There is currently no single echocardiographic parameter to define severe MR, but integration of multiple qualitative and quantitative measurements is recommended. Accurate assessment of LV dimensions and function is important in patients with chronic severe MR. Methods of determining the LV ejection fraction include visual estimation and volumetric analysis. Owing to the volume of blood exiting the left ventricle through both the mitral and aortic valves during systole, the ejection fraction will be increased. In the presence of severe MR, a normal LV ejection fraction approaches 70%, and LV dysfunction is deemed anything less than 60%. Even what would otherwise be considered a mildly reduced ejection fraction may indicate significant myocardial dysfunction in the presence of MR. Left atrial enlargement as a rule is found in chronic severe MR, and its absence should lead to reconsideration of the diagnosis. Exercise echocardiography can play an important role in patients with MR, especially in those with severe MR who report few symptoms, as it is an objective means to assess functional capacity and can also be used to assess changes in pulmonary pressures with exercise. In patients who have mild MR at rest but severe exertional symptoms, exercise echocardiography can identify ischemic MR with concomitant regional wall motion abnormalities.

Cardiac catheterization is performed in many patients with suspected severe MR. Right heart catheterization with measurement of right atrial, right ventricular, pulmonary arterial, and pulmonary capillary wedge pressures and cardiac outputs can help determine volume status and assess for pulmonary hypertension. Attention should be paid to the pulmonary capillary wedge

**TABLE 3** Paradigm for Management of Mitral Regurgitation Based on Etiology and Surgical Risk

	PRIMARY (DEGENERATIVE)	SECONDARY (FUNCTIONAL)
Low surgical risk	Surgical repair or replacement	CHF therapy TEER or surgery in selected patients
High surgical risk	Percutaneous repair in selected patients	CHF therapy ± TEER with MitraClip

CHF, Congestive heart failure. TEER, transcatheter edge-to-edge repair.

waveform, with large “v” waves, corresponding to ventricular systole, suggestive of severe MR. Left heart catheterization with selective coronary angiography is recommended to identify concomitant obstructive coronary artery disease. Left ventriculography using contrast is commonly performed, and the presence of contrast in the left atrium suggests MR. However, the clinical utility of left ventriculography is limited with the ready availability of echocardiography. The visual estimation of MR by contrast ventriculography is subjective, and the etiology of valve pathology is unable to be defined precisely. Furthermore, in a patient with congestive heart failure, the contrast load may result in acute decompensation.

Magnetic resonance imaging (MRI) is not currently a routinely used test in the evaluation of severe MR but may provide more reproducible quantification of the regurgitant volume and fraction and more accurate measurements of LV size and function. Given the importance of defining the severity of the MR and abnormalities of LV function in the management of MR, MRI may eventually have a central role in the evaluation of patients and is strongly recommended when echocardiographic data is not satisfactory.

### Management and Treatment

The etiology of MR dictates its treatment (Table 3). Primary (degenerative) MR is a mechanical problem of the valve or its apparatus and requires a mechanical solution such as a surgical or percutaneous repair or replacement. Secondary (functional) MR is a problem of the left ventricle and treatment of the underlying ventricular pathology is indicated. Transcatheter edge-to-edge repair with MitraClip (Abbott Laboratories, Abbott Park, IL) in secondary MR is currently indicated in patients with LV dysfunction who remain symptomatic despite guideline-directed medical therapy.

In patients with acute severe MR, the role of medical therapy is to stabilize the patient until surgery. Afterload reduction is the initial treatment strategy, which allows for greater flow through the aortic valve, thereby increasing cardiac output while diminishing the MR. Afterload reduction may be accomplished with intravenous vasodilators such as sodium nitroprusside (Nitropress)<sup>1</sup> or with an intraaortic balloon pump if the clinical situation requires. The role of medical therapy for chronic severe degenerative MR is less clear, especially in asymptomatic patients with normal LV function. Symptomatic patients with a reduced ejection fraction (<60%) may be treated with heart failure therapy such as angiotensin-converting enzyme (ACE) inhibitors or angiotensin receptor blockers (ARBs), beta-adrenergic blockers, or aldosterone antagonists, in addition to loop diuretics for symptomatic relief while awaiting surgery. Ultimately most patients with severe primary MR will be referred to surgery (Table 4), and valve repair is preferable to replacement provided the anatomy is amenable to repair. If valve replacement is necessary, options include mechanical and bioprosthetic valves. Mechanical valves provide superior hemodynamic results and durability but are prone to thrombus formation and therefore require lifelong anticoagulation with warfarin (Coumadin). If after consultation with a cardiac surgeon the patient is deemed to be at prohibitive risk

<sup>1</sup>Not FDA approved for this indication.

**TABLE 4** Indications for Intervention in Severe Primary (Degenerative) Mitral Regurgitation

**SYMPTOMATIC**

Recommended if LVEF >30%  
May be considered if LVEF ≤30%  
TEER may be considered if severely symptomatic with reasonable life expectancy but prohibitive surgical risk

**ASYMPTOMATIC**

Recommended if LV dysfunction (LVEF 30%–60% or LVESD <40 mm)  
Reasonable if preserved LV function (LVEF >60% and LVESD >40 mm) if >95% chance of successful repair with <1% mortality risk  
Reasonable if preserved LV function with new-onset atrial fibrillation or PASP >50 mm Hg if high likelihood of successful repair

LV, Left ventricular; LVEF, left ventricular ejection fraction; LVESD, left ventricular end-systolic dimension; PASP, pulmonary arterial systolic pressure; TEER, transcatheter edge-to-edge repair.

for surgery, transcatheter edge-to-edge repair with the MitraClip device is a reasonable alternative. This procedure is performed under general anesthesia with fluoroscopic and transesophageal echocardiographic guidance, and from the femoral vein via transseptal access, a clip is delivered to the regurgitant orifice of the mitral valve, grasping the anterior and posterior leaflets, thereby improving leaflet coaptation.

For patients with secondary MR, the target for treatment is the left ventricle. Medical therapy for the underlying cardiomyopathy is recommended, with administration of ACE inhibitors or ARBs ± neprilysin inhibitors, aldosterone antagonists, and beta-blockers. If indicated, these patients may require cardiac resynchronization therapy. With medical and device therapy, LV remodeling and function may improve, with reduction in the degree of MR. If severe MR persists despite maximally tolerated medical therapy, percutaneous mitral valve repair with the MitraClip device is the only interventional therapy currently approved that significantly reduces mortality and heart failure rehospitalizations at 2 years while improving heart failure symptoms. In patients with ischemic cardiomyopathy secondary to obstructive coronary artery disease with severe secondary MR, surgical revascularization and concomitant mitral valve repair is frequently performed if the surgical risk is not prohibitive.

MR can progress over time, as the volume overload can lead to LV dilation and worsening mitral leaflet coaptation. As the disease process may be slow and without sudden worsening of symptoms, patients will require close follow-up. Mild MR can be followed by serial transthoracic echocardiography every 3 to 5 years, and moderate MR every 1 to 2 years. In patients with asymptomatic severe MR who do not undergo surgery, transthoracic echocardiography should be performed at least annually, with special attention to LV dimensions and function.

**VENOUS THROMBOSIS**

Method of

Andrea T. Obi, MD; and Thomas W. Wakefield, MD

**CURRENT DIAGNOSIS**

- Although clinical assessment and D-dimer levels are useful to rule out thrombosis, there is no combination of clinical findings and biomarker testing at this time that can rule in the diagnosis.
- Duplex ultrasound imaging is the gold standard for the diagnosis of deep venous thrombosis (DVT).
- Spiral computed tomography (CT) scanning, especially higher-resolution multidetector-row CT imaging, is preferred as the initial imaging test to establish the diagnosis of pulmonary embolism.

**CURRENT THERAPY**

- Initial preventative therapy includes anticoagulation, compression garments, and ambulation.
- The new direct oral anticoagulants (DOACs) are favored over warfarin for acute venous thromboembolism (VTE) treatment and no cancer. Rivaroxaban (Xarelto) and apixaban (Eliquis) are administered as monotherapy whereas dabigatran (Pradaxa) and edoxaban (Savaysa) require a low-molecular-weight heparin (LMWH) bridge. No bridge is needed with rivaroxaban or apixaban.
- When warfarin, dabigatran or edoxaban are used, LMWH should be administered for at least 5 days at the onset of therapy. If warfarin is used, it should be therapeutic (international normalized ratio 2.0–3.0) for 2 consecutive days before stopping LMWH.
- The duration of anticoagulation depends on a number of factors, including the presence of risk factors for thrombosis, the type of thrombosis (unprovoked or provoked), the number of times thrombosis has occurred, and risk factors for bleeding.
- Reduced-dose DOACs lessen VTE recurrences more than placebo or aspirin for long-term treatment after initial anticoagulant therapy is complete.
- Significant iliofemoral DVT may be treated with aggressive pharmacomechanical thrombolysis if a trial of anticoagulation fails to improve moderate to severe symptoms and the patient is ambulatory, has no contraindications to thrombolysis, and places a strong value on reducing the severity of postthrombotic syndrome (PTS) while accepting the inherent bleeding risk. Pulmonary embolism causing hemodynamic deterioration or right heart strain should be treated with thrombolysis.

## Epidemiology

Venous thromboembolism (VTE) includes deep venous thrombosis (DVT) and pulmonary embolism (PE). VTE affects up to 900,000 patients per year and results in up to 300,000 deaths per year. The incidence has remained constant and may be increasing since the 1980s and increases with age. The annual VTE rate among persons of European ancestry ranges from 104 to 183 per 100,000 person years. Overall VTE incidence may be higher in Black populations and lower in Asians and Asian- and Native Americans. The increasing prevalence of obesity, cancer, and surgery account in part for the persistent VTE incidence. Treatment of an acute VTE appears to be associated with incremental direct medical costs of \$12,000 to \$15,000 (2014 US dollars) with subsequent complications to increase cumulative costs up to \$18,000 to \$23,000 per incident case. Sequelae from VTE including recurrent VTE, postthrombotic syndrome (PTS), ulcers, and varicosities increase the incident cost by an average of 75%. The annual incident cost to the US health-care system is \$7 to \$10 billion dollars each year.

## Risk Factors

Risk factors for VTE include acquired and genetic factors. Acquired factors include increasing age, malignancy, surgery, immobilization, trauma, oral contraceptives and hormone replacement therapy, pregnancy and the puerperium, neurologic disease, cardiac disease, obesity, sepsis, pneumonia, calf muscle pump dysfunction, and inflammatory bowel disease. Genetic factors include antithrombin deficiency, protein C deficiency and protein S deficiency, factor V Leiden, prothrombin 20210A, blood group non-O, abnormalities in fibrinogen and plasminogen, elevated levels of clotting factors (e.g., factors XI, IX, VII, VIII, X, and II), and elevation in plasminogen activator inhibitor-1. When a patient presents with an unprovoked VTE, family history of thrombosis, recurrent thrombosis, or thrombosis in unusual locations, a workup for hypercoagulability, including testing for the conditions noted in the previous sentence, may be indicated, although even in these situations testing is controversial. Routine testing for hypercoagulable states in the setting of a provoked DVT is generally not indicated. Hematologic diseases associated with VTE include heparin-induced thrombocytopenia and thrombosis syndrome, disseminated intravascular coagulation, antiphospholipid antibody syndrome, myeloproliferative disorders, thrombotic thrombocytopenic purpura, and hemolytic uremic syndrome. There are a number of risk prediction scores that have been advanced, the most widely used being the Caprini risk score (<https://www.mdcalc.com/caprini-score-venous-thromboembolism-2005>). Using the score, factors that have been found to be associated with VTE are counted and summed, and a score is then calculated, which indicates VTE risk, especially in the context of surgical interventions.

## Pathophysiology

Although Virchow's triad of stasis, vein injury, and hypercoagulability has defined the events that predispose to VTE formation since the mid-19th century, the understanding today of events that occur at the level of the vein wall and thrombus, including the inflammatory response on thrombogenesis, thrombus resolution, and the subsequent changes to the vein wall and venous valves, is increasingly becoming apparent and may direct therapy in the future. COVID-19 has also been associated with the development of VTE. Infection with COVID-19 induces overlapping pathways that link the inflammatory response to the coagulation response. The overwhelming inflammatory response in patients with COVID-19 infection leads to a hypercoagulable state, microthrombosis, large vessel thrombosis, and ultimately can lead to death. The endothelium in multiple organs, especially the lungs, appears to play a significant role in the process going from reversible dysfunction to irreversible endothelial dysfunction. In COVID-19 critically ill patients, the rate of VTE has generally been reported between 20% and 40%.

## Diagnosis

### Deep Venous Thrombosis

The diagnosis of DVT can be ruled out with a clinical scoring system known as the Wells score (<https://www.mdcalc.com/wells-criteria-dvt>) and a negative D-dimer. Wells has classified patients into a system that emphasizes physical presentation, and the most common physical finding is edema. Characteristics that score points in the Wells system include active cancer, paralysis or paresis, recent plaster/cast immobilization of the lower extremity, being recently bedridden for 3 days or more, localized tenderness along the distribution of the deep venous system, swelling of the entire leg, calf swelling that is at least 3 cm larger on the involved side than on the noninvolved side, pitting edema in the symptomatic leg, collateral superficial veins (nonvaricose), and a history of previous DVT. With extensive proximal iliofemoral DVT there may be significant swelling, cyanosis, and dilated superficial collateral veins. The negative predictive value of a low- or intermediate-risk patient as stratified by Wells score and a negative D-dimer is near 100%. The incidence of DVT over the next 3 months in this patient cohort is 0.0% to 0.6%, suggesting that additional testing is unlikely to improve outcomes.

Duplex ultrasound imaging is the gold standard for ruling in the diagnosis of DVT. Duplex imaging includes both a B-mode image and Doppler flow pattern. Duplex imaging demonstrates sensitivity and specificity rates greater than 95%. According to the grade criteria for the strength of medical evidence, duplex ultrasound is given a 1B level of evidence, depending on the pretest probability for DVT. Even at the level of the calf, duplex imaging is an acceptable technique in symptomatic patients. Duplex imaging is painless, requires no contrast, can be repeated, and is safe during pregnancy. Duplex imaging also identifies other causes of a patient's symptoms. Other tests available for making the diagnosis include magnetic resonance imaging (MRI) (especially good for assessing central pelvic vein and inferior vena cava [IVC] thrombosis) and spiral computed tomography (CT) scanning (especially with chest imaging during examination for PE).

A single complete negative lower extremity duplex scan is accurate enough to withhold anticoagulation with minimal long-term adverse thromboembolic complications. This requires that all venous segments of the leg have been imaged and evaluated. If the duplex scan is indeterminate owing to technical issues or to edema, treatment may be based on factors such as biomarkers, with the duplex repeated in 24 to 72 hours. Combining clinical characteristics with a high-sensitivity D-dimer assay can decrease the number of duplex scans performed in the low-risk patient. Although clinical characteristics and D-dimer levels are useful to rule out thrombosis, the converse is not true, and there is no combination of biomarkers and clinical presentation that can rule in the diagnosis. Work is ongoing to establish new biomarkers based on the inflammatory response to DVT. We have data suggesting that a combination of soluble P-selectin and the Wells score can rule in the diagnosis of DVT, whereas D-dimer plus Wells is still the best combination to rule out the diagnosis of DVT.

Conditions that may be confused with DVT include lymphedema, muscle strain, muscle contusion, and systemic problems such as cardiac, renal, or hepatic abnormalities. These systemic problems usually lead to bilateral edema.

Rarely, massive iliofemoral DVT can result in phlegmasia alba dolens (white swollen leg) or phlegmasia cerulea dolens (blue swollen leg). If phlegmasia is not aggressively treated, it can lead to venous gangrene when the arterial inflow becomes obstructed owing to venous hypertension. Alternatively, arterial emboli or spasm can occur and contribute to the pathophysiology. Venous gangrene is often associated with underlying malignancy and is always preceded by phlegmasia cerulea dolens. Venous gangrene is associated with significant rates of amputation and PE and with mortality.

## Pulmonary Embolism

The diagnosis of PE historically has involved ventilation-perfusion scanning and pulmonary angiography. However, the most current techniques include spiral CT scanning and MRI, along with assessments of pretest probability and high-sensitivity D-dimer measurements. Age-adjusted D-dimer measurements may increase the diagnostic usefulness of these measurements. CT scanning demonstrates excellent specificity and sensitivity. Emboli down to the subsegmental level can be identified. The sensitivity for isolated chest CT imaging is increased when clinical analysis is added and when adding lower extremity imaging to the chest scan, although with the introduction of higher resolution multidetector-row CT imaging, the need for lower extremity imaging combined with CT is being questioned. Useful alternate techniques when there are contraindications to CT imaging include MRI and ventilation-perfusion imaging.

In low-risk individuals, a score of 0 on the PE Rule-out Criteria (<https://www.mdcalc.com/perc-rule-pulmonary-embolism>) gives confidence that further testing (D-dimer and CT) is not necessary. The PE Rule-out Criteria include (1) age older than 50 years, (2) pulse less than 100 beats/min, (3) oxygen saturation greater than 95% on room air, (4) absence of unilateral leg swelling, (5) absence of hemoptysis, (6) no recent trauma or surgery, (7) no prior history of VTE, and (8) no exogenous estrogen use.

## Axillary and Subclavian Vein Thrombosis

Thrombosis of the axillary and subclavian veins accounts for less than 5% of all cases of DVT. However, it may be associated with PE in up to 10% to 15% of cases and can be the source of significant disability. Upper extremity DVT may be primary (approximately 20%), such as from thoracic outlet syndrome, effort thrombosis, or idiopathic, or secondary (approximately 80%), such as from catheter-related, cancer-associated, surgery-related, or mediastinal tumors. Primary axillary and subclavian vein thrombosis results from obstruction of the axillary vein in the thoracic outlet from compression by the subclavius muscle and the costoclavicular space, the Paget-Schrötter syndrome, noted especially in muscular athletes. Patients with axillary and subclavian vein thrombosis present with arm pain, edema, and cyanosis. Superficial venous distention may be apparent over the arm, forearm, shoulder, and anterior chest wall.

Upper extremity venous duplex ultrasound scanning is used to make the diagnosis of axillary and subclavian vein thrombosis. A secondary DVT (such as related to a central venous catheter or other risk factor) is treated with anticoagulation alone, with the same recommendation regarding anticoagulant type, dose, and duration. If Paget-Schrötter syndrome is suspected, thrombolysis and phlebography are considered as next interventions. If phlebography is performed, it is important that the patient undergo positional phlebography with the arm abducted to 120 degrees to confirm extrinsic subclavian vein compression at the thoracic outlet once the vein has been cleared of thrombus. Because a cervical rib may be the cause of such obstruction, chest x-ray should be obtained to exclude its presence (although its incidence is quite low). Ultimately, decompression of the thoracic outlet with first rib resection (and cervical rib, if present), is necessary to prevent recurrent DVT.

## Treatment

### Standard Therapy for Venous Thromboembolism

The traditional treatment of VTE is systemic anticoagulation, which reduces the risk of PE, extension of thrombosis, and thrombus recurrence. Because the recurrence rate for VTE is higher if anticoagulation is not therapeutic in the first 24 hours, immediate anticoagulation should be undertaken. For PE, this usually means anticoagulation followed by testing. For DVT, because duplex imaging is rapidly obtained, usually testing precedes anticoagulation. Recurrent DVT can still occur in up to one-third of patients over an 8-year period, even with appropriate anticoagulant therapy.

The first line of therapy in the modern-day treatment of VTE is DOACs. Currently four DOACs are approved by the US Food and

Drug Administration (FDA) for the treatment of DVT and one for prophylaxis of VTE. These include rivaroxaban (Xarelto) and apixaban (Eliquis) as oral monotherapy (both require a loading dose period followed by a lower dose) and dabigatran (Pradaxa) and edoxaban (Savaysa), which require a LMWH bridge, and betrixaban (Bevyxxa)<sup>2</sup> for prophylaxis. Alternatively, LMWH or unfractionated heparin is given for 5 days, during which time oral anticoagulation with vitamin K antagonists (warfarin) is begun and LMWH is discontinued as soon as anticoagulation is therapeutic. With warfarin, it is recommended that the international normalized ratio be therapeutic for 2 consecutive days before stopping heparin or LMWH.

The new oral anticoagulants are favored over warfarin (grade 2B) for acute VTE and no cancer. Dabigatran targets activated factor II (factor IIa), whereas rivaroxaban, apixaban, and edoxaban target activated factor X (factor Xa). Dabigatran etexilate is FDA approved for stroke and systemic embolization prevention in patients with nonvalvular atrial fibrillation and for treatment and reduction of DVT and PE in patients who have been treated with a parenteral anticoagulant for 5 to 10 days. It is approved for DVT prophylaxis after hip replacement. Dabigatran etexilate has also been approved in oral pellet form to treat children 3 months to younger than 12 years old with VTE after they have been treated with a blood thinner given by injection for at least 5 days and to prevent recurrent VTE among patients 3 months to younger than 12 years old who completed treatment for their first VTE. In addition, it was approved in capsule form to treat VTE and reduce the risk of VTE recurrence for patients 8 years and older.

Rivaroxaban is FDA approved for VTE prophylaxis in patients undergoing hip or knee replacements, for stroke and systemic embolization prevention in patients with nonvalvular atrial fibrillation, and for VTE treatment. Rivaroxaban has also been approved to prevent VTE in certain adult patients hospitalized for an acute illness and for those patients after discharge who are at higher risk of VTE due to the decreased ability to move without a high risk of bleeding. It has also received two pediatric indications: (1) the treatment of VTE and reduction in the risk of recurrent VTE in patients from birth to younger than 18 years of age after at least 5 days of initial parenteral anticoagulant treatment, and (2) thromboprophylaxis in children age 2 years and older with congenital heart disease who have undergone a Fontan procedure. Apixaban is currently FDA approved for the prevention of complications of nonvalvular atrial fibrillation, for prophylaxis of DVT after hip or knee replacement surgery, for the treatment of DVT/PE, and for the reduction in risk of recurrence of DVT/PE. Edoxaban has been approved for prevention of stroke and non-CNS systemic embolism in patients with nonvalvular atrial fibrillation and for treating DVT and PE in patients who have been treated with a parenteral anticoagulant for 5 to 10 days. Betrixaban<sup>2</sup> is indicated for the prophylaxis of VTE in adult patients hospitalized for an acute medical illness who are at risk for thromboembolic complications due to restricted mobility and other risk factors. When an anticoagulant bridge is required, LMWH is the standard for initial treatment. LMWH is preferred because it is administered subcutaneously, it requires no monitoring (except in certain circumstances such as renal insufficiency or morbid obesity), and it is associated with a lower bleeding potential. Additionally, LMWH demonstrates less direct thrombin inhibition, more factor Xa inhibition, and antiinflammatory properties. Compared with standard unfractionated heparin, LMWH has significantly improved bioavailability, less endothelial cell binding and protein binding, and an improved pharmacokinetic profile. The half-life of LMWH is dose independent. LMWH is administered in a weight-based fashion.

Warfarin (Coumadin), when used, should be started after heparinization is therapeutic to prevent warfarin-induced skin

<sup>1</sup>Not FDA approved for this indication.

<sup>2</sup>Not available in the United States.

**TABLE 1** Case Scenarios for Treatment and Prevention of Venous Thrombosis

INITIAL MANAGEMENT		DECISION POINT	
PRIMARY TREATMENT (3–6 MONTHS)		SECONDARY PREVENTION	
CASE	INITIAL MANAGEMENT	PRIMARY TREATMENT	SECONDARY PREVENTION
Provoked DVT of right leg following a prolonged car ride in an otherwise healthy 61-year-old man	Apixaban 10 mg BID for 7 days or rivaroxaban 15 mg daily for 21 days	Apixaban 5 mg BID for 3 months or rivaroxaban 20 mg daily for 3 months	None
PE in 79-year-old man with prostate cancer	Apixaban 10 mg bid for 7 days	Apixaban 5 mg bid	Apixaban 5 mg BID
Pulmonary emboli in a 48-year-old with ESRD	Intravenous heparin	Vitamin K antagonist (Warfarin)	None (secondary to bleeding risk with ESRD)
Unprovoked DVT in a 50-year-old male with factor V Leiden	Apixaban 10 mg BID for 7 days or rivaroxaban 15 mg daily for 21 days	Apixaban 5 mg BID for 3 months or rivaroxaban 20 mg daily for minimum of 3–6 months	Apixaban 2.5 mg BID, rivaroxaban 10 mg daily or low-dose aspirin

BID, Twice daily; DVT, deep venous thrombosis; ESRD, end-stage renal disease.

necrosis. For standard unfractionated heparin, this requires a therapeutic activated partial thromboplastin time (aPTT); for LMWH, warfarin is administered after an appropriate weight-based dose of LMWH is administered and allowed to circulate. Warfarin causes inhibition of protein C and S before factors II, IX, and X, leading to paradoxical hypercoagulability at the initiation of therapy. The goal for warfarin dosing is an international normalized ratio between 2.0 and 3.0.

Fondaparinux (Arixtra) is also approved for the treatment of VTE. It is a synthetic pentasaccharide that has an antithrombin sequence identical to heparin and targets factor Xa. Fondaparinux has been additionally approved for thrombosis prophylaxis in patients with total hip replacement, total knee replacement, and hip fracture; in extended prophylaxis in patients with hip fracture; and in patients undergoing abdominal surgery. It is administered subcutaneously and has a 17-hour half-life. Dosage is based on body weight. It exhibits no endothelial or protein binding and does not produce thrombocytopenia. However, no antidote is readily available. For the treatment of VTE, fondaparinux was found equal to LMWH for DVT, and for PE, it was found equal to standard heparin.

Although LMWH has been the historic standard of care for treating cancer-associated VTE, the DOACs edoxaban<sup>1</sup> and rivaroxaban<sup>1</sup> have been found effective but with a higher risk of bleeding than LMWH. A recent study found that apixaban<sup>1</sup> at therapeutic dose was noninferior to the LMWH dalteparin (Fragmin) with no increased risk of major bleeding for treatment of cancer-associated VTE.

With significant thrombotic complications with COVID-19, there are many studies ongoing evaluating anticoagulant treatment in these patients, to treat not only diagnosed macrothrombosis but also microthrombosis with the intent to improve mortality. Therapeutic-dose heparin (LMWH preferred) should be used for patients who have a D-dimer above the upper level of normal, require low-flow oxygen, and have no increased bleeding risk (platelet count  $<50 \times 10^9/L$ , hemoglobin  $<8g/dL$ , need for dual antiplatelet medication, known bleeding within the past 30 days, known history of bleeding disorder, or an inherited or active acquired bleeding disorder).

Prophylactic dose heparin should be used for those patients who are receiving intensive care unit level of care. Intermediate or therapeutic dose heparin is not recommended in these patients. Several randomized trials have demonstrated that therapeutic anticoagulation does not decrease mortality in these patients but may have a higher risk of bleeding events.

#### Duration of Treatment

The recommended duration of anticoagulation after a first episode of provoked VTE is 3 months for both proximal (grade 1B

evidence) and distal thrombi (if symptomatic, grade 2C evidence) (Table 1). After a second episode of VTE, the usual recommendation is prolonged oral anticoagulation indefinitely (grade 1B), unless the patient is at high bleeding risk (two or more risk factors, grade 2B) or the patient is very young at the time of presentation. VTE recurrence is increased with homozygous factor V Leiden and prothrombin 20210A mutation, protein C or protein S deficiency, antithrombin deficiency, antiphospholipid antibodies, and cancer until resolved. Long-term oral anticoagulation is usually recommended in these situations. However, heterozygous factor V Leiden and prothrombin 20210A do not carry the same risk as their homozygous counterparts, and the length of oral anticoagulation is shortened for these conditions.

Regarding unprovoked DVT, in those with a low bleeding risk, the recommended length of treatment is extended therapy for more than 3 months (grade 2B evidence), provided the patient is at low or moderate risk of bleeding. Patients at high risk of bleeding should be treated for 3 months (grade 1B) and reevaluated. Additional tools that can aid in the decision making to continue or discontinue anticoagulation include thrombosis risk factors, residual thrombus burden, and coagulation system activation. The HERDOO2 score (<https://www.mdcalc.com/herdoo2-rule-discontinuing-anticoagulation-unprovoked-vte>) has been suggested as a way for identifying women at low risk of recurrent VTE for whom anticoagulation can be stopped. In addition, there is growing evidence that in certain circumstances, such as active cancer, the use of LMWH is superior to LMWH converted to warfarin for long-term treatment, for at least the first 3 to 6 months (grade 2C evidence). There is now evidence that rivaroxaban and apixaban may be as effective as LMWH in cancer patients, with the convenience of an oral medication. However, due to a slightly increased risk of GI bleeding, DOACs should be restricted to those patients with a non-GI malignancy and low bleeding risk.

Extended therapy is now recommended with low-dose DOACs when the risk-benefit relationship favors continued treatment. Extended rivaroxaban showed a significant decrease in recurrent VTE without a significant increase in major bleeding compared with aspirin for an additional 6 to 12 months of therapy after initial therapy. Apixaban as extended treatment of VTE has also been found to provide long-term protection against recurrent VTE. After initial treatment, an additional 12 months of apixaban therapy has been compared with placebo. There was a significant decrease in the rate of VTE without an increase in bleeding risk. In patients who cannot continue on DOACs after initial therapy for VTE and who do not have a contraindication, aspirin should be administered to prevent recurrent thrombosis. Bridging has been a complicated issue when patients on chronic anticoagulation with vitamin K antagonists (with long 5–7 days' half-lives) must undergo an operative procedure and the anticoagulation must be stopped and restarted. However, in low- to

<sup>2</sup>Not available in the United States.

moderate-risk patients, bridging is associated with no decrease in thrombotic events but with a higher bleeding risk. In fact, bridging is only indicated currently in those patients with atrial fibrillation and a recent stroke, atrial fibrillation and a high CHADS<sub>2</sub> score (5–6), a recent VTE within the past 3 months, and mechanical cardiac valves, especially mitral valves. The availability of DOACs, with short half-lives, has dramatically decreased the need for LMWH-based bridging. In most circumstances, DOACs need to be held only for 1 day for minor procedures and 2 days for major procedures and can be started back as soon as it is felt safe from the surgical or procedural perspective.

### Complications

Bleeding is the most common complication of anticoagulation. Risk factors for bleeding while on anticoagulation include age >65, previous bleeding, cancer, renal or liver failure, thrombocytopenia, previous stroke, diabetes, anemia, concurrent antiplatelet therapy, poor anticoagulant control, recent surgery, frequent falls, alcohol abuse, and nonsteroidal antiinflammatory drug use. Presence of zero risk factors (low risk) confers an absolute risk of major bleeding of 0.8% per year. Patients with one risk factor have a risk of 1.6% per year, and those with two or more have a 6.5% risk or higher per year. With standard heparin, bleeding occurs over the first 5 days in approximately 10% of patients. Warfarin is associated with a major bleeding rate of 1% to 2% per year. Even with the new DOACs, bleeding (major plus minor) may occur in 5% to 10% of cases, although the risk of intracerebral bleeding appears to be less than with warfarin. A recent real-world study of non-valvular atrial fibrillation patients suggested that rates of bleeding may be different between DOACs, with ranges between 11% and 16%. Problems specific to the DOACs include the difficulty to reliably reverse their anticoagulant effects and the difficulty with laboratory monitoring. A monoclonal antibody idarucizumab (Praxbind) for the reversal of dabigatran and a recombinant modified human Factor Xa protein andexanet alfa (Andexxa) for the reversal of Factor Xa inhibitors have been FDA approved; however, expense may limit their use. Aripazine<sup>5</sup> (a Factor Xa inhibitor) is under development for the neutralization of apixaban, rivaroxaban, edoxaban, and dabigatran.

Heparin-induced thrombocytopenia (HIT) occurs in 0.6% to 30% of patients. Although historically morbidity and mortality rates have been high, it has been found that early diagnosis and appropriate treatment have decreased these rates. HIT usually begins 3 to 14 days after unfractionated heparin is begun, although it can occur earlier if the patient has been exposed to heparin in the past. A heparin-dependent antibody binds to platelets, activates them with the release of procoagulant microparticles, leading to an increase in thrombocytopenia, and results in both arterial and venous thrombosis. Both bovine and porcine unfractionated heparin and LMWH have been associated with HIT, although the incidence and severity of the thrombosis is less with LMWH. Even small exposures to heparin, such as heparin coating on indwelling catheters, can cause the syndrome. The diagnosis should be suspected with a 50% or greater drop in platelet count, when the platelet count falls below 100,000/ $\mu$ L, or when thrombosis occurs during heparin or LMWH therapy. The enzyme-linked immunosorbent assay detects the antiheparin antibody in the plasma. This test is highly sensitive but poorly specific. The serotonin release assay is used as a confirmatory test that is more specific but less sensitive than the enzyme-linked immunosorbent assay test.

When the diagnosis is made, heparin must be discontinued. Oral anticoagulation should not be given until an adequate alternative anticoagulant has been established and until the platelet count has normalized. Because LMWHs demonstrate high cross-reactivity with standard heparin antibodies, they cannot be substituted for standard heparin in patients with HIT. Agents that have been FDA approved as alternatives include the direct

thrombin inhibitor argatroban. Fondaparinux (Arixtra)<sup>1</sup> has also been found effective for treatment of HIT in most cases, but it is not FDA approved for this indication.

### Nonpharmacologic Treatments

The symptoms of swelling and leg fatigue can be controlled after DVT by the use of compression stockings. Additionally, walking with good compression does not increase the risk of PE, whereas it significantly decreases the incidence and severity of the PTS. A recent multicenter randomized trial has suggested that stockings do not prevent development of PTS after a first proximal DVT, and for that reason, the most recent ACCP guidelines suggest not using compression stockings to prevent PTS (grade 2B evidence). It must be remembered that the use of strong compression and early ambulation after DVT treatment can significantly reduce the symptoms of pain and swelling resulting from the DVT, even if the development of PTS is not prevented, and a new study suggests that certain surrogate markers for PTS may be lessened by the application of immediate compression, and it also reduced residual vein obstruction, which correlated with PTS. Thus, the story on the use of compression stockings to prevent PTS is still evolving.

### Aggressive Therapies for Venous Thromboembolism

The goals of DVT treatment are to prevent extension or recurrence of DVT, prevent PE, and minimize the late sequela of thrombosis, namely chronic venous insufficiency. Standard anticoagulants accomplish the first two goals but not the third goal. The PTS (venous insufficiency related to venous thrombosis) occurs in up to 30% to 50% of patients after DVT and in an even higher percentage of patients with iliofemoral level DVT. It has been hypothesized that reopening the vein will alleviate venous hypertension or prevent PTS. This is known as the “open vein hypothesis.” The following evidence suggests more aggressive therapies for extensive thrombosis are indicated: experimentally, prolonged contact of the thrombus with the vein wall increases damage. The thrombus initiates an inflammatory response in the vein wall that can lead to vein wall fibrosis and valvular dysfunction. The longer a thrombus is in contact with a vein valve, the more chance that valve will no longer function.

Venous thrombectomy has proved superior to anticoagulation over 6 months to 10 years as measured by venous patency and prevention of venous reflux. Catheter-directed thrombolysis has been used in many nonrandomized studies and, in small, randomized trials, was more effective than standard therapy. Quality of life was improved with thrombus removal, and results appear to be optimized further by combining catheter-directed thrombolysis with mechanical devices. These devices include but are not limited to the Angiojet rheolytic catheter, the EKOS ultrasound accelerated catheter, and new larger bore extraction devices (Penumbra and angiovac). With these devices, thrombolysis is hastened, the amount of thrombolytic agent is decreased, and bleeding is thus decreased. Additionally, the use of venous stents for iliac venous obstruction has been shown to decrease the incidence of PTS, decrease chronic venous insufficiency, and improve disease-specific quality of life at 1, 6, and 24 months after the treatment.

To more fully elucidate the role of aggressive therapy in proximal iliofemoral venous thrombosis, the ATTRACT trial randomized 692 patients with acute proximal DVT to either anticoagulation alone or anticoagulation plus pharmacomechanical thrombolysis. This study found that more aggressive therapy did not decrease the incidence of PTS but did result in more major bleeding. The severity of the PTS was lessened by the pharmacomechanical thrombolysis, suggesting that more aggressive therapy should be offered to patients with significant iliofemoral venous thrombosis, who do not respond appropriately to a course of anticoagulation. This result also suggests that other factors need to be addressed to prevent PTS in addition to opening up the thrombosed vein.

<sup>1</sup>Not FDA approved for this indication.

<sup>5</sup>Investigational drug in the United States.

For PE, evidence exists that thrombolysis is indicated when there is hemodynamic compromise from the embolism. It is controversial whether thrombolysis should be used in situations in which there is no hemodynamic compromise, but there is evidence of right heart dysfunction or there are positive biomarkers. For PE, PE response teams (PERTs) have become common, and they allow for a multidisciplinary group of providers to treat PE in a rapid and coordinated fashion. These teams include (for example) noninvasive clinicians, emergency physicians, clinical pharmacists, endovascular proceduralists, and cardiac, thoracic, and/or vascular surgeons. The efficacy of these teams for treatment of PE is an area of active investigation.

### Inferior Vena Cava Filters

Traditional indications for the use of IVC filters include failure of anticoagulation, a contraindication to anticoagulation, or a complication of anticoagulation. Protection from PE is greater than 95% using cone-shaped, wire-based permanent filters in the IVC. With the success of these filters, indications have expanded to the presence of free-floating thrombus tails, prophylactic use when the risk for anticoagulation is excessive, when the risk of PE is thought to be high, and to allow the use of perioperative epidural anesthesia. IVC filters are not recommended as first-line therapy in patients who are treated with anticoagulants.

IVC filters can be either permanent or retrievable. If a retrievable filter is left, then it becomes a permanent filter; the long-term fate of these filters has yet to be defined adequately in the literature. Thus great efforts need to be made to remove retrievable IVC filters when the risk period is over. Most filters are placed in the infrarenal location in the IVC. However, they may be placed in the suprarenal position or in the superior vena cava.

Indications for suprarenal placement include high-lying thrombi, pregnancy or women of childbearing age, or previous device failure filled with thrombus. Although some have suggested that sepsis is a contraindication to the use of filters, sepsis has not been found to be a contraindication because the trapped material can be sterilized with intravenous antibiotics. Filters may be inserted under x-ray guidance or using ultrasound techniques, either external ultrasound or intravascular ultrasound.

## Digestive System

### ACUTE AND CHRONIC PANCREATITIS

Method of

George Van Buren II, MD; and William E. Fisher, MD

#### CURRENT DIAGNOSIS

- Acute pancreatitis is usually caused by gallstones, and chronic pancreatitis is usually caused by alcohol abuse.
- Other less-common causes of acute and chronic pancreatitis are considered only when gallstones and alcohol are definitively ruled out.
- Pancreatic cancer and chronic pancreatitis can sometimes be difficult to distinguish.

#### CURRENT THERAPY

- There has been a recent trend toward conservative medical therapy for acute and chronic pancreatitis, reserving surgery for select patients.
- In acute pancreatitis, try to avoid necrosectomy except in the setting of infected necrosis with organ failure.
- Asymptomatic pseudocysts can generally be observed.
- Persistent symptomatic pseudocysts can often be addressed endoscopically.
- Medical therapy for chronic pancreatitis includes pain management, nutrition, diabetes control, and cessation of drinking alcohol and smoking.
- Surgical treatment for chronic pancreatitis currently favors strict patient selection and consideration of various surgical techniques.

#### Acute Pancreatitis

Acute pancreatitis is an inflammatory disease of the pancreas that is associated with little or no fibrosis of the gland. It can be initiated by several factors including gallstones, alcohol, trauma, and infections, and in some cases it is hereditary (Box 1). Very often, patients with acute pancreatitis develop additional complications such as sepsis, shock, and respiratory and renal failure, resulting in considerable morbidity and mortality.

#### Epidemiology

The annual incidence of acute pancreatitis is probably about 50 cases per 100,000 population in the United States. Approximately 3000 of these cases are severe enough to lead to death. Studies worldwide have shown a rising but variable incidence of acute pancreatitis, including large increases in incidence in pediatric populations.

#### Risk Factors

Biliary tract stone disease accounts for 70% to 80% of the cases of acute pancreatitis. Alcoholism accounts for another 10%, and

the remaining 10% to 20% is accounted for either by idiopathic disease or by a variety of iatrogenic and miscellaneous causes including trauma, endoscopy, surgery, drugs, heredity, infection, and toxins. Medications appear to cause less than 5% of all cases of acute pancreatitis. The drugs most strongly associated with the disorder are azathioprine (Imuran), 6-mercaptopurine (Purinethol), didanosine (Videx), valproic acid (Depakote), angiotensin-converting-enzyme inhibitors, and mesalamine (Asacol). It is difficult to determine whether the drug is responsible. Tobacco use has also been heavily linked to pancreatitis. Meta-analysis has shown cigarette smoking to be associated with acute pancreatitis development in a dose-response manner.

#### Pathophysiology

Pancreatitis begins with the activation of digestive zymogens inside acinar cells, which cause acinar cell injury. Digestive zymogens are co-localized with lysosomal hydrolase, and cathepsin-B catalyzed trypsinogen activation occurs, resulting in acinar cell injury and necrosis. This triggers acinar cell inflammatory events with the secretion of inflammatory mediators. Studies suggest that the ultimate severity of the resulting pancreatitis may be determined by the events that occur subsequent to acinar cell injury. These include inflammatory cell recruitment and activation, as well as generation and release of cytokines, reactive oxygen species, and other chemical mediators of inflammation, ultimately leading to ischemia and necrosis. Early mortality in severe acute pancreatitis is caused by a systemic inflammatory response syndrome with multiorgan failure. If the patient survives this critical early period, a septic complication caused by translocated bacteria, mostly gram-negative microbes from the intestine, leads to infected pancreatic necrosis. Late deaths are caused by infected necrosis, leading to septic shock and multiorgan failure.

#### Prevention

Gallstones are present in about 15% to 20% of patients older than 60 years, but only a fraction become symptomatic. Although gallstone pancreatitis can rarely be the first symptom of gallstones, most patients have symptoms of cholecystitis before developing pancreatitis. Thus it is important to make early and prompt referral of patients with symptomatic cholelithiasis for laparoscopic cholecystectomy to prevent life-threatening complications such as acute pancreatitis.

#### Clinical Manifestations

All episodes of acute pancreatitis begin with severe pain, generally following a substantial meal. The pain is usually epigastric, but it can occur anywhere in the abdomen or lower chest. It has been described as penetrating through to the back, and it may be relieved by the patient's leaning forward. It precedes the onset of nausea and vomiting, with retching often continuing after the stomach has emptied. Vomiting does not relieve the pain, which is more intense in necrotizing than in edematous pancreatitis.

On examination the patient may show tachycardia, tachypnea, hypotension, and hyperthermia. The temperature is usually only mildly elevated in uncomplicated pancreatitis. Voluntary and involuntary guarding can be seen over the epigastric region. The bowel sounds are decreased or absent. There are usually no

**BOX 1** Common Causes of Acute Pancreatitis Gallstones

Alcoholism

 Hypertriglyceridemia  
 Trauma (including iatrogenic: ERCP or surgery)  
 Drugs: azathioprine (Imuran), furosemide, mercaptopurine (Purinethol), opiates, pentamidine (Pentam), steroids, sulfasalazine (Azulfidine), sulindac (Clinoril), tetracycline, trimethoprim-sulfamethoxazole (Bactrim), valproic acid (Depakote)  
 Tumor  
 Infection (parasitic and viral)  
 Idiopathic

ERCP, Endoscopic retrograde cholangiopancreatography.

palpable masses. The abdomen may be distended with intraperitoneal fluid. There may be pleural effusion, particularly on the left side. With increasing severity of disease, the intravascular fluid loss may become life-threatening as a result of sequestration of edematous fluid in the retroperitoneum. Hemoconcentration then results in an elevated hematocrit. However, there also may be bleeding into the retroperitoneum or the peritoneal cavity. In some patients (about 1%), the blood from necrotizing pancreatitis can dissect through the soft tissues and manifest as a bluish discoloration around the umbilicus (Cullen sign) or in the flanks (Grey Turner sign). The severe fluid loss can lead to prerenal azotemia, with elevated blood urea nitrogen and creatinine levels. There also may be hyperglycemia, hypoalbuminemia, and hypocalcemia sufficient in some cases to produce tetany.

### Diagnosis

The definition of acute pancreatitis is based on the fulfillment of two out of three of the following criteria: clinical (upper abdominal pain), laboratory (serum amylase or lipase  $>3\times$  upper limit of normal) and/or imaging (computed tomographic [CT], magnetic resonance imaging [MRI], ultrasonography) criteria. Although serum amylase is often elevated in acute pancreatitis, there is no significant correlation between the magnitude of serum amylase elevation and severity of pancreatitis. Other pancreatic enzymes also have been evaluated to improve the diagnostic accuracy of serum measurements. Specificity of these markers ranges from 77% to 96%, the highest being for lipase. Measurements of many digestive enzymes have methodologic limitations and cannot be easily adapted for quantitation in emergency laboratory studies. Because serum levels of lipase remain elevated for a longer time than total or pancreatic amylase, it is the serum indicator of highest probability of the disease.

Abdominal ultrasound examination is the best way to confirm the presence of gallstones in suspected biliary pancreatitis. It also can detect extrapancreatic ductal dilations and reveal pancreatic edema, swelling, and peripancreatic fluid collections. However, in about 20% of patients, the ultrasound examination does not provide satisfactory results because of the presence of bowel gas, which can obscure sonographic imaging of the pancreas.

A CT scan of the pancreas is more commonly used to diagnose pancreatitis. CT scanning is used to distinguish milder (non-necrotic) forms of the disease from more severe necrotizing or infected pancreatitis, in patients whose clinical presentation raises the suspicion of advanced disease (Figures 1 and 2). Pancreatic protocol CT scan of the abdomen and pelvis is recommended when not limited by renal insufficiency: a tri-phasic thin, multislit CT scan with an arterial, venous, and delayed phase in conjunction with sagittal and coronal views; no oral contrast, instead drink 1000 cc water to opacify the stomach. The scan assesses the degree of pancreatic necrosis, peripancreatic fluid collections, and the surrounding vascular structures. This tri-phasic scan can also help to detect underlying mass lesions.

**Figure 1** Computed tomographic scan confirming acute edematous pancreatitis.

**Figure 2** Computed tomographic scan confirming acute necrotizing, emphysematous pancreatitis.

Magnetic resonance cholangiopancreatography (MRCP) is also of value to assess the pancreatic duct and biliary tree. This can often reveal pancreatic ductal disruption.

### Differential Diagnosis

The clinical diagnosis of pancreatitis is one of exclusion. Hyperamylasemia can also occur as a result of conditions not involving pancreatitis. The other upper abdominal conditions that can be confused with acute pancreatitis include perforated peptic ulcer and acute cholecystitis, and occasionally a gangrenous small bowel obstruction. Because these conditions often have a fatal outcome without surgery, urgent intervention is indicated in the small number of cases in which doubt persists. A tumor should be considered in a non-alcoholic patient with acute pancreatitis who has no demonstrable biliary tract disease. Approximately 1% to 2% of patients with acute pancreatitis have pancreatic carcinoma, and an episode of acute pancreatitis can be the first clinical manifestation of a periampullary tumor.

### Treatment

The severity of acute pancreatitis covers a broad spectrum of illness, ranging from the mild and self-limiting to the life-threatening necrotizing variety. Some cases are so mild they can be treated in an outpatient setting. However, most cases require hospitalization for observation and diagnostic study. A conservative approach

**BOX 2** Treatment of Acute Pancreatitis

- Assessment of severity
- Fluid resuscitation and oxygenation
- Early nasojejunal feeding
- Avoid prophylactic antibiotics (reserve antibiotic therapy for specific infections)
- Avoid or postpone necrosectomy if possible
- Options for necrosectomy
  - Open anterior approach with closed lavage
  - Open anterior approach with packing and reoperation
  - Open retroperitoneal approach
  - Laparoscopic anterior approach with closed lavage
  - Video-assisted retroperitoneal débridement

**BOX 3** Ranson Criteria

There are 11 Ranson signs. Five of the signs are evaluated when the patient is admitted to the hospital, and the remaining six are evaluated 48 h after admission. The signs are added to reach a score:

- If the score <3, severe pancreatitis is unlikely.
  - If the score  $\geq 3$ , severe pancreatitis likely.
- or
- Score 0–2: 2% mortality
  - Score 3–4: 15% mortality
  - Score 5–6: 40% mortality
  - Score 7–8: 100% mortality

**At Admission**

- Age in years >55 years
- White blood cell count >16,000 cells/mm<sup>3</sup>
- Blood glucose >11 mmol/L (>200 mg/dL)
- Serum AST >250 IU/L
- Serum LDH >350 IU/L

**At 48 Hours**

- Calcium (serum calcium) <2.0 mmol/L (<8.0 mg/dL)
- Hematocrit fall >10%
- Oxygen (hypoxemia  $P_{O_2}$  <60 mm Hg)
- BUN increased by  $\geq 1.8$  mmol/L ( $\geq 5$  mg/dL) after intravenous fluid hydration
- Base deficit (negative base excess) >4 mEq/L
- Sequestration of fluids >6 L

AST, Aspartate aminotransferase; BUN, blood urea nitrogen.

has been advocated in the treatment of acute pancreatitis (Box 2). Severity is assessed with imaging results and clinical parameters and is quantitated with scores such as Ranson criteria (Box 3), the Atlanta classification, and the APACHE II (Acute Physiology and Chronic Health Evaluation) score. Severe acute pancreatitis is defined by associated organ dysfunction. The Atlanta classification is based on an international consensus conference held in Atlanta in 1992 and has been updated. APACHE II was designed to measure the severity of disease for adult patients admitted to intensive care units. Though not specific to pancreatitis, APACHE II can be used in an effort to differentiate patients with mild and severe acute pancreatitis. APACHE II scores of 8 points or more correlate with a mortality rate of 11% to 18%.

Upon confirmation of the diagnosis, patients with severe disease should be transferred to the intensive care unit for observation and maximum support. Adequate fluid resuscitation optimizing organ perfusion and oxygenation is essential. The use of prophylactic intravenous antibiotics in the initial stages of severe acute pancreatitis is not proved to be useful. Two randomized, controlled studies failed to show any benefit from antibiotics. Prophylactic antibiotics did not decrease the incidence of

infected pancreatic necrosis or lower mortality. Data from these well-designed trials refute prior data from less-rigorous studies suggesting prophylactic antibiotics were useful. Additional studies are required, but there is increasing concern that the prolonged use of potent antibiotics might result in an increased prevalence of fungal infections and possibly increased mortality. Currently, antibiotic therapy should be reserved for treatment of specific infections such as positive blood, sputum, and urine cultures or percutaneous or operative cultures of necrotic tissue.

Randomized clinical trials have also shown a benefit from early nasojejunal feeding compared to total parenteral nutrition. Gastric decompression with a nasogastric tube is selectively used in patients with severe ileus and vomiting but is not necessary in a majority of cases. A debate remains regarding the optimal nutritional management in the majority of pancreatitis patients. There has been a trend toward oral enteric feeding in the less severe cases.

In biliary pancreatitis, the gallbladder must eventually be removed or recurrent acute pancreatitis will occur in 30% to 60% of cases. The timing of the cholecystectomy depends on the severity of the pancreatitis. Usually laparoscopic cholecystectomy is performed during the index admission as soon as the attack of acute pancreatitis has resolved. In more severe cases, the cholecystectomy is delayed and often combined with interventions for late complications of acute pancreatitis. In cases with severe comorbidity, endoscopic sphincterotomy has been considered as an alternative to cholecystectomy. However, if the patient has a postinflammatory fluid collection, bacteria can be introduced during endoscopic retrograde cholangiopancreatography (ERCP), and sphincterotomy should be delayed.

Currently, there is no role for routine early laparotomy and necrosectomy or resection in the setting of acute necrotizing pancreatitis. If the necrotic pancreas becomes infected and the patient fails to respond to conservative treatment, then necrosectomy may be warranted. Patients with infected necrosis are rarely managed conservatively without eventual surgical intervention. However, even in the setting of infected necrosis, there has been consideration for antibiotic therapy until the acute inflammatory response has subsided, if possible, with the view that surgery that is deferred for several weeks is more easily accomplished with one intervention. Patients who suffer from infected necrosis without having clinical signs of sepsis or other systemic complications might not need immediate surgical necrosectomy.

A nonsurgical alternative for the treatment of infected necrosis is percutaneous catheter drainage. This is considered a temporary measure to allow stabilization of the patient so that a safer surgical necrosectomy can be done at a later time. Multiple large drains are required, and patients frequently undergo repeat CT and revision of the drains. Current recommendations are to postpone surgery for as long as possible, usually beyond the second or third week of the disease or later, when necrotic tissue can be easily distinguished from viable pancreas and débridement without major blood loss can be performed. When surgery is performed, tissue-preserving digital necrosectomy is the usual technique rather than a classic surgical resection of the pancreas (Figure 3).

Necrosectomy can be performed by an open anterior approach with closed lavage or with leaving the abdomen open and packing. The packing is replaced at intervals of 24 to 72 hours. Sometimes a left lateral retroperitoneal approach is helpful. Newer approaches are the video-assisted retroperitoneal débridement (VARD). This procedure is a combination of percutaneous drainage and the open lateral retroperitoneal approach. An anterior laparoscopic approach has also been described and mimics the open anterior approach using laparoscopic ports. Surgical necrosectomy is indicated in patients with sepsis caused by infected necrosis and in selected patients with extended sterile necrosis causing severe systemic organ dysfunction and sepsis without a septic focus.

In some cases, the acute inflammatory process can lead to erosion into retroperitoneal vessels, and acute hemorrhage occurs. This acute emergent complication is best managed with immediate

**Figure 3** Necrotic material débrided from the retroperitoneum in a case of acute necrotizing pancreatitis.

angiography to determine the exact site of bleeding and can often be treated with embolization rather than surgery (Figure 4).

Although previously frowned upon, there has been a move toward enteric drainage of all necrotic collections (even when infected) when technically feasible. This can be initiated through either an endoscopic or surgical approach.

#### Monitoring

Despite a conservative operative approach, endocrine and exocrine insufficiency develop in as many as half of the patients and are determined by the extent of pancreatic necrosis. Therefore patients must be monitored with blood glucose measurements, stabilization of body weight, and proper nutrition.

#### Complications

The most common complication after successful management of acute pancreatitis is a pseudocyst. The term “pseudocyst” is currently used to broadly categorize most pancreatic and peripancreatic fluid collections (including walled-off pancreatic necrosis [WOPN] and acute peripancreatic fluid collection). The Acute Pancreatitis Classification Working Group recently proposed a revised Atlanta classification that refers to collections within 4 weeks of symptom onset as either acute peripancreatic fluid collections (APFC) or postnecrotic pancreatic fluid collections (PNPFC), depending upon the absence or presence of pancreatic/peripancreatic necrosis, respectively. After 4 weeks of the onset of symptoms, persistent collections with discrete walls are referred to as pseudocyst or WOPN, again depending upon the absence or presence of necrosis, respectively. In addition, these collections are further classified as sterile or infected and the term “pancreatic abscess” has been abolished.

The management of pseudocysts has followed a minimally invasive trend. Most pseudocysts resolve spontaneously, even beyond 6 weeks, so asymptomatic pseudocysts are usually observed (70% of pseudocysts will resolve without intervention). Endoscopic cystogastrostomy is the approach of choice for symptomatic fluid-predominant pseudocysts when there is minimal necrosis. If there is significant necrotic debris or a solid-predominant pseudocyst, surgical drainage with laparoscopic cystogastrostomy is preferred (Figure 5). This can also be performed with the traditional open technique. Cystojejunostomy (laparoscopic or open) is used in cases in which the site of the pseudocyst precludes drainage into the posterior aspect of the stomach.

#### Chronic Pancreatitis

Chronic pancreatitis is a chronic fibro-inflammatory disease of the pancreas characterized by irreversible morphologic changes that typically are associated with pain or permanent loss of function, or both.

**Figure 4** Acute necrotizing pancreatitis. (A) Erosion into the splenic artery as seen on computed tomography. (B) Erosion into the splenic artery as seen on angiogram. (C) This complication of acute pancreatitis is best treated with angiographic embolization.

**Figure 5** Computed tomographic scan showing fluid-predominant (A) and solid-predominant (B) pseudocysts. The former can be treated with endoscopic cystogastrostomy, and the latter is best treated with laparoscopic cystogastrostomy.

### Epidemiology

Population studies suggest a prevalence of chronic pancreatitis that ranges from 5 to 27 persons per 100,000 population, with considerable geographic variation. Autopsy data are difficult to interpret because a number of changes associated with chronic pancreatitis, such as fibrosis, duct ectasia, and acinar atrophy, are also present in asymptomatic elderly patients. Differences in diagnostic criteria, regional nutrition, alcohol consumption, and medical access account for variations in the frequency of the diagnosis, but the overall incidence of the disease has risen progressively since the 1960s. Chronic pancreatitis in the United States currently results in more than 120,000 outpatient visits and more than 50,000 hospitalizations per year.

### Risk Factors

Alcohol consumption and alcohol abuse are associated with chronic pancreatitis in up to 70% of cases. Other major causes include tropical (nutritional) and idiopathic disease, as well as hereditary causes. There is a linear relationship between exposure to alcohol and the development of chronic pancreatitis. The incidence is highest in heavy drinkers (15 drinks/day or 150 g/d). Prolonged alcohol use (four to five drinks daily over a period of more than 5 years) is required for alcohol-associated pancreatitis; the overall lifetime risk of pancreatitis among heavy drinkers is 2% to 5%. The duration of alcohol consumption is definitely associated with the development of pancreatic disease. The onset of disease typically occurs between ages 35 and 40 years, after 16

to 20 years of heavy alcohol consumption. Recurrent episodes of acute pancreatitis are typically followed by chronic symptoms after 4 or 5 years. In most cases, chronic pancreatitis has already developed and the acute clinical presentation represents a flare superimposed on chronic pancreatitis.

Tobacco use has also been heavily linked to pancreatitis. Meta-analysis has shown that both ever and current smokers had higher risks of developing pancreatitis compared with never smokers. This causative relationship was verified by the reduced or eliminated risk after smoking cessation. In comparison with current smokers, the risk of pancreatitis decreased for those who were former smokers.

### Pathophysiology

Multiple episodes (or a prolonged course) of pancreatic injury ultimately leading to chronic disease is widely accepted as the pathophysiologic sequence. Abundant data indicate that acute pancreatitis may progress to recurrent acute pancreatitis and then to chronic pancreatitis in a disease continuum. Most investigators believe that alcohol metabolites such as acetaldehyde, combined with oxidant injury, result in local parenchymal injury that is preferentially targeted to the pancreas in predisposed persons. Repeated or severe episodes of toxin-induced injury activate a cascade of cytokines, which in turn induces pancreatic stellate cells to produce collagen and cause fibrosis.

The most common form of chronic pancreatitis is the calcifying type, characterized by the development of intraductal stones; the predominant causative agent is alcohol. Progressive functional impairment can develop from the dilated main pancreatic duct. Furthermore inflammatory enlargement of the pancreatic head may cause local complications such as stenosis of the pancreatic or bile duct, duodenal obstruction, or compression of retropancreatic vessels.

The pain caused by chronic pancreatitis is thought to be due to increased pressure in the pancreatic ducts and tissue, “parenchymal hypertension” from pancreatic ductal obstruction. Neural and perineural inflammation is also thought to be important in pathogenesis of pain in chronic pancreatitis. Neuropeptides released from enteric and afferent neurons and their functional interactions with inflammatory cells might play a key role.

### Prevention

Because alcohol is the cause of most cases of chronic pancreatitis, cessation of alcohol consumption is recommended to prevent progression to chronic pancreatitis. Unfortunately, the majority of patients are not able to recover from alcoholism, and relapse is common.

### Clinical Manifestations

Symptoms of chronic pancreatitis may be identical to those of acute pancreatitis, typically midepigastic pain penetrating through to the back. Patients with chronic pancreatic pain typically flex their abdomen and either sit or lie with their hips flexed, or lie on their side in a fetal position. Unlike ureteral stone pain or biliary colic, the pain causes the patient to be still. Nausea or vomiting can accompany the pain, but anorexia is the most common associated symptom. Patients with continuous pain can have a complication of chronic pancreatitis, such as an inflammatory mass, a cyst, or even pancreatic cancer. Other patients have intermittent attacks of pain with symptoms similar to those of mild to moderate acute pancreatitis. The pain sometimes is severe and lasts for many hours or several days.

As chronic pancreatitis progresses, endocrine and exocrine insufficiency begin to appear. Patients describe a bulky, foul-smelling, loose (but not watery) stool that may be pale and float on the surface of toilet water. Patients often describe a greasy or oily appearance to the stool or describe an “oil slick” on the water’s surface. In severe steatorrhea, an orange, oily stool is often reported. As exocrine deficiency increases, symptoms of steatorrhea are often accompanied by weight loss. Patients might describe a good appetite despite weight loss, or they might have

**Figure 6** Computed tomographic scan of a patient with autoimmune pancreatitis and an inflammatory mass in the head of the pancreas. Preoperative diagnosis is not always possible, but surgery should be avoided because this disease often responds to steroid therapy.

diminished food intake due to abdominal pain. The combination of decreased food intake and malabsorption of nutrients usually results in chronic weight loss. As a result, many patients with severe chronic pancreatitis are below ideal body weight. Usually islet cells are spared early in the disease process despite being surrounded by fibrosis, but eventually the insulin-secreting beta cells are also destroyed, gradually leading to diabetes.

### Diagnosis

The diagnosis of chronic pancreatitis depends on the clinical presentation, a limited number of indirect measurements that correlate with pancreatic function, and selected imaging studies. Diagnosis is usually simple in the late stages of the disease because of the presence of structural and functional alterations of the pancreas. Early in the disease, the diagnosis is more difficult. Various classification systems have been developed. The Cambridge classification uses imaging tests such as ERCP, CT, and ultrasound to grade severity. The Mayo Clinic system is based on functional as well as imaging results. Tests of pancreatic function include the secretin-erulein test, Lundh test, fecal excretion of pancreatic enzymes, and quantitation of fecal fat.

Chronic pancreatitis can be classified as calcifying (lithogenic), obstructive, inflammatory, autoimmune, tropical (nutritional), hereditary, or idiopathic. Autoimmune and hereditary pancreatitis have recently been better understood and diagnosed more than before. Autoimmune pancreatitis is associated with fibrosis, a mononuclear cell (lymphocyte, plasma cell, or eosinophil) infiltrate, and an increased titer of one or more autoantibodies. It is usually associated with autoimmune diseases such as Sjögren syndrome. Increased levels of serum  $\beta$ -globulin or immunoglobulin (Ig)G<sub>4</sub> are often present, however autoimmune pancreatitis can present without these markers. This disease can be mistaken for chronic pancreatitis, with an inflammatory mass in the head of the pancreas suspicious for pancreatic cancer (Figure 6). Diagnosis is important because steroid therapy is uniformly successful in ameliorating the disease, including any associated bile duct compression.

Hereditary pancreatitis first occurs in adolescence with abdominal pain; patients develop progressive pancreatic dysfunction, and the risk of cancer is greatly increased. The disease follows an autosomal dominant pattern of inheritance with 80% penetrance and variable expression. Recent mutational analysis has revealed a missense mutation resulting in an Arg to His substitution at position 117 of the cationic trypsinogen gene, or *PRSS1*, one of the primary sites for proteolysis of trypsin. This mutation prevents trypsin from being inactivated by itself or other proteases, and it results in persistent and uncontrolled proteolytic activity and autodestruction within the pancreas. Similarly, *PSTI*,

### BOX 4 Treatment of Chronic Pancreatitis

- Pancreatic enzyme replacement
- Proper nutrition and vitamin supplementation
- Blood sugar control
- Long-acting narcotic analgesics at lowest effective doses
- Cessation of alcohol and tobacco
- Endotherapy (pancreatic duct stenting and removal of stones)
- Parenchymal preserving surgery (Frey, Beger) in carefully selected patients

also known as *SPINK1*, has been found to have a role in hereditary pancreatitis and some cases of sporadic chronic pancreatitis. *SPINK1* specifically inhibits trypsin action by competitively blocking the active site of the enzyme.

It is likely that many of the “idiopathic” forms of chronic pancreatitis, as well as some patients with the more common forms of the disease, will be found to have a genetic linkage or predisposition.

### Differential Diagnosis

There are several clinical conditions from which chronic pancreatitis needs to be distinguished. Other causes of upper abdominal pain, such as peptic ulcer disease, biliary tract disease, mesenteric vascular disease, or malignancy must be excluded. The major difficulty in the differential diagnosis of chronic pancreatitis is distinguishing it from pancreatic ductal adenocarcinoma. Chronic pancreatitis can closely mimic pancreatic cancer, both clinically and morphologically. In addition, chronic pancreatitis is a risk factor for the development of pancreatic cancer. Although in pancreatic resection specimens this problem may be finally resolved, distinguishing these two diseases preoperatively in small (needle) biopsy specimens is a formidable challenge for the pathologist. Therefore especially in the setting of an inflammatory mass in the head of the pancreas, consideration of pancreatic cancer and surgical referral is important. Workup of these patients should include a pancreatic protocol CT scan, an MRCP, and an endoscopic ultrasound to evaluate the parenchyma and the ducts of the pancreas.

### Treatment

Therapy for chronic pancreatitis is aimed at managing associated digestive dysfunction and relieving pain (Box 4). It is important to first address malabsorption, weight loss, and diabetes. When pancreatic exocrine capacity falls below 10% of normal, diarrhea and steatorrhea develop. Lipase deficiency tends to manifest itself before trypsin deficiency, so the presence of steatorrhea may be the first functional sign of pancreatic insufficiency. As pancreatic exocrine function deteriorates further, the secretion of bicarbonate into the duodenum is reduced, which causes duodenal acidification and further impairs nutrient absorption. Frank diabetes is seen initially in about 20% of patients with chronic pancreatitis, and impaired glucose metabolism can be detected in up to 70% of patients.

The medical treatment of chronic or recurrent pain in chronic pancreatitis requires the use of analgesics, a cessation of alcohol use, oral enzyme therapy, and endoscopic stent therapy. Administration of pancreatic enzyme (e.g., Pancrease MT, Pancrelipase, Creon) serves to reverse the effects of pancreatic exocrine insufficiency and might also reduce or alleviate the pain<sup>1</sup> experienced by patients. Interventional procedures to block visceral afferent nerve conduction or to treat obstructions of the main pancreatic duct are also an adjunct to medical treatment. It has been taught that the pain of chronic pancreatitis decreases with increasing duration of the disease, the so-called burn-out phase, where endocrine and exocrine insufficiency occurs and the pain decreases.

<sup>1</sup>Not FDA approved for this indication

However, recent studies have called this concept into question, demonstrating continued pain in patients with chronic pancreatitis despite long-standing disease and pancreatic insufficiency. Cessation of alcohol abuse, if possible, causes the pain to stop in about half of the patients.

Pain relief usually requires the use of narcotics, but these should be titrated to achieve pain relief with the lowest effective dose. Opioid addiction is common, and the use of long-acting analgesics by transdermal patch together with oral agents for pain exacerbations slightly reduces the sedative effects of high-dose oral narcotics. Celiac plexus neurolysis has been an effective form of analgesic treatment in patients with pancreatic carcinoma. However, its use in chronic pancreatitis has been disappointing, with about half of the patients deriving a benefit that lasts 6 months or less.

Pancreatic duct stenting is used for treatment of proximal pancreatic duct stenosis, decompression of a pancreatic duct leak, and drainage of pancreatic pseudocysts that can be catheterized through the main pancreatic duct. Pancreatic duct stones can also be removed endoscopically. Stent therapy in chronic pancreatitis definitely plays a role and can help select patients for successful operative therapy. However, the duration of success with stent therapy for chronic pancreatitis is probably less than with surgical therapy.

There has been significant debate over the years regarding the role and type of surgical therapy in chronic pancreatitis. Progressive functional pancreatic impairment can be delayed by surgical decompression of the dilated main pancreatic duct. Furthermore, inflammatory enlargement of the pancreatic head may cause local complications that require further treatment, such as stenosis of the pancreatic or bile duct, duodenal obstruction, or compression of retropancreatic vessels. Surgery may be superior to conservative or endoscopic treatment in terms of pain relief and preservation of pancreatic function and quality of life. Major pancreatic resections for chronic pancreatitis have a significant complication rate, both early and late. Patients with large duct disease who can have nutrition restored, are working, are not drinking alcohol, and have a supportive family structure fare better with surgical therapies. Failure to carefully select patients for either drainage or resection procedures leads to disappointing results. The surgical management of pancreatic duct stones and stenosis has been shown to be superior to endoscopic treatment in randomized clinical trials. Beger introduced the duodenum-preserving pancreatic head resection (DPPHR) in the early 1980s. Later in the decade, Frey and Smith described the local resection of the pancreatic head with longitudinal pancreaticojejunostomy, which included excavation of the pancreatic head including the ductal structures in continuity with a long ductotomy of the dorsal duct. This operation is basically a hybrid of the Beger and Puestow (Partington-Rochelle modification) procedures and is more popular in the United States (Figures 7 and 8).

Previous randomized prospective studies have compared the Whipple, Beger, and Frey procedures for chronic pancreatitis. Patients who had a Beger procedure had a shorter hospital stay, greater weight gain, less postoperative diabetes, and less exocrine dysfunction than standard Whipple patients over a 3- to 5-year follow-up. Pain control was similar between the two procedures. In a study comparing the pylorus-preserving Whipple to the Frey procedure, there was a lower postoperative complication rate associated with the Frey procedure (19%) compared to the pylorus-preserving Whipple group (53%), and the global quality-of-life scores were better (71% vs. 43%, respectively). Both operations were equally effective in controlling pain over a 2-year follow-up. Operation times, intraoperative blood loss, and transfusion requirements have been shown to be decreased with the Frey and Beger procedures compared to the Whipple procedure. In long-term (>8 years) follow-up, there was no difference between the Beger and Frey procedures in pain relief, pancreatic insufficiency, quality of life, and late mortality. Compared to the Whipple procedure, the Beger and Frey procedures may produce a lower incidence of immediate complications and diabetes but no significant differences in pain relief. Although

**Figure 7** Computed tomographic scan of a patient with chronic calcific pancreatitis and a massively dilated pancreatic duct. (A) Axial view with calcified pancreatic head. (B) Axial view with dilated pancreatic duct.

these limited pancreatic procedures have a lower initial rate of endocrine dysfunction, the long-term risk of diabetes is more related to the progression of the underlying disease than to the effects of operation.

Recent multicenter randomized, controlled, double-blinded, trial compared DPPHR to partial pancreatoduodenectomy with a primary endpoint of quality of life within 24 months after surgery. The results showed that DPPHR was not superior to partial pancreatoduodenectomy in terms of the primary endpoint, long-term postoperative quality of life. With both resection and drainage procedures offering viable options for treatment, patient selection becomes critical in assuring there is clinical improvement postoperatively.

Recent refinements in the methods of harvesting and preserving pancreatic islets, and standardization of the methods by which islets are infused into the portal venous circuit for intrahepatic engraftment, have improved the success and rekindled interest in islet autotransplantation for chronic pancreatitis. The ability to recover a sufficient quantity of islets from a sclerotic gland depends on the degree of disease present, so the selection of patients as candidates for autologous islet transplantation is important. As success with autotransplantation increases, patients with nonobstructive, sclerotic pancreatitis may be considered for resection and islet autotransplantation earlier in their course, because end-stage fibrosis bodes poorly for transplant success. Patient selection and surgeon experience play a very large role in the outcomes of autotransplantation.

**Figure 8** (A) The pancreatic duct is opened to reveal a preoperatively placed pancreatic duct stent. (B) The residual stones removed from the pancreatic duct. (C) In the Frey procedure, the head of the pancreas is cored out in addition to a longitudinal pancreatic ductotomy. The pancreas is drained with a Roux-en-Y limb of jejunum.

### Monitoring

Chronic pancreatitis is of course a chronic disease, so continued monitoring and maintenance therapy is essential after an acute exacerbation of chronic pancreatitis. Pain control, proper nutrition, and alcohol and smoking cessation must be maintained as an outpatient. The clinician must also be looking for the development of common complications. An annual physical exam and CT or MRI should be considered in this population to assess for the progression of disease.

### Complications

Pseudocysts in the setting of chronic pancreatitis are less likely to resolve without intervention. Often, the pancreatic duct and

bile duct are compressed, and the compression might need to be addressed at the same time as the pseudocyst. A trend toward minimally invasive management remains appropriate, with endoscopic drainage preferred over laparoscopic cystogastrostomy unless additional procedures are required. Resection of a pseudocyst is sometimes indicated for cysts located in the pancreatic tail, or when a midpancreatic duct disruption has resulted in a distally located pseudocyst. Distal pancreatectomy for removal of a pseudocyst, with or without splenectomy, can be a challenging procedure in the setting of prior pancreatitis. An internal drainage procedure of the communicating duct, or of the pseudocyst itself, should be considered when distal resection is being contemplated.

Pancreatic ascites results from a disrupted pancreatic duct with extravasation of pancreatic fluid that does not become sequestered as a pseudocyst but drains freely into the peritoneal cavity. Occasionally, the pancreatic fluid tracks superiorly into the thorax, causing a pancreatic pleural effusion. Both complications are seen more often in patients with chronic pancreatitis, rather than after acute pancreatitis. Paracentesis or thoracentesis reveals noninfected fluid with a protein level greater than 25 g/L and a markedly elevated amylase level. Paracentesis is critical to differentiate pancreatic from hepatic ascites.

ERCP is most helpful to delineate the location of the pancreatic duct leak and to elucidate the underlying pancreatic ductal anatomy. Pancreatic duct stenting may be considered at the time of ERCP. Paracentesis and antisecretory therapy with the somatostatin analogue octreotide acetate, together with bowel rest and parenteral nutrition, is successful in more than half of patients. Reapposition of serosal surfaces to facilitate closure of the leak is considered a part of therapy, and this is accomplished by complete paracentesis. For pleural effusions, a period of chest tube drainage can facilitate closure of the internal fistula. Surgical therapy is reserved for those who fail to respond to medical treatment.

## ACUTE DIARRHEA

Method of

Tate de Leon, MD

### CURRENT DIAGNOSIS

#### History

- Onset, duration, and frequency of diarrhea
- Related symptoms (fever, abdominal pain, nausea, emesis, bloody stool)
- Current medications, including recent antibiotic use
- Recent sick contacts or hospitalizations
- Recent foreign travel
- Exposure to contaminated water source or undercooked meats and seafood
- Immune status

#### Physical Examination

- Hydration status
- Abdominal examination

#### Laboratory Testing

- Acute secretory diarrhea: normally not necessary
- Acute bloody diarrhea: complete blood count, stool culture, consider ova and parasite testing and *Clostridium difficile* evaluation

### CURRENT THERAPY

- Symptomatic therapy
- Rehydration: enteral versus parenteral
- Antibiotics (depending on duration, severity, and other risk factors)
  - Empiric therapy
    - Adults
      - Fluoroquinolones
        - Ciprofloxacin (Cipro) 500 mg PO twice daily for 3–7 days
        - Levofloxacin (Levaquin)<sup>1</sup> 500 mg PO four times daily for 3–5 days
      - Children
        - Azithromycin (Zithromax)<sup>1</sup> 5–12 mg/kg PO four times daily for 3–5 days
    - *C difficile*
      - Metronidazole (Flagyl)<sup>1</sup> 500 mg PO every 8 hours for 10–14 days
      - Vancomycin (Vancocin) 125 mg PO every 6 hours for 10 days
  - Antidiarrheal medications (if no contraindications such as fever or hematochezia)
    - Loperamide (Imodium) Initial 4 mg PO followed by 2 mg PO with each loose stool. Max 16 mg per day
  - Probiotics<sup>2</sup>

<sup>1</sup>Not FDA approved for this indication.

<sup>2</sup>Not available in the United States.

Acute diarrhea in the United States is one of the most common diagnoses in general practice. Acute diarrhea can have a functional definition of a greater number of loose stools from normal lasting less than 14 days. If the episode lasts more than 14 days, it is called persistent diarrhea. If the episode lasts for more than 30 days, it is deemed chronic diarrhea. These episodes may be accompanied by nausea, vomiting, abdominal cramping, other systemic symptoms, and malnutrition. The majority of acute diarrhea cases are self-limited and do not need medical intervention.

Most often, these cases are caused by infectious agents such as viruses, bacteria, or parasites. Infection is often spread through contaminated food or drinking water or from person-to-person. Pathogens that cause diarrhea are usually transmitted through a fecal–oral route. The main risk factor for this transmission is poor hand hygiene. Other risk factors include improper food preparation, inadequate food refrigeration, and exposure to contaminated water.

Thorough investigation of a patient with acute diarrhea should include a detailed history, physical examination, and laboratory testing when indicated (Boxes 1 and 2). Acute diarrhea can be classified into two subtypes: secretory diarrhea and inflammatory diarrhea. Determining the subtype of the diarrhea is useful for suggesting the etiology and therefore the management of the diarrhea.

Secretory diarrhea is an electrolyte absorption impairment that leads to profuse, watery diarrhea that contains little or no blood or leukocytes. These episodes can last from a few hours to days. The main concern is dehydration and weight loss if oral intake is not continued. Clinical signs of severe dehydration include lethargy or unconsciousness, dry or sunken eyes, dry mouth, decreased skin turgor, and a history of poor or absent fluid intake.

Inflammatory diarrhea is bloody, usually has leukocytes, and produces less volume. The most common causes are *Salmonella*, *Campylobacter*, *Shigella*, *Escherichia coli* O157:H7, and *Entamoeba histolytica*. The main concerns related to inflammatory diarrhea are intestinal damage, sepsis, and malnutrition. Stool cultures and evaluation for ova and parasites are recommended.

Preventive measures can help reduce the spread of infectious agents. Proper hand hygiene with soap and water, especially after exposure to feces or individuals with acute diarrhea, can help

### BOX 1 Clinical History of Acute Infectious Diarrhea

- Description of diarrhea
  - Duration
  - Frequency
  - Presence of blood, pus, in stool
  - Symptoms of fever, tenesmus, dehydration
  - Weight loss
- Other gastrointestinal symptoms
  - Anorexia
  - Cramping
  - Emesis
  - Nausea
- Previous episodes with similar symptoms
- Recent antibiotic exposure
- Other medication exposure
  - Anticholinergics
  - Antimotility agents
  - Aspirin (ASA)
  - Proton pump inhibitors
- Recent dietary history
  - Shellfish
  - Undercooked meat (chicken)
  - Unsanitary water
  - Animal or reptile contacts
- Travel history
  - Travel to endemic or epidemic areas
- Sexual history
- Vaccination history
- Contact with institutions, e.g., hospitals, nursing homes, day care facilities
- Employment history
- Immune status
  - Presence of HIV
  - Presence of other congenital or acquired immunodeficiencies

## BOX 2 Physical Examination for Acute Infectious Diarrhea

- Vital signs
- Blood pressure (look for postural changes)
- Heart rate (look for postural changes)
- Respiratory rate
- Temperature
- Weight changes (particularly useful to assess effects of rehydration)
- Cardiovascular examination
  - Volume status
- Respiratory examination
- Rule out hyperventilation (compensatory respiratory alkalosis for metabolic acidosis resulting from dehydration and loss of bicarbonate)
- Abdominal examination
- Focal tenderness
- Guarding
- Hepatosplenomegaly
- Consider rectal examination (look for bloody stool)
- Decreased skin turgor
- Lymphadenopathy
- Rashes

limit the spread of infection. Barrier precautions are an effective adjunct when dealing with the possibility of exposure to feces in a hospital setting. For children, vaccinations have been shown to be effective in reducing rotavirus infections. Furthermore, it is imperative to separate diaper-changing areas from food-preparation areas. Proper sanitization with a bleach-based cleaner is recommended. Proper food handling and storage, along with water purification, are important means to help prevent the spread of infectious agents. Probiotics<sup>2</sup> are finding a home in the prevention and treatment of diarrhea. Initial studies have suggested that probiotics are useful in reducing antibiotic-associated diarrhea. Currently, more studies are needed to confirm their usefulness. Prophylactic antibiotics are usually only reserved for possible exposure to traveler's diarrhea.

### Epidemiology

Worldwide, acute diarrhea still accounts for significant morbidity and mortality. The very young, the very old, and the immunocompromised populations are the most adversely affected. Acute infectious diarrhea is more prevalent in developing countries and among travelers to developing countries. Diarrhea is the second leading cause of death worldwide in children under 5 years of age. The World Health Organization estimates that globally, there are over 1.7 billion cases of acute diarrhea each year and attributes 760,000 deaths to it annually. The majority of these deaths are in children who are younger than age 5 and live in developing countries. In the United States, foodborne infectious diarrhea accounts for approximately 325,000 hospitalizations and 5000 deaths each year.

### Etiology and Treatment

The precise cause of acute diarrhea is usually not found. Causes can be both infectious and noninfectious. Noninfectious causes can include medications, food allergies, and other gastrointestinal diseases. In general, clinical investigation of acute infectious diarrhea is more useful in identifying consequences of diarrhea, such as dehydration, than it is in revealing the precise etiology. Most cases of diarrhea are likely viral, as indicated by negative stool culture results in most studies. Severe cases of diarrhea tend to be a result of bacterial infection. The most common pathogens for bacteria-induced diarrhea is discussed below. To date, the optimal strategy for obtaining stool cultures has not been ascertained. It is thus reasonable to treat the patient symptomatically

for several days before obtaining a stool culture for mild to moderate cases because most cases of diarrhea are self-limited. The clinician should take into consideration individual comorbidities, immune status, the presence of severe or bloody diarrhea, underlying inflammatory bowel disease, and occupation (food handlers, day care employment, etc.) as possible indications for stool evaluation.

### Bacteria

#### *Campylobacter*

*Campylobacter* is a common cause of diarrhea in the United States. The pathogen is often spread by consumption of undercooked meat and poultry. Symptoms may present 2 to 5 days after exposure and last up to 1 week. The patient presents with diarrhea (possibly bloody), abdominal pain, nausea, vomiting, and fever. Stool cultures are needed for a definitive diagnosis. Prevention includes thoroughly cooking all meat products, good hand and utensil hygiene before preparing foods, and avoiding unpasteurized milk. The treatment for severe *Campylobacter* diarrhea includes azithromycin (Zithromax)<sup>1</sup> and ciprofloxacin (Cipro), although resistance to fluoroquinolones is growing. Antimicrobial susceptibility testing is required for specific resistance. Positive stool cultures should be reported to the local health department. *Campylobacter* infections have been linked to both rheumatoid arthritis and also Guillain-Barré syndrome.

#### *Clostridium difficile*

*C difficile* is the organism of antibiotic-associated colitis. Antibiotics disrupt the normal flora of the GI tract, which in turn provides a window of opportunity for *C difficile* to produce toxins and flourish. The most frequent antibiotics implicated are clindamycin (Cleocin), fluoroquinolones, and beta-lactam antibiotics. *C difficile* is treated with oral metronidazole<sup>1</sup> (Flagyl 500mg PO every 8 hours for 10–14 days) and vancomycin (Vancocin 125mg PO every 6 hours for 10 days). The diagnosis is confirmed with either polymerase chain reaction (PCR), enzyme immunoassay, or anaerobic culture. Endoscopy and biopsy can also be obtained if there is a high clinical suspicion for *C difficile* with negative laboratory results or if the patient did not respond to antibiotic treatment.

#### *E coli*

*E coli* are a large and versatile group of pathogens that can cause widespread disease and affect multiple organ systems. *E coli* is a part of the normal flora of both human and animal digestive tract. Certain *E coli* strains can cause acute diarrhea. Pathogenic strains include enterotoxigenic *E coli* (ETEC), enteropathogenic *E coli*, enteroaggregative *E coli*, enteroinvasive *E coli*, diffusely adherent *E coli*, and enterohemorrhagic *E coli* (EHEC may also be referred as Shiga toxin-producing *E coli* or verocytotoxin-producing *E coli*). The two most common and notorious strains are ETEC and EHEC. ETEC is a major cause of traveler's diarrhea and diarrhea in children of developing countries. EHEC has led to high-profile outbreaks of diarrhea as a result of contaminated meats.

ETEC is a type of *E coli* that produces toxins that stimulate the intestines to secrete excessive fluid, thus producing diarrhea. ETEC produces two different toxins: heat-stable toxin and heat-labile toxin. Both types of toxins produce similar illnesses. Contaminated food and water is the usual source of infection. Although stool culture is needed for definitive diagnosis, ETEC infections are usually diagnosed on history and clinical symptoms. Symptoms usually appear after 1 to 2 days after exposure and may last from 5 to 7 days. Most cases of ETEC diarrhea are treated symptomatically with adequate rehydration alone. Oral rehydration salts may be used and purchased over the counter to help address electrolyte losses. Both bismuth compounds (e.g., Pepto-Bismol) and antiperistalsis agents (e.g. loperamide [Imodium]) can help reduce severity of symptoms; they both may prolong the time the body takes to clear the toxin. Antibiotics are reserved for moderate to severe disease. The most common effective antibiotics

<sup>2</sup>Not available in the United States.

<sup>1</sup>Not FDA approved for this indication.

include fluoroquinolones. Antibiotics can shorten the duration of symptoms but are usually not required.

EHEC is a strain of *E coli* that produces a Shiga toxin. The toxin acts on vascular endothelium of small vessels of multiple organ systems. The toxin causes the breakdown and hemorrhage of the endothelium. When the toxin affects the vascular endothelium of the digestive tract, it causes bloody diarrhea. The pathogen often invades the kidney and lungs. Sequelae of EHEC infection include hemorrhagic diarrhea, hemolytic uremic syndrome, and thrombotic thrombocytopenic purpura. *E coli* O157 is the most common strain of EHEC. The infection is spread via the oral–fecal route, which includes consumption of contaminated food, unpasteurized milk and cheeses, and unsanitary water. Good hand hygiene is imperative. Symptoms usually appear 3 to 4 days after exposure and may last as long as 10 days. Positive stool cultures should be reported to the local health department. Supportive treatment, including rehydration, is the cornerstone of treatment. Antibiotics are contraindicated because of evidence of increased Shiga toxin release and thus increased risk of hemolytic uremic syndrome.

### Salmonella

*Salmonella* is the most common foodborne cause of diarrhea in the United States. It is associated with ingestion of infected poultry, eggs, and milk products. *Salmonella* can also be transmitted from pets, especially reptiles. Stool cultures are required for definitive diagnosis. Fluoroquinolones remain the antibiotic of choice, although sensitivities will guide antibiotic usage.

### Shigella

*Shigella* is the pathogen that causes dysentery and is a major cause of morbidity in developing countries. Dysentery usually presents as high fever, abdominal cramping, and bloody diarrhea. Positive stool cultures usually warrant treatment with fluoroquinolones.

### Vibrio

*Vibrio cholera* is endemic to developing countries. Symptoms usually present 1 to 3 days after exposure. Symptoms usually include profuse watery diarrhea (rice-water stools), abdominal cramping, and vomiting. Fever is infrequent. Rehydration with appropriate electrolyte replacement is paramount. Antibiotics can be an adjunct to rehydration and include fluoroquinolones and tetracycline at 500 mg PO every 8 hours for 3 days.

### Yersinia

*Yersinia enterocolitica* infections are less common. Symptoms include diarrhea, fever, abdominal pain, and vomiting. Stool cultures are needed to confirm the diagnosis.

### Viruses

Viral pathogens are likely responsible for the majority of gastroenteritis in the United States. Given the transient nature and characteristic symptoms, the specificity of the exact virus is not usually obtained. The most common viral etiologies tend to be adenovirus, rotavirus, norovirus, and astrovirus. Rotavirus tends to affect infants and children from 3 to 36 months of age, resulting in a spectrum of disease from asymptomatic shedding to severe gastroenteritis. Vaccination has played an important role in decreasing the cases of rotavirus infections.

Norovirus (i.e., Norwalk virus) is responsible for many high-profile outbreaks in daycare centers, cruise ships, and hospitals. Norovirus can be easily transmitted from person to person, from contact of contaminated surfaces, or from exposure to contaminated food or water. Symptoms present 1 to 3 days after exposure. Symptoms include fever, explosive vomiting, and diarrhea. PCR testing can confirm the diagnosis but is not usually necessary unless there seems to be an outbreak.

### Parasite

*Entamoeba histolytica*, *Cryptosporidium*, *Giardia*, and *Cyclospora* spp. are the most common parasitic or protozoal infections that

cause diarrhea. Protozoa infections are even less common. It is usually not cost-effective to evaluate for ova and parasites unless there are specific indications, such as a history of immunocompromise, exposure to daycare centers, or history of exposure to contaminated water. Multiple stool samples are needed if there are concerns of parasite infection resulting from possible intermittent shedding. *E histolytica* can cause amoebic dysentery and lead to bloody diarrhea. Microscopy, antigen testing, and serology are all possible tests for diagnosis. Parasitic infections are usually treated with metronidazole (Flagyl), tinidazole (Tindamax 2 g PO four times daily for 1–3 days) or albendazole<sup>1</sup> (Albenza 400 mg PO four times daily for 5 days).

### Traveler's Diarrhea

Traveler's diarrhea is common to individuals from developed countries traveling to developing countries. Episodes can be caused by bacteria, viruses, and parasites. The most common pathogen is *E coli* (ETEC). Travelers should choose their food and water sources carefully. Water purification and avoiding foods prepared with contaminated water is useful. Prolonged or other symptoms such as fever or bloody stool should be further investigated.

### Treatment

Fluid and electrolyte replacement are the most important therapies for acute diarrhea. The route of administration depends on the severity of the dehydration. For mild cases of diarrhea in a normally healthy individual, adequate oral intake of juices, soups, and electrolyte-infused water can be sufficient. For severe dehydration, IV fluids or oral rehydration therapy with isotonic electrolyte solutions may be needed. Oral hydration is preferred over IV fluids if possible. IV fluids are more expensive and less practical than oral rehydration. The World Health Organization has a lower-osmolarity oral rehydration solution (ORS), which is very effective in reducing stool volume and the need for switching to IV therapy in children. A number of effective ORSs are also available over the counter, including Pedialyte and Rehydralyte. IV fluids, including normal saline and lactated Ringers solution, are indicated in severe dehydration or in patients who cannot tolerate oral fluid intake.

Antimicrobial agents have a secondary role in treatment of acute diarrhea. Given the fact that most cases of diarrhea are mild, self-limited, and caused by nonbacterial pathogens, antibiotics should be used sparingly. Antibiotic treatment should be used in invasive bacterial infections, traveler's diarrhea, or in patients with immunosuppression. Empirical antibiotics can be appropriate as described above for *Campylobacter* or *C difficile* infections.

Antidiarrheal medications can be useful to help alleviate symptoms in patients with no other contraindications, such as fever or bloody diarrhea. Loperamide (Imodium initial 4 mg PO followed by 2 mg PO with each loose stool, maximum 16 mg per day) decreases intestinal peristalsis and facilitates intestinal absorption. Bismuth (Pepto-Bismol) is less effective. Bismuth produces both antisecretory and antimicrobial effects in the gastrointestinal tract.

<sup>1</sup>Not FDA approved for this indication.

## BLEEDING ESOPHAGEAL VARICES

Method of

Cecilio M. Azar, MD; and Ala I. Sharara, MD

### CURRENT DIAGNOSIS

- Endoscopic screening for esophageal varices is recommended in patients with liver cirrhosis.
- Noninvasive predictors of the presence of large varices, such as splenomegaly and thrombocytopenia, have limited accuracy.
- A combination of clinical and endoscopic findings including the Child-Pugh class, size of varices, and the presence of red wale markings correlates with the risk of first bleeding in patients with cirrhosis.
- Measurement of hepatic venous pressure gradient may be the best indicator of risk and severity of bleeding in patients with varices. It is an invasive test and is not widely available or used routinely in practice.

### CURRENT THERAPY

- Nonselective  $\beta$ -blockers and endoscopic band ligation are both effective first-line therapy in the primary prophylaxis of esophageal varices.
- The management of acute variceal hemorrhage consists of prompt resuscitation and correction of coagulation abnormalities, followed by endoscopic and pharmacologic therapy with vasoactive agents. Antibiotic prophylaxis is given to decrease the risk of infection and of rebleeding. Transjugular intrahepatic portosystemic shunt (TIPS) is reserved for refractory, uncontrolled, acute variceal bleeding.
- Strategies for secondary prophylaxis of variceal bleeding include endoscopic band ligation, pharmacologic therapy with nonselective  $\beta$ -blockers with or without nitrates, TIPS, and surgical shunts.
- Comparative cost-effectiveness of secondary prophylaxis strategies is unknown but should take into consideration the cost of failed therapy (e.g., rebleeding, shunt revision) and that of treatment related-complications (e.g., encephalopathy, esophageal stricture).

### Epidemiology

Bleeding of esophageal varices is a major complication of portal hypertension, usually in the setting of liver cirrhosis, accounting for 10% to 30% of all cases of upper gastrointestinal hemorrhage. More than any other cause of gastrointestinal bleeding, this complication results in considerable morbidity and mortality, prolonged hospitalization, and increased affiliated costs. Variceal bleeding develops in 25% to 35% of patients with cirrhosis and accounts for up to 90% of upper gastrointestinal bleeding episodes in these patients. About 10% to 30% of these episodes are fatal, and as many as 70% of survivors rebleed following an index variceal hemorrhage. Following such events, the 1-year survival is 34% to 80%, being inversely related to the severity of the underlying liver disease.

Treatment of patients with esophageal varices includes preventing the initial bleeding episode (primary prophylaxis), controlling active variceal hemorrhage, and preventing recurrent bleeding after a first episode (secondary prophylaxis). Data on the optimal management of gastric varices are much more limited, and this topic is not covered in this article.

### Pathophysiology

Chronic liver disease leading to cirrhosis is the most common cause of portal hypertension. The level of increased resistance to

flow varies with the level of circulatory breach and can be divided into prehepatic, hepatic or sinusoidal, and posthepatic. In cirrhosis, several organ systems are involved in the pathophysiology of portal hypertension. At the splanchnic vascular bed level there is marked vasodilatation and increase in angiogenesis, leading to increase in portal blood flow and formation of collateral circulation, such as gastroesophageal varices, along with decrease in response to vasoconstrictors. At the systemic circulation level, there is an increase in cardiac output, decrease in vascular resistance, and hypervolemia. This hyperkinetic syndrome leads to an effective hypovolemia, with a resultant increase in vasoactive factors to maintain a normal arterial blood pressure.

Varices represent portosystemic collaterals derived from dilatation of preexisting embryonic vascular channels, such as those between the coronary and short gastric veins and the intercostal, esophageal, and azygous veins. In the distal esophagus, over an area extending 2 to 5 cm from the gastroesophageal junction, veins are found more superficially in the lamina propria rather than the submucosa. This results in reduced support from surrounding tissues owing to the predominant intraluminal location of these varices and might explain the predilection for bleeding at this site. The opening and dilation of portosystemic collaterals appears to depend on a threshold portal pressure gradient (measured as hepatic venous pressure gradient [HVPG]) of 12 mm Hg, below which varices do not form. This pressure gradient is necessary but not sufficient for the development of gastroesophageal varices.

### Diagnosis

The current consensus states that every patient with liver cirrhosis should undergo an upper endoscopy to detect gastroesophageal varices. The main aim behind screening for gastroesophageal varices is to identify patients requiring prophylactic treatment or further surveillance. Esophageal varices are present in 52% of screened patients and are more prevalent in more advanced disease (43% for Child-Pugh class A versus 72% in Child-Pugh class B or C). On the other hand, gastric varices are present in up to 33% of patients with portal hypertension, with progression rates for both esophageal and gastric varices from small, medium, to large varices of 10% to 15% per year. Several invasive and noninvasive procedures help in detecting portal hypertension and can, with variable accuracy, predict the presence of gastroesophageal varices. Unfortunately, none are sensitive enough to replace endoscopy. A recent meta-analysis showed that transient elastography may be a useful screening tool for the detection of significant liver fibrosis and associated portal hypertension, but it is not useful at predicting the presence or size of esophageal varices. Smaller trials have evaluated the usefulness of spleen and liver MR elastography in assessing portal hypertension and varices, but this modality has not yet found its way into clinical practice. The combination of an elastography value below 20 kPa together and a platelet count above 150,000 nearly excludes the presence of esophageal varices requiring treatment. Endoscopic videocapsule is a new modality introduced for visualizing the esophagus; it allows correct identification of varices in 80% of cases but can have poor accuracy in identifying the presence of hypertensive gastropathy and gastric varices.

Not all esophageal varices bleed; hemorrhage occurs in only 30% to 35% of patients with cirrhosis. Variceal rupture is directly related to physical factors such as the radius, thickness, and elastic properties of the vessel in addition to intravariceal and intraluminal pressure and tension. Endoscopic findings that predict a higher risk of bleeding include larger size of varices and the presence of endoscopic red signs (described as red wale markings) on the variceal wall, indicating dilated intraepithelial and subepithelial superficial veins. A combination of clinical and endoscopic findings, including the Child-Pugh class, size of varices, and the presence or absence of red wale markings, was found to correlate highly with the risk of first bleeding in patients with cirrhosis. Hemodynamic parameters examined as predictors of bleeding include HVPG, azygous blood flow, and direct measurement of intravariceal pressure.

**TABLE 1** Summary of Therapy for Esophageal Varices

	FIRST-LINE THERAPY	COMMENTS	ALTERNATIVE THERAPY	COMMENTS
Primary prophylaxis*		In advanced cirrhosis, the best therapy is unclear (probably band ligation) Transplantation should be considered for these patients		The effectiveness of combined $\beta$ -blockers and band ligation is unknown Neither TIPS nor sclerotherapy is recommended for primary prophylaxis
Active variceal bleeding	Somatostatin, <sup>2</sup> octreotide (Sandostatin), <sup>1</sup> vapreotide (Sanvar), <sup>5</sup> or terlipressin (Glypressin) <sup>2</sup>	Vasoconstrictors should be continued for $\geq 2$ days after endoscopic therapy Band ligation is superior to endoscopic sclerotherapy	Balloon tamponade or SEMS (self-expandable metal stent)  TIPS	Tamponade is indicated primarily as a temporizing measure if first-line treatment fails  TIPS is reserved for refractory or recurrent early bleeding but should also be considered when basal HVPG $>20$ mm Hg
	<i>plus</i> Endoscopic therapy	Antibiotic prophylaxis should be initiated	Shunt surgery	Surgery is reserved for patients with compensated liver disease in whom TIPS fails or is not technically feasible
Secondary prophylaxis	$\beta$ -Blockers $\pm$ nitrates <i>or</i> Band ligation	The combination of band ligation and $\beta$ -blockers $\pm$ nitrates may be more effective than either alone Nitrates alone are not recommended Patients with advanced liver disease are often intolerant of $\beta$ -blockers	TIPS	TIPS is best used after failure of first-line therapy or as a bridge to transplantation in patients with advanced liver disease
			Shunt surgery	Shunt surgery is reserved for selected patients with compensated cirrhosis in whom TIPS fails or is not feasible

Abbreviations: HVPG = hepatic venous pressure gradient; TIPS = transjugular intrahepatic portosystemic shunt.

<sup>3</sup>Investigational drug in the United States.

\*Upon documentation of varices, variceal hemorrhage occurs in 25%–30% of patients by 2 years.  $\beta$ -Blockers reduce the risk to 15%–18%, and combination  $\beta$ -blockers plus nitrates reduce the risk to 7.5%–10%.

HVPG, calculated by the gradient of wedged and free hepatic vein pressure (normal value, 5 mm Hg), is used most often and provides reliable measurement of portal pressure in patients with cirrhosis. The extent of elevation of HVPG may be the best indicator of risk of bleeding, severity of bleeding, and survival. A rise in pressure in a patient with known varices increases the risk of bleeding, and the extent of portal pressure elevation has an inverse relationship to prognosis after hemorrhage has occurred. In general, however, a linear relationship between the degree of portal hypertension and the risk of variceal hemorrhage or formation of varices does not exist, so this technique cannot be used routinely to identify individual patients at high risk for bleeding.

## Treatment

### Primary Prophylaxis

The natural evolution of gastroesophageal varices without treatment is characterized by an increase in size from small to large varices, which eventually rupture and bleed. The progression rate ranges from 5% to 30% per year. The incidence of bleeding from small esophageal varices is estimated to be 4% per year, and it is as high as 15% per year for medium to large varices. In a randomized, controlled trial, the nonselective  $\beta$ -blocker timolol (Blocadren)<sup>1</sup> failed to reduce the development of varices or variceal bleeding in patients without varices. Adverse events were more common in the timolol group. Therefore, it is not recommended to start  $\beta$ -blockers in patients who do not yet have esophageal varices.

Based on prospective studies of cirrhotic patients with varices identified at endoscopy and of untreated groups in randomized controlled trials, the risk of bleeding from esophageal varices has been estimated at 25% to 35% at 1 year. Therapy for primary

prophylaxis against variceal bleeding (prevention of a first variceal bleeding) is summarized in Table 1.

### Pharmacologic Therapy

The general objective of pharmacologic therapy for variceal bleeding is to reduce portal pressure and consequently intravariceal pressure. Drugs that reduce portocollateral venous flow (vasoconstrictors) or intrahepatic vascular resistance (vasodilators) have been used and include  $\beta$ -blockers, nitrates,  $\beta_2$ -adrenergic blockers, spironolactone (Aldactone), pentoxifylline (Trental),<sup>1</sup> molsidomine (Corvaton),<sup>2</sup> and simvastatin (Zocor).<sup>1</sup> Because varices do not bleed at an HVPG less than 12 mm Hg, reduction to this level is ideal, but substantial reductions in HVPG (i.e., by  $>20\%$ ) are also clinically meaningful.

$\beta$ -Blockers exert their beneficial effect on portal venous pressure by diminishing splanchnic blood flow and consequently gastroesophageal collateral and azygous blood flow. The effectiveness of  $\beta$ -blockers for primary prophylaxis against variceal bleeding has been demonstrated in several controlled trials. Meta-analyses have revealed a 40% to 50% reduction in bleeding and a trend toward improved survival. The estimated overall response rate is 49%, with bleeding rates of 6% in responders and 32% in nonresponders, with a number needed to treat (NNT) of 10.

The nonselective  $\beta$ -blockers, such as propranolol (Inderal)<sup>1</sup> and nadolol (Corgard),<sup>1</sup> are preferred because of the dual benefit of  $\beta_1$ - and  $\beta_2$ -receptor blockade. In the absence of HVPG determination,  $\beta$ -blockers are titrated to achieve a reduction in resting heart rate to 55 beats/min or 25% of baseline. Propranolol is generally given

<sup>1</sup>Not FDA approved for this indication.

<sup>1</sup>Not FDA approved for this indication.

<sup>2</sup>Not available in the United States.

as a long-acting preparation and titrated to a maximum dose of 320 mg/day. Nadolol is initiated at 80 mg daily up to a maximum daily dose of 240 mg. Carvedilol (Coreg)<sup>1</sup> is initiated at 6.25 mg daily and increased if tolerated to 12.5 mg/day. Carvedilol is superior to propranolol at reducing portal hypertension although available data do not allow a satisfactory comparison of adverse events. The portal pressure-reducing effects of  $\beta$ -blockers are not predictable; the resultant reduction in heart rate or the measurement of drug blood levels are not good indicators of response to therapy. For example, portal venous pressure is reduced in about 60% to 70% of patients who receive propranolol therapy, but only 10% to 30% of these patients show a substantial response (i.e., >20% reduction). Additionally, approximately 20% to 25% of patients have no measurable decline in portal pressure despite increasing dosage of propranolol. Non-selective beta-blockers (NSBB) are effective in preventing first and recurrent variceal hemorrhage both in patients with and without ascites. NSBB-induced reduction in portal pressure is associated with lowering the progression of cirrhosis and even death.

Refractory ascites and spontaneous bacterial peritonitis (SBP) are not absolute contraindications to NSBB as previously thought. However, high-dose NSBB (with resultant decrease in mean arterial pressure) should be used with caution because it can be associated with deleterious outcomes. Hence, careful dosing is necessary in these patients with dose reduction/discontinuation for systolic blood pressure <90 mm Hg.

In addition to  $\beta$ -blockers, a number of vasodilators have been investigated in patients with portal hypertension and in animal models of portal hypertension, most notably isosorbide mononitrate (Imdur).<sup>1</sup> Of note, there is increasing evidence that the use of  $\beta$ -blockers can be deleterious in patients with decompensated liver cirrhosis, refractory ascites, and severe circulatory dysfunction (systolic blood pressure 90 mm Hg, serum sodium <30 meq/L, or hepatorenal syndrome). The exact mechanism of action of nitrates is unclear but is thought to be mediated primarily by reducing intrahepatic resistance and possibly by splanchnic arterial vasoconstriction induced in response to venous pooling and vasodilation in other regional vascular beds. Monotherapy with nitrates is ineffective in primary prophylaxis and can have detrimental effects, particularly in cirrhotic patients with ascites, and should not be used.

The addition of isosorbide mononitrate to  $\beta$ -blockers, however, has been shown to result in an enhanced reduction in portal pressure in humans. In a randomized, controlled trial involving 42 patients with cirrhosis and esophageal varices, a reduction of greater than 20% in HVPG was documented in only 10% in the propranolol group compared to 50% in the combination therapy group. In patients with Child-Pugh class A and B cirrhosis, the addition of isosorbide mononitrate to nadolol has been shown, in a randomized trial, to result in a greater than 50% additional reduction in variceal bleeding rate when compared with nadolol monotherapy (12% versus 29%). However, a large subsequent double-blind, placebo-controlled study failed to confirm these results. Based on the existing evidence, the combination of  $\beta$ -blockers and isosorbide is not recommended in primary prophylaxis.

### Endoscopic Therapy

Endoscopic therapies play a prominent role in treatment of esophageal varices. Endoscopic band ligation (EBL) is the endoscopic procedure of choice in the management of esophageal varices. As of 2010, 16 randomized, controlled trials have compared EBL to  $\beta$ -blockers in the primary prevention of variceal bleeding. These studies suffered from significant heterogeneity, and a large number were published in abstract form. Two meta-analyses of these trials showed a slight advantage of EBL over  $\beta$ -blockers in terms of primary prevention of variceal bleeding, but there were no differences in mortality. A recent Cochrane database systematic review found a beneficial effect of band ligation compared to  $\beta$ -blockers in primary prevention of upper gastrointestinal bleeding in adult patients with esophageal varices. Again, there was no difference in mortality.

$\beta$ -Blockers are cheaper and much easier to administer but are associated with issues of noncompliance and a higher incidence of adverse events (e.g., hypotension, impotence, insomnia) than EBL. However, most of these side effects are easy to manage and none require hospitalization or result in direct mortality. On the other hand, adverse events related to EBL, such as bleeding from band-related ulcers, albeit infrequent, are more significant, often requiring hospitalization and blood transfusion, and may rarely be associated with death.

According to the Baveno consensus conference, nonselective  $\beta$ -blockers should be considered as a first choice for preventing first variceal bleeding in high-risk patients who have not bled, and EBL should be provided for patients with contraindications or intolerance to  $\beta$ -blockers. The recent guidelines by the American College of Gastroenterology (ACG) and American Association for the Study of Liver Diseases (AASLD) recommend using  $\beta$ -blockers in low-risk patients who have medium to large varices but suggest both EBL and  $\beta$ -blockers for high-risk patients as first-line therapy. The optimal primary prophylaxis in patients with decompensated cirrhosis remains unclear and is arguably expedited liver transplantation. The combination of pharmacologic plus endoscopic therapy has been investigated in such patients with conflicting results. In one study, EBL plus  $\beta$ -blockers offered no benefit in terms of prevention of first bleeding when compared to EBL alone. In a more recent study, combination therapy significantly reduced the occurrence of the first episode of variceal bleeding and improved bleeding-related survival in a group of cirrhotic patients with high-risk esophageal varices awaiting liver transplantation.

### Management of Acute Variceal Hemorrhage

Variceal hemorrhage is usually an acute clinical event characterized by rapid gastrointestinal blood loss manifesting as hematemesis (which can be massive), with or without melena or hematochezia. Hemodynamic instability (tachycardia, hypotension) is common. Although variceal bleeding is common in patients with cirrhosis presenting with acute upper gastrointestinal hemorrhage, other causes of bleeding, such as ulcer disease, must be considered. Urgent initiation of empiric pharmacologic therapy with vasoactive agents is indicated in situations where variceal hemorrhage is likely. Subsequently, direct endoscopic examination is critical to establish an accurate diagnosis and to provide the rationale for immediate and subsequent therapies. The immediate steps in the management of acute variceal bleeding include: volume resuscitation, prevention of complications, ensuring hemostasis, and initiating measures to prevent early and delayed rebleeding.

Using a MELD-based analysis, the overall 6-week mortality is estimated at 16% (5%–20%), with mortality rates worsening with more advanced disease. Recurrence rates are up to 60% within 1 to 2 years if untreated, and mortality rates as high as 33%.

Patients with variceal hemorrhage and ascites are at increased risk for bacterial infections, particularly spontaneous bacterial peritonitis. This risk appears to be increased in the setting of uncontrolled hemorrhage or as a result of transient bacteremia following endoscopic sclerotherapy or variceal ligation. Short-term systemic antibiotics (e.g., third-generation cephalosporins or fluoroquinolones for 4–10 days) have been shown to decrease the risk of bacterial infections and to reduce rebleeding as well as mortality in cirrhotic patients with gastrointestinal bleeding.

A restrictive transfusion strategy should be used, aiming for a hemoglobin of 7 to 8 gm/dL to avoid volume overexpansion and perpetuation of bleeding. The role of platelet transfusion or fresh frozen plasma administration has not been assessed appropriately. The routine administration of fresh frozen plasma in patients with active variceal bleeding may in fact be detrimental because of the resultant volume expansion and should be discouraged. Hypofibrinogenemia should be treated with cryoprecipitate aiming for levels >100 mg/dL. The use of recombinant activated coagulation factor VII (rFVIIa [Novoseven]),<sup>1</sup> which corrects

<sup>1</sup>Not FDA approved for this indication.

prothrombin time in cirrhotic patients, has been assessed in two randomized, controlled trials. The first trial showed, in a post hoc analysis, that rFVIIa administration might significantly improve the results of conventional therapy in patients with moderate and advanced liver failure (Child-Pugh B and C) without increasing the incidence of adverse events. A more recent trial tested rVIIa in patients with active bleeding at endoscopy and with a Child-Pugh score 8 points or higher. This trial failed to show a benefit of rVIIa in terms of decreasing the risk of 5-day failure, but it did show improved 6-week mortality. In a small prospective study involving cirrhotic patients with acute variceal bleeding and new portal vein thrombosis identified by positive intra-thrombus enhancement on contrast ultrasonography, the use of low molecular weight heparin after hemostasis is achieved by band ligation was shown to be safe, well tolerated, and effective, with complete recanalization of the portal vein within 2 to 11 days and no recurrence of bleeding.

### Pharmacologic Therapy

Pharmacologic therapy can be administered early, requires no special technical expertise, and is thus a desirable first-line option for managing acute variceal hemorrhage. Drugs that reduce portocollateral venous flow (vasoconstrictors) or intrahepatic vascular resistance (vasodilators) or both have been used to achieve this effect. Vasoconstrictors work by decreasing splanchnic arterial flow, and vasodilators are used in combination with vasoconstrictors to reduce their systemic side effects, but they can also exert an added beneficial effect on intrahepatic resistance (see Table 1).

**Vasopressin and Terlipressin.** Vasopressin (Pitressin)<sup>1</sup> is a nonselective vasoconstricting agent that causes a reduction of splanchnic blood flow and thereby a reduced portal pressure. Vasopressin, which is associated with severe vascular complications, has been largely replaced by other vasoconstrictors such as its synthetic analogue, triglycyl-lysine vasopressin (terlipressin [Glypressin]).<sup>2</sup> Terlipressin has fewer side effects and a longer biological half-life, allowing its use as a bolus intravenous injection (2 mg every 4 hours for the initial 24 hours, then 1 mg every 4 hours for the next 24–48 hours). Terlipressin has been shown in numerous placebo-controlled trials to control bleeding in about 80% of cases and is the only pharmacologic therapy proven, as of 2010, to reduce mortality from acute variceal hemorrhage. In patients with esophageal variceal bleeding, a 24-hour course of terlipressin was shown to be as effective as a 72-hour course when used as adjunct therapy to successful variceal band ligation. Terlipressin is not currently available in the United States.

**Somatostatin, Octreotide, and Vapreotide.** Somatostatin,<sup>2</sup> a naturally occurring peptide, and its analogues, octreotide (Sandostatin)<sup>1</sup> and vapreotide (Sanvar),<sup>1</sup> stop variceal hemorrhage in up to 80% of patients and are generally considered equivalent to vasopressin (Pitressin), terlipressin<sup>2</sup> (Glypressin), and endoscopic therapy for the control of acute variceal bleeding. Their precise mechanism of action is unclear but might result from an effect on the release of vasoactive peptides or from reduction of postprandial hyperemia. Somatostatin is used as a continuous intravenous infusion of 250 µg/hour following a 250-µg bolus injection. Octreotide is used as a continuous infusion of 50 µg/hour and does not require a bolus injection. Side effects are minor, including hyperglycemia and mild abdominal cramps. The addition of octreotide or vapreotide to endoscopic sclerotherapy or banding improves control of bleeding and reduces transfusion requirements, with no change in overall mortality. A continuous infusion of octreotide or vapreotide is therefore recommended for 2 to 5 days following emergency endoscopic therapy.

### Endoscopy

Endoscopic sclerotherapy stops variceal hemorrhage in 80% to 90% of cases. Its drawbacks include a significant risk of local complications including ulceration, bleeding, stricture, and perforation. Rare systemic complications have been reported including bacteremia with endocarditis, formation of splenic or brain abscesses, and

portal vein thrombosis. Randomized trials in patients with acute variceal bleeding have shown that EBL is essentially equivalent to endoscopic sclerotherapy in achieving initial hemostasis with lesser complications. These include superficial ulcerations, transient chest discomfort, and, rarely, stricture formation. Erythromycin infusion before endoscopy<sup>1</sup> in patients with acute variceal bleeding has been shown to significantly improve endoscopic visibility and to shorten the duration of the procedure.

### Balloon Tamponade/SEMS

The use of the Sengstaken-Blakemore or Minnesota tube for hemostasis of variceal bleeding is based on the principle of the application of direct pressure on the bleeding varix by an inflatable—esophageal or gastric—balloon fitted on a rubber nasogastric tube. When properly applied, balloon tamponade is successful in achieving immediate hemostasis in almost all cases. However, early rebleeding following balloon decompression is high. Complications of balloon tamponade include esophageal perforation or rupture, aspiration, and asphyxiation from upper airway obstruction. Balloon tamponade or use of SEMS is generally not recommended and should largely be reserved for rescue of cases of hemorrhage uncontrolled by pharmacologic and endoscopic methods and as a temporary bridge to more definitive therapy. Self-expandable metal stents (SEMS) have recently been shown to be effective in controlling severe bleeding.

### Transjugular Intrahepatic Portosystemic Shunt

Treatment with a transjugular intrahepatic portosystemic shunt (TIPS) consists of the vascular placement of an expandable metal stent across a tract created between a hepatic vein and a major intrahepatic branch of the portal system. TIPS can be successfully performed in 90% to 100% of patients, resulting in hemodynamic changes similar to a partially decompressive side-to-side portocaval shunt while avoiding the morbidity and mortality associated with a major surgical procedure. According to the American Association for the Study of Liver Diseases (AASLD) Practice Guidelines, the indications for TIPS are: (1) as rescue therapy for acute variceal hemorrhage refractory to medical and endoscopic intervention; (2) recurrent variceal hemorrhage despite medical and endoscopic treatment; and (3) an emerging indication is early TIPS within 24 to 72 hours of acute variceal hemorrhage in a select patients (e.g., those with basal HVPG >20 mm Hg). The left gastric vein is frequently embolized (embolotherapy) during TIPS creation. TIPS has been shown to be effective in treating refractory, uncontrolled, acute variceal bleeding. Patients with advanced liver disease and multiorgan failure at the time of TIPS have a 30-day mortality that approaches 100%.

### Surgery

Surgery is generally considered in the setting of continued hemorrhage or recurrent early rebleeding—uncontrolled by repeated endoscopic or continued pharmacologic therapy—and when TIPS is not available or is not technically feasible. Surgical options include portosystemic shunting or esophageal staple transection alone or with esophagogastric devascularization and splenectomy (Sugiura procedure). Devascularization procedures may be useful in patients who cannot receive a shunt because of splanchnic venous thrombosis. Regardless of the choice of surgical technique, morbidity is high and the 30-day mortality for emergency surgery approaches 80% in some series. Understandably, rescue liver transplantation is not a practical option in patients with uncontrolled variceal hemorrhage.

### Secondary Prophylaxis

Variceal hemorrhage recurs in approximately two thirds of patients, most commonly within the first 6 weeks after the initial episode. Patients with advanced liver disease (MELD [model for end-stage liver disease] score ≥18) have an increased risk of early rebleeding and death. Early rebleeding (within the first 5 days) is

<sup>2</sup>Not available in the United States.

<sup>1</sup>Not FDA approved for this indication.

**Figure 1** Relative effectiveness of available therapies for preventing recurrent variceal bleeding. The estimates shown are based on the cumulative data available in the literature for recurrent bleeding at 1 year. *Abbreviations:* EBL = endoscopic band ligation; ES = endoscopic sclerotherapy; TIPS = transjugular intrahepatic portosystemic shunt.

reduced by the adjuvant use of octreotide<sup>1</sup> or vapreotide<sup>5</sup>—and possibly terlipressin<sup>2</sup> and somatostatin<sup>2</sup>—after initial endoscopic or pharmacologic control of hemorrhage.

The severity of portal hypertension correlates closely with the severity and risk of rebleeding as well as actuarial probability of survival following an index episode. In a cohort of patients presenting with variceal hemorrhage, those with an initial HVPG greater than 20 mm Hg had a 1-year mortality of 64% compared to 20% for patients with lesser elevations in portal pressure. Given the high risk of recurrent hemorrhage and its associated morbidity and mortality, strategies aimed at prevention should be rapidly instituted following the index episode. The choice of preventive therapy should, therefore, take into consideration the efficacy of therapy, the side effects of the selected treatment, the patient's expected survival, and overall cost. Preventive strategies include pharmacologic, endoscopic, and surgical methods and are listed in **Table 1**. Relative effectiveness of these strategies is shown in **Figure 1**.

### Pharmacologic Therapy

Reducing the portal pressure by more than 20% from the baseline value pharmacologically results in a reduction in the cumulative probability of recurrent bleeding from 28% at 1 year, 39% at 2 years, and 66% at 3 years to 4%, 9%, and 9%, respectively. Although adjustment of medical therapy based on portal pressure measurement would be ideal, HVPG determination might not be readily available, and treatment must be adjusted using empiric clinical parameters. Several randomized, controlled trials, including a meta-analysis, have demonstrated that β-blockers prevent rebleeding and prolong survival. The addition of isosorbide mononitrate<sup>1</sup> to β-blockers appears to enhance the protective effect of β-blockers alone for preventing recurrent variceal bleeding but offers no survival advantage and reduces the tolerability of therapy. A recent randomized controlled trial showed that carvedilol<sup>1</sup> is as effective as the combination of nadolol (Corgard)<sup>1</sup> plus isosorbide-5 mononitrate in the prevention of gastroesophageal variceal rebleeding, with fewer severe adverse

events and similar survival. Compared with either sclerotherapy or endoscopic band ligation, combination medical therapy is superior in reducing the risk of recurrent bleeding in patients with esophageal variceal hemorrhage, primarily in patients with Child-Pugh class A and B cirrhosis. Notably, in patients who show a significant hemodynamic response to therapy (defined as a reduction in the hepatic venous pressure gradient to <12 mm Hg or >20% of the baseline value), the risk of recurrent bleeding and of death is significantly reduced.

### Endoscopy

Endoscopic therapy has been established over the past decade as a therapeutic cornerstone for preventing esophageal variceal rebleeding. Gastric varices, however, are not effectively treated by sclerotherapy or ligation. Patients with recurrent gastric variceal hemorrhage are best treated by *N*-butyl-2-cyanoacrylate injection<sup>1</sup> or by nonendoscopic means such as TIPS. On the other hand, EBL is highly effective at obliterating esophageal varices and is considered the endoscopic therapy of choice for secondary prophylaxis.

Combination modality approaches, usually including an endoscopic and pharmacologic treatment, are pathophysiologically attractive and may be more effective than single therapy. Two randomized, controlled trials have shown that adding β-blockers to EBL reduces the risk of rebleeding and variceal recurrence, suggesting that if EBL is used, it should be used in association with β-blockers. One randomized, controlled trial has evaluated whether EBL could improve the efficacy of the combined administration of nadolol<sup>1</sup> plus isosorbide.<sup>1</sup> In this study, adding band ligation to nadolol plus isosorbide was shown to be superior to nadolol plus isosorbide alone in preventing variceal rebleeding, but there were no significant differences in mortality. The combination of the best endoscopic treatment (EBL) and the best pharmacologic treatment (β-blockers plus isosorbide) may be the best choice in preventing rebleeding but needs further studies for confirmation. Statins improve liver generation of NO and hepatic endothelial dysfunction in experimental models of cirrhosis and may also reduce liver fibrosis. Randomized placebo-controlled trials found that simvastatin<sup>1</sup> decreased HVPG and improved liver perfusion and had an additive effect in patients treated with NSBB, and showed survival benefit in patients with early stages of cirrhosis and variceal bleeding.

### Transjugular Intrahepatic Portosystemic Shunt

Transjugular shunting is more effective than endoscopic therapy for preventing variceal rebleeding but offers no survival benefit. The cumulative risk of rebleeding following TIPS placement is 8% to 18% at 1 year. The trade-off, however, is that TIPS is associated with a higher incidence of clinically significant hepatic encephalopathy (new or worsened portosystemic encephalopathy was noted in about 25% of patients after TIPS). Advanced liver disease is the main determinant of poor outcome following TIPS. Consequently, in patients with advanced liver disease, TIPS is best used as a bridge to liver transplantation.

TIPS, using bare stents, has been compared with surgical shunts in two studies (8 mm portocaval H-graft shunt in one and distal splenorenal shunt in the second). Although the first study showed a significantly lower rebleeding rate in the surgical group, the second and larger trial did not find any differences in rebleeding rates, hepatic encephalopathy, or mortality, but it found a significantly higher reintervention rate in the TIPS group. However, the obstruction and reintervention rates are markedly decreased with the recent use of polytetrafluoroethylene (PTFE)-covered stents. According to these data, TIPS using PTFE-covered stents represents the best rescue therapy for failures of medical and endoscopic treatment. In addition to TIPS, balloon-occluded retrograde transvenous obliteration (BRTO) is reserved primarily for prevention of recurrent bleeding, and has recently been included in the AASLD practice guidelines. Typically, it is utilized in patients who are at high risk for TIPS, such as those with elevated MELD (>18), right-sided heart failure, or hepatic encephalopathy.

<sup>5</sup>Investigational drug in the United State.

<sup>1</sup>Not FDA approved for this indication.

## Surgery

Portosystemic shunt surgery is the most effective means by which to reduce portal pressure. Although effective at eradicating varices and preventing rebleeding, nonselective portocaval shunts are associated with a significant incidence of hepatic encephalopathy, portal vein thrombosis, and occasionally liver failure. Commonly used shunts include the distal splenorenal shunt and the low-diameter (mesocaval or portocaval) interposition shunt. Rates of recurrent bleeding are on the order of 10%, with the highest risk of bleeding occurring in the first month after surgery. Devascularization procedures (i.e., esophageal transection and gastroesophageal devascularization) are usually considered in patients who cannot receive shunts because of splanchnic venous thrombosis and should be performed only by experienced surgeons. Surgical therapy has been largely supplanted by TIPS.

## Cost-Effectiveness of Available Therapies

Data examining the cost of variceal bleeding and the cost-effectiveness of commonly used therapies are limited. The treatment cost of an episode of variceal bleeding has been estimated at \$15,000 to \$40,000. The cost-effectiveness of diagnostic methods used to guide therapy is unclear. For example, HVPG determination, which can accurately predict pharmacologic response to therapy, is an attractive, although invasive, adjunct in the management of patients with variceal bleeding, but its cost-effectiveness remains in question. Further, screening endoscopy for detecting large varices, while recommended, has not been demonstrated to be cost-effective.

There are areas in which management is controversial and not standardized. For example, given the right expertise, secondary prophylaxis with surgical shunts or TIPS may be more effective than medical or endoscopic therapy in Child-Pugh class A patients. On the other hand, patients with advanced cirrhosis are often intolerant of  $\beta$ -blockers—let alone in combination with nitrates—and therefore the use of combination therapy remains controversial in such patients. Arguably, the preferred treatment for such patients is TIPS as a bridge to early liver transplantation.

Therefore, when choosing a specific treatment plan, the clinician must take into consideration the direct costs of health care utilization, as well as the efficacy and morbidity of therapy. The treatment chosen should be tailored to fit the patient's clinical condition while also taking into account the possibility that the patient's liver disease can progress and thus necessitate transplantation. The cost-effectiveness of various treatment modalities should factor in the cost of failed therapy (e.g., rebleeding, shunt revision) and that of treatment-related complications (e.g., encephalopathy, esophageal stricture).

## Summary

Esophageal variceal hemorrhage is a common and devastating complication of portal hypertension and is a leading cause of morbidity and mortality in patients with cirrhosis. Because the clinical outcomes are poor once variceal bleeding has occurred, primary prophylaxis with  $\beta$ -blockers or EBL should be considered in high-risk patients. The treatment of acute variceal hemorrhage is aimed at judicious volume resuscitation and ensuring hemostasis with pharmacologic agents and endoscopic techniques as well as prevention of complications, such as infections by the use of prophylactic antibiotics. Both NSBB and EVL are effective therapeutic options for primary prophylaxis for bleeding. NSBB have additional beneficial effects on the natural course of the disease. EVL is the treatment of choice for patients with contraindication or who are intolerant to NSBB. In patients with small size varices, NSBB is the first-line treatment option. In patients with advanced decompensated cirrhosis (arterial hypotension, hyponatremia, renal dysfunction), NSBB should be used with caution and EVL may be an alternative.

A high risk of rebleeding after an index episode mandates the institution of preventive strategies. Wedge pressure-guided medical therapy may be the preferred mode of secondary prophylaxis in patients with Child Pugh class A or B cirrhosis, but is invasive and not widely available. Patients at high risk for rebleeding, including those with decompensated or advanced liver disease, should be considered for TIPS followed by liver transplantation when applicable. Treatment with a combination of methods is pathophysiologically attractive, but the choice of therapy should ultimately be tailored to fit the patient's clinical condition, risk factors, and prognosis, taking into account issues of risk-to-benefit ratio, compliance, and cost.

## CALCULOUS BILIARY DISEASE

Method of

Zachary L. Smith, DO; and Mick S. Meiselman, MD

### CURRENT DIAGNOSIS

- True biliary colic is characterized by the abrupt onset and cessation of severe mid-epigastric or, less commonly, right upper quadrant pain.
- Pain commonly starts 1 to 2 hours after eating and can be localized or radiate to the back, right shoulder, or chest.
- The onset of biliary colic commonly occurs during sleep.
- Nausea and vomiting commonly follow the onset of pain.
- Elevations of total and conjugated bilirubin, ALP, and GGT with modest elevations in AST and ALT support a suspected diagnosis of choledocholithiasis.
- A normal serum biochemistry profile has a negative predictive value of 97% for ruling out choledocholithiasis.
- Transabdominal ultrasonography is a useful and cost-effective test for diagnosing cholelithiasis; however, it has significantly lower utility for choledocholithiasis.
- For intermediate-risk patients with suspected choledocholithiasis, examination of the common bile duct with magnetic resonance cholangiopancreatography (MRCP) or endoscopic ultrasonography (EUS) is warranted.

### CURRENT THERAPY

- The treatment of choice for symptomatic cholelithiasis is laparoscopic cholecystectomy. Elective laparoscopic cholecystectomy should only be performed for true biliary colic. Vague symptoms such as bloating, dyspepsia, and atypical abdominal pain are not commonly related to gallstone disease and thus are not an indication for gallbladder removal.
- Laparoscopic cholecystectomy should generally take place within 72 hours of presentation for acute cholecystitis in appropriate surgical candidates.
- Laparoscopic cholecystectomy is recommended in pregnant patients with symptomatic cholelithiasis and acute cholecystitis. This is best done by experienced surgeons in the second or early third trimesters.
- Patients who should undergo preoperative ERCP for choledocholithiasis include those with high risk stratification and those deemed intermediate risk in whom a common bile duct stone is identified on MRCP or endoscopic ultrasonography.

## Cholelithiasis

### Epidemiology

Gallstone disease is common in Western populations, affecting 10% to 15% of adults. It is estimated that 6.3 million men and 14.2 million women in the United States have gallstones. Although the vast majority of patients remain asymptomatic throughout their lifetime, roughly one third develop symptoms or complications.

### Pathophysiology

Gallstones can be categorized based on their composition. Of patients with gallstone disease in the Western world, 80% to 90% have cholesterol stones or cholesterol-predominant stones (mixed stones). Pigment gallstones account for the remaining 5% to 10%. Patients with hemolytic disorders are prone to pigment stone formation, and therefore the correspondence with disorders such as sickle cell anemia, hereditary spherocytosis, and Gilbert's syndrome is high.

### Risk Factors

Risk factors for gallstone disease include female sex, age greater than 40 years, white, Latin American, and Native American descent, family history, obesity, rapid weight loss, starvation, total parenteral nutrition, bariatric surgery, diabetes mellitus, and hypertriglyceridemia.

### Clinical Manifestations

The typical symptomatic presentation of gallstone disease is biliary colic. This is described as severe pain located in the mid-epigastrium or, less commonly, the right upper quadrant, that begins and ceases abruptly. The pain is typically constant, occurring 1 to 2 hours after a meal, and can either be localized or radiate to the back or right shoulder. Often the onset of pain occurs during sleep. Nausea and vomiting commonly accompany biliary pain, and, as with most surgical entities, pain typically precedes the onset of these symptoms. Biliary colic can also manifest as chest pain and is occasionally mistaken for cardiac angina. Prolonged episodes of pain localized to the right upper quadrant often herald cholecystitis rather than biliary colic. A clinical history containing the cardinal features of biliary colic carries a high diagnostic accuracy.

### Diagnosis

Transabdominal ultrasonography is the preferred initial imaging test for cholelithiasis. The sensitivity for detecting the presence of gallstones within the gallbladder lumen on ultrasonography is 97%.

### Biliary Sludge

Biliary sludge is often diagnosed on transabdominal ultrasonography. It appears as low-amplitude nonshadowing echoes that layer in dependent portions of the gallbladder. The clinical course of biliary sludge varies from patient to patient. Some patients remain symptom free, and others develop overt biliary colic. A fraction of patients demonstrate resolution of biliary sludge on repeat imaging. Symptomatic biliary sludge should be treated the same as cholelithiasis. Similarly, patients with asymptomatic biliary sludge should be managed expectantly.

### Treatment

In patients with symptomatic cholelithiasis, treatment should be aimed at acute pain control and prevention of recurrent episodes. In patients without contraindications, cholecystectomy is the preferred choice for treatment of symptomatic uncomplicated cholelithiasis. This is preferably done via laparoscopy, which offers lower rates of complications and postoperative pain along with better cosmetic results when compared with open cholecystectomy.

Because of the high incidence of cholelithiasis, true biliary colic should be identified before a decision is made to proceed with laparoscopic cholecystectomy. Vague symptoms such as bloating or atypical abdominal pain are not typical of gallstone disease and thus often persist after surgery. In cases of asymptomatic uncomplicated cholelithiasis, elective cholecystectomy is not recommended unless the patient is diabetic or is undergoing an operation such as gastric bypass surgery, after which there is an increased risk of gallstone formation.

There is a very limited role for medical management of gallstone disease. Nonoperative management of symptomatic cholelithiasis involves bile dissolution with ursodeoxycholic acid (Actigall). The use of medical therapy is limited based on poor efficacy and high rates of recurrence and thus should be reserved only rarely for nonsurgical candidates.

Analgesia is an important adjunct in the treatment of symptomatic cholelithiasis. In patients with severe symptoms requiring narcotic pain medication, meperidine (Demerol) is preferred over morphine because it has less effect on the sphincter of Oddi. Nonsteroidal antiinflammatory drugs (NSAIDs) are another mainstay of therapy. Parenterally administered ketorolac (Toradol) is perhaps the most commonly used agent for biliary colic in the acute care setting. Studies have shown that NSAIDs are beneficial in the

management of pain due to gallstones, and at least one study has suggested that early administration of NSAIDs might decrease the progression to acute cholecystitis.

### Complications

Complications that can potentially arise from cholelithiasis include acute cholecystitis, cholangitis, pancreatitis, obstructive jaundice, and, rarely, gallstone ileus.

### Choledocholithiasis

Choledocholithiasis often manifests concomitantly with symptomatic gallstone disease and is a finding in 5% to 10% of patients undergoing laparoscopic cholecystectomy for symptomatic cholelithiasis. The workup for suspected choledocholithiasis combines history, physical examination, laboratory data, and various imaging modalities. If the clinical history and physical examination are suggestive, the clinician should obtain serum liver biochemistry tests including alanine aminotransferase (ALT), aspartate aminotransferase (AST), total and fractionated bilirubin, alkaline phosphatase (ALP), and  $\gamma$ -glutamyl transpeptidase (GGT).

The typical pattern of serum biochemistry is one of cholestasis. A conjugated hyperbilirubinemia along with high levels of GGT and ALP are seen often in the setting of modest elevation of the transaminases. ALP is usually elevated out of proportion to the transaminases; however, extreme levels of AST and ALT have been described. Transaminase levels greater than 1000 U/L, although rare in gallstone disease, should not dissuade the clinician from a diagnosis of choledocholithiasis. Serum biochemistries provide the most utility in ruling out common bile duct stones. A normal biochemical profile has a negative predictive value of 97%. Clinical predictors for assessing the likelihood of choledocholithiasis in patients with symptomatic cholelithiasis are listed in [Box 1](#).

### Diagnosis

A variety of modalities are available for diagnosing choledocholithiasis. Perhaps the least expensive and most widely available test is transabdominal ultrasound. Although the sensitivity for cholelithiasis is quite high with transabdominal ultrasound, identifying stones in the common bile duct ([Figure 1](#)) is more difficult. Prospective studies have reported sensitivities ranging from 22% to 55% for detecting common bile duct stones; however, in our clinical experience the sensitivity is much lower. Other indirect indicators of choledocholithiasis such as common bile duct dilation (77%–88% sensitivity) can provide additional diagnostic clues. Based on the high false-negative rates for common bile duct stones and dilation, a negative transabdominal ultrasound scan cannot rule out choledocholithiasis. CT scanning has a higher sensitivity

for choledocholithiasis than transabdominal ultrasound. Levels of radiation and cost have limited its use as a first-line diagnostic tool.

Three nonsurgical modalities offer true visualization of the common bile duct with comparable sensitivities: Magnetic resonance cholangiopancreatography (MRCP), endoscopic retrograde cholangiopancreatography (ERCP), and endoscopic ultrasonography (EUS). MRCP has a diagnostic sensitivity of 85% to 92% for detecting choledocholithiasis, and, although it is useful for helping determine which intermediate-risk patients would benefit from preoperative ERCP, small and distal common bile duct stones are often missed.

EUS and ERCP are both minimally invasive techniques useful in the diagnosis and management of choledocholithiasis. Owing to the proximity of the extrahepatic bile duct to the proximal duodenum, EUS provides high sensitivity (89%–94%) for detecting common bile duct stones and is especially useful for detecting stones less than 5 mm in diameter. ERCP provides similar diagnostic sensitivity; however, ERCP offers therapeutic capability. Because of the reasonably high risk of complications including pancreatitis (1.3%–15.1%), infection (0.6%–5.0%), gastrointestinal hemorrhage (0.3%–2.0%), and perforation (0.1%–1.1%), ERCP as an initial modality should be reserved for patients who have a high pretest probability for choledocholithiasis and particularly for those with complications such as acute cholangitis or severe pancreatitis.

Research has evaluated the use of ultrasound-guided ERCP with the goal of avoiding unnecessary bile duct cannulation, and reserving its use for therapeutic purposes only. A systematic review from 2009 showed that compared with ERCP alone, the use of EUS avoided unnecessary ERCP in 67.1% of patients in whom no common bile duct stone was identified. As more gastroenterologists become trained in this modality, EUS-guided ERCP might prove to be the preferred diagnostic modality in intermediate-risk patients for the diagnosis and initial therapy of choledocholithiasis.

### Treatment

Patients with choledocholithiasis should be treated to avoid recurrent symptoms and development of complications. Stones can be extracted from the common bile duct via ERCP or laparoscopic cholecystectomy with bile duct exploration. Studies have shown similar efficacies without significant differences in morbidity or mortality; however, clinical expertise varies widely with the laparoscopic approach. Ultimately, cholecystectomy should be performed to prevent recurrence in surgical candidates. In patients undergoing laparoscopic cholecystectomy for suspected choledocholithiasis, perioperative management differs based on the risk stratification of the patient (see [Box 1](#)). High-risk patients should

#### BOX 1

Strategy to Assign Risk of Choledocholithiasis in Patients with Symptomatic Cholelithiasis, Based on Clinical Predictors

#### Predictors of Choledocholithiasis

##### High Risk

1. Common bile duct stone on ultrasound, CT scan or MRI
2. Total bilirubin >4 mg/dl and dilated common bile duct
3. Ascending cholangitis

##### Intermediate Risk

1. Other abnormal liver chemistry (e.g. total bilirubin 1-8-3.9 mg/dl, elevated AST, ALT, alkaline phosphatase)
2. Age >55 years
3. Dilated common bile duct on imaging

##### Low Risk

None of the above are present

From ASGE Standards of Practice Committee Buxbaum JL, Abbas SM, Sultan S, et al. ASGE guideline on the role of endoscopy in the evaluation and management of choledocholithiasis. *Gastrointest Endosc*. 2019;89(6):1075–1105.e15.

**Figure 1** A large gallstone in the common bile duct (CBD) with dilatation of the CBD proximally. The endoscopic ultrasound probe is visualized in the top of the image, and a large cone-shaped shadow is cast distal to the gallstone.

proceed directly to ERCP before surgery for attempted stone extraction. In intermediate-risk patients, a preoperative MRCP or EUS should be performed, and, if the results are positive, the patient should undergo ERCP as a prelude to surgery. For suspected choledocholithiasis in low-risk patients, surgery should be performed without further imaging of the common bile duct.

### Complications

The two most common adverse complications of choledocholithiasis are gallstone pancreatitis and acute cholangitis. Gallstone pancreatitis develops in 3% to 7% of patients with gallstones and is the most common cause of acute pancreatitis in the United States. The diagnosis and management of acute pancreatitis is discussed in a separate chapter.

Acute cholangitis is caused by obstruction and stasis of the biliary tract with complicating bacterial infection. The syndrome is characterized by fever, jaundice, and abdominal pain, also known as Charcot's triad. Patients who develop hypotension and changes in mental status (Reynold's pentad) have a poorer prognosis. Elderly patients often do not demonstrate the classic signs of acute cholangitis, but they can develop a delayed-sepsis-like syndrome, of which hypotension is the most pronounced feature. High biliary pressures promote the translocation of bacteria from the portal circulation into the biliary tree. The most common bacterial organism seen in acute cholangitis is *Escherichia coli* (25%–50%), followed by *Klebsiella*, *Enterobacter*, and *Enterococcus* species.

Treatment for acute cholangitis should focus on antimicrobial therapy and biliary drainage. Empiric antibiotic regimens should provide adequate activity against gram-negative and anaerobic organisms. Common regimens include monotherapy with ampicillin and sulbactam (Unasyn) or piperacillin and tazobactam (Zosyn) or combination therapy with a fluoroquinolone plus metronidazole (Flagyl).

Patients without hypotension or mental status changes commonly show initial improvement after empiric antibiotics are administered, and thus biliary drainage can be done nonurgently. In patients demonstrating signs of sepsis or severe infection, emergency biliary drainage via ERCP is warranted. Patients who are not candidates for ERCP may undergo percutaneous transhepatic biliary drainage as an alternative.

### Acute Cholecystitis

Acute cholecystitis is a syndrome defined by right upper quadrant pain, fever, and leukocytosis in the setting of gallbladder inflammation. Nausea and vomiting often occur as concurrent symptoms. Patients commonly have a positive Murphy's sign on physical examination, which is defined as abrupt cessation of inspiration on deep palpation of the gallbladder fossa, just beneath the liver edge. Approximately 95% of patients with acute cholecystitis have gallstones. In these instances, cholecystitis is thought to be precipitated by obstruction of the cystic duct and by local irritation of the gallbladder wall. Local inflammation is followed by release of pro-inflammatory prostaglandins. Superimposed bacterial infection might or might not complicate acute cholecystitis. As with cholangitis, the main bacteria responsible for infections during acute cholecystitis are *E. coli* and *Klebsiella*, *Enterobacter*, and *Enterococcus* species.

### Diagnosis

The diagnosis of acute cholecystitis can often be made on physical examination alone. The most common laboratory finding in acute cholecystitis is leukocytosis. Mild elevations in AST and ALT can also be seen. Elevations of bilirubin and ALP are typical of biliary obstruction and are not commonly seen in acute cholecystitis. These abnormalities, if present, should raise suspicion for other conditions such as choledocholithiasis, cholangitis, or Mirizzi's syndrome. Mirizzi's syndrome is a rare cause of obstructive jaundice characterized by an impacted cystic duct stone that causes mass effect and compression of the common bile duct or common hepatic duct.

The initial imaging study of choice for acute cholecystitis is transabdominal ultrasound. Findings suggestive of cholecystitis

include cholelithiasis, pericholecystic fluid (Figure 2), and a sonographic Murphy's sign (Figure 3). Thickening of the gallbladder wall supports a diagnosis of acute cholecystitis, but it is a nonspecific finding. Transabdominal ultrasound has a sensitivity of 88% for diagnosing acute cholecystitis. Hepatobiliary cholescintigraphy (HIDA scan) (Figure 4) is recommended if the suspicion of cholecystitis remains after a negative transabdominal ultrasound. MRCP and CT scan are typically not necessary for the diagnosis, although CT scan can be useful if complications from cholecystitis such as perforation are suspected.

### Treatment

The treatment for acute cholecystitis involves supportive care, analgesia, antibiotics, and either surgery or percutaneous gallbladder drainage. If treatment is delayed or inadequate, numerous potential complications can result. These include emphysematous or gangrenous cholecystitis and gallbladder perforation. All patients with acute cholecystitis should be admitted to the hospital and given supportive care including intravenous fluids. NSAIDs and opioid analgesics are typically used for pain control.

Although bacterial etiologies complicate less than half of all episodes, empiric antibiotics are commonly administered to patients with acute cholecystitis. Appropriate antibiotic regimens are the same as those used in the setting of acute cholangitis (see the discussion of complications of choledocholithiasis).

In patients who are adequate surgical candidates, cholecystectomy should be performed within 72 hours of initial presentation. Numerous prospective trials and a Cochrane Database review have evaluated early versus delayed (6–12 weeks) cholecystectomy. There is overwhelming consensus that early surgery carries no increase in complications or perioperative morbidity and is associated with shorter hospital stays. Furthermore, early laparoscopic cholecystectomy eliminates the risk of recurrent episodes of acute cholecystitis.

### Acute Acalculous Cholecystitis

An estimated 5% to 10% of cases of acute cholecystitis develop without the presence of gallstones. Acute acalculous cholecystitis is often seen in the setting of serious medical illness, complicated surgery, severe blunt trauma, and burn injuries. Other conditions such as diabetes mellitus, vasculitis, AIDS, and congestive heart failure have also been implicated as risk factors. Acute acalculous cholecystitis carries major risks of gangrene (50%) and

**Figure 2** Computed tomography (CT) scan demonstrating acute cholecystitis. The *outline arrow* indicates gallstones within the gallbladder lumen. The two *solid arrows* highlight mural thickening of the gallbladder wall and small amounts of pericholecystic fluid. Image courtesy of Richard M. Gore, MD, Department of Radiology, NorthShore University Health System, Evanston, IL.

**Figure 3** Acute cholecystitis: ultrasound. Gallbladder (g) is distended, with mural thickening (arrowhead) and a stone in the gallbladder neck (arrow). Positive sonographic Murphy sign was present.

**Figure 4** Hepatobiliary iminodiacetic acid (HIDA) scan demonstrating acute cholecystitis. Gore, MD, Department of Radiology, North-Shore University Health System, Evanston, IL.

perforation (10%), and mortality ranges from 30% to 50%. Numerous organisms have been associated with acute acalculous cholecystitis, including bacterial, viral, fungal, and parasitic infections.

The diagnosis is difficult. Patients are often critically ill and unable to elicit their symptoms. Transabdominal ultrasound is the best modality to evaluate acute acalculous cholecystitis in the critically ill patient owing to its availability, cost, and ease of performance. Hepatobiliary iminodiacetic acid (HIDA) and computed tomography (CT) scanning can have a role in difficult-to-diagnose acute acalculous cholecystitis and should be considered if ultrasound is nondiagnostic. Whereas false-positive test results can occur, a normal HIDA scan has a high negative predictive value in evaluating acute acalculous cholecystitis.

Because of the high rate of gangrene and perforation, early cholecystectomy should be performed in patients who are surgical candidates. In patients too ill to undergo surgery, biliary drainage with percutaneous cholecystostomy should be considered.

### Gangrenous Cholecystitis, Emphysematous Cholecystitis, and Gallbladder Perforation

Gangrenous cholecystitis is most often seen in elderly patients and diabetics along with patients who delay seeking medical treatment for their symptoms. It is the most common complication of acute cholecystitis and carries a high mortality. Emphysematous cholecystitis is caused by gas-forming bacteria that infect the gallbladder. *E coli* and *Clostridium* species are most commonly implicated. Gas in the gallbladder may be seen on imaging, particularly CT or magnetic resonance imaging (MRI). Patients with gangrenous or emphysematous cholecystitis are at an elevated risk for gallbladder perforation. Early empiric antibiotics and cholecystectomy are crucial in the management of these complications to minimize mortality and prevent perforation of the gallbladder, a condition that carries a mortality rate of 42% to 60%.

### Gallbladder Disease in Pregnancy

Pregnancy is a major risk factor for cholesterol gallstone formation. Because of anatomic changes secondary to the gravid uterus, biliary colic can be difficult to delineate from other causes of abdominal pain. Pregnant patients often have gallstones on transabdominal ultrasound, and thus a detailed history and physical

examination are needed to diagnose a patient's abdominal pain as biliary. Patients with other symptoms including bloating or dyspepsia should be evaluated for other etiologies.

In pregnant patients with recurrent symptomatic cholelithiasis, laparoscopic cholecystectomy remains the treatment of choice. The second and early third trimesters are the best times to perform cholecystectomy owing to ease and lower rates of complications. Nonsurgical management of gallstones is limited in pregnancy. NSAIDs are generally avoided late in pregnancy owing to the risk of premature closure of the ductus arteriosus, especially after 30 to 32 weeks of gestation.

After appendicitis, acute cholecystitis is the second most common nonobstetric surgical emergency during pregnancy. As with nonpregnant patients, pregnant women with acute cholecystitis should be treated with cholecystectomy in addition to medical management. Early surgery for pregnant patients with acute cholecystitis has been found to decrease relapse rates and hospital readmissions. No differences in maternal or fetal morbidity and mortality have been found in patients treated conservatively versus surgically for acute cholecystitis during pregnancy.

## CHRONIC DIARRHEA

Method of

André de Leon, MD

### CURRENT DIAGNOSIS

#### History

- Duration, frequency, and timing
- Presence of fever/blood
- Food/medication intake
- Travel history

#### Physical Examination

- Gastrointestinal examination
- Hydration status
- Digital rectal examination
- Other systems: endocrine, ophthalmologic, skin

#### Testing

- Fecal occult blood testing
- Stool for ova/parasites, *Clostridium difficile* and other bacteria
- Stool antigen for cryptosporidium, giardia
- Fecal electrolytes (Na, K, Osm)
- Fecal leukocytes
- Erythrocyte sedimentation rate (ESR)
- Complete blood count (CBC)
- Other: iron panel (celiac sprue), TSH (hyperthyroidism), liver function tests (LFTs)
- Colonoscopy with biopsy

### CURRENT THERAPY

- Supportive care and rehydration, if necessary
- Trial of discontinuation of possible offending medication/food (lactose, gluten, sorbitol)
- Dietary modification with increased fiber intake (dietary or supplementation)
- Specific therapy as directed by culture and susceptibilities or biopsy
- Empiric therapy trial with antibiotics
- Empiric trial of probiotics<sup>1</sup> (limited evidence of efficacy in healthy adults with chronic diarrhea)

<sup>1</sup>Not FDA approved for this indication.

Chronic diarrhea has traditionally been defined based on consistency, volume, and frequency of stools. However, recent studies have found that there is considerable variability in definition when using these markers. Therefore the American Gastroenterological Association has released a consensus statement suggesting that chronic diarrhea should be defined as a decrease in fecal consistency lasting for 4 or more weeks.

#### Epidemiology

Chronic diarrhea is a common cause of mortality in developing countries as well as the second leading cause of overall mortality in children 1 to 59 months old. The prevalence in the general population in developed nations and economic impact of chronic diarrhea has not been well established. This could be related to the variable nature of the studies that have been performed with regard to definition, population characteristics, and overall study design. The American Gastroenterological Association Burden of Illness study estimates that the direct costs of chronic diarrhea are \$524 million per year and indirect costs are at least \$136 million

per year. A meta-analysis of current studies suggest that chronic diarrhea can affect anywhere from 1%–5% of the population.

#### Classification Based on Etiology

Elucidating the exact cause of chronic diarrhea can be very challenging, as there are several hundred conditions that can be related. Consideration of comorbid symptoms and epidemiologic clues can help in constructing a differential diagnosis. Chronic diarrhea can be evaluated based on two etiologies: functional and organic. The functional chronic diarrhea category includes conditions when abdominal pain accompanies the diarrhea (e.g., irritable bowel syndrome) and when abdominal pain is absent. Organic disorders are conditions that are associated with physiologic, structural, or biochemical abnormalities. Organic disorders are more likely in adults with alarm features such as gastrointestinal (GI) bleeding, fevers, or significant weight loss.

#### Functional Disorders

Functional diarrhea is characterized by chronic or recurrent diarrhea not explained by structural or biochemical abnormalities. Causes may include physiologic factors (small bowel bacterial overgrowth), psychological factors (stress and anxiety), and dietary factors (carbohydrate malabsorption). Patients with functional diarrhea should not meet criteria for irritable bowel syndrome (IBS) as based on the Rome IV criteria. Patients with functional diarrhea may have abdominal pain and/or bloating, but unlike IBS, these are not predominant symptoms.

#### Functional Disorders: Irritable Bowel Syndrome

Multiple investigations have shown conflicting data, and no abnormality has been found to be specific for this disorder. The traditional focus has been on alterations in gastrointestinal motility and on visceral hypersensitivity; however, more recent studies have considered the role of inflammation, alterations in fecal flora, and bacterial overgrowth as possible causes. The role of food sensitivity is also being considered as a possible cause. The Rome criteria help to provide a framework for the diagnosis of IBS and emphasize pain. When these criteria are not met, then other etiologies should be considered and evaluated. The Rome criteria emphasize chronic abdominal pain that is relieved by defecation and associated with a change in stool frequency or consistency. Psychological stress also appears to correlate to the diagnosis of IBS. Patients with IBS can experience altered bowel habits with a predominance of diarrhea vs. constipation or alternating between the two (mixed type). IBS can also be postinfectious, following recovery from *Clostridium difficile* and other bacterial infections.

#### Organic Disorders

Organic disorders leading to chronic diarrhea are conditions that are associated with structural, physiologic, or biochemical abnormalities. Alarm features such as gastrointestinal (GI) bleeding, fever, significant weight loss, occurrence after 50 years of age, and positive family history of colorectal cancer or inflammatory bowel disease (IBD) are more likely in organic disorders.

#### Organic Disorders: Fatty/Malabsorptive

Malabsorptive diarrhea is, as the name implies, secondary to impaired absorption along the gut. This can be due to structural abnormalities (gastric bypass, short bowel syndrome, celiac sprue, pancreatic insufficiency), structural abnormalities related to vascular compromise (mesenteric ischemia), or lack of enzymes that aid in digestion (e.g., lactose intolerance). Impaired absorption can also occur secondary to infections such as *Tropheryma whippelii* (Whipple's Disease), *Giardia*, small bowel bacterial overgrowth, and tropical sprue. Medications such as aminoglycoside antibiotics, orlistat (Xenical, Alli), thyroid supplementation, acarbose (Precose), and ticlopidine (Ticlid) can also cause malabsorptive diarrhea.

#### Organic Disorders: Inflammatory

Inflammation leading to diarrhea is often due to autoimmune, infectious, or neoplastic processes or radiation exposure.

Autoimmune processes are felt to play a large role in inflammatory bowel disease (IBD), which often manifests as Crohn disease or ulcerative colitis. Microscopic colitis may also have laboratory findings suggesting an underlying autoimmune disorder. Infections such as *Clostridium difficile*, *Mycobacterium tuberculosis*, *Yersinia*, *Campylobacter*, *Giardia*, *Cryptosporidium*, *Amebae*, *Strongyloides*, cytomegalovirus, and herpes simplex virus can lead to a diarrhea with associated inflammation of the bowel. Colon cancer (villous adenocarcinoma) and lymphoma can also cause inflammatory diarrhea.

#### Organic Disorders: Postcholecystectomy

In the absence of a gallbladder, bile acids drain directly and more continuously into the small bowel. This increase may overcome the terminal portion of the ileum's absorptive capacity. The increased bile acids then are allowed to reach the colon, leading to diarrhea (choleraic diarrhea).

#### Clinical Manifestations

**History.** Thorough investigation of a patient complaining of ongoing diarrhea-like features should always include a detailed medical history. A clear understanding of the patient's symptoms is vital: not all complaints may truly be defined as diarrhea but may rather be symptoms related to an interplay between fecal incontinence and stool impaction. A detailed history of travel, food intake, and medication use is essential. This can help direct the early workup and diagnostic testing. Stool frequency, volume, consistency, and timing can aid in categorization; however, they are no longer what define the condition, as noted previously. If considering the diagnosis of irritable bowel syndrome (IBS), use of the Rome IV criteria will be beneficial.

**Physical Examination.** The physical examination is very important to the workup and diagnosis of chronic diarrhea. Ophthalmologic findings such as episcleritis or exophthalmia can be related to IBD; skin findings such as dermatitis herpetiformis can be related to celiac sprue (seen in 15%–25% of patients with celiac disease). Prominent lymphadenopathy and weight loss can be suggestive of possible infection or malignancy. A thorough abdominal examination should include the evaluation of bowel sounds (hypermotility), skin for scars (surgical cause of diarrhea), tenderness (infection/inflammation), and masses (neoplasia) and should be followed by a digital rectal examination with fecal occult blood testing. Anoscopy can also be used to detect for ulcerations or fecal impaction, given that seepage around impacted stools can create a picture similar to diarrhea.

#### Testing for Diagnosis

Serum testing for chronic diarrhea should include a complete blood count (CBC), serum electrolytes, liver function tests, serum albumin, thyroid-stimulating hormone, and erythrocyte sedimentation rate. An iron panel should be performed if indicated based on the results of the CBC. Serum anti-tissue transglutaminase antibody testing may be helpful if symptoms are suggestive of celiac sprue. Stool evaluation may include fecal occult blood testing, fecal leukocytes, stool ova and parasites, stool culture (including *Salmonella*, *Shigella*, and *Campylobacter*), and stool antigen for *Giardia*. Stool testing for *Cryptosporidium* should be considered, especially in the immunocompromised. Stool pH and electrolytes may be helpful, especially when the patient is lactose intolerant. Stool testing for *C. difficile* should be performed if the patient has recently used antibiotics or been hospitalized. If medication abuse is suspected as a possible cause, a stool laxative screen (i.e., stool phenolphthalein test) may be warranted. Diagnostic testing may include a colonoscopy with biopsy.

#### Treatment

The exact cause of chronic diarrhea can prove elusive, and treatment trials may be warranted. Specific treatment

**TABLE 1** Medications Commonly Associated with Diarrhea

##### Antiarrhythmic medications

- Digoxin
- Quinidine

##### Antibiotic medications

- Aminoglycosides
- Macrolides

##### Antihypertensive medications

- ACE inhibitors
- Beta blockers

##### Antiinflammatory medications

- 5-aminosalicylates
- Nonsteroidal antiinflammatory drugs (NSAIDs)

##### Antiretroviral medications (many)

##### Chemotherapeutic medications (many)

##### Dermatologic medications

- Isotretinoin (occasionally causes diarrhea)

##### Endocrine medications

- Alpha-glucosidase inhibitors (cause diarrhea in  $\geq 20\%$  of patients)
- Biguanides (cause diarrhea in  $\geq 20\%$  of patients)
- Thyroid hormones

##### Gastrointestinal medications

- Acid-reducing medications
  - H<sub>2</sub>-receptor blocker
  - Proton pump inhibitors
- Antacid medications (magnesium containing)

##### Parasympathetic nervous system medication

- Cholinergic agonists

##### Psychiatric medications

- Selective serotonin reuptake inhibitors

##### Respiratory medications

- Xanthine derivative (Theophylline)

Data from Schiller LR, Sellin JH. Sleisenger and Fordtran's Gastrointestinal and Liver Disease: Pathophysiology/Diagnosis/Management. 9th Edition, Philadelphia, 2010, Elsevier; and Soriano M, Vaziri H. Clinical Gastroenterology, Diarrhea: Diagnostic and Therapeutic Advances, New York, 2010, Humana Press, Springer.

depends on the specific diagnosis. If there is concern about possible bacterial or protozoa infection, an empiric trial of vancomycin (Vancocin), ciprofloxacin (Cipro), or metronidazole (Flagyl) may be warranted. If there is concern for possible medication (Table 1) or food relation to diarrhea, a trial of discontinuation of offending substance/food may be reasonable. The effectiveness of probiotics<sup>7</sup> looks favorable; however, large intervention studies and epidemiologic investigations of long-term probiotic effects on healthy adults are largely missing. At this time, probiotics have been found efficacious in treatment of acute diarrhea, prevention of antibiotic-associated diarrhea, and prevention of traveler's diarrhea. Dietary modification continues to be an important starting point for treatment, with increased intake in bulk-forming agents such as fiber. Treatment of specific disorders such as Crohn's disease and ulcerative colitis are discussed in other chapters.

<sup>7</sup>Available as dietary supplement.

## CIRRHOSIS

Method of

Andres F. Carrion, MD; and Paul Martin, MD

The term *cirrhosis* is a neologism derived from the Greek *kirrhós*, which describes the yellowish discoloration of the liver during advanced stages of chronic liver disease, and the suffix *osis*, which denotes a specific condition in medical terminology. Morphologically, cirrhosis reflects the consequences of chronic hepatic necroinflammatory activity with an incomplete and disorganized repair process that results in regenerative nodules and extensive fibrosis replacing normal hepatic parenchyma with disturbance of normal hepatic physiology. Cirrhosis can result from any etiology of chronic liver disease (Table 1). Activation of hepatic stellate cells into myofibroblasts and matrix deposition are key steps in the pathogenesis of cirrhosis.

### Epidemiology

The prevalence of cirrhosis varies significantly in different regions of the world and is directly influenced by the epidemiology of individual chronic liver diseases that lead to progressive hepatic fibrosis. The estimated global prevalence of cirrhosis is 4.5% to 9.5%; however, this estimate likely underestimates the real magnitude of disease burden, as a sizable proportion of asymptomatic individuals remain undiagnosed. Similarly, it is difficult to obtain accurate estimates of mortality related to cirrhosis, but countries in Central and South America and Southern Europe exhibit the highest mortality rates, particularly in males. Epidemiologic trends of cirrhosis have changed considerably over time in many countries, underscoring variations in the incidence and prevalence of specific etiologies of chronic liver disease. For instance, widespread immunization against hepatitis B virus (HBV) has markedly reduced its incidence, prevalence, and associated liver disease including cirrhosis. Alcohol consumption has varied strikingly across different regions of the globe over the past several decades. A steady decline in mortality due to cirrhosis has occurred in some European countries (mainly Mediterranean) as alcohol use has diminished. A similar trend has also been noted in North America; however, hospitalizations for acute alcoholic hepatitis have increased over the recent past in the United States. In contrast, a significant increase in mortality related to cirrhosis has been noted in some Eastern European countries with increased alcohol consumption. In addition, eradication of hepatitis C virus (HCV) is associated with a reduction in hepatic dysfunction, liver-related and all-cause mortality, and complications of cirrhosis such as hepatocellular carcinoma (HCC) and portal hypertension. The impact of highly effective direct-acting antiviral agents against HCV on the epidemiology of cirrhosis and its complications has resulted in

**TABLE 1** Etiologies of Cirrhosis

ETIOLOGY	EXAMPLES
Infectious	Hepatitis B Hepatitis C Hepatitis D
Autoimmune and cholestasis	Autoimmune hepatitis Biliary atresia Primary biliary cholangitis Primary sclerosing cholangitis Secondary biliary cirrhosis Secondary sclerosing cholangitis
Toxins	Alcohol Arsenic Drugs
Metabolic	Nonalcoholic steatohepatitis Alpha-1 antitrypsin deficiency Hemochromatosis Wilson disease Glycogen storage diseases Lysosomal storage diseases Galactosemia
Vascular	Cardiac cirrhosis Budd-Chiari syndrome Sinusoidal obstruction syndrome
Granulomatous	Sarcoidosis Tuberculosis Syphilis
Cryptogenic	Unrecognized metabolic-associated fatty liver disease, infections, or drugs

a decline in liver transplant listings for HCV. In contrast, the growing prevalence of metabolic-associated fatty liver disease (MAFLD), previously known as nonalcoholic fatty liver disease, is reflected in its current prominence as a cause of cirrhosis. MAFLD is anticipated to become the single most frequent cause of chronic liver disease and cirrhosis in the mid to second half of this century.

### Clinical Findings

In the absence of hepatic decompensation, the overwhelming majority of individuals with cirrhosis are asymptomatic and may only exhibit subtle clinical findings. Clues to the presence of cirrhosis can include elevated serum aminotransferases and/or bilirubin, decreased albumin, and prolongation of the prothrombin time. Approximately 10% to 17% of individuals with unexplained elevation of aminotransferases have unrecognized cirrhosis. Thrombocytopenia in the absence of a primary hematologic explanation is another clue to the presence of cirrhosis and primarily reflects hypersplenism due to portal hypertension but also diminished production of thrombopoietin, a platelet growth and development factor synthesized by the liver. A platelet count below  $160 \times 10^9/\mu\text{L}$  provides the highest diagnostic accuracy for cirrhosis among routine blood tests (sensitivity 74%, specificity 88%, positive likelihood ratio 6.3, negative likelihood ratio 0.29). Thrombocytopenia is also a component of noninvasive scoring systems that predict fibrosis, such as the AST (aspartate aminotransferase) to Platelet Ratio Index (APRI) and Fibrosis-4 (FIB-4).

Physical examination may reveal somewhat diminished liver span by percussion and a firm liver edge on palpation. Splenomegaly is suggested by dullness to percussion in the left upper abdominal quadrant or a palpable spleen tip. Cutaneous signs of cirrhosis include palmar erythema, spider nevi, facial telangiectasia, decreased chest and/or axillary hair, inversion of the normal male pubic hair pattern, Terry nails (“ground glass” appearance of nails with absent lunula), and Muehrcke nails (paired, white, transverse bands separated by normal color). Nail clubbing may also be present in individuals with cirrhosis, particularly in those

**TABLE 2** Stages of Cirrhosis Based on Clinical Complications and 1-Year Outcome Probabilities

CIRRHOSIS	D'AMICO STAGE	COMPLICATIONS	PROBABILITY OF ADVANCING TO NEXT STAGE	1-YEAR MORTALITY
Compensated	Stage 1	(-) varices (-) ascites	7%	1%
	Stage 2	(+) varices (-) ascites	6.6%	3.4%
Decompensated	Stage 3	(+) ascites (+) varices	7.6%	20%
	Stage 4	(+) variceal hemorrhage (+) ascites	–	57%

From D'Amico G, Garcia-Tsao G, Pagliaro L: Natural history and prognostic indicators of survival in cirrhosis: A systematic review of 118 studies. *J Hepatol* 44:217–231, 2006.

**TABLE 3** Child-Turcotte-Pugh Classification

CLINICAL AND LABORATORY CRITERIA	POINTS		
	1	2	3
Albumin (g/dL)	>3.5	2.8–3.5	<2.8
Ascites	None	Mild to moderate (diuretic responsive)	Severe (diuretic refractory)
Bilirubin (mg/dL)	<2	2–3	>3
Encephalopathy	None	Mild to moderate (grade 1 or 2)	Severe (grade 3 or 4)
Prothrombin time	<4 <1.7	4–6 1.7–2.3	>6 >2.3
Prolongation in seconds			
International normalized ratio			

with hepatopulmonary syndrome. Dupuytren contracture is relatively common in alcohol-related cirrhosis but its pathogenesis is not well understood. Palmar erythema due to altered sex hormone metabolism is more evident on the thenar and hypothenar eminences and typically spares the central portion of the palm. Hypogonadism in both sexes and gynecomastia and testicular atrophy in males can be detected, reflecting altered sex hormone metabolism (increased production of androstenedione, enhanced aromatization to estrone, and increased conversion to estradiol). The catabolic effects of advanced cirrhosis often result in marked sarcopenia, which adversely affects quality of life and survival and is also associated with poorer outcomes after liver transplantation.

Various noninvasive methods for evaluation of liver fibrosis are now widely used in clinical practice for staging of hepatic fibrosis and diagnosis of cirrhosis. These include vibration-controlled transient elastography (Fibroscan), acoustic radiation force impulse (ARFI), shear wave and point quantification elastography, and magnetic resonance elastography.

### Natural History of Cirrhosis and Prognostic Models

Cirrhosis may be broadly categorized into two distinct clinical phases, regardless of the etiology: compensated and decompensated. Compensated cirrhosis implies the absence of index complications such as jaundice, ascites, hepatic encephalopathy, or gastroesophageal variceal hemorrhage. In contrast, hepatic decompensation indicates an advanced phase of the disease, which is rapidly progressive and characterized by development of one or more complications and diminished hepatocellular function with prolongation of the prothrombin time and hypoalbuminemia. Characterizing cirrhosis

**Figure 1** Relationship between Model for End-Stage Liver Disease (MELD) score and survival at 3 months. From Carrion AF, Martin P. In: *Sleisenger and Fordtran's Gastrointestinal and Liver Disease*, 11th ed., Chapter 97, page 1538. Elsevier; 2021.

as compensated or decompensated is simple and reproducible and offers useful prognostic information for clinical practice (Table 2).

More precise prognostic models such as the Child Turcotte Pugh (Table 3) and the Model for End-Stage Liver Disease (MELD) are also widely used, the latter being considered the most accurate predictor of short-term mortality for individuals with cirrhosis and serving as the basis for the current organ allocation system in liver transplantation in the United States and elsewhere (calculator available at <https://optn.transplant.hrsa.gov/resources/allocation-calculators/meld-calculator/>). The most recent modification of the MELD score resulted in inclusion of the serum sodium into the formula: MELD-Na. Incorporation of the serum sodium in the MELD formula increases its prognostic accuracy in patients with relatively low scores and hyponatremia.

The specific etiology of cirrhosis may help determine its prognosis. For instance, persistent viremia in individuals with chronic HBV or HCV infection is implicated in the development of decompensated cirrhosis. Effective antiviral therapy can abort progression of chronic viral hepatitis to cirrhosis and decompensation.

Although cirrhosis per se is not an indication for liver transplantation, it is important to identify individuals with cirrhosis who should be considered for liver transplantation. Development of an index complication of cirrhosis such as gastroesophageal variceal hemorrhage, ascites, or hepatic encephalopathy is an indication to refer a patient for liver transplantation and initiate pretransplant evaluation. The MELD score provides objective and reproducible prognostication of short-term survival without liver transplantation (Figure 1), and data from a seminal study showed that liver transplantation is associated

**TABLE 4** Recommendations for Primary Prophylaxis Against Esophageal Variceal Hemorrhage

SIZE OF VARICES	RISK OF HEMORRHAGE	SURVEILLANCE INTERVAL	PRIMARY PROPHYLAXIS
No varices	CTP class A	EGD every 2 years if ongoing liver injury (i.e., obesity or alcohol abuse) or every 3 years if liver injury is quiescent (i.e., viral eradication or alcohol abstinence)	None
	CTP class B/C	EGD yearly	None
Small esophageal varices	CTP class A	EGD yearly if ongoing liver injury (i.e., obesity or alcohol abuse) or every 2 years if liver injury is quiescent (i.e., viral eradication or alcohol abstinence)	BB may be used
	CTP class B/C	EGD yearly; if BB are used, repeat EGD unnecessary	BB recommended
Large esophageal varices	CTP class A/B/C	If BB are used, repeat EGD unnecessary; if no BB, repeat EGD for EVL every 2–8 weeks until variceal eradication, then once in 3–6 months, and regularly every 6–12 months	Either BB or EVL recommended

BB, Beta blocker; CTP, Child-Turcotte-Pugh; EGD, esophagogastroduodenoscopy; EVL, endoscopic variceal ligation. Child-Turcotte-Pugh class obtained by adding points for each variable.

Class A: 5 to 6 points (compensated cirrhosis); class B: 7 to 9 points (decompensated cirrhosis); class C: 10 to 15 points (decompensated cirrhosis)

with improved survival in individuals with MELD scores greater than 17.

## Major Complications of Cirrhosis

### Portal Hypertension

Although portal hypertension can be inferred by clues such as splenomegaly with thrombocytopenia in a patient with cirrhosis, it is defined by a hepatic venous pressure gradient (HVPG) greater than 5 mm Hg. This gradient is calculated by subtracting the measured free hepatic vein pressure from the wedged hepatic venous pressure (a measurement that reflects portal venous pressure by using the same hemodynamic principle as the wedged pulmonary capillary pressure to assess left atrial pressure). Clinically significant portal hypertension typically occurs when the HVPG is 10 mm Hg or greater, at which threshold gastroesophageal varices and ascites occur. Unfortunately, accurate noninvasive measurement of portal pressure is not available, limiting its use in routine clinical practice as it requires passage of a transjugular catheter.

Increased intrahepatic resistance to portal venous flow aggravated by increased splanchnic blood flow in cirrhosis leads to portal hypertension. In addition to cirrhosis, which is the most common cause of portal hypertension in Western countries (hepatic schistosomiasis is the leading cause in areas where this infection is common), other disorders may result in pre- or posthepatic portal hypertension. Portal vein thrombosis is a common cause of prehepatic portal hypertension. Cardiomyopathy, constrictive pericarditis, Budd-Chiari syndrome, and inferior vena cava webs may result in posthepatic portal hypertension. Ascites and gastroesophageal variceal hemorrhage are the two most common complications of portal hypertension in cirrhosis. Less common but clinically significant complications include portal hypertensive gastropathy, hepatic hydrothorax, hepatopulmonary syndrome, portopulmonary hypertension, and hepatorenal syndrome.

### Gastroesophageal Variceal Hemorrhage

Portal hypertension leads to formation of multiple portosystemic collaterals, including gastroesophageal varices. Formation of gastroesophageal varices typically occurs when the HVPG is 10 mm Hg or greater, with the risk for variceal hemorrhage increasing once HVPG is greater than 12 mm Hg. Gastroesophageal varices are present in approximately 50% of patients with cirrhosis and are more common in patients with hepatic decompensation (Child-Turcotte-Pugh class C). Variceal hemorrhage is the most dramatic complication of cirrhosis and occurs at a rate of 5% to 15% per year. Risk factors for variceal hemorrhage include larger variceal size, more advanced

**TABLE 5** Classification of Gastroesophageal and Gastric Varices and Recommendations for Primary Prophylaxis

TYPE OF VARICES	CHARACTERISTICS	PRIMARY PROPHYLAXIS
Gastroesophageal varices type 1 (GOV1)	Extension of esophageal varices along the lesser curvature into the gastric cardia	Similar to esophageal varices
Gastroesophageal varices type 2 (GOV2)	Extension of the esophageal varices along the greater curvature into the gastric fundus	BB can be used, although data not as strong as for esophageal varices
Isolated gastric varices type 1 (IGV1)	Gastric varices localized in the fundus	If high risk, consider BB or cyanoacrylate injection
Isolated gastric varices type 2 (IGV2)	Gastric varices localized in the antrum	No data, consider BB if high risk

BB, Beta blocker.

hepatic decompensation, and presence of vascular “red wale” signs during endoscopic evaluation. Esophageal varices are classified according to their size as small ( $\leq 5$  mm) or large ( $> 5$  mm).

Screening for gastroesophageal varices with esophagogastroduodenoscopy (EGD) is recommended when cirrhosis is suspected. Management strategies for patients with esophageal varices that have not previously bled (primary prophylaxis) are summarized in Table 4.

Management of esophageal varices that have previously bled (secondary prophylaxis) includes a combination of a nonselective beta blocker with endoscopic variceal ligation (EVL). The dose of the nonselective beta blocker should be titrated to the maximal tolerated dose (resting heart rate of 55–60 beats/min or 25% decrease from baseline) and EVL should be repeated frequently (every 2 weeks or so) until complete variceal obliteration. Recurrence of esophageal varices may occur following EVL; thus surveillance EGD is recommended: first EGD performed 3 to 6 months after variceal obliteration and then at 6- to 12-month intervals.

Gastric varices are classified according to relationship with esophageal varices and location (Table 5).

Acute variceal hemorrhage occurs at a yearly rate of 5% to 15% and is associated with high mortality (at least 20% at 6 weeks). Adequate resuscitation is crucial in acute variceal hemorrhage with some additional precautions. Patients with variceal hemorrhage are at high risk for aspiration, and endotracheal intubation for airway protection should be performed prior to endoscopy. Overly aggressive expansion of blood volume should be avoided as it may result in increased portal venous pressure. A target hemoglobin level of between 7 and 9 g/dL is appropriate. Current guidelines recommend against correcting the international normalized ratio (INR) by use of fresh frozen plasma or recombinant factor VIIa, as this has not shown a clear benefit in individuals with acute variceal hemorrhage. There are no data to support or recommend against transfusion of platelets in this clinical scenario. Prophylactic broad-spectrum antibiotics (i.e., intravenous ceftriaxone [Rocephin]<sup>1</sup>) reduce bacterial infections, risk of rebleeding, and mortality. Administration of vasoactive drugs such as octreotide (Sandostatin)<sup>1</sup> or terlipressin (Lucassin)<sup>5</sup> results in increased rates of initial endoscopic control of bleeding, reduced 7-day mortality, and lower transfusion requirements. EGD is recommended within 12 hours and EVL is the endoscopic treatment of choice for management of esophageal varices. Balloon tamponade (i.e., Sengstaken Blakemore, Minnesota, or Linton-Nachlas tubes) or esophageal stenting are effective rescue therapies when variceal hemorrhage cannot be controlled with standard endoscopic therapy. The role of transjugular intrahepatic portosystemic shunt (TIPS) has expanded from a salvage intervention for individuals with recurrent variceal hemorrhage following EVL to an early “preemptive” intervention in carefully selected individuals at high risk for treatment failure (Child-Turcotte-Pugh class B or C but with MELD scores  $\leq 13$ ) following EVL, in which case it appears to be superior to beta blocker plus EVL. Patients who survive an episode of variceal hemorrhage should receive secondary prophylaxis with a combination of a nonselective beta blocker and repeated EVL until complete obliteration of the varices is achieved. Cyanoacrylate injection, TIPS, or balloon occluded transvenous obliteration (BRTO) are the treatments of choice for management of gastric variceal hemorrhage.

### Ascites

Ascites denotes pathologic accumulation of fluid in the peritoneal cavity (>25 mL) and is the most common complication of cirrhosis. Portal hypertension is required for development of cirrhotic ascites, as individuals with HVPG less than 12 mm Hg do not develop this complication. Importantly, sinusoidal hypertension appears to be a requirement for development of ascites, as prehepatic portal hypertension does not invariably result in development of this complication. Other relevant mechanisms include splanchnic vasodilatation and its consequences such as humorally mediated sodium retention and diminished free-water excretion by the kidneys, hypoproteinemia and reduced oncotic pressure, and disruption of normal lymphatic drainage in the liver due to extensive fibrosis.

Ascites can be demonstrated by physical examination when its volume is greater than 1500 mL, although ultrasonography can detect as little as 100 mL. Clinical signs include flank dullness on percussion, shifting dullness, and, if the amount of ascites present is large, demonstration of a fluid wave. A diagnostic paracentesis is mandatory in the following settings: new-onset ascites, change in clinical status including hospitalization of a patient with previously diagnosed ascites, and suggestion of spontaneous bacterial peritonitis (SBP). The following tests on the fluid are indicated: leukocyte count with differential (purple or lavender top tube with ethylenediaminetetraacetic acid [EDTA]), culture (on two blood culture bottles inoculated at the bedside), total protein, and albumin (red top tube). The appearance of the ascitic fluid may yield important clinical clues (Table 6). The serum-to-ascites albumin

**TABLE 6** Characteristics of Ascitic Fluid and Differential Diagnosis

FLUID APPEARANCE	DIFFERENTIAL DIAGNOSIS	BIOCHEMICAL HINTS ON FLUID ANALYSIS
Clear	Uncomplicated transudative ascites due to cirrhosis	WBC <500 cells/ $\mu$ L, PMN <250 cells/ $\mu$ L, SAAG $\geq 1.1$
Turbid/cloudy	Infection	PMN $\geq 250$ cells/ $\mu$ L
Bloody	Traumatic paracentesis, hemoperitoneum	RBC >10,000 cells/ $\mu$ L
Milky	Chylous ascites due to obstruction or trauma of lymphatic vessels or thoracic duct	Triglycerides >200 md/dL

PMN, Polymorphonuclear cells; SAAG, serum-to-ascites albumin gradient; WBC, white blood cell.

gradient (SAAG), obtained by subtracting the ascitic fluid albumin value from the serum albumin value, helps make a distinction between transudative and exudative ascites. A gradient of 1.1 g/dL or greater confirms portal hypertension as the etiology of ascites, whereas a value less than 1.1 g/dL suggests etiologies other than portal hypertension. The absolute number of polymorphonuclear (PMN) cells in the ascitic fluid is an important clue to SBP.

Cirrhotic ascites is unlikely to resolve without specific therapeutic intervention. Management of ascites is centered on sodium restriction rather than free-water restriction; total dietary intake of sodium should be less than 2000 mg (88 mmol) per day and compliance with this intervention can be documented by monitoring urinary sodium concentrations. A sodium-to-potassium concentration ratio of greater than 1 on a random urine sample correlates well with a 24-hour sodium excretion greater than 78 mmol/day and implies compliance with sodium restriction. Nevertheless, dietary restriction of sodium is efficacious in only 10% of patients, and enhanced natriuresis is typically needed to provide adequate control of ascites. Combining diuretics that work at different sites of the nephron is more effective than using a single agent. Aldosterone is upregulated in cirrhosis owing to diminished effective arterial blood volume and consequential increased renin and angiotensin activity, resulting in enhanced renal sodium and free water retention. Spironolactone (Aldactone) competitively inhibits aldosterone-dependent sodium-potassium exchange in the distal convoluted renal tubule and the collecting ducts. The recommended initial dose of spironolactone for patients with ascites due to portal hypertension is 100 mg orally daily. Administration of a loop-acting diuretic such as furosemide (Lasix)<sup>1</sup> is recommended in addition to spironolactone, as it potentiates natriuresis. The recommended initial dose for furosemide is 40 mg orally daily. Further increases in doses of diuretics should be made maintaining this 100:40 ratio to a maximum dose of 400 mg orally daily of spironolactone and 160 mg orally daily of furosemide, as it prevents hypo- or hyperkalemia. Renal function and electrolytes must be monitored regularly, particularly after dose modifications. Tender gynecomastia is an unpleasant side effect of spironolactone, and some patients may need to discontinue it, in which case amiloride (Midamor)<sup>1</sup> (10–20 mg orally daily) can be used. Two outcomes may occur in patients with ascites that is not adequately controlled with diuretics: (1) refractory ascites to maximum diuretic doses and sodium restriction, which typically recurs rapidly following large-volume paracenteses (LVP)

<sup>1</sup>Not FDA approved for this indication.

<sup>5</sup>Investigational drug in the United States.

<sup>1</sup>Not FDA approved for this indication.

and (2) inability to increase diuretic doses owing to symptomatic hypotension or deterioration in renal function as evidenced by increasing serum creatinine levels.

Repeated LVP with removal of more than 5 L of ascitic fluid per session is a safe and effective intervention to treat refractory ascites; however, mortality within 6 months is 20% once this develops, reflecting the severity of the underlying liver disease, and thus patients should be referred for evaluation for liver transplantation. Continued dietary restriction of sodium is necessary to avoid overly frequent LVP, and continuation of diuretics should be assessed on a case-by-case basis, taking into consideration potential benefits and adverse reactions. Expansion of plasma volume for patients undergoing LVP is endorsed by current guidelines and supported by data demonstrating reduced postparacentesis circulatory dysfunction and improved survival. Plasma volume should be expanded with albumin at a dose of 6 to 8 g/L of ascitic fluid removed during or immediately after LVP.

Insertion of TIPS corrects portal hypertension and offers an attractive alternative for amelioration of refractory ascites in selected patients. TIPS is a minimally invasive technique in which an endovascular stent is used to create an intrahepatic portocaval shunt and has replaced surgical shunts. Transplant-free survival is superior with TIPS compared with repeated LVP. Assessment of systolic and diastolic heart functions is recommended prior to TIPS as significant hemodynamic changes occur following the creation of the portosystemic shunt that can result in post-TIPS heart failure in individuals with underlying systolic or diastolic dysfunction.

The MELD score is a prognostic model that was initially developed to assess risk of death following TIPS placement, and data demonstrate that patients with a MELD score greater than 18 are at high risk of death; thus TIPS should be avoided in this population. TIPS results in hepatic encephalopathy in a high proportion of patients, but pharmacologic therapy typically provides adequate treatment for this complication.

### Spontaneous Bacterial Peritonitis

Cirrhosis and portal hypertension are associated with abnormal intestinal permeability leading to bacterial translocation resulting in SBP. The most commonly isolated microorganisms responsible for SBP are *Escherichia coli* (43%), *Klebsiella pneumoniae* (11%), *Streptococcus pneumoniae* (9%), other streptococcal species (19%), *Enterobacteriaceae* (4%), *Staphylococcus* (3%), and miscellaneous organisms depending on the region of the world (10%). A small-volume diagnostic paracentesis (30–60 mL) rather than LVP (which can increase the risk of hepatorenal syndrome in the setting of SBP) is mandatory for diagnosis of SBP and should be performed prior to administration of antibiotic therapy. Aerobic and anaerobic blood culture bottles should be inoculated at the bedside to avoid contamination and to increase diagnostic yield. Diagnosis of SBP is supported by the presence of 250 PMN/ $\mu$ L or more in the ascitic fluid without an obvious source of infection. Based on the PMN count and the microbiologic analysis of the ascitic fluid, four clinical scenarios summarized in Table 7 may be encountered.

Treatment of SBP is centered on administration of broad-spectrum empiric antibiotics with bactericidal activity against the likely infecting bacteria. Third-generation cephalosporins such as cefotaxime (Claforan) 2 g intravenously every 8 hours or ceftriaxone (Rocephin) 2 g intravenously daily offer appropriate antimicrobial coverage and are initial agents of choice for treatment of SBP. For patients allergic to beta-lactams, alternatives include fluoroquinolones such as levofloxacin (Levaquin),<sup>1</sup> although this agent exhibits less penetration into the ascitic fluid compared with a third-generation cephalosporin.

Current guidelines do not recommend routinely performing a follow-up paracentesis in patients with a typical initial presentation of SBP and when antibiotic therapy results in rapid clinical improvement. Repeat paracentesis, however, may be indicated to document sterility of ascitic fluid and reduction in the PMN count

**TABLE 7** Spontaneous Bacterial Peritonitis and Associated Conditions Based on Characteristics of the Ascitic Fluid

CLINICAL ENTITY	POLYMEROPHONUCLEAR CELL COUNT	CULTURE RESULTS	ANTIBIOTICS RECOMMENDED
Spontaneous bacterial peritonitis	$\geq 250$ cells/ $\mu$ L	Positive, single organism	Yes
Culture-negative neutrocytic ascites	$\geq 250$ cells/ $\mu$ L	Negative	Yes
Monomicrobial nonneutrocytic bacterascites	$< 250$ cells/ $\mu$ L	Positive, single organism	Yes
Polymicrobial bacterascites	$< 250$ cells/ $\mu$ L	Positive, multiple organisms	Yes

in patients with a slow or absent response to antibiotic therapy or in those with atypical microorganisms on initial culture results.

Plasma volume expansion with albumin is an important adjunct to antibiotic therapy in patients with SBP, as it decreases the incidence of acute kidney injury and reduces mortality. The physiologic effects of intravenous infusion of albumin include increased oncotic pressure with consequential expansion of the effective arterial blood volume, as well as its ability to bind a wide range of endogenous and exogenous ligands including bacterial lipopolysaccharides, reactive oxygen species, nitric oxide and other nitrogen reactive species, and prostaglandins, thus modulating the inflammatory response. Current guidelines recommend a selective approach for administration of intravenous albumin to patients with SBP. Specifically, this therapy should be reserved for high-risk individuals such as those with serum creatinine greater than 1 mg/dL, blood urea nitrogen greater than 30 mL/dL, or total serum bilirubin greater than 4 mg/dL. The recommended dosage of albumin is 1.5 g/kg of body weight within 6 hours of establishing the diagnosis of SBP and a second dose of 1 g/kg on day 3.

Following an episode of SBP, recurrence occurs in 69% of individuals within 1 year; thus secondary prophylaxis is indicated, and current guidelines recommend long-term use of norfloxacin (Noroxin)<sup>1</sup> 400 mg orally twice daily or trimethoprim/sulfamethoxazole (Bactrim DS)<sup>1</sup> one double-strength tablet orally daily. Risk factors for recurrent SBP include ascitic fluid total protein concentration less than 1 g/dL and gastroesophageal variceal hemorrhage. Recommended antibiotic prophylaxis for patients hospitalized with gastroesophageal variceal hemorrhage include ceftriaxone<sup>1</sup> 1 g intravenously daily; once the patient is able to tolerate oral antibiotics, this may be changed to trimethoprim/sulfamethoxazole<sup>1</sup> one double-strength tablet orally daily, ciprofloxacin (Cipro)<sup>1</sup> 500 mg orally daily, or norfloxacin<sup>1</sup> 400 mg orally twice daily for a total of 7 days of antibiotic therapy. Importantly, some data suggest an increased risk for SBP in patients with cirrhosis and ascites taking proton pump inhibitors; thus unnecessary use of these agents should be avoided. The exact mechanism by which acid suppression increases the risk of SBP in cirrhosis is unclear, but intestinal bacterial overgrowth, increased intestinal permeability, and altered intestinal immune response may play important roles.

### Hepatorenal Syndrome

The ominous significance of impaired renal function as a predictor of mortality in patients with cirrhosis is reflected by inclusion of the serum creatinine level in the MELD score. Renal dysfunction is commonly encountered in patients with cirrhosis,

<sup>1</sup>Not FDA approved for this indication.

particularly in those with hepatic decompensation. Some studies reported acute kidney injury (AKI) in approximately 20% of hospitalized patients with cirrhosis. The differential diagnosis of AKI in patients with cirrhosis is broad and includes common etiologies such as acute tubular necrosis and nephrotoxicity, but specific glomerulopathies associated with HBV and HCV must be considered (i.e., membranous and membranoproliferative glomerulonephritides). In addition, nonalcoholic steatohepatitis is characterized by a high prevalence of type 2 diabetes mellitus and systemic hypertension; thus patients are at increased risk for diabetic and hypertensive nephropathies. Hepatorenal syndrome (HRS) is one of several potential causes of AKI that occurs in patients with cirrhosis and portal hypertension but has also been recognized in patients with acute liver failure. Importantly, HRS is a diagnosis of exclusion, and other etiologies of AKI should be considered. The pathophysiology of HRS includes splanchnic vasodilatation causing a decline in renal perfusion with consequent reductions in the glomerular filtration rate and renal excretion of sodium (typically <10 mEq/L).

There are two distinct types of HRS depending on the acuity and severity of renal dysfunction. HRS-AKI, previously known as type I HRS, is characterized by rapid deterioration of renal function with at least a twofold increase in serum creatinine to a level greater than 2.5 mg/dL and is often precipitated by SBP, acute alcoholic hepatitis, or gastrointestinal hemorrhage. Criteria for diagnosis of HRS-AKI includes: (1) cirrhosis with ascites; (2) diagnosis of AKI according to the International Club of Ascites (ICA)-AKI criteria (increase in serum creatinine by  $\geq 0.3$  mg/dL within 48 hours, or increase in serum creatinine to  $\geq 1.5$  times baseline within 7 days); (3) absence of shock; (4) no sustained improvement of renal function (serum creatinine <1.5 mg/dL) following at least 2 days of diuretic withdrawal and volume expansion with albumin at 1 g/kg/day up to 100 g/day; (5) no current or recent exposure to nephrotoxic agents; and (6) absence of parenchymal renal disease as defined by proteinuria <0.5 g/day, no microhematuria (<50 red cells/high-power field), and normal renal ultrasonography. HRS-chronic kidney disease (CKD), previously referred to as type II HRS, is more indolent and is associated with less severe renal impairment, typically resulting in ascites resistant to diuretics. Prognosis also differs significantly for both types of HRS, with the median survival in the absence of liver transplantation being 2 weeks for HRS-AKI and 6 months for HRS-CKD.

Discontinuation of all diuretics and nephrotoxic agents is critical in patients with HRS. Plasma volume expansion with administration of intravenous albumin<sup>1</sup> at a dose of 1 g/kg of body weight (up to a maximum of 100 g/day) to increase renal perfusion is recommended. HRS is characterized by absent or minimal proteinuria (<500 mg/day) and normal urine sediment reflecting the lack of intrinsic renal disease. Renal ultrasonography is also recommended as it provides good assessment for chronic parenchymal changes that may suggest the presence of a chronic underlying renal disease and accurately rules out obstructive nephropathy.

Patients with HRS require either improvement in hepatic function or liver transplantation for renal function to recover. Pharmacotherapy can be used as a bridge to liver transplantation. Based on the pathophysiology of HRS-AKI, vasoconstriction with alpha-adrenergic agonists (i.e., midodrine [ProAmatine]<sup>1</sup> or norepinephrine [Levophed]<sup>1</sup>) or vasopressin analogs (i.e., terlipressin [Lucassin]<sup>5</sup>) is the therapy of choice along with plasma volume expansion achieved with intravenous albumin infusion. The use of norepinephrine is reserved for critically ill patients with HRS-AKI. Terlipressin is not licensed for use in the United States. The combination of the somatostatin analog octreotide<sup>1</sup> along with oral midodrine and intravenous albumin infusion appears to have beneficial effects based on results from small clinical trials and is currently recommended in the United States for noncritically ill patients with HRS-AKI. Data from a meta-analysis support the efficacy of vasoconstrictor therapy (terlipressin, octreotide +

**TABLE 8** West Haven Criteria for Grading Hepatic Encephalopathy

GRADE	LEVEL OF CONSCIOUSNESS	INTELLECT AND BEHAVIOR	NEUROLOGIC FINDINGS
0	Normal	Normal	Normal examination, abnormal neuropsychiatric testing
1	Mild lack of awareness	Shortened attention span	Impaired addition or subtraction, mild asterixis
2	Lethargy	Mild–moderate disorientation, inappropriate behavior	Severe asterixis, slurred speech
3	Somnolence but arousable	Severe disorientation, inexplicable behavior	Clonus, hyperreflexia, muscular rigidity
4	Coma	Coma	Decerebrate posture

midodrine, or norepinephrine) in combination with intravenous albumin in reducing short-term mortality in patients with type I HRS. The largest randomized clinical trial to date evaluating terlipressin in combination with albumin versus placebo plus albumin showed no difference in reversal of HRS-AKI, but the terlipressin group had greater improvement in renal function. Renal replacement therapy may be needed for patients with HRS not responding to pharmacologic therapy awaiting liver transplantation; however, mortality is exceedingly high and hypotensive episodes commonly occur during hemodialysis. Following liver transplantation, renal function improves in approximately 60% of patients with HRS.

### Hepatic Encephalopathy

Hepatic encephalopathy (HE) is a clinical syndrome of reversible neuropsychiatric impairment of varying severity. There is continuing controversy about its exact pathogenesis, but gut-derived toxins, including ammonia, are clearly implicated. Features of HE may be subclinical (covert) or clinically evident (overt) and include a wide range of neuropsychiatric signs and symptoms. The prevalence of HE varies depending on the clinical subtype and the severity of liver disease, with cumulative prevalence rates of up to 80% for covert HE and 30% to 40% for overt HE in patients with cirrhosis. Although the West Haven criteria are widely used for grading the severity of HE (Table 8), current guidelines recommend using three additional axes to classify HE based on the etiology, time course, and presence or absence of a precipitating factor (Table 9).

Covert HE is considered preclinical and encompasses minimal HE (features of HE that are only diagnosed by specialized neuropsychiatric testing) and grade 1 HE as per West Haven criteria. In contrast, overt HE is characterized by clinical findings of HE ranging from subtle changes in orientation and presence of asterixis to hepatic coma (grades 2–4 per West Haven criteria).

Specialized testing is necessary to establish a diagnosis of covert HE. The psychometric HE score is regarded as the gold standard, but additional assessments include the number connection test, computerized tests such as the inhibitory control test, the cognitive drug research battery, and electroencephalogram. These tests, however, are not applicable in routine clinical practice and usually require consultation with a specialist. A smartphone application that evaluates psychomotor speed and cognitive alertness has been developed and validated as a point-of-care screening tool for covert HE: EncephalApp Stroop.

<sup>1</sup>Not FDA approved for this indication.

<sup>5</sup>Investigational drug in the United States.

**TABLE 9** Classification of Hepatic Encephalopathy Based on Four Different Axes

TYPE OF HEPATIC ENCEPHALOPATHY	GRADE		TIME COURSE	SPONTANEOUS/PRECIPITATED
A (acute liver failure)	MHE	Covert	Episodic (one episode in 6 months)	Spontaneous: no precipitating factor discovered
B (portosystemic bypass)	1	Covert	Recurrent (more than one episode in 6 months)	Precipitated by one or more specific factors
	2	Overt	Persistent (no return to normal baseline)	
C (cirrhosis)	3	Overt		
	4	Overt		

From Patidar KR, Bajaj JS: Covert and overt hepatic encephalopathy: diagnosis and management. *Clin Gastroenterol Hepatol* 13:2048–2061, 2015.

The diagnosis of overt HE is clinical and supported by the presence of a wide spectrum of global neurologic deficits. Severe HE, grades 3 and 4 West Haven criteria, should prompt attention to airway protection, and endotracheal intubation ought to be considered.

There are no laboratory markers that can be accurately used to diagnose overt HE. Blood ammonia levels lack sensitivity and specificity and correlate poorly with the severity of encephalopathy. Furthermore, a normal ammonia level does not preclude the presence of HE, and venous ammonia levels are influenced by several other factors including phlebotomy technique and handling of the blood specimen. Efforts must be directed at identifying potential precipitating factors for HE, such as compliance with treatment of HE, new medications, gastrointestinal bleeding, AKI, electrolyte imbalances, and infections.

Management of covert and overt HE is centered on the use of nonabsorbable disaccharides and antibiotics. Lactulose (Enulose) is the most widely used nonabsorbable disaccharide. Although the exact mechanism responsible for its therapeutic efficacy is still unclear, this agent is degraded by colonic microbiota to short-chain organic acids, resulting in acidification of the intestinal lumen and increased conversion of absorbable ammonia to nonabsorbable ammonium. The starting dosage for lactulose depends on the acuity and severity of HE but must be titrated to achieve two to four soft bowel movements per day. For patients who cannot tolerate oral administration (i.e., high risk for aspiration or coma), lactulose can be administered as an enema (300 mL of lactulose solution 10 g/15 mL in 700 mL of saline or water). The cathartic effects of nonabsorbable disaccharides may result in profuse diarrhea, dehydration, and hypernatremia. Rifaximin (Xifaxan) is a broad-spectrum antibiotic with activity against gram-positive, gram-negative, and anaerobic enteric bacteria that can be used in addition to lactulose for prevention of recurrent episodes of HE. Data from clinical trials show marked reductions in HE-related hospitalization and significant improvements in health-related quality of life in patients treated with a combination of lactulose and rifaximin without an increased rate of adverse events.

The efficacy and safety of other pharmacologic therapies such as probiotics,<sup>7</sup> branched-chain amino acids<sup>7</sup>, L-ornithine L-aspartate (LOLA),<sup>7</sup> ammonia scavengers, and other laxatives (i.e., polyethylene glycol [MiraLax]<sup>1</sup>) need to be further confirmed by clinical trials. Because of concerns about oto- and nephrotoxicity, neomycin is no longer used.

Creation of a portosystemic shunt (now usually with TIPS) for management of complications of portal hypertension is associated with a 13% to 36% incidence of overt HE. Careful patient selection prior to insertion of TIPS and medical therapy with nonabsorbable disaccharides with or without additional rifaximin remain standard therapy; however, despite compliance, approximately 3% to 7% of patients have recurrent or persistent overt HE post-TIPS. For these patients, endovascular techniques aimed at decreasing the size of the shunt should be considered.

Liver transplantation offers definitive therapy for patients with end-stage liver disease, resulting in restoration of hepatic synthetic function and resolution of complications associated with portal hypertension. However, residual cognitive impairments may persist following liver transplantation, adversely impacting health-related quality of life.

### Hepatocellular Carcinoma

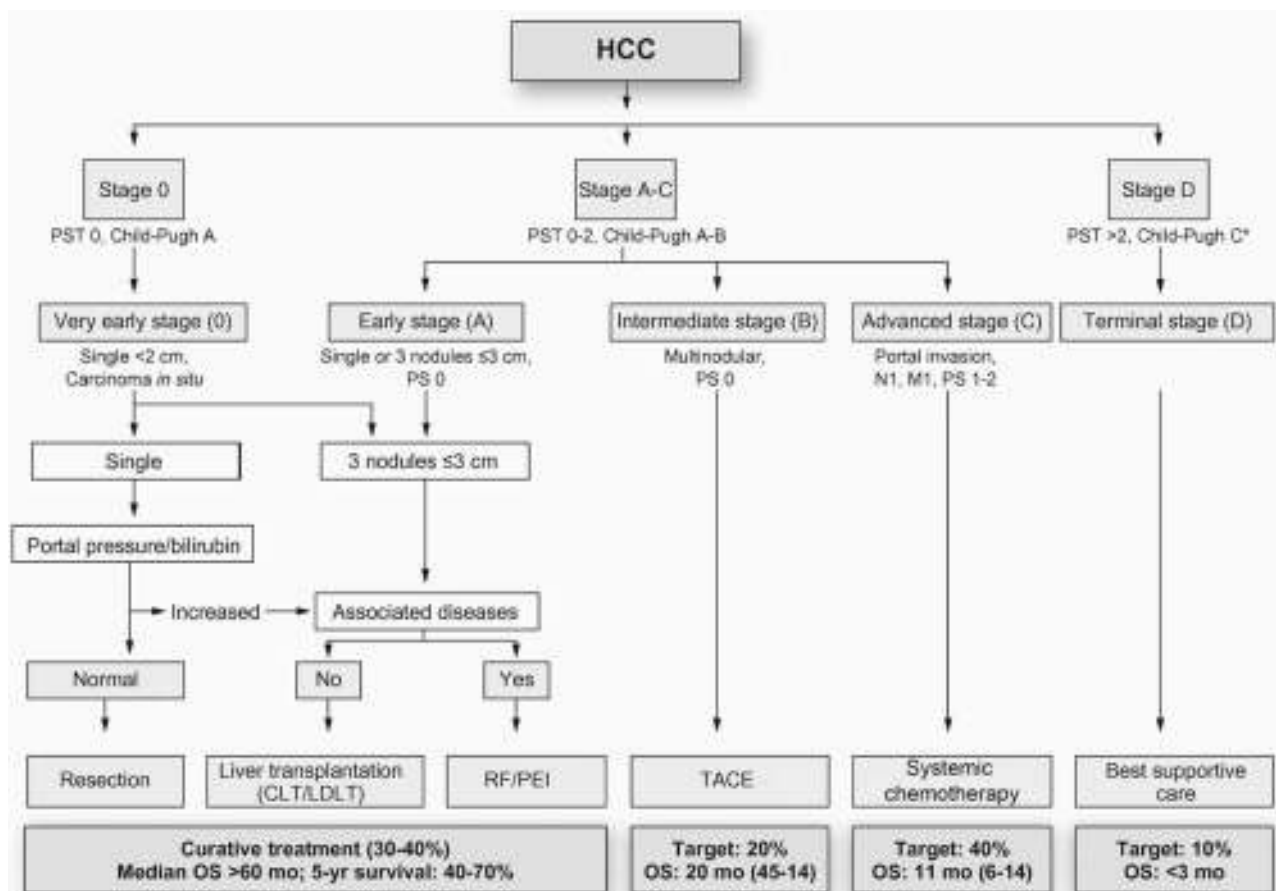

Hepatocellular carcinoma (HCC) is the most common primary hepatic malignancy in adults, currently representing the fifth most common cancer and the second leading cause of cancer-related death worldwide. The epidemiology of HCC varies significantly by region and ethnicity. The majority of patients with HCC in Western populations (95%) have underlying cirrhosis (predominantly due to chronic HCV infection, alcohol-related liver disease, and nonalcoholic steatohepatitis), thus limiting applicability of surgical resection (see later) as curative therapy. In contrast, only 60% of patients with HCC in Eastern populations have cirrhosis, largely reflecting the high prevalence of chronic HBV infection and its oncogenic potential. Regions of the world with intermediate to high incidence of this malignancy (more than 3 cases per 100,000 persons per year) include Asia, sub-Saharan Africa, and Western Europe. North and South America have been typically considered low-incidence regions; however, over the past two decades there has been a steady increase in the incidence of HCC, particularly in the United States.

Current guidelines endorse implementation of surveillance strategies for early diagnosis of HCC in individuals at risk for this malignancy and recommend the use of ultrasonography every 6 months as the primary surveillance modality. Populations at risk for HCC that benefit from surveillance include individuals with cirrhosis of any etiology, Asian males with chronic HBV over age 40, Asian females with chronic HBV over age 50, patients with chronic HBV and family history of HCC, African/North American Black populations with chronic HBV, and individuals with stage 4 primary biliary cholangitis.

HCC can be accurately diagnosed without the need for liver biopsy by contrast-enhanced multiphase cross-sectional imaging modalities such as computed tomography (CT) or magnetic resonance imaging (MRI) based on specific patterns of contrast enhancement of the tumor in relation to the hepatic parenchyma. Key diagnostic characteristics for HCC on CT or MRI are contrast enhancement of the tumor during the early arterial phase and “washout” of contrast from the tumor during the portal venous and delayed phases. Additional features include presence of a capsule and interval growth of the lesion when previous imaging studies are used for comparison. Biopsy of the tumor carries a small risk for tumor seeding in the biopsy-needle tract (approximately 3%) and is rarely required to diagnose HCC owing to high accuracy of CT and MRI. The use of serum alpha-fetoprotein (AFP) has been controversial for routine surveillance owing to its low sensitivity and poor specificity; however, data from a recent meta-analysis suggest that addition of AFP to ultrasound increases the sensitivity of HCC detection. If not previously available, once a

<sup>1</sup>Not FDA approved for this indication.

<sup>7</sup>Available as a dietary supplement.

**Figure 2** Barcelona Clinic Liver Cancer (BCLC) staging system for hepatocellular carcinoma (HCC). *CLT*, Cadaveric liver transplantation; *LDL*, living donor liver transplantation; *OS*, overall survival; *PEI*, percutaneous ethanol injection; *PST*, performance status; *RF*, radiofrequency ablation; *TACE*, transarterial chemoembolization. From EASL-EORTC Clinical Practice Guidelines: Management of hepatocellular carcinoma, *J Hepatol* 56(4):908–943, 2012.

focal liver lesion is identified on imaging studies, AFP should be obtained as an additional diagnostic tool. AFP levels greater than 200 ng/mL are highly specific for HCC, and longitudinal follow-up of serum levels permits evaluation of response to therapeutic interventions. Additional serologic markers for HCC include the L3 isoform of AFP (AFP-L3) and des-gamma carboxy prothrombin (DCP); however, further validation of these tests for surveillance of individuals at risk for HCC is still required.

The Barcelona Clinic Liver Cancer (BCLC) staging system can be used to categorize patients with HCC and to assist with therapeutic decisions (Figure 2). Surgical resection of HCC is reserved for patients with a single lesion and no evidence of cirrhosis or portal hypertension. Locoregional therapies include radiofrequency ablation, percutaneous ethanol injection, transarterial chemoembolization, radioembolization, and microwave ablation. These modalities are typically used for patients with early and intermediate stages (BCLC stages A and B, respectively). Liver transplantation is an effective treatment for patients with cirrhosis and HCC within the so-called Milan criteria: a single lesion up to 5 cm or no more than three lesions with the largest one being less than 3 cm, and in the absence of portal venous invasion or metastatic disease. Liver transplantation for HCC within these limits results in long-term survival equivalent to that seen in patients with cirrhosis but no HCC. Under the current organ allocation policy in the United States, patients with HCC within Milan criteria are listed for liver transplantation with their biologic MELD score (calculated by the MELD formula and without exception points) for 6 months, after which time they automatically accrue MELD exception points and the score increases to 28, with 10% increments thereafter every 3 months until the maximum score of 34 is reached. MELD exception points are granted to patients

with HCC 2 cm or greater in an effort to balance risk of death that is not adequately represented by the degree of hepatic dysfunction. For patients with HCC listed for liver transplantation, the use of locoregional therapies is recommended to prevent tumor progression that may result in dropout from the waiting list. Furthermore, active surveillance is recommended to evaluate for tumor recurrence or progression, development of new lesions, and metastatic disease while awaiting liver transplantation.

The number of systemic treatments licensed for use in patients with HCC has expanded significantly in recent years, with multiple options now available for first- and second-line therapy. First-line agents include sorafenib (Nexavar), nivolumab (Opdivo) plus pembrolizumab (Keytruda), lenvatinib (Lenvima), and bevacizumab (Avastin) plus atezolizumab (Tecentriq), cabozantinib (Cabometyx), and ramucirumab (Cyramza). Second-line therapies include nivolumab (Opdivo) either as monotherapy or in combination with ipilimumab (Yervoy), pembrolizumab (Keytruda), regorafenib (Stivarga), cabozantinib (Cabometyx), and ramucirumab (Cyramza). Adverse reactions, tolerability, and potential benefits must be carefully weighed and individualized according to overall health and performance status, as well as severity of hepatic dysfunction. The survival benefit of these agents is modest.

#### Portopulmonary Hypertension

Pulmonary artery hypertension in a patient with established portal hypertension is indicative of portopulmonary hypertension (PPHTN), but other etiologies of pulmonary hypertension must be excluded prior to establishing this diagnosis. The prevalence of PPHTN varies depending on the severity of liver disease and has been reported in 0.7% of patients with cirrhosis but can be as high as 12.5% in patients undergoing evaluation for liver transplantation.

The exact pathophysiology of PPHTN remains enigmatic, but increased exposure to humoral vasoconstrictors in the pulmonary vasculature due to portosystemic shunting and hyperdynamic circulation is among the most widely accepted hypotheses. Histologic findings in the pulmonary vasculature of patients with PPHTN are indistinguishable from those found in idiopathic pulmonary arterial hypertension and include medial hypertrophy with remodeling of the pulmonary artery walls and occasional *in situ* microthrombosis.

The majority of patients with PPHTN remain largely asymptomatic for extended periods of time. Symptoms associated with PPHTN are similar to those of other types of pulmonary arterial hypertension and include dyspnea on exertion, syncope, chest pain, fatigue, hemoptysis, and orthopnea. Physical examination may demonstrate jugular venous distention and lower extremity edema, the latter typically being out of proportion to the severity of ascites. Cardiopulmonary auscultation usually reveals normal clear breath sounds throughout both lung fields, an accentuated pulmonic component of the second heart sound, and a systolic murmur located along the left sternal border that is accentuated with inspiration (tricuspid regurgitation). Chest radiographs may demonstrate right ventricular enlargement and a prominent pulmonary artery.

The diagnostic workup for PPHTN should begin with thoracic echocardiography, which provides an estimate of right ventricular and pulmonary arterial pressures and rules out left ventricular dysfunction. An estimated right ventricular systolic pressure greater than 50 mm Hg is typically used as a threshold to obtain more accurate direct hemodynamic measurements through right heart catheterization. Hemodynamic criteria used to diagnose PPHTN include mean pulmonary artery pressure (mPAP) greater than 25 mm Hg, pulmonary capillary wedge pressure less than 15 mm Hg, and pulmonary vascular resistance greater than or equal to 240 dyn  $\cdot$  s  $\cdot$  cm<sup>-5</sup> by right heart catheterization.

Pharmacologic therapy has been extrapolated from studies performed in patients with idiopathic pulmonary arterial hypertension and includes endothelin receptor antagonists (bosentan [Tracleer]<sup>1</sup> and ambrisentan [Letairis]<sup>1</sup>), phosphodiesterase inhibitors (sildenafil [Revatio]<sup>1</sup>), and prostacyclin analogs (epoprostenol [Flolan]<sup>1</sup> and iloprost [Ventavis]<sup>1</sup>).

Survival in PPHTN correlates with the severity of right ventricular dysfunction, and the safety and efficacy of liver transplantation are reliant on the severity of pulmonary arterial hypertension. Liver transplantation may be offered to selected patients with PPHTN but is typically contraindicated in those with mPAP greater than 35 mm Hg despite medical management, particularly if right ventricular dysfunction is present, due to considerable perioperative mortality.

### Hepatopulmonary Syndrome

Hepatopulmonary syndrome (HPS) is characterized by hypoxemia due to intrapulmonary vascular dilatations with right-to-left shunting in the setting of cirrhosis and portal hypertension. Although intrapulmonary vasodilatation is encountered in over 50% of patients with cirrhosis undergoing evaluation for liver transplantation, only 15% to 30% have hypoxemia and true HPS. The most widely accepted pathophysiologic mechanism responsible for HPS is increased pulmonary synthesis of nitric oxide. Similar to PPHTN, the majority of patients with HPS are largely asymptomatic.

Clinical manifestations include dyspnea of insidious onset and two characteristic clinical findings: platypnea and orthodeoxia (worsening dyspnea and hypoxemia in upright posture, respectively). Other, more obvious but nonspecific clinical findings include spider angiomas, digital clubbing, and cyanosis. Screening for HPS relies on point-of-care oximetry indicating peripheral arterial oxygen saturation (SpO<sub>2</sub>) less than 96% at rest and at sea level. Hypoxemia must be confirmed by arterial blood gas analysis demonstrating an arterial partial pressure of oxygen (PaO<sub>2</sub>) less than 70 mm Hg and a widened alveolar-arterial oxygen gradient greater than or equal to 15 mm

Hg ( $\geq 20$  mm Hg for patients 65 years of age or older). Importantly, blood for arterial gas analysis should be obtained with the patient sitting upright, at rest, and breathing ambient air. After establishing a diagnosis of hypoxemia, documentation of pulmonary vascular dilatations with right-to-left blood shunting is necessary. Two-dimensional contrast-enhanced thoracic echocardiography offers high sensitivity and is widely available. Agitated saline to produce microbubbles is injected intravenously as contrast, and under normal cardiopulmonary physiology the gas bubbles are rapidly seen in the right atrium and ventricle but then diffuse into alveoli during normal flow through the pulmonary capillaries. In patients with HPS, the presence of intrapulmonary right-to-left shunting due to vascular dilatations results in the presence of the microbubbles opacifying the left heart chambers at least three heartbeats after being seen in the right ventricle. Intracardiac right-to-left blood shunting (i.e., atrial or ventricular septal defects, patent foramen ovale) should be suspected if contrast is seen in the left heart within three heartbeats. Radionuclide lung perfusion scintigraphy using technetium-labeled macroaggregated albumin particles (<sup>99m</sup>Tc-MAA scan) is less sensitive than contrast-enhanced echocardiography for diagnosis of HPS but is more specific and permits accurate quantification of the intrapulmonary shunt fraction, even in the presence of coexisting intrinsic lung disorders. Shunt fractions greater than 6% confirm the diagnosis of HPS in the appropriate clinical setting.

HPS is associated with increased mortality and diminished quality of life compared with patients with cirrhosis but no HPS. Following the diagnosis of HPS, median survival is 10.6 months; thus patients with HPS should undergo prompt liver transplantation evaluation. Under current organ allocation policies by the United Network for Organ Sharing (UNOS), patients with HPS and PaO<sub>2</sub> less than 60 mm Hg are eligible for standard MELD exception score of 22 points at the time of listing, regardless of their calculated (biologic) MELD score, and a 10% mortality equivalent increase in points every 3 months. Liver transplantation remains the definitive therapy for HPS based on marked improvement or even resolution of hypoxemia in more than 85% of transplant recipients; however, clinically meaningful changes may be slow and take up to 1 year following transplantation.

### Hepatic Hydrothorax

Hepatic hydrothorax is a transudative process leading to accumulation of more than 500 mL of fluid in the pleural space in patients with cirrhosis and portal hypertension in the absence of primary cardiopulmonary disease. Hepatic hydrothorax is thought to result from passage of ascitic fluid from the peritoneal cavity into the pleural spaces (typically on the right in up to 85% of patients) via subcentimeter defects and/or microscopic fenestrations in the tendinous portion of the diaphragm and is facilitated by negative intrathoracic pressure generated during inspiration. Clinical features include dyspnea, nonproductive cough, pleuritic chest pain, and even hypoxemia and hypotension in cases of tension hydrothorax. Fluid analysis demonstrates similar chemical characteristics than ascites: high serum-to-pleural fluid albumin gradient ( $>1.1$  g/dL) and low total protein concentration ( $<2.5$  g/dL).

Management of noninfected hepatic hydrothorax follows the same principles as those for ascites: sodium restriction, diuretics, repeated thoracenteses, and placement of TIPS for refractory cases. Importantly, indwelling pleural catheters should be avoided because of the high risk for complications including severe infections that may jeopardize possible liver transplant candidacy in the future.

In patients with fevers and worsening pleuritic chest pain, spontaneous bacterial empyema (SBEM) must be excluded. Similar to the diagnostic criteria for SBP, a diagnosis of SBEM is established by a PMN count greater than 250 cells/ $\mu$ L and a positive bacterial culture in the absence of a parapneumonic effusion. In cases in which bacterial cultures are negative, a PMN count threshold of greater than 500 cells/ $\mu$ L should be

<sup>1</sup>Not FDA approved for this indication.

used to diagnose SBEM. Microorganisms responsible for this infection are also similar to those responsible for SBP; thus third-generation cephalosporins remain the antibacterial agents of choice for empiric therapy.

### Liver Transplantation

Liver transplantation is effective in salvaging patients with acute liver failure (ALF) and decompensated cirrhosis, as well as selected patients with HCC (see earlier), with excellent short- and long-term outcomes. Survival after 1 and 5 years following liver transplantation is approximately 80% to 90% and 60% to 75%, respectively. Cirrhosis per se is not an indication to initiate evaluation for liver transplantation, as it is not associated with survival benefit in patients with low MELD scores. Consequently, patients should be referred for liver transplantation evaluation when the MELD score is 15 or higher or when an index complication of cirrhosis such as ascites or variceal hemorrhage occurs. Organ allocation in the United States and many other countries is based on disease severity as reflected by the MELD score for patients 12 years of age or older and the Pediatric End-Stage Liver Disease (PELD) score for patients younger than 12 years of age (includes international normalized ratio, bilirubin, albumin, and growth failure). The most recent modification of the MELD score now includes serum sodium in the mathematical equation (MELD-Na), as hyponatremia is an independent predictor of mortality in patients with cirrhosis. Some etiologies of cirrhosis result in diminished survival that is not accurately predicted by the MELD score or are associated with extremely poor quality of life; thus MELD exceptions exist. Standardized MELD exception criteria are summarized in Table 10. For patients with complications related to liver disease and associated increased morbidity and mortality not adequately reflected by the MELD score and not qualifying for standard MELD exceptions, additional points may be petitioned by the transplant center to the regional review board on a case-by-case basis with no guarantee that they will be granted. Some examples of conditions that may receive additional MELD points include recurrent bacterial cholangitis in patients with primary sclerosing cholangitis, intractable and debilitating pruritus in patients with primary biliary cholangitis, ascites refractory to maximum-tolerated doses of diuretics, HE refractory

to medical therapy, and recurrent variceal hemorrhage despite adequate therapy.

Contraindications to liver transplantation continually evolve over time. Relative contraindications are usually associated with suboptimal outcomes following liver transplantation and vary widely across different transplant centers. Absolute contraindications imply that a successful outcome following liver transplantation is unlikely; thus it should not be pursued (Table 11).

ALF is an uncommon but important indication for liver transplantation owing to the high mortality associated with this condition. Although a significant proportion of patients with ALF may have spontaneous recovery, its clinical course is usually unpredictable and early referral for liver transplantation is recommended, regardless of the etiology. Patients with ALF have the highest priority for organ allocation if they meet specific criteria for UNOS status 1A (Table 12).

Evaluation for liver transplantation is a multidisciplinary process carried out over multiple encounters aimed to unveil additional medical, surgical, behavioral, social, and economic issues that may affect liver transplantation candidacy and/or outcomes. Once the patient's candidacy is deemed appropriate, formal listing occurs with UNOS. Blood type (ABO) is the major determinant for organ compatibility, and appropriate size (based on body weight) must be taken into consideration.

Living-donor liver transplantation was developed as an alternative owing to ongoing shortage of deceased-donor organs; however, living donation carries important risks for the donor that must be carefully taken into consideration. The advantages

**TABLE 10** Medical Conditions That Qualify for Standard MELD Exception Points

CONDITIONS	REMARKS
Hepatocellular carcinoma	T2 lesions (at least 2 cm in diameter) within Milan criteria
Hepatopulmonary syndrome	PaO <sub>2</sub> <60 mm Hg on ambient air
Portopulmonary hypertension	Mean pulmonary arterial pressure <35 mm Hg with treatment
Familial amyloid polyneuropathy	Confirmed by DNA analysis and histology
Primary hyperoxaluria	Need simultaneous liver–kidney transplant
Cystic fibrosis	Forced expiratory volume in 1 s (FEV <sub>1</sub> ) <40%
Hilar cholangiocarcinoma	Stage I or II, liver transplantation center must have a UNOS-approved protocol
Hepatic artery thrombosis	Within 14 days of liver transplantation, not meeting criteria for status 1A

MELD, Model for End-Stage Liver Disease; UNOS, United Network for Organ Sharing.

**TABLE 11** Absolute Contraindications to Liver Transplantation

CONTRAINDICATIONS TO LIVER TRANSPLANTATION
Uncontrolled sepsis
Acquired immunodeficiency syndrome
Active alcohol or substance abuse
Advanced cardiac or pulmonary disease
Intrahepatic cholangiocarcinoma
Hepatic hemangiosarcoma
Hepatocellular carcinoma with metastasis
Extrahepatic malignancy
Anatomic abnormalities that preclude liver transplantation
Lack of social support
Persistent nonadherence to medical care

**TABLE 12** Criteria for Status 1A Designation in Patients With Acute Liver Failure

Age >18 years
Life expectancy <7 days without liver transplantation
Onset of encephalopathy within 8 weeks of first symptom of liver disease
Absence of preexisting liver disease
Admission to intensive care unit, and one of the following: <ul style="list-style-type: none"> <li>• Ventilator dependence</li> <li>• Requirement of renal replacement therapy</li> <li>• International normalized ratio &gt;2</li> </ul>
Fulminant Wilson disease
Primary graft nonfunction
Hepatic artery thrombosis

**TABLE 13** Advantages and Disadvantages of Living-Donor Liver Transplantation

ADVANTAGES	DISADVANTAGES
Thorough donor screening process	Only offered in selected liver transplantation centers
Elective timing of liver transplantation permitting optimization of therapies	Donor morbidity and mortality
Diminished wait time with consequent reduction in dropout from the waiting list	Higher risk for biliary complications in the donor and recipient
Minimal cold ischemia time	

and disadvantages of living-donor liver transplantation are summarized in [Table 13](#).

Additional approaches to try to expand donor organ supply include donation after cardiac death, using grafts from hepatitis B core antibody–positive and hepatitis C–positive donors, and splitting a graft for use in adult and pediatric recipients.

Adequate long-term immunosuppression prevents graft rejection and is currently centered on the use of calcineurin inhibitors (tacrolimus [Prograf] primarily, and less often cyclosporine [Neoral]) with or without concomitant antimetabolite agents such as mycophenolic acid (Myfortic) or its prodrug mycophenolate mofetil (CellCept). Additional agents include inhibitors of the mammalian target of rapamycin (mTOR) such as sirolimus (Rapamune)<sup>1</sup> and everolimus (Zortress).

Long-term care of liver transplant recipients should not by any means focus exclusively on graft function and prevention of rejection, but rather be comprehensive and aimed at maintaining an overall good state of health by instituting preventive health strategies and monitoring for other complications that may ensue, such as diabetes mellitus, hypertension, dyslipidemia, renal dysfunction, obesity, and alcohol relapse, among many others.

<sup>1</sup>Not FDA approved for this indication.

## DIVERTICULA OF THE ALIMENTARY TRACT

Aaron D. Sinclair, MD

### CURRENT DIAGNOSIS

- Endoscopy or barium swallow study may be used in the evaluation of most upper alimentary tract diverticula.
- Symptomatic small intestinal diverticula are difficult to diagnose and require a high index of suspicion and radiographic examination (nuclear medicine scans, capsule endoscopy, or computed tomography scans).
- Diverticulitis of the colon is most accurately identified and the treatment planned with computed tomography of the abdomen and pelvis.
- Diverticulitis of the colon that is slow to resolve may require additional imaging or direct visualization with endoscopy to identify an alternative diagnosis.

### CURRENT THERAPY

- Most asymptomatic diverticula are identified incidentally and may require only monitoring.
- Surgical management of symptomatic diverticula may require surgical resection.
- Early in the disease process, uncomplicated diverticulitis of the colon may be managed on an outpatient basis with a conservative no-intervention approach or oral antibiotics.
- Complicated diverticulitis of the colon should be managed in conjunction with a surgeon and in the hospital with intravenous antibiotics.

A diverticulum is an abnormal sacular protrusion from the wall of the alimentary tract. Diverticula may be classified as either true or false. The wall of the alimentary tract is composed of submucosal, mucosal, and muscular layers. A false diverticulum is a protrusion of the submucosa and mucosa through a defect in the muscular wall of the alimentary tract. A true diverticulum is a protrusion of all layers of the alimentary tract wall. Many diverticula are asymptomatic and require no treatment. Some diverticula cause symptoms depending on their anatomic location or associated pathophysiologic complications (e.g., obstruction, infection, inflammation, or bleeding). This chapter categorizes alimentary canal diverticula by their location.

### Esophagus

#### Zenker Diverticulum

Zenker diverticulum is a false diverticulum that develops in the upper posterior esophagus in an area known as Killian triangle, located between the inferior pharyngeal constrictors and the cricopharyngeal muscles. Zenker diverticulum typically presents after age 60 and has a male predominance for reasons that are unclear. It affects only 2 per 100,000 patients per year. Although it can be asymptomatic for years before the development of symptomatology, patients may experience dysphagia, aspiration, and regurgitation of undigested food. The exact cause is unclear, but proposed mechanisms suggest a dysfunction in coordinated swallowing muscle movement and increased intraluminal pressure in the esophagus. There may be an additive component of long-term upper esophageal sphincter irritation from acid reflux.

Diagnosis is primarily made through barium swallow, although small diverticula may be missed (Figure 1). Although endoscopic direct visualization is possible, caution should be exercised owing to the risk of perforation. Small asymptomatic diverticula can be monitored. Zenker diverticulum that are less than 2 cm but symptomatic should be evaluated for possible surgical repair. Zenker

diverticulum greater than 2 cm in size, regardless of symptomatology, should be surgically evaluated and repair considered. Methods for closure include endoscopic (flexible and rigid) diverticulostomy and myotomy or traditional surgical resection. Although most patients (>90%) demonstrate symptom improvement, recurrence rates can be as high as 35%. Surgery is associated with much higher morbidity and mortality than endoscopic approaches. Emerging technologies have used different techniques (harmonic scalpel, stapler, etc.) during endoscopic repair. Morbidity and mortality are largely operator dependent.

#### Traction Diverticulum

Traction diverticula are the only true diverticula of the esophagus. Traction diverticula are rare. Their size tends to stay less than 2 cm. Owing to the proposed mechanism of formation, traction diverticula are isolated to the middle third of the esophagus. It is not fully clear how traction diverticula form. One proposed mechanism is related to a precedent pulmonary infection, most commonly tuberculosis or histoplasmosis, with resultant mediastinal lymph node formation. After the active infection subsides, resultant fibrosis and scarring between the tissues surrounding the mediastinal lymph nodes and esophagus occur. Initially, a small diverticulum develops from this fibrosis, which produces “traction” or a lack of mobility. Diverticular progression results when age-related changes from the dysfunction of coordinated swallowing muscle movement and increased intraluminal pressure in the esophagus develop. Surgical management is rarely needed unless these diverticula become symptomatic or complications, such as fistulas, occur.

#### Epiphrenic Diverticulum

Epiphrenic diverticula are false diverticula of the distal esophagus affecting only 0.015% of the general population. They are thought to arise secondary to mucosal injury from gastroesophageal reflux and muscle dysmotility. They occur within 10 cm of the gastroesophageal junction, and symptoms include dysphagia, spasmodic chest pain, and gastroesophageal reflux. There does not appear to be a correlation with between diverticular size and symptomatology. With progression of diverticular size, obstruction can become a potential complication. Diagnostic measures start with barium swallow and may be followed with additional tests, including endoscopy, 24-hour pH probe, and esophageal manometry.

**Figure 1** Zenker diverticulum. (Image courtesy Gastrolab—The Gastrointestinal Site. <http://www.gastrolab.net> [Accessed August 25, 2014].)

Management depends on patient symptoms and size of the diverticulum. If small (<5 cm) and asymptomatic, routine clinical and endoscopic surveillance is permissible. However, any symptomatology necessitates surgical evaluation and repair. Surgical options include open resection and laparoscopy. Partial fundoplication may be indicated, depending on the severity of gastroesophageal reflux present as indicated by ancillary testing of a 24-hour pH probe. Less invasive endoscopic myotomy procedures, successfully used to treat Zenker diverticulum, are judiciously being used to treat epiphrenic diverticulum.

## Stomach

### Gastric Diverticula

Gastric diverticula are rare, with an endoscopic incidence of 0.01%. Gastric diverticulum may be either true or false in nature. True gastric diverticulae (70% to 75%) are typically congenital and situated along the dorsal wall of the fundus within 2 to 3 cm of the gastroesophageal junction. False diverticulae, which are less common and typically acquired, are located around the antrum of the stomach. Most are asymptomatic and small (<3 cm). Symptoms may include epigastric pain, dyspepsia, and emesis. Rarely, ulcerations, perforations, or bleeding can occur. Diagnosis involves endoscopy, barium swallow, or contrast-aided computed tomography (CT) scan. If symptomatic, typical treatment includes a proton pump inhibitor and monitoring for symptom improvement. Continued symptoms should prompt endoscopic evaluation with biopsies of suspicious lesions with raised or irregular borders. Gastric cancers have been reported in and around gastric diverticulum. Persistent symptoms may necessitate gastrectomy of the diverticulum, especially if concerns about cancer exist.

## Small Intestine

### Duodenal Diverticula

Diverticula located in the duodenum are relatively common, affecting up to 22% of the general population (Figure 2). Duodenal diverticula may be either true or false diverticula. The most common location is the second portion of the duodenum. Although usually asymptomatic, ulcerative bleeding, perforation, or intermittent obstruction, particularly after eating, may occur. The size and position of the diverticula may lead to complications such as obstruction of the sphincter of Oddi and/or impingement of hepatobiliary tree drainage. This impingement may result in jaundice, right upper quadrant pain, or infection signs/symptoms similar to cholecystitis. Obstruction of the bile duct leading to cholangitis is referred to as Lemmel syndrome.

Duodenal diverticula may be identified on barium swallow, contrast-enhanced CT, magnetic resonance imaging, or endoscopy. Duodenal diverticula found incidentally do not require

**Figure 2** Duodenal diverticulum. (Image courtesy Gastrolab—The Gastrointestinal Site. <http://www.gastrolab.net> [Accessed August 25, 2014].)

treatment. If symptoms arise, endoscopic evaluation and surgical resection should be considered. However, intervention should be considered with caution owing to a high risk (30%) of complications, in particular fistula formation and mortality.

### Jejunal and Ileal Diverticula

Jejunal and ileal diverticula occur throughout the length of the small intestine in 1% to 2% of the population. There does not appear to be any statistically significant relationship with morbidity or mortality of these types of diverticula with respect to location, gender, size, number, and so forth. These false diverticula are located predominantly where the blood vessels penetrate the muscular wall of the mesenteric side of the bowel. Most are noted incidentally on radiographic studies, but some manifest with symptoms secondary to bleeding, obstruction, or infection. These symptoms are believed to be due to bacterial overgrowth that may occur within the cavity of the diverticulum. Diagnosis can be made with capsule endoscopy or a small bowel barium contrast follow through study, although some may be noted on MRI with intravenous contrast and/or CT with intravenous and oral contrast. Advanced endoscopic procedures such as push enteroscopy and double balloon endoscopy can be used to further evaluate symptomatic diverticula.

Asymptomatic jejunal and ileal diverticula should not be resected. Bacterial overgrowth symptoms may respond to antibiotic treatment and intestinal promotility drug therapy. If diverticulitis is seen radiographically, intravenous antibiotics and bowel rest should be initiated. Surgical intervention with small bowel resection is indicated if symptomatic diverticula persist despite conservative management.

### Meckel Diverticulum

Meckel diverticulum is a true diverticulum—a congenital anomaly that occurs owing to incomplete closure of the vitelline duct. This duct typically obliterates during the ninth week of gestational age. Owing to the embryologic origin of the diverticulum, it is almost always located within 2 feet of the ileocecal valve. Meckel diverticulum has a prevalence of 1% to 2% of the population, with a 2:1 male predominance. Approximately 2% of all existing Meckel diverticula will become symptomatic. Symptomatic diverticula most commonly cause nausea, vomiting, and abdominal pain. The sign most commonly associated with Meckel diverticulum is intussusception. This occurs owing to residual fibrous attachments to the umbilicus causing a lead point for the proximal bowel to involute onto the distal bowel. It most commonly presents with bloody mucoid stools, abdominal pain, and vomiting in children younger than 6 years of age, most commonly within the first 2 years of life. However, other symptoms may occur if ectopic tissue exists in the diverticulum. Gastric ectopic tissue may cause abdominal pain and bloody stools from ulceration of the underlying ileal tissue. Duodenal and pancreatic tissues have been identified in Meckel diverticulum but are very rare and do not typically cause symptoms.

Diagnosis in adults requires a high level of suspicion and is aided by the use of a technetium 99m ( $^{99m}\text{Tc}$ ) scan to identify ectopic gastric mucosa in those patients with bleeding and symptoms of ulceration. For children with obstructive signs or symptoms, the diagnosis may be aided by ultrasound and/or computed tomographic scans. Plain film radiographs of the abdomen have low sensitivity and specificity for the diagnosis of intussusception. The sensitivity of the Meckel scan for the pediatric population is 85% to 97% but is much lower in the adult population at 62%. The choice of imaging procedure is dictated by the experience of the radiologic personnel performing the procedure.

Symptomatic Meckel diverticulum should be surgically resected. Up to 90% of intussusception secondary to Meckel diverticulum may be reduced using diagnostic ultrasonography with saline or pneumatic enema. Treatment of Meckel diverticulum largely depends on age and symptomatology because operating on asymptomatic Meckel diverticulum has been shown to have a fivefold increase in complications, such as postoperative bowel obstruction, leaks, ileus, and infection. Many experts have

advocated that incidental, asymptomatic Meckel diverticulum should not be resected. Some experts advocate for selective surgical resection of asymptomatic patients with an incidentally noted Meckel diverticulum for the following: healthy young children, healthy adults younger than 50 years of age with palpable abnormalities suggestive of heterotrophic tissue, size longer than 2 cm, or a broad base wider than 2 cm.

## Colon

### Diverticulosis

The colon is where most diverticula occur in the alimentary tract. Owing to this predominance, this condition is commonly termed *diverticulosis* or *diverticular disease*. Diverticulum of the colon is of the false type. The incidence increases with age. The incidence of left-sided diverticulosis approaches 5% at age 40 and increases to greater than 60% at age 80. Diverticulosis is most commonly located in the sigmoid colon.

The exact pathogenesis of diverticulosis is unclear. The proposed mechanism of colonic diverticular formation places an emphasis on intraluminal pressure buildup. The pressure across the colonic wall increases as the radius of the wall decreases. Accordingly, the radius is the smallest in the sigmoid colon and thus the most likely location of diverticulosis. Normally, pressure is constant throughout the colon. However, as diverticular disease develops, abnormal pressure segmentations occur, resulting in pressure gradient changes in the colon. With increased pressure, the integrity of collagen and elastin in the wall muscle changes, the circular muscles thicken, colonic segments shorten, and the lumen narrows, leading to propagation of the disease. Several risk factors have been associated with the development of diverticular disease: smoking, lack of physical activity, and obesity. By increasing the amount of dietary fiber, it is theorized that the resultant bulking of the stools may decrease the pressure in the colon lumen and prevent diverticular disease progression. Yet, mixed results have been noted on studies of fiber intake and diverticular development and progression of disease. There is no associated risk with the ingestion of caffeine, alcohol, popcorn, seeds, or nuts and the development of diverticulosis, diverticular bleeding, or diverticulitis.

### Colonic Diverticular Bleeding

Diverticula tend to develop where an arteriole penetrates the circular muscle layer of the colon. This results in vessels arching over the dome of the diverticulum. This leaves fragile vessels in a vulnerable position of a relatively thin mucosal layer prone to trauma and resultant diverticular bleeding. Bleeding typically manifests as hematochezia—a darkish to bright red bleeding that is typically characterized as brisk and acute in nature. Diverticulosis is attributed to 30% to 50% of all hematochezia. Fifteen

percent of patients will experience at least one episode of bleeding in their lifetime, with a recurrent bleeding risk of up to 38%. Most patients presenting with diverticular bleeding are asymptomatic, but some may experience bloating or cramping.

Selection of the diagnostic modality depends largely on the degree of bleeding and the cardiovascular stability of the patient. Endoscopy is the preferred treatment modality for stable patients owing to its potential for diagnosis and treatment options. Up to 80% of diverticular bleeding can be isolated with direct endoscopic visualization (Figure 3).

Endoscopic failure to identify or control diverticular bleeding may occur in the patient with massive or intermittent bleeding. Depending on the patient's cardiovascular stability and degree of bleeding, the typical evaluative progression if the site of bleeding is not identified is endoscopy, followed by tagged red blood cell scan, and then angiography. Hemodynamically unstable patients may have a high complication risk from the bowel preparation, sedation, or the procedure. Radionuclide imaging can be considered in unstable patients, nondiagnostic endoscopy, or bleeding recurrence. Radionuclide imaging requires that bleeding be active (at least 0.05 to 0.1 mL/min) to accurately isolate the location of the diverticulum. Radionuclide imaging using  $^{99m}\text{Tc}$  sulfur colloid (shorter half-life, thus used for acute bleeding) or  $^{99m}\text{Tc}$  pertechnetate (longer half-life more useful for intermittent bleeding)-labeled autologous red blood cells can be used to isolate the location of obscure gastrointestinal bleeding. However, numerous studies have produced highly variable sensitivities (26% to 91%). Many advocate for radionuclide imaging to be used as an ancillary test for directing more definitive treatments such as surgery or angiography-directed therapies. Angiography can be used if bleeding is active (at least 0.5 mL/min) and can isolate the bleeding location with a diagnostic yield of 40% to 78%. Angiography can be combined with embolization and/or vasopressin infusion to achieve hemostasis; however, complications may occur, including bowel infarction, rebleeding, and contrast-induced nephrotoxicity.

### Diverticulitis

Diverticulosis is largely asymptomatic. Only approximately 4% will develop inflammation and infection known as diverticulitis. The disease severity and complications occur along a spectrum. The proposed mechanism of diverticulitis may be a blocked diverticulum or increased intraluminal pressure inducing. Subsequent vascular compromise and microperforation may occur, leading to localized infection and inflammation. These microperforations are usually sequestered and may lead to small localized abscess formation. This process is generally referred to as uncomplicated diverticulitis. Complicated diverticulitis is classified when a localized abscess or infection infiltrates into adjacent organs or viscera causing macroperforations, fistulas, obstructions, or enlarged abscesses.

**Figure 3** Colonoscopy in a patient with hematochezia from the source isolated to a diverticulum (A) and hemostasis noted after placement of two hemoclips (B). (Courtesy Janak Shah. From Feldman M. *Sleisenger and Fordtran's Gastrointestinal and Liver Disease*. 9th ed. Philadelphia: Elsevier; Figure 117.8.)

**TABLE 1** Antibiotic Therapy for Diverticulitis

OPTIONAL REGIMENS	DOSAGE (ADULT)
<b>Uncomplicated Diverticulitis</b>	
Outpatient (10–14 days)	
Ciprofloxacin (Cipro) and Metronidazole (Flagyl)	500 mg PO bid 500 mg PO tid
Amoxicillin-clavulanate (Augmentin) <sup>1</sup>	875 mg PO bid
Moxifloxacin (Avelox)	400 mg PO daily
<b>Complicated Diverticulitis</b>	
<b>Inpatient Transitioning to Outpatient (10–14 Days Total)</b>	
Piperacillin-tazobactam (Zosyn) <sup>1</sup>	3.375–4.5 g IV every 6 h
Imipenem-cilastatin (Primaxin)	500 mg IV every 6 h
Levofloxacin (Levaquin) <sup>1</sup> and Metronidazole	500 mg IV every 24 h 500 mg IV every 8 h
Ceftriaxone (Rocephin) and Metronidazole	1 g IV every 24 h 500 mg IV every 8 h

<sup>1</sup>Not FDA approved for this indication.

Clindamycin (Cleocin) may be substituted in metronidazole intolerance/allergy.

Antibiotics continued in complicated diverticulitis cases until negative cultures, clinical improvement, or sensitivities obtained on any surgical specimens.

*bid*, Twice a day; *tid*, three times a day.

Modified from Jacobs DO. Clinical practice: diverticulitis. *N Engl J Med*. 2007;357:2057–2066.

The clinical presentation often begins with mild left lower abdominal pain, fever, and leukocytosis. Patients who seek care later in the disease process may present with sepsis or diffuse peritonitis. Initial diagnosis should be accomplished with history, physical examination, radiographic imaging, and laboratory evaluation. Abdominal radiography has limited utility but may reveal severe complications of diverticulitis such as bowel perforation or bowel obstruction. Ultrasonography and magnetic resonance imaging can be used with high levels of sensitivity and specificity in centers with demonstrated expertise. Ultrasonography has sensitivities and specificities of 92% and 90% for the detection of diverticulitis, respectively. With sensitivities and specificities of 94% and 99%, respectively, CT appears to be the imaging test of choice. This is especially true, as an alternative diagnosis was more likely to be identified with CT than with ultrasonography (50% to 100% vs. 33% to 78%). Those patients with a past medical history of diverticulitis may be empirically treated without imaging, although imaging may be needed if no clinical improvement is noted within 48 hours.

New trials indicate no added benefit with antimicrobial therapy in select patients with uncomplicated diverticulitis. Factors such as pain control, hospitalization rates, and revisits were found to be similar between patients randomized to conservative management and antibiotic administration plus conservative measures. Thus patients may be treated with a liquid diet, analgesics, and close clinical follow-up without antibiotics. Outpatient management is reasonable if the diagnosis is made early in the disease process. Complicated diverticulitis occurs in 25% of all diverticulitis diagnoses, requiring a surgical evaluation and intervention. Optional antibiotic regimens for gram-negative coverage and anaerobic coverage are listed in Table 1. Inpatient management is recommended with any high-risk comorbid conditions, immunosuppression, high-grade fever, leukocytosis, inability to tolerate oral fluids, and/or for elderly patients. Patient improvement should be seen within 48 hours. Those who do not improve should undergo additional evaluation such as repeat imaging or endoscopy. This is done to evaluate for underlying pathology such as cancer or inflammatory bowel disease, which would change the management strategy.

Follow-up scanning should also be considered for cases of slow-resolving diverticulitis. In the past, up to 10% of CT scans in which diverticulitis was the primary diagnosis, cancer could not be fully excluded. As CT scanner resolution has improved,

**Figure 4** Diverticulitis. (A) Computed tomography (CT) image demonstrates thickened wall of the sigmoid colon (arrows) with stranding in the adjacent fat (\*) indicative of diverticulitis. Fat stranding refers to abnormally increased attenuation of fat from edema and engorgement of lymphatics. (B) CT image slightly more caudal demonstrates an air-filled abscess cavity (arrows) with adjacent thickened sigmoid colon wall. (From McNally PR. *GI/Liver Secrets Plus*, 4th ed. Noninvasive Gastrointestinal Imaging: *Ultrasound, Computed Tomography, Magnetic Resonance Imaging*. Philadelphia: Mosby Elsevier; 2010, Figure 70–16.)

newer studies have demonstrated only a small number of underlying cancers or indeterminate findings. A colonoscopy should be performed to evaluate the extent of diverticular disease and to rule out other comorbid pathology in all patients. Colonoscopy is typically recommended 6 weeks after diverticulitis symptoms have resolved, if one has not been done within the last year. Introduction of stool softeners and a high-fiber diet should begin immediately and continued indefinitely for all patients to help decrease the intraluminal pressure within the colon.

Diverticulitis that is complicated with abscess formation should be evaluated by a surgeon or radiologist for percutaneous drainage using CT or ultrasonography (Figure 4). Depending on location, aspiration or drainage tubes may be used to facilitate drainage. A general recommendation exists for consideration of drainage, preferably with interventional radiology localization, for any abscess measuring greater than 3 to 4 cm.

New research to prevent recurrent diverticulitis with medical management is emerging. Rifaximin (Xifaxan)<sup>1</sup> may help prevent recurrent episodes of diverticulitis. Probiotics<sup>7</sup> have not been shown to prevent recurrence. Fiber may be used as a beneficial supplement for the prevention of recurrent diverticulitis. Debate exists regarding elective segmental colectomy for patients who have experienced recurrent episodes of diverticulitis. Current recommendations suggest surgical consultation with discussion of the benefits and risks of surgery compared with the risks of recurrent diverticulitis. This discussion should take into account the diverticulitis frequency and severity, the impact on the patient's lifestyle, and the patient's other comorbid conditions. This consultation should at a minimum occur after the fourth recurrence of diverticulitis in patients older than age 50. There is insufficient evidence to advise a patient who has experienced fewer than four recurrent cases of diverticulitis or who is younger than age 50 on the benefit of a segmental colectomy.

<sup>1</sup>Not FDA approved for this indication.

<sup>7</sup>Available as a dietary supplement.

## DYSPHAGIA AND ESOPHAGEAL OBSTRUCTION

Method of

Christopher Vélez, MD; John E. Pandolfino, MD; Kumar Krishnan, MD

### CURRENT DIAGNOSIS

- The evaluation of dysphagia begins with a careful history, though additional diagnostic testing is often required.
- Oropharyngeal dysphagia is best initially evaluated with a video fluoroscopic examination, whereas esophageal dysphagia is best evaluated with endoscopy.
- Esophageal dysphagia with negative endoscopy and biopsy should be evaluated next with esophageal physiological testing (esophageal manometry or endoscopic functional lumen imaging probe EndoFLIP).

### CURRENT THERAPY

- Underlying neuromuscular conditions such as amyotrophic lateral sclerosis, myasthenia gravis, or Guillain-Barré syndrome should be treated accordingly.
- Endoscopic therapy with dilation (often multiple) is the mainstay of treating fibrotic esophageal strictures regardless of etiology.
- Achalasia can be treated surgically or with dilation, which are equally effective. Minimally invasive endoscopic therapy for achalasia is now a well established alternative treatment approach.

Dysphagia is a symptom generated by the perceived sensation of difficulty or inability to swallow. It ranges in severity from mild difficulty with no associated clinical sequelae, to a complete inability to swallow with aspiration and severe malnutrition. Dysphagia can coexist with and must be distinguished from odynophagia, which is pain when swallowing, with associated swallowing aversion. The etiology of dysphagia is protean and includes two main categories, mechanical obstruction and motor dysfunction.

### Epidemiology

Dysphagia is a common condition. In studies of outpatients, 22.6% of patients have reported dysphagia at least several times per month. Only half of these patients had discussed their symptoms with their physician. Elderly patients and women were more likely to note symptoms of dysphagia.

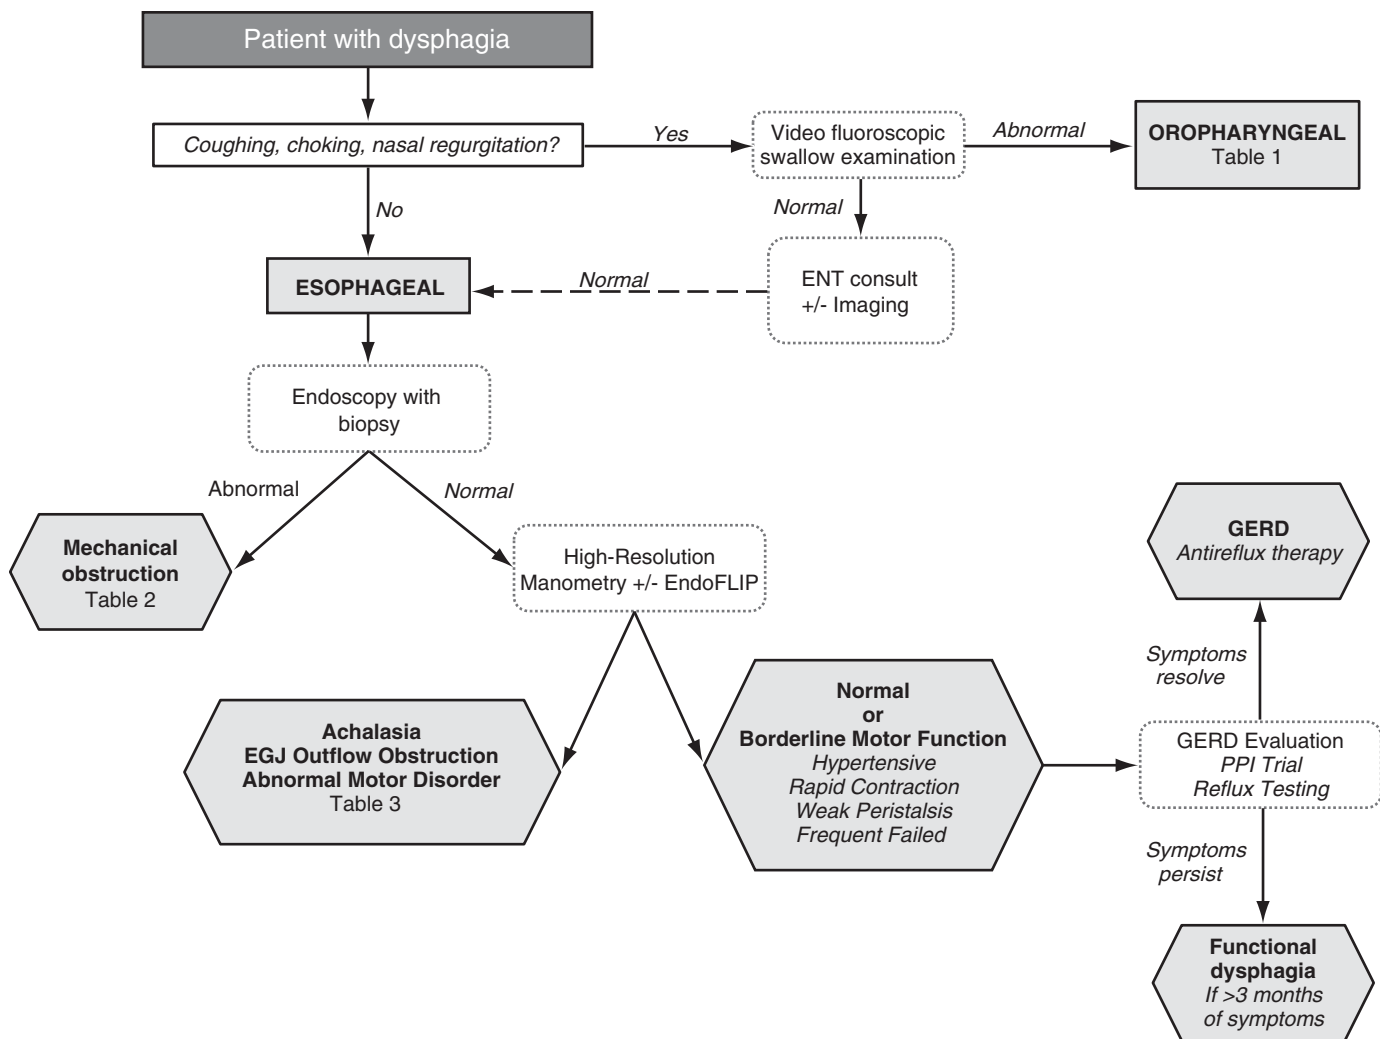

### Pathophysiology

Effective swallowing and transfer of food bolus into the stomach requires multiple steps. These steps can be broadly placed into two phases: the oropharyngeal phase and the esophageal phase. The oropharyngeal phase of swallowing ultimately transforms the hypopharynx from a respiratory organ to a digestive organ. It requires five main coordinated steps to occur: (1) elevation of the soft palate and closure of the nasopharynx, (2) relaxation of the upper esophageal sphincter (UES), (3) traction opening of the UES, (4) closure of the laryngeal vestibule and, hence, airway protection, and (5) propulsion of the food bolus by the tongue and pharyngeal constrictors. This process is a carefully coordinated neuromuscular phenomenon with both autonomic and volitional components.

The esophageal phase of swallowing begins when a food bolus passes through the UES. During swallowing, the rapidity of bolus transit into the stomach is accomplished primarily by gravity. Esophageal peristalsis is a secondary contributor that functions to strip the bolus and clear the esophagus. Primary peristalsis is associated with oropharyngeal swallowing and propagates down through the predominantly striated muscle of the esophagus via a sequential activation pattern originating from the brainstem. This propagation then involves the esophageal smooth muscle where it also engages the intrinsic enteric nervous system to promote peristalsis through a similar but distinct mechanism. Secondary peristalsis is stimulated by distention of the proximal esophagus and will generate a propagating peristaltic contraction similar to primary peristalsis without a swallow-induced trigger. The strength, propagation velocity, and order of peristaltic contractions can be altered, with perturbations potentially leading to motor abnormalities associated with dysphagia.

### Diagnosis

Dysphagia is never a normal symptom and always requires additional investigation. The first step in the diagnostic evaluation of dysphagia begins with a careful history to distinguish true dysphagia from other associated conditions such as odynophagia and globus sensation. Odynophagia can coexist with dysphagia;

**Figure 1** The workup of dysphagia and esophageal obstruction. The first step in the workup of dysphagia focuses on distinguishing oropharyngeal from esophageal dysphagia, which can be done with a history and careful assessment of swallowing during liquid swallows. The workup once this distinction is made is very different. Oropharyngeal dysphagia is typically evaluated by speech pathology and otolaryngology (ENT) based on the results of a video fluoroscopic swallow evaluation. Esophageal dysphagia is evaluated primarily with endoscopy because biopsies and interventions are often required. The primary indication for manometry is to rule out a major motor disorder in patients with a negative endoscopy. Alternatively, the functional lumen imaging probe (FLIP) can be utilized at the time of endoscopy to assess for a primary motor disorder. If a major motor abnormality is not seen on manometry or FLIP, a diagnosis of functional dysphagia should be considered; however, underlying GERD must also be addressed.

however, the predominant symptom is pain during swallowing. Globus is a sensation of a lump in the throat. It is likely a pharyngeal hypersensitivity that may coexist with other esophageal diseases or occur alone as a functional disorder. Unlike dysphagia, the symptoms in globus persist between swallows and may actually improve during the swallow.

After the above conditions have been ruled out, the next step focuses on distinguishing oropharyngeal dysphagia from esophageal dysphagia. Asking patients if their difficulty swallowing is “above-the-gulp” can differentiate oropharyngeal dysphagia. Unfortunately, patients have a difficult time communicating their symptoms because localization of the point of perceived obstruction is hampered by poor discriminant capacity and may be masked by compensatory mechanisms. Localization of dysphagia to the throat or sternal notch is unreliable because the point of obstruction may be further down in the body. However, localization in the midchest or below is more reliable that the obstruction is esophageal in origin.

As a result, the most useful and underused test for distinguishing oropharyngeal and esophageal dysphagia focuses on observing the patient swallow sips of water in the office. Often this allows the distinction between oropharyngeal and esophageal dysphagia to become apparent. Patients with oropharyngeal dysphagia will have difficulty almost immediately after initiating

a swallow, such as coughing, choking, and nasal regurgitation. Patients who can initiate a swallow without difficulty, but note symptoms soon after the swallow, are likely to have esophageal dysphagia. Furthermore, this exercise may be able to elicit associated odynophagia or regurgitation.

Physical examination plays a minor role in evaluating dysphagia outside of assessing the patient’s baseline status to rule out malnutrition and dehydration because this will determine whether an expedited evaluation is required. A careful assessment of the oropharynx and a careful neck examination may unmask a mass lesion (i.e. of the thyroid), and a neurologic examination should be performed if oropharyngeal dysphagia is suspected. Additionally, a skin examination and assessment of the oropharyngeal mucosa may be helpful in assessing for potential dermatologic diseases that are associated with esophageal dysphagia. Regardless of findings, most patients will ultimately be referred for diagnostic testing, and this is dependent on the anatomic zone of interest—oropharyngeal versus esophageal (Figure 1).

## Diagnostic Testing

### Oropharyngeal Dysphagia

Once a distinction is made that the patient is experiencing oropharyngeal dysphagia, the next step in the evaluation should be referral for a video fluoroscopic swallowing examination, also

known as a modified barium study. Standard upper endoscopy is of limited value given the general inability to evaluate lesions in the hypopharynx and the upper esophageal sphincter. Video fluoroscopic swallow examinations have the added benefit of providing functional information in addition to anatomic information. They differ from a standard fluoroscopic examination (i.e., esophogram) by offering the patient various radiopaque food items of different consistency and are often performed by a speech pathologist. They can evaluate delay in initiation of pharyngeal swallowing, aspiration of solids and liquids, retrograde flow of ingested bolus, and residual pharyngeal contents.

If there is a suspicion for a malignancy or mechanical obstruction, a referral to otolaryngology is required. Direct laryngoscopy is used to evaluate for anatomic lesions in the nasopharynx and hypopharynx. In addition to anatomic abnormalities, function can be assessed by having the patient drink liquids with the nasal endoscope positioned in the hypopharynx. Oropharyngeal pooling of liquid indicates ineffective hypopharyngeal clearance and can suggest a high aspiration risk. Cross-sectional imaging is often an adjunct to the functional assessment of videoscopic imaging or direct laryngoscopy when an obstruction is noted without a clear lesion noted on direct examination.

### Esophageal Dysphagia

If oropharyngeal dysphagia is excluded on history, the evaluation of dysphagia should proceed to upper endoscopy to rule out a mechanical obstruction. Although an esophogram can be used to assess for obstruction, most patients will eventually require endoscopy to obtain biopsies to rule out malignancy or eosinophilic esophagitis. Additionally, endoscopy has the added benefit of being therapeutic in some circumstances, and thus it is more cost-effective to begin the evaluation with endoscopy. If the endoscopy is negative, the next step is to evaluate for an underlying esophageal motor disorder. This is traditionally done by performing esophageal manometry. Recently, a novel method of assessing esophageal motor function has been developed. The functional lumen imaging probe (FLIP) is a catheter that can be placed at the time of endoscopy. Using a variety of sensors positioned along the length of the probe, it measures diameter and pressure along the esophagus. This information can be used to evaluate for contractility of the esophageal body and esophageal distensibility at the EGJ, thus providing a comprehensive assessment of esophageal motility that is complementary to esophageal manometry and can help resolve borderline cases of motility abnormality prior to the recommendation of potentially invasive surgical or endoscopic therapy. If these studies are negative, a careful evaluation for the presence of gastroesophageal reflux disease (GERD) should be performed and if suspected, the patient may benefit from ambulatory reflux testing or an empiric trial of proton pump inhibitors. Patients with no evidence of obstruction, abnormal esophageal motor function, or evidence of GERD may be classified as having functional dysphagia and they benefit from the use of neuromodulation (with agents used to treat functional gastrointestinal disorders such as tricyclic antidepressants) to improve sensory function.

### Oropharyngeal Dysphagia

#### Differential Diagnosis

The etiology of oropharyngeal dysphagia can be broadly separated based on neuromuscular causes and anatomic causes (Table 1). The most common neurologic cause is cerebrovascular accident (CVA), with an incidence reported between 20% and 80%. CVAs involving the cerebrum, cerebellum, and brainstem can each lead to swallow dysfunction. Cerebral CVA can lead to impairment in mastication and the oral phase of swallowing and can interrupt normal pharyngeal peristalsis. CVA involving the brainstem can lead to disruption of the sensory afferents in the pharynx that help trigger pharyngeal swallow, and can also lead to motor dysfunction of laryngeal elevation, glottic closure, and cricopharyngeal relaxation/opening. Tumors in these areas can also produce similar effects. While difficulty swallowing liquids can be associated

**TABLE 1** Oropharyngeal Dysphagia

#### Iatrogenic

- Medication side effects (chemotherapy, neuroleptics, etc.)
- Postsurgical muscular or neurogenic
- Radiation
- Corrosive (pill injury, intentional)

#### Infectious

- Diphtheria
- Botulism
- Lyme disease
- Syphilis
- Mucositis (herpes, cytomegalovirus, candida, etc.)

#### Metabolic

- Amyloidosis
- Cushing's syndrome
- Thyrotoxicosis
- Wilson's disease

#### Myopathic

- Connective tissue disease (overlap syndrome)
- Dermatomyositis
- Myasthenia gravis
- Myotonic dystrophy
- Oculopharyngeal dystrophy
- Polymyositis
- Sarcoidosis
- Paraneoplastic syndromes

#### Neurologic

- Brainstem tumors
- Head trauma
- Stroke
- Cerebral palsy
- Guillain-Barré syndrome
- Huntington's disease
- Multiple sclerosis
- Polio
- Postpolio syndrome
- Tardive dyskinesia
- Metabolic encephalopathies
- Amyotrophic lateral sclerosis
- Parkinson's disease
- Dementia

#### Structural

- Cricopharyngeal bar
- Zenker's diverticulum
- Cervical webs
- Oropharyngeal tumors
- Osteophytes and skeletal abnormalities
- Congenital abnormalities (cleft palate, diverticula, pouches, etc.)

with oropharyngeal dysphagia, distinguishing between liquid versus solid food dysphagia is not a reliable way to differentiate this type of dysphagia from esophageal dysphagia.

A variety of neuromuscular disease can lead to bulbar symptoms, which manifest as dysphagia. This includes myasthenia gravis, amyotrophic lateral sclerosis (ALS), and Guillain-Barré syndrome (GBS). Clinicians need to be able to identify systemic manifestations of these conditions because dysphagia can often be the first manifestation of neuromuscular disorders.

The most common structural abnormalities of the hypopharynx associated with dysphagia are hypopharyngeal diverticula and cricopharyngeal bars. Acquired hypopharyngeal diverticula are most common in men after age 60 and typically present with symptoms of dysphagia, halitosis, post-swallow regurgitation, or even aspiration of material from the pharyngeal pouch. Hypopharyngeal diverticula are the result of a restrictive myopathy

associated with diminished compliance of the cricopharyngeus muscle. The treatment of hypopharyngeal diverticula is cricopharyngeal myotomy with or without a diverticulectomy. Good or excellent results can be expected in 80% to 100% of Zenker's patients treated by transcervical myotomy combined with diverticulectomy or diverticulopexy. Small diverticula may spontaneously disappear following myotomy.

Other anatomic causes associated with oropharyngeal dysphagia that should be considered are cervical osteophytes and head and neck cancers. Cervical osteophytes are associated with cervical spine arthritis and may be confused with a cricopharyngeal bar because the dysphagia is structural and localized to the area of the upper esophageal sphincter. It is easily differentiated on contrast studies because the cervical osteophyte can be seen impinging on the upper sphincter. Additionally, head and neck lesions of the larynx, tonsil, tongue, oral cavity, vocal cord, and nasopharynx may also impair bolus transit into the esophagus. Rapid weight loss in a patient with oropharyngeal dysphagia warrants further evaluation for malignancy; however, it is often difficult to distinguish weight loss resulting from malignancy from weight loss secondary to dysphagia. Constitutional symptoms (night sweats, fever, etc.) associated with oropharyngeal dysphagia should raise the suspicion for lymphoma.

### Management

The management of oropharyngeal dysphagia is dependent on the underlying cause. Neuromuscular conditions such as stroke may respond to speech therapy and rehabilitation. Systemic neuromuscular dysfunction from conditions such as myasthenia gravis, GBS, or ALS will require treatment of the underlying condition. Patients who cannot safely take oral nutrition may need a temporary enteral feeding tube until swallow function is intact.

Management of dysphagia in patients with head and neck cancers requires a multidisciplinary approach and treatment of the underlying malignancy. Some patients are able to take adequate nutrition with dietary modification (soft or full liquid diet) while undergoing therapy. Patients who are losing weight, are dehydrated, or are unable to meet nutritional requirement by dietary modification alone may require enteral nutrition in the form of a gastrostomy tube. Although endoscopic gastrostomy tube placement is typically safe, and routinely performed in patients with head and neck cancer, there are reports of seeding the gastrostomy tube tract with malignant cells from the pharynx. In such circumstances, a direct gastrostomy tube placed by a radiologist may be preferable.

### Esophageal Dysphagia

Esophageal dysphagia can be easily separated into mechanical causes and motor abnormalities after upper endoscopy is performed. Mechanical causes can be further separated into malignant and benign causes of dysphagia, and motor disorders can be conceptualized as primary motor abnormalities versus borderline motor abnormalities. Patients who have symptoms in the context of a normal endoscopy (negative biopsies for eosinophilic esophagitis) and no evidence of a primary motor disorder may also have underlying GERD or functional dysphagia (see [Figure 1](#)).

### Differential Diagnosis: Mechanical Obstruction ([Table 2](#))

#### Stricture

Fibrotic esophageal strictures are common and can be caused by erosive esophagitis (peptic stricture), radiation therapy, surgical anastomosis, eosinophilic esophagitis, and desquamating lesions (pemphigus, lichen planus, etc.). Peptic strictures are common and are the result of long-standing erosive esophagitis. They typically occur in the distal esophagus. Such patients often have underlying physiologic derangements that favor aggressive reflux (weak lower esophageal sphincter, hiatal hernia, poor esophageal clearance). Postsurgical anastomotic strictures are an unfortunate consequence of surgical therapy for esophageal disease, but these lesions are often amenable to endoscopic therapy.

**TABLE 2** Esophageal Dysphagia (Mechanical)

Mucosal disease
GERD (peptic stricture)
Esophageal rings
Esophageal cancer
Caustic injury (e.g., lye ingestion, pill esophagitis, sclerotherapy)
Radiation injury
Infectious esophagitis
Eosinophilic esophagitis
Anastomotic stricture
Submucosal disease
Gastrointestinal stromal tumor
Sarcoidosis
Invasive carcinoma (primary or secondary)
Mediastinal disease
Tumors (lymph nodes, lung cancer)
Infection (histoplasmosis, tuberculosis)
Vascular compression
Dysphagia lusoria
Dysphagia aortica

### Eosinophilic Esophagitis

Eosinophilic esophagitis (EoE) requires some focused discussion because its prevalence in patients presenting with dysphagia is increasing. EoE is a condition characterized by marked eosinophilic infiltrate within the esophageal epithelium. This infiltrate results in characteristic endoscopic findings of esophageal rings, furrows, exudate, and eventually stricture formation. The most common symptom in patients with EoE is dysphagia, which often leads to food bolus impaction. Patients are typically young Caucasians and there is a clear male predominance. Atopic conditions are more prevalent in patients with EoE. Patients should initially be treated with proton pump inhibitor (PPI) therapy because there is an overlap between GERD and EoE. Patients with persistent eosinophilia on PPI therapy can be treated by swallowing inhaled formulations of steroids (fluticasone [Flovent],<sup>1</sup> budesonide [Pulmicort]<sup>1</sup>) or a food elimination diet (avoid: soy, nuts, wheat, eggs, dairy, seafood) to reduce the inflammatory component of the disease. Additional therapy with dilation will be required in many patients because histologic improvement does not always result in regression of fibrotic strictures. The esophageal body is more prone to fracture in EoE, and deep mucosal tears are often associated with dilation therapy; thus these lesions may require a more gradual and careful dilation protocol.

### Rings/Webs

Esophageal webs can exist along the length of the esophagus and lead to dysphagia. The classic triad of proximal esophageal web, iron deficiency anemia, and dysphagia is Plummer-Vinson syndrome. The etiology of this condition is not entirely known; however, it is thought that iron deficiency leads to a decrease in iron-dependent oxidative enzymes, which results in degradation of esophageal tissue, resulting in web formation. Interestingly, iron supplementation alone may result in resolution of symptoms. Whereas Plummer-Vinson syndrome is a rare condition, esophageal webs are relatively common and should prompt an evaluation for caustic pill injury if localized to the transition zone along the aortic impression or distal esophagus. Medications that can be associated with pill esophagitis include NSAIDs, tetracycline, iron, bisphosphonates, potassium, and quinidine.

### Malignancy

Dysphagia is often the presenting symptom in a patient with esophageal cancer. There are two subtypes of mucosal cancer in the esophagus, squamous cell and adenocarcinoma. In general,

<sup>1</sup>Not FDA approved for this indication.

**TABLE 3** Esophageal Dysphagia (Abnormal Motor Function)

Achalasia
EGJ outflow obstruction
Absent peristalsis
Spasm
Jackhammer

esophageal cancer has a male predominance and is slightly more prevalent among African Americans. The racial disparity is largely due to squamous cell carcinoma, which has noted a sharp decline since the 1960s. Adenocarcinoma tends to be a disease of white men (SEER database). Squamous cell carcinoma typically occurs in the mid esophagus, whereas adenocarcinoma is localized to the distal esophagus where it is associated with intestinal metaplasia (Barrett's esophagus).

### Management for Esophageal Obstruction

Endoscopic dilation therapy is the most common therapeutic intervention for patients with nonmalignant mechanical dysphagia. This can be done with a single, large-diameter dilating balloon or semirigid bougie over a guide wire. There has not been any convincing data to demonstrate superiority of balloon dilators over bougie dilators. In cases of membranous webs or Schatzki rings, the goal of endoscopic therapy is to tear the lesion with a single, large-diameter dilation. In the case of a Schatzki ring, postdilation PPI therapy is associated with decreased recurrence rates.

When treating fibrotic strictures (peptic, anastomotic, radiation, EoE), the goal should be gradual stretching of the stricture. The choice of initial dilation size is based on an estimate of the diameter of the stricture. The extent to which a stricture can be dilated is expressed by the endoscopic axiom of the "rule of threes." This refers to the approach whereby the diameter of the stricture is approximated, and no more than three subsequent dilations are performed at 1-mm intervals once resistance is noted. Although there is no controlled trial for support, this approach is used to minimize the most serious risks of dilation therapy, perforation, and bleeding.

In patients with refractory strictures despite dilation therapy, several therapies have been attempted with variable efficacy. Temporary self-expanding stents have been placed to maintain lumen patency. When placed across a stricture, stents serve two purposes. First, they relieve symptoms of dysphagia by maintaining a patent lumen. In addition, the self-expanding nature of the stent provides ongoing radial force, which gradually stretches the lumen. The main disadvantage of stents is their tendency to migrate.

An alternative endoscopic approach is incisional therapy with an electrocautery knife. This is used to make incisions in the mucosa and fibrotic submucosa. This approach has been best studied in the setting of refractory anastomotic strictures; however, no head-to-head comparisons have been made between incisional therapy and other modalities.

Treatment of malignant etiologies for dysphagia will ultimately depend on the tumor type and extent of disease. Benign tumors and early-stage lesions can be treated with endoscopic resection or surgery. Endoscopic therapy using stents is also an important component of the treatment of malignancy and may be used during the treatment phase of malignant disorders or as a palliative technique for later-stage disease.

### Differential Diagnosis: Motility Disorders (Table 3)

Esophageal motor disorders are defined based on patterns of contractile vigor, propagation, and the presence of deglutitive relaxation. The most common classification scheme is the "Chicago classification," at the time this chapter was written

currently in its fourth version. This scheme takes advantage of advanced high-resolution manometry with modifications based on refining disorders into clinically relevant phenotypes compared to earlier classification iterations.

#### Achalasia

The diagnosis of achalasia is made by esophageal manometry and requires two main manometric criteria: (1) inability of the lower esophageal sphincter to relax and (2) absence of peristalsis. Recently achalasia has been subdivided into three different phenotypes using high-resolution manometry, which are associated with varying clinical outcomes. Patients typically describe both solid and liquid dysphagia. Other common symptoms are regurgitation (especially nocturnal), chest pain, and aspiration. Weight loss and malnutrition may be dominant symptoms as the disease progresses. Given that there is no treatment to reverse absent peristalsis, the treatment is focused on improving esophagogastric junction (EGJ) opening by disrupting the poorly relaxing lower esophageal sphincter. Currently, three modalities exist to treat achalasia: (1) pneumatic dilation with rigid balloons ranging in size from 3 to 4 cm; (2) surgical myotomy paired with or without a fundoplication; (3) per-oral endoscopic myotomy or POEM. It appears that the three treatment approaches are associated with good outcomes with surgery having a more durable single intervention success rate, pneumatic dilation typically requiring multiple sessions and POEM combining the benefit of one treatment session with a non-surgical approach. Botulinum toxin type A (Botox)<sup>1</sup> injected into the lower esophageal sphincter has been shown to reduce EGJ pressure and improve symptoms; however, this treatment only provides temporary relief and should only be reserved for poor surgical candidates or patients unwilling to undergo surgery, dilation, or endoscopic myotomy. Occasionally, esophageal dilatation may progress to a point where EGJ-directed treatment is not adequate and esophagectomy must be performed to prevent severe complications, such as aspiration and severe malnutrition. At times, dysphagia can recur after EGJ-directed therapy; EndoFLIP can help identify patients requiring re-treatment.

#### Esophagogastric Junction Outflow Obstruction

This pattern of motor disturbance is associated with preserved peristalsis and evidence of high pressures through the EGJ during swallowing. This may be an achalasia variant or could be associated with a subtle obstruction at the distal esophagus not evident on endoscopy. Thus recognition of this pattern should prompt an evaluation for an infiltrating tumor or other potential etiology of obstruction. Treatment is focused on the underlying cause of the obstruction. If distensibility is normal on EndoFLIP, then watchful waiting is appropriate.

#### Absent Peristalsis

Absent peristalsis is defined as complete absence of contractile activity on all swallows in the context of a normal or low EGJ relaxation pressure. This pattern was previously categorized as scleroderma esophagus if it was found in the context of a hypotensive lower esophageal sphincter; however, this has been abandoned because this pattern may be found in patients with severe GERD without scleroderma. Treatment is focused on aggressive antireflux therapy and lifestyle modifications to reduce dysphagia and caustic injury to the esophagus.

#### Distal Esophageal Spasm

Distal esophageal spasm is a rare primary motor disorder that can provoke dysphagia and is associated with premature contraction of the esophageal body. Treatment for this disorder is extremely

<sup>1</sup>Not available in the United States.

difficult and focuses on medical management with smooth muscle relaxants, such as calcium channel blockers,<sup>1</sup> nitrates,<sup>1</sup> and 5-phosphodiesterase inhibitors.<sup>1</sup>

### Jackhammer

Jackhammer esophagus is an extreme form of nutcracker esophagus associated with contractile vigor not encountered in asymptomatic controls or under normal conditions. Previous definitions for hypertensive esophagus had a significant overlap with data from cohorts of asymptomatic controls, and thus the clinical significance of these disorders was unclear. This pattern is associated with dysphagia and chest pain and is typically treated similar to distal esophageal spasm. This motor pattern can also be seen with distal esophageal obstruction, and this should be considered in the differential diagnosis because it would alter management to focus on the obstruction.

### Borderline Motor Abnormalities

Borderline motor abnormalities are those associated with ineffective esophageal motility and mild abnormalities of peristaltic propagation (rapid contraction) or hypertensive contraction. These disorders are not considered to be primary motor disorders, and secondary cause for symptoms, such as GERD and visceral sensitivity, should be considered and treated.

### Monitoring

Patients with dysphagia or esophageal obstruction should be monitored for three important complications:

- Evidence of aspiration and nocturnal regurgitation because these can be associated with severe complications, such as chemical pneumonitis and aspiration pneumonia.
- Malnutrition and dehydration because this may prompt more aggressive therapy or consideration of non-oral feeding methods.
- Progressive symptoms because this could lead to progression of the disease and early therapy may avoid the above complications.

## GASTRITIS AND PEPTIC ULCER DISEASE

Method of

Kyle Vincent, MD

### CURRENT DIAGNOSIS

- Diagnosis of gastritis and peptic ulcer disease (PUD) is based on history of dyspepsia and elimination of other conditions.
- *Helicobacter pylori* (*H. pylori*) and nonsteroidal anti-inflammatory drugs (NSAIDs) are the most common cause of ulcer disease. Hypersecretory conditions such as Zollinger-Ellison syndrome are rare.
- If testing for *H. pylori* is indicated (test and treat strategy), IgG antibody, urea breath test, and fecal antigen test are available.
- Young patients with no “warning signs” can usually be managed on an outpatient basis without immediate endoscopy.
- Patients older than 55 with bleeding, anemia, loss of more than 10% of body weight, dysphagia, odynophagia, early satiety, history of previous malignancy, lymphadenopathy, abdominal mass, or a previously documented ulcer should undergo upper endoscopy promptly.

### CURRENT TREATMENT

- The two principal strategies are empiric treatment or test and treat.
- In areas with an *H. pylori* infection rate of less than 10% a 4–8 week course of proton-pump inhibitors (PPIs) given empirically is appropriate.
- In patients who fail empiric PPI treatment or in areas with an *H. pylori* infection rate of greater than 10%, a test and treat strategy should be employed. A verified noninvasive *H. pylori* test should be used.
- First-line treatment of *H. pylori* consists of a PPI, clarithromycin (Biaxin), and amoxicillin (Amoxil) all taken twice a day for 14 days.
- Test of cure should be undertaken in any patient treated for *H. pylori*.
- NSAIDs should be discontinued or standard dose PPI for ulcer prophylaxis used to treat any dyspepsia.

### Epidemiology

An estimated four million Americans have active gastric ulcers with 350,000 new cases diagnosed each year. The lifetime prevalence of this condition is around 10%. The incidence was previously higher in men but is currently equal in men and women. Familial clustering is now believed to result from transmission of *Helicobacter pylori* (*H. pylori*) from person to person or a genetic predisposition to infection with *H. pylori* rather than a genetic predisposition to gastric ulcers.

### Risk Factors

Most gastric and duodenal ulcers can be attributed to *H. pylori*, NSAID use, severe physiologic stress, or hypersecretory conditions. In America, 10% of young adults harbor *H. pylori* infections, and this incidence increases with age. Lower socioeconomic status and recent immigration from areas with high rates of infection also increase the incidence of *H. pylori* infection. Hypersecretory conditions such as Zollinger-Ellison syndrome are rare, estimated to be responsible for only 0.1% of all ulcers. These conditions should not be routinely considered except in refractory or recurrent cases or in patients who have multiple ulcers.

## Pathophysiology

The low pH of gastric acid is required to kill ingested bacteria and to promote proteolysis and activation of pepsin. Postprandial gastric acid production is stimulated by expression of gastrin from G cells and is inhibited in a negative feedback loop by somatostatin from antral D cells. Contrary to previous beliefs, peptic ulcer disease is not simply due to excessive acid production. Almost all patients with gastric ulcer have normal acid production and only one-third of patients with duodenal ulcer have evidence of increased acid production. The protective mechanisms of the mucosa play an important role in maintaining mucosal integrity.

The gastric and duodenal mucosa forms a gelatinous layer that is impermeable to gastric acid and pepsin. Mucosal blood flow as well as the production of mucus and bicarbonate secretion are largely regulated by E type prostaglandins (PGE). Anything that can disrupt the balance between acid production and the protective barrier has the potential to cause loss of mucosal integrity and tissue exposure to gastric acid and pepsin with subsequent inflammation and potential ulceration.

Two major mechanisms contribute to gastritis and/or ulcer formation. *H. pylori* is a gram-negative curved rod that produces ammonia to control the surrounding pH. Ammonia is toxic to epithelial cells, causing gastritis or duodenitis and damaging mucosal integrity. Many patients with gastritis also have a marked decrease in the number of somatostatin secreting antral D cells, leading to diminished feedback to control acid secretion during gastrin stimulation.

## Prevention

The United States Preventative Task Force does not currently recommend routine screening for *H. pylori* in asymptomatic individuals. Prevention is based on avoidance or minimization of risk factors. Long-term NSAID use should be avoided. Prophylactic antisecretory medication should be considered when prolonged NSAID use is necessary. Proton pump inhibitors (PPIs) have better protective efficacy than histamine receptor antagonists (H2RAs) when prolonged NSAID use is necessary. Patients with a previous history of ulcer disease who use steroids or are older than 65 years of age should strongly be considered for prophylaxis with an antisecretory medication. Because of the high risk of gastric ulceration, prophylaxis is recommended for patients experiencing severe physiologic stress such as mechanical ventilation for longer than 48 hours, hypoperfusion, high dose corticosteroids, and large surface area burns (>35% total body surface). Histamine receptor antagonists such as famotidine (Pepcid),<sup>1</sup> cimetidine (Tagamet),<sup>1</sup> and ranitidine (Zantac)<sup>1</sup> or PPIs are recommended. No agent has shown to be clearly superior for prophylaxis in patients on steroids or undergoing physiologic stress.

No immunization against *H. pylori* is currently available but early stage animal trials are in progress.

## Clinical Manifestations

Dyspepsia is defined by the American College of Gastroenterology as chronic or recurrent pain or discomfort centered in the upper abdomen. Discomfort is defined as a subjective negative feeling that is not painful. Discomfort can incorporate a variety of symptoms including early satiety or upper abdominal fullness. A thorough history alone is usually sufficient to establish the diagnosis and to differentiate gastritis and peptic ulcers from other common conditions, though gastritis and peptic ulcer disease are difficult to differentiate from each other. Patients with peptic ulcer disease tend to have symptoms more pronounced with food intake. A patient with a duodenal ulcer usually reports increased pain 2-3 hours after a meal; conversely, a patient with a gastric ulcer tends to have pain precipitated or exacerbated by food intake. However,

these classical findings are not reliable diagnostic indicators. Physical examination is important to rule out serious complications from peptic ulcer disease. Patient with a rigid abdomen, rebound tenderness, or guarding should be evaluated with imaging and by a surgeon to rule out perforation. The most common physical finding in peptic ulcer disease is tenderness in the epigastrium.

## Differential Diagnosis

The differential diagnosis for gastritis and peptic ulcer disease is broad given its nonspecific nature, but can be narrowed down fairly quickly by a good initial history. The differential diagnosis includes gastroesophageal reflux disease (GERD), cardiac disease, gastric cancer, pancreatitis, pancreatic neoplasm, biliary disease including cholelithiasis or cholecystitis, delayed gastric emptying, or bowel ischemia. Patients presenting with a predominant complaint of heartburn or abdominal pain with heartburn more than once per week should be considered to have GERD until proven otherwise. Any symptoms associated with dyspnea or chest pressure should raise concern for a cardiac etiology. Biliary pain often radiates to the right shoulder and is associated with fatty or greasy foods. Patients with pancreatitis usually describe a severe boring type pain in the epigastrium. They may also get relief from leaning forward.

## Diagnosis

While most dyspepsia symptoms can be treated on a nonurgent basis, specific “warning signs” should prompt referral or performance of upper endoscopy. These include age 55 or older, bleeding, anemia, loss of more than 10% of body weight, dysphagia, odynophagia, early satiety, history of previous malignancy, lymphadenopathy, abdominal mass, or a previously documented ulcer.

*H. pylori* testing is a cornerstone of managing dyspepsia. However, most other laboratory studies are usually not helpful in establishing the diagnosis in uncomplicated peptic ulcer disease or gastritis but may be helpful in eliminating other conditions in the differential diagnosis.

## Noninvasive Testing

**Antibody Test**—Serum IgG antibodies are typically present at 21 days after the onset of *H. pylori* infection but can persist long after active infection. Antibody testing has a sensitivity of 85% and specificity of 79%. The positive predictive value is greatly influenced by the prevalence of the organism in the community and therefore it is less useful in areas with lower rates of *H. pylori* infection. The excellent negative predictive value makes IgG testing a good screening test. However, given that the IgG antibodies can persist for up to a year or longer after infection, it is not as helpful in the acute phase.

**Urea Breath Test**—This test identifies infection through urease activity. The patient ingests urea labeled with either <sup>13</sup>C or <sup>14</sup>C. In the presence of *H. pylori*, urease activity produces labeled CO<sub>2</sub> that is expired and can be collected and measured. Sensitivities and specificities of this test exceed 95%. It maintains a strong positive and negative predictive value despite the prevalence of *H. pylori*, but the test is not universally available.

**Fecal Antigen Test**—This assay uses either polyclonal or monoclonal antibodies to identify *H. pylori* antigens in the stool. The sensitivity and specificity exceed 90% in most studies. Like the breath test, it is unaffected by prevalence, however, both tests are affected by previous exposure to bismuth, antibiotics, and PPIs.

## Treatment

The treatment of dyspepsia was revolutionized in the 1990s following the discovery of the role of *H. pylori* in pathogenesis. For patients who present with dyspepsia but no “warning signs,” two separate and approximately equivalent treatment strategies are recommended. The “test and treat” option recommends using a validated noninvasive test for *H. pylori* and treatment of positive

<sup>1</sup>Not FDA approved for this indication.

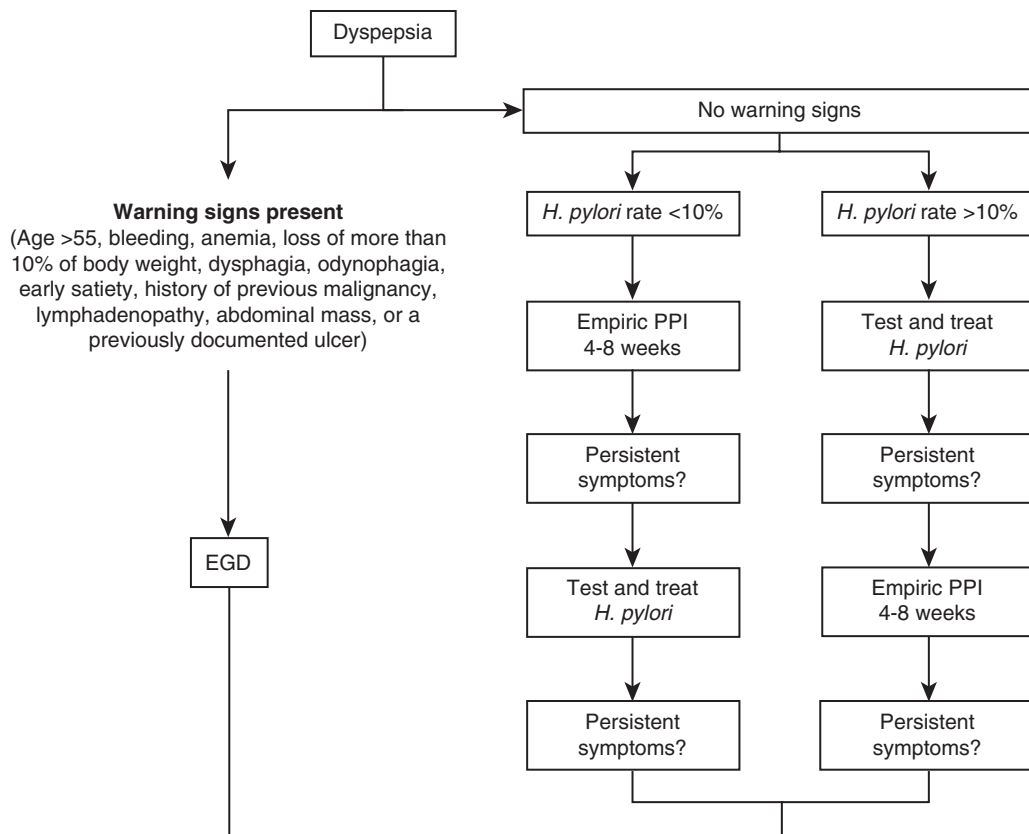

Figure 1 The treatment of dyspepsia.

tests. The “empiric” acid suppression option recommends treating with a PPI for 4-8 weeks without testing for *H. pylori*. The test and treat strategy is recommended for populations where the *H. pylori* infection rate is higher than 10%, in patients with active or past PUD, low-grade gastric mucosa-associated lymphoid tissue (MALT) lymphoma, or history of endoscopic resection of early gastric cancer. As the US prevalence varies from 10% to 40% in different communities, either strategy may be appropriate. The test and treat strategy is more appropriate for most urban areas and in communities with a high immigrant population or known high rates of *H. pylori* infection. In populations with low *H. pylori* prevalence, such as high socioeconomic areas, empiric acid suppression is an appropriate first strategy, followed by *H. pylori* testing in those patients who have continued symptoms (Figure 1).

The recommendations for eradication of *H. pylori* were updated by the American College of Gastroenterology in 2017. Previous regimens had focused on specific PPI medications. This has been replaced with a general recommendation for standard or double dose PPI of choice. There are two key considerations for selection for initial treatment: (1) Is there a penicillin allergy? and (2) Has there been any previous macrolide exposure for any reason? Current first-line treatment is the so-called triple therapy with standard or double dose PPI, clarithromycin (Biaxin), and amoxicillin (Amoxil) for 14 days. This regimen has an eradication rate of 70% to 85%. Studies show no statistical difference between 7- and 10-day treatment regimens; however, there were trends toward higher eradication rates with the longer regimen. In addition, these studies have not been duplicated in the U.S. population where 7-day regimens have shown efficacy rates below 80%. Therefore, regimens less than 10 days are not recommended and 14-day treatment should be considered. In patients who are penicillin allergic, metronidazole (Flagyl)<sup>1</sup> may be substituted for amoxicillin, but resistance rates for metronidazole are more than double those for amoxicillin. Second-line

therapy for those with previous macrolide exposure or penicillin allergy is the so-called quadruple therapy. This consists of standard dose PPI, bismuth subcitrate,<sup>2</sup> tetracycline (Sumycin),<sup>1</sup> and metronidazole (Flagyl).<sup>1</sup> Bismuth subcitrate, metronidazole, and tetracycline are available as a combination product, Pylera, which is approved to use with omeprazole for the treatment of patients with *H. pylori* infection and duodenal ulcer disease. There are multiple other regimens with similar eradication rates in European studies that have not been well validated in North America. Nonetheless, they are recommended by the American College of Gastroenterology and can be used for patients who are having difficulty with intolerance to the more common regimens. They are listed in Table 1.

### Monitoring

The recommendations for routine testing for eradication of *H. pylori* were updated in 2017. Although strong evidence is lacking, expert consensus supports testing for eradication in most cases. There is clear benefit in testing patients who have persistent symptoms despite the test and treat strategy, any patient with an *H. pylori*-associated ulcer, any patient who has had a resection of any early gastric cancer, or those with an *H. pylori*-associated MALT lymphoma. In these patients, testing should be done no sooner than 4 weeks after the completion of eradication treatment. Patients requiring follow-up endoscopy, such as for an ulcer or MALT lymphoma, should undergo endoscopic testing for eradication. Patients who are not undergoing endoscopy can be tested for eradication with fecal antigen or urea breath testing. The serum antibody test is unreliable for follow-up as it can remain positive for quite some time after successful treatment.

The most common causes of treatment failure are poor compliance with the medications and antibiotic resistance by the organism. Patients should be counseled on the side effects of their regimen and the importance of compliance. About 10% of

<sup>a</sup>In patients with penicillin allergy, metronidazole (Flagyl) 500 mg TID can be substituted, although not FDA approved.

<sup>b</sup>14-day courses should be considered secondary to increased eradication rates.

<sup>c</sup>Not FDA approved for this treatment regimen.

<sup>1</sup>Not FDA approved for this indication.

<sup>2</sup>Not available in the United States.

patients report headaches and diarrhea with PPI use. Clarithromycin (Biaxin) can cause diarrhea, gastrointestinal upset, and altered taste. Similar effects can be seen with amoxicillin and metronidazole. Metronidazole also has disulfiram-like effects if taken with alcohol. Bacterial resistance is relatively rare, with multicenter U.S. data showing resistance rates to be 37% for metronidazole, 10% for clarithromycin, 3.9% for both antibiotics, and 1.4% for amoxicillin. For patients with persistent *H. pylori* infections, a new regimen should be attempted that does not include previously used antibiotics.

Patients who continue to have dyspepsia after successful eradication of *H. pylori* or who have persistent symptoms after a negative test and acid suppression should be considered for upper endoscopy.

### Complications

Peptic ulcer disease can have severe complications, almost always requiring hospital admission. The most significant complications are gastric bleeding, perforation, or outlet obstruction.

Gastrointestinal bleeding is the most common cause of death in patients with peptic ulcer disease. Most cases of massive hemorrhage are due to erosion of a posterior ulcer into the gastroduodenal artery. Although the most common site of such hemorrhage is proximal to the ligament of Trietz, profuse bleeding can result in bright red blood from the rectum.

Approximately 5% of peptic ulcers cause perforation. This usually occurs anteriorly through the duodenum or lesser curve of the stomach. These patients often present in extremis with fever, tachycardia, dehydration, and abdominal findings of rigidity and rebound due to chemical peritonitis. Free air is commonly present

under the diaphragm. Perforation is almost always requires surgical management.

Gastric outlet obstruction can occur acutely due to inflammation from peptic ulcer disease or more chronically secondary to inflammation and healing that lead to scarring and fibrosis of the duodenum. These patients can present with severe hypochloremic hypokalemic alkalosis due to the loss of hydrogen, potassium, and chloride from gastric secretions. Electrolyte derangements must be corrected prior to any attempted surgery. Initial treatment with balloon dilation can be attempted, especially in cases with newly diagnosed *H. pylori*. If the patient is negative for *H. pylori* or has successfully eradicated the organism, the long-term outcomes of dilation do not compare well to surgery.

## GASTROESOPHAGEAL REFLUX DISEASE (GERD)

Method of

Mustafa Abdul-Hussein, MD, MSCR; and Donald O. Castell, MD

Gastroesophageal reflux disease (GERD) is a motility disorder of the lower esophageal sphincter (LES). The definition of this disease has evolved over time, reflecting better understanding of the roles that transient LES relaxations and acid/pepsin contact with esophageal mucosa play, as well as the ability to identify these events. The diagnosis of GERD has changed from identification of a hiatal hernia, to identification of erosive esophagitis, to the currently accepted patient-centered definition: any symptom or injury to esophageal mucosa resulting from reflux of gastric contents into the esophagus. GERD should not be confused with physiologic gastroesophageal reflux, which is not associated with symptoms or esophageal mucosal injury.

The prevalence of GERD is difficult to ascertain, although several studies have indicated it to be as high as 50% of adults in Western countries, with 10% to 18% experiencing heartburn on a daily basis. Studies using health care utilization data may underestimate the prevalence because of self-treatment by individuals in the community, whereas population surveys may overestimate it because of inaccurate assessment of symptoms and absence of objective data. Regardless of the real number, the management of this disease costs more than \$10 billion annually in the United States. GERD has been called a disease of white males, although recent data suggest increasing prevalence in Asia and Pacific regions.

### Pathophysiology

GERD is a motility disorder of the LES characterized by inappropriate or transient relaxations that allow gastric contents to reflux into the esophagus. The LES is a tonically contracted ring of smooth muscle fibers innervated by the vagus nerve. Vagal stimulation during swallowing produces physiologic LES relaxation and is a likely source for transient LES relaxations. Gastroesophageal reflux occurs most frequently during postprandial periods, at a rate of six reflux episodes per hour, but averages two episodes per hour over the entire day. Increasing frequency of reflux in the postprandial period results from gastric distention after a meal and stimulation of tension receptors in the proximal stomach leading to transient LES relaxations (Box 1). A chronically hypotensive LES is not a major mechanism for GERD in most patients but can be seen in cases of severe erosive esophagitis.

Reflux of acidic gastric contents can lead to injury of the esophageal mucosa, including inflammation, ulceration, stricturing, Barrett's metaplasia, and adenocarcinoma. Peristaltic clearance, tissue resistance, and salivary bicarbonate make up host defense mechanisms that work by clearing reflux and neutralizing the acid residue on the mucosa. Erosive esophagitis or strictures

result in the most severe form of GERD, which includes nocturnal reflux with longer acid contact times, decreased salivary production, and lower frequency of swallowing during sleep.

### Complications

Acid reflux can lead to significant morbidity if it is not recognized and treated appropriately. Habitual contact of acid and activated pepsin with the stratified squamous epithelium, along with impaired defense mechanisms, results in tissue injury (Box 2). The end result of this process can be ulceration, fibrosis with stricture formation, Barrett's esophagus, or adenocarcinoma. These complications can produce alarm symptoms (Box 3). Patients presenting with alarm symptoms should undergo immediate diagnostic evaluation with an esophagogastroduodenoscopy (EGD).

### Erosive Esophagitis

The endoscopic finding of erosive esophagitis is seen in fewer than 50% of patients with heartburn. The severity is stratified according to the Los Angeles Classification of Esophagitis. Treatment with a proton pump inhibitor (PPI) for 4 to 12 weeks heals erosive esophagitis in 78% to 95% of cases. The healing effect of antisecretory therapy, and particularly PPIs, demonstrates the important role of acid reflux in causing tissue injury. The recurrence rates for erosive esophagitis are high after discontinuation of PPI maintenance therapy (75%–92%), necessitating continuation of gastric acid suppression.

### Strictures

Most strictures caused by GERD are peptic in origin and are located at the squamocolumnar junction. Patients with GERD and strictures, compared to those without strictures, are more likely to have a hypotensive LES, abnormal peristalsis, and prolonged acid clearance time. Stricture formation decreases the

### BOX 3 Alarm Symptoms of Gastroesophageal Reflux Disease

Presence of any of the following symptoms requires immediate evaluation:

- Dysphagia
- Odynophagia
- Weight loss
- Spontaneous resolution of GERD symptoms
- Iron deficiency anemia
- Gastrointestinal bleeding

luminal diameter, resulting in solid food dysphagia. Dysphagia in these patients is often a combination of decreased luminal diameter and dysmotility of the distal esophageal body with low-amplitude peristalsis. Patients with GERD who develop dysphagia should have immediate barium radiography and an endoscopic evaluation.

### Barrett's Esophagus

Barrett's esophagus (BE) is a premalignant condition that may evolve into esophageal adenocarcinoma. The histologic abnormality involves intestinal-like metaplasia of the stratified squamous epithelium. Epidemiologic studies show Barrett's to be more common among Caucasians, males, and the elderly (mean age, 60 years). The relative risk of esophageal adenocarcinoma (EAC) in BE patients was thought to be 30- to 125-fold with an incidence of 0.5% per patient year; however, recent population studies have shown a lower incidence of 0.12% to 0.13%. Despite the prevalent use of PPIs in the treatment of GERD, the incidence of adenocarcinoma has been increasing. Current guidelines encourage endoscopic surveillance for patients with Barrett's esophagus, yet there are sparse data showing the cost-effectiveness or mortality benefit of this strategy.

### Adenocarcinoma

Approximately 50% of esophageal cancers are adenocarcinomas. Since the 1970s, the incidence has been rising for reasons that are still unknown. GERD is a risk factor for esophageal adenocarcinoma, and the risk increases with the duration and severity of GERD symptoms. There is a suggestion that cagA strains of *Helicobacter pylori* are protective against development of Barrett's esophagus and adenocarcinoma. The declining incidence of *H. pylori* may be a possible explanation for the rising incidence of adenocarcinoma.

### Diagnosis

GERD is largely a clinical diagnosis under the current definition (i.e., any symptom or tissue injury resulting from reflux of gastric contents into the esophagus). Patients with the typical symptoms of heartburn and regurgitation most often associated with meals have a high pretest probability of having GERD. A well-obtained history and symptom questionnaire are usually sufficient to form a presumptive diagnosis and are more cost-effective than ambulatory reflux testing or EGD. An empiric trial of PPI therapy that leads to a significant reduction or resolution of symptoms likely confirms the diagnosis.

The pathophysiology of GERD is much more complex than previously thought. It involves more than acid reflux, because nonacid reflux with a pH greater than 4 can be a common source of symptoms. This entity is unmasked when PPI therapy is found to control gastric acid secretion and impedance-pH testing identifies a temporal relationship between symptoms and episodes of nonacid reflux.

Direct-to-consumer marketing and the availability of over-the-counter PPI medications (e.g., Prilosec OTC) have led to self-treatment of GERD-type symptoms and a consequent change in the type of patients seeking medical care for their symptoms. Patients with typical GERD symptoms that do not completely respond to therapy with PPIs, including over-the-counter and prescription PPIs, warrant a more detailed evaluation of their symptoms. A separate population requiring earlier diagnostic evaluation includes patients with exclusively atypical GERD symptoms such as cough, hoarseness, throat clearing, asthma attacks, and chest pain. Less commonly, patients presenting with signs or symptoms of tissue injury, such as solid food dysphagia, should also be more rigorously tested for GERD (Box 4).

Patients who have symptoms associated with GERD, whether typical or atypical, are frequently treated empirically with PPI therapy. With a lack of discrimination regarding symptom types, this population is very heterogeneous and comprises patients with symptoms that are truly associated with GERD, not at all associated with GERD, and a combination of both. The pretest

## BOX 4 Clinical Spectrum of Gastroesophageal Reflux Disease–Related Symptoms and Tissue Injury

- Reflux asthma
- Pulmonary fibrosis
- Pharyngitis
- Recurrent otitis media

probability of GERD in this group is diluted, and nonresponders to empiric therapy are numerous. Partial responders and nonresponders to PPI therapy should undergo ambulatory reflux testing using combined multichannel intraluminal impedance (MII)-pH or standard pH. MII-pH catheters measure both esophageal pH changes and impedance changes that occur as an ion-rich refluxate passes a pair of ring electrodes, resulting in a drop in the resistance to a low-voltage current between the electrodes. The change in impedance can detect gastroesophageal reflux regardless of the acid content and can distinguish reflux types as liquid, gas, or mixed.

The goals of ambulatory reflux testing are to determine whether the esophageal acid contact time is abnormal, whether there are an abnormal number of reflux episodes, and whether a relationship between reflux and symptoms exists. The advantage of combined MII-pH is its ability to identify both acid and nonacid reflux, so that testing can be done while the patient is on acid-suppression therapy and the artifact of acidic food or beverage ingestion is eliminated; pH-only testing is affected by both of these conditions. The major disadvantage is that MII-pH testing is less available than conventional pH testing.

EGD is specific for detecting reflux-related tissue injury but is not sensitive, because fewer than 50% of patients with GERD-related heartburn have endoscopic findings of reflux. If erosive esophagitis or Barrett's esophagus is found on endoscopy, aggressive antisecretory therapy with a PPI is warranted.

A barium esophagram is unlikely to add useful diagnostic information in patients with GERD symptoms without dysphagia. It is a useful tool in distinguishing obstructive from nonobstructive dysphagia and may even be more sensitive than EGD in detecting causes of obstructive dysphagia. Achalasia is often mistaken for GERD during the onset of symptoms, and early use of esophagography may help make this diagnosis.

### Management

GERD is predominantly a postprandial event involving transient LES relaxations. The primary focus in management of this disease is to eliminate or improve symptoms and prevent tissue injury. In most patients with recurrent GERD symptoms, this can be accomplished by controlling gastric acid secretion with antisecretory therapy. PPIs are the most effective pharmacologic therapy for improving symptoms and preventing tissue injury from acid reflux. Individuals with only occasional heartburn

may successfully treat symptoms with a combination of lifestyle modifications and over-the-counter antacids, histamine 2 receptor antagonists, or a PPI.

Patients presenting with typical symptoms and a history consistent with GERD should be given a trial of PPI once daily for at least 4 weeks. A validated GERD symptom assessment questionnaire such as the Reflux Disease Questionnaire should be used as an initial screening tool, because symptom response is the primary outcome measure, and subsequent questionnaire responses are useful in comparison with the initial responses for measuring treatment efficacy. If symptoms have not responded or have responded only partially after this trial, then the dosing or frequency of the PPI should be increased over another 4-week period. If the response is still unsatisfactory, diagnostic testing with ambulatory combined MII-pH or pH-only monitoring is indicated.

PPIs are an effective maintenance therapy for most patients with GERD and may be stepped down or used on demand, but GERD is a chronic condition with a high recurrence rate of symptoms without some form of maintenance therapy. This creates a large population of patients on antisecretory therapy for a disease with a low mortality rate, which raises the question of drug safety. There are insufficient data available that would warrant a recommendation against long-term PPI therapy. Clinical judgment in specific patient populations should be used to determine the optimal PPI regimen.

At present, pharmacologic reflux reduction therapy consists solely of the use of baclofen (Lioresal),<sup>1</sup> which has been shown to reduce transient LES relaxations and associated gastroesophageal reflux. The drawback of this medication is its unwanted side effects, which include somnolence and dizziness, limiting its tolerability and clinical utility as a stand-alone therapy.

Antireflux surgery is another alternative that is effective in limiting GERD symptoms in patients with a positive reflux-symptom relationship. Candidates for surgery include younger patients who do not want to continue chronic PPI therapy and patients with symptomatic nonacid reflux. Today, most antireflux surgery is performed laparoscopically with a 360-degree Nissen fundoplication. The associated mortality rate is small (0.5%–1%), and this approach is preferred to open laparotomy. Traditional predictors for surgical success have included the presence of typical symptoms (heartburn and regurgitation), symptom response to a trial of PPIs, and an abnormal ambulatory pH study. These criteria exclude the important group of patients with atypical symptoms or symptoms related to nonacid reflux. However, such patients should be considered candidates for antireflux surgery if a positive reflux-symptom relationship can be demonstrated.

In recent years, several endoscopic therapeutic procedures have been developed for treatment of GERD. Among these procedures, transoral incisionless fundoplication (TIF) and Stretta are well studied and viable options. Stretta is the delivery of radiofrequency energy to the gastro-esophageal junction (GEJ). Stretta efficacy lays in increasing thickness of LES, decreasing compliance of GEJ without fibrosis, and decreased transient lower esophageal sphincter relaxations. Randomized trials showed improvement in GERD symptoms compared to sham procedure, though follow-up periods in these trials were only 6–12 months. A meta-analysis of 18 studies and 1441 patients concluded that Stretta is safe, well tolerated, effective in GERD symptom relief, and significantly reduces acid exposure to the esophagus, though it did not consistently normalize pH. In a recent meta analysis of 28 studies of 2468 patients with mean follow-up time of 25.4 months, Stretta improved quality-of-life scores and heartburn scores. However, 49% of the patients were still using PPIs at follow-up.

Patients with alarm symptoms and those who are partial responders to PPI therapy should also undergo EGD to aid in

determining the cause of the symptoms, such as obstructive dysphagia from peptic strictures, adenocarcinoma, and bleeding esophageal ulcers (which can cause anemia). EGD findings that suggest GERD are a result of acid reflux. However, the incidence of these findings has declined with the use of PPIs.

Nonerosive reflux disease is increasingly common as more patients are converted from acid refluxers to nonacid refluxers with PPI therapy. By definition, these patients have no findings on endoscopy to suggest ongoing GERD. Absence of endoscopic findings does not exclude GERD, however, because tissue injury can occur at the microscopic as well as the macroscopic level. Patients with either erosive esophagitis or nonerosive reflux disease have dilated intercellular spaces on electron microscopy.

As previously discussed, patients with GERD may develop Barrett's esophagus. The metaplastic transformation from normal stratified squamous epithelium to an intestinal-type, columnar-lined epithelium creates a premalignant lesion with a 0.5% per year risk of progression to adenocarcinoma. Screening for Barrett's esophagus remains controversial. There is no evidence that screening results in a mortality benefit due to early detection of esophageal adenocarcinoma. Screening of all patients with GERD for Barrett's esophagus is clearly not cost-effective, but it is reasonable to target the highest-risk populations, such as Caucasian men older than 50 years of age with chronic reflux symptoms. Current American College of Gastroenterology guidelines recommend surveillance endoscopy in patients with known Barrett's esophagus at intervals determined by the degree of dysplasia. Because there have been no long-term, controlled studies, it is a grade C recommendation.

# HEMORRHOIDS, ANAL FISSURE, AND ANORECTAL ABSCESS AND FISTULA

Method of

Mary R. Kwaan, MD, MPH

## CURRENT DIAGNOSIS

- Although most anorectal complaints are caused by a benign process, it is important to be mindful that the etiology can be a malignancy or other serious medical condition, such as anorectal Crohn's disease.
- A thorough, focused history is often the most helpful diagnostic tool for patients with anorectal complaints.
- In patients in whom no etiology for bleeding is found or there has been a change in bowel movements, a further diagnostic workup should be performed.
- Pain is the predominant symptom with anal fissure, thrombosed external hemorrhoids, and anorectal abscess but is not prominently featured with internal hemorrhoids.

## CURRENT THERAPY

- External thrombosed hemorrhoids are treated with evacuation in their early development (<72 hours) but with expectant, supportive management only in their subacute phase.
- Most internal hemorrhoids can be treated with outpatient treatments, including measures to normalize bowel movements and hemorrhoidal banding or injection therapy.
- Anal fissures are treated conservatively with medical therapy but require operative therapy in a minority of cases.
- Anal fistula repair techniques have variable success rates and may require multiple procedures to treat effectively.

A number of conditions cause anorectal symptoms, but the majority of patients present with a complaint of “hemorrhoids.” Most anorectal conditions can be diagnosed with a focused history and physical examination. Treatment is aimed at the relief of symptoms, education of the patient, and prevention of further symptoms. Although most anorectal complaints are caused by a benign process, it is important for clinicians to be mindful that in some cases the etiology can be a malignancy or other serious medical condition, such as anorectal Crohn's disease.

## History

A thorough, focused history is often the most helpful diagnostic tool for patients with anorectal complaints. Clinicians should inquire about pain, itching, discharge, extra tissue or a lump, and bleeding. It is particularly important to understand the patient's bowel habits with respect to constipation or diarrhea as well as any change in defecatory habits. Other relevant history items include previous anorectal procedures and related medical conditions such as Crohn's disease, malignancy, sexually transmitted diseases, or immunosuppression.

Pain is an important symptom to elicit from patients. In most cases, pain is the predominant symptom with anal fissure, thrombosed external hemorrhoids, and anorectal abscess. Although discomfort from internal hemorrhoids can cause aching, burning, or itching in the setting of tissue prolapse, internal hemorrhoid disease is most often painless. In contrast, external hemorrhoids that are acutely thrombosed cause pain that is severe, constant, and associated with a lump. Fissure pain is often described as a

tearing sensation or the feeling of “razor blades” during bowel movements that can continue for more than 1 hour following defecation. Patients with anal fissures might also express a fear of having bowel movements because of pain. Anorectal abscess is often associated with pain, and patients can also present with an acute lump and occasionally a fever. Anal fistula typically is not associated with much pain, rather patients describe irritation and drainage.

Anal discharge and difficulty with anorectal hygiene are also common complaints. The discharge associated with prolapsing internal hemorrhoids might contain mucus or fecal smearing. In contrast, an anorectal fistula or abscess can spontaneously drain with associated purulent and blood-tinged output.

When a patient has bleeding, specific details to inquire about include color (bright red versus dark blood), amount, frequency, and length of time. When no etiology for bleeding is found, a flexible sigmoidoscopy or colonoscopy should be performed to evaluate for a proximal source. Even if patients are found to have some hemorrhoids, endoscopic evaluation should be strongly considered in patients older than 40 years of age. Although uncommon, the incidence of colorectal malignancy has increased in this age group. Furthermore, patients who are 45 years of age and older should initiate colorectal cancer screening regardless of symptoms based on updated 2021 U.S. Preventive Services Task Force (USPSTF) guidelines. Stool-based screening modalities identify blood in the stool. Therefore patients with anal bleeding should be encouraged to proceed with colonoscopy for screening.

## Diagnosis

Although the prone jackknife position allows the greatest exposure, the left lateral decubitus position with the knees up is preferred by patients and usually allows adequate exposure for the anorectal examination. It is critically important to have adequate lighting with a headlight as well as appropriate instrumentation to perform the anoscopy. An adjunctive test that can also be helpful in patients where mucosal (hemorrhoidal) or full-thickness rectal prolapse is suspected is to have patients bear down on the commode and then to examine externally.

The perianal skin is the skin immediately surrounding the anal verge (Figure 1). Perianal inspection includes careful examination of the surrounding skin for excoriation, an external draining orifice in the case of an anorectal fistula, lichenified skin with chronic irritation, other dermatitis, and the presence of perianal lesions. A low-lying anal fistula can be palpated as a fibrotic tract that heads from the external draining site to the anus. The anal verge is the entrance to the anal canal and is defined by the intersphincteric groove. There is frequently a clear demarcation between hair-bearing and non-hair-bearing skin in this location.

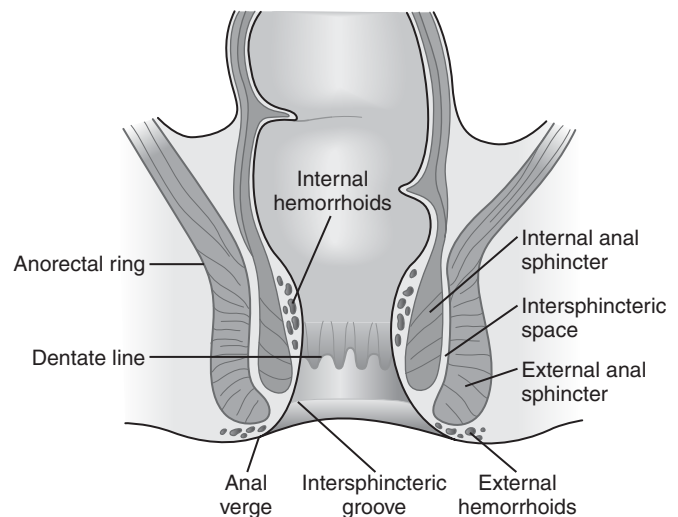

Figure 1 Anatomy of the anal canal.

Careful separation of the anoderm can help visualize an anal fissure located at the anal verge and extending into the anal canal.

A digital rectal examination is helpful for assessing resting and squeeze anorectal tone, palpating the prostate in men, assessing for rectocele in women, detecting any palpable anorectal lesions, and evaluating for tenderness within the anal canal or at the level of the levator ani muscles at the anorectal ring. Internal hemorrhoids, however, are not usually palpable as they readily compress with digital pressure and are not associated with fibrosis. Anoscopy is used to visually examine the anal canal, which is between 4 and 5 cm in length starting at the anal verge and extending to the top of the anorectal ring (top of external sphincter and levator ani muscles). Within the anal canal is the dentate line, which acts as a landmark anatomically and is located approximately 2 cm from the anal verge. The dentate line represents the transition from squamous epithelial lining of the anus to the columnar epithelial lining of the rectum. Sensation above the dentate line is mediated by autonomic fibers and results in a relative lack of sensation compared with the highly sensitive, somatically innervated tissue below the dentate line. The dentate line is also the location of the crypt anal glands from which anorectal abscesses and fistulas originate.

### Hemorrhoids

Hemorrhoids are anal vascular cushions that are present as normal structures in everyone. In the case of internal hemorrhoids, these cushions are arteriovenous channels that have overlying mucosa, submucosal smooth muscle, and supportive fibroelastic connective tissue. It is believed that internal hemorrhoids function by aiding with fine control of fecal continence of liquids and gases. Internal hemorrhoids enlarge and become symptomatic as fixation by submucosal smooth muscle and connective tissue becomes disrupted and loosens. This results in a sliding or prolapsing of the anal canal lining and further engorgement of the internal hemorrhoid tissues. Common exacerbating factors include constipation, diarrhea, aging, and increased abdominal pressure that can occur with chronic straining, pregnancy, heavy lifting, and decreased venous return. Internal hemorrhoids are not palpable on digital rectal examination and instead must be observed on anoscopy. Internal hemorrhoids are typically staged on a scale from I to IV based on the extent of prolapse (Table 1).

Internal hemorrhoids, when symptomatic, most commonly present with painless bright red bleeding or prolapsing tissue (Figure 2). Patients describe bleeding with or after bowel movements. Other symptoms include itching and leakage of mucus in the setting of tissue prolapse. Pain is rarely a prominent symptom except in the case of mixed hemorrhoid disease, when there is a thrombosed external component, or in the case of grade IV incarcerated hemorrhoids.

The central principles for conservative treatment of internal hemorrhoids and for long-term prevention of worsening symptoms are the normalization of bowel habits and avoidance of straining. Ideal bowel habits include having regular, soft, and formed stool resulting in minimal straining with elimination. An ideal diet should have high fiber content along with sufficient fluid intake. A total of at least 30 g of fiber per day is generally recommended. For most patients, this is most easily achieved with the addition of a fiber supplement such as psyllium. Other medical treatment of hemorrhoids includes local anesthetic topical ointments, such as lidocaine gel or ointment, which relieve symptoms but do not improve the hemorrhoids, and steroid ointments, which should only be prescribed for a defined short course for symptoms of itching and irritation. Topical hydrocortisone can thin and atrophy the overlying tissue if used regularly.

Internal hemorrhoids might benefit from further treatment in the setting of persistent prolapse or bleeding. Injection sclerotherapy works through shrinking and scarring the internal hemorrhoid by injecting a sclerosing agent (most commonly 5% phenol in oil<sup>1</sup> or sodium morrhuate<sup>1</sup>). Alternatively, infrared coagulation

**TABLE 1** Staging of Hemorrhoidal Disease

GRADE	DESCRIPTION
I	Protrude only inside the lumen; seen only with an anoscope
II	Protrude during defecation; reduce spontaneously
III	Protrude during defecation; require manual reduction
IV	Permanently prolapsed and irreducible

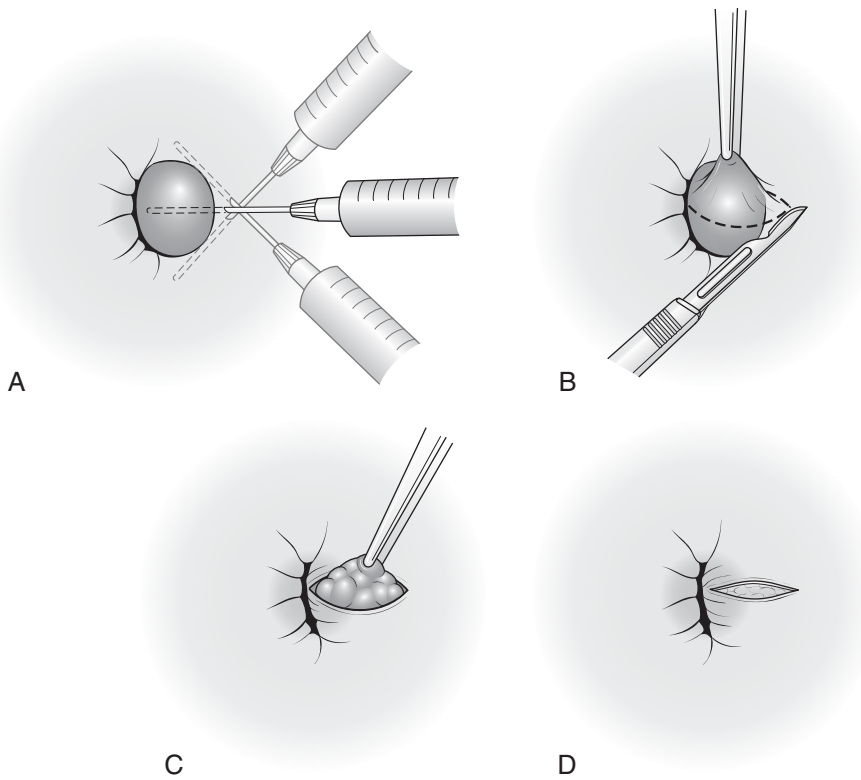

**Figure 2** Prolapsing (grade III) hemorrhoids showing a prominent external component (*right*) and two sites of recent bleeding (*left*).

may be administered at the apex of the hemorrhoid. Both procedures have moderate effectiveness but are considered less effective than rubber-band ligation, which is widely used in the office setting with favorable results.

Rubber-band ligation, an office procedure, requires the use of a rubber-band ligator (either suction type or a ligator with a clamp) and is performed by placing a rubber band around excess hemorrhoidal tissue at the apex of the hemorrhoid. Rubber-band ligation works by strangulating and cutting off blood flow to the hemorrhoid and by creating a scar that helps fix tissue into place. The band must be placed well above the dentate line to prevent pain. Most patients experience a sensation of pressure with the procedure. Rarely, this procedure can cause significant pain, bleeding, or a vasovagal reaction. In general, only one or two band applications are performed in the same setting to prevent excessive pain or a vasovagal reaction. Multiple rounds of hemorrhoid banding can be used to improve the patient's quality of life and has been shown to be more cost effective than hemorrhoid surgery, which is reserved for more severe prolapse.

Surgical treatment for hemorrhoidal disease should be considered in patients with grade III or IV internal hemorrhoids. Grade IV hemorrhoids, especially associated with dusky prolapsed rectal mucosa, urinary retention, or significant pain should be evaluated urgently by a surgeon, as necrotic tissue requires operative debridement. Surgery is also a consideration in cases in which office procedures and conservative treatment have been ineffective or when internal hemorrhoids are circumferential. In the United States, most hemorrhoidectomies continue to be performed using a closed technique in which the hemorrhoid is excised and the defect sutured closed. Stapled hemorrhoidectomy (also known as a *procedure for prolapsed hemorrhoids* (PPH) or *hemorrhoidopexy*) is used for patients who have more circumferential disease and is performed by excising the rectal mucosa and disrupting blood flow,

<sup>1</sup>Not FDA approved for this indication.

**Figure 3** Excision and evacuation of an external thrombosed hemorrhoid. **A**, A local anesthetic is injected into the subcutaneous surrounding tissue and at the base of the hemorrhoid. **B**, The skin over the hemorrhoid is lifted, and a small elliptical excision of skin is made. **C**, The thrombotic clot is evacuated. Additional dissection is sometimes needed in the subcutaneous tissue to extract the clot. **D**, The appearance of the evacuated area. The incision is left open, and the skin heals by secondary intention.

thereby shrinking hemorrhoidal tissue and lifting the prolapsing tissue into the anal canal. Although stapled hemorrhoidectomy has been demonstrated to be effective and on average less painful, it does not address external hemorrhoids, costs significantly more, and has been associated with rare but severe complications, including pelvic sepsis, rectal perforation, and rectovaginal fistula.

External hemorrhoids are generally painless, except in the case of thrombosis, and they normally appear as more prominent external perianal tissue or painless skin tags. Thrombosed external hemorrhoids, in contrast, are associated with severe pain and a prominent external lump, but not with bleeding or fever. On examination, an external thrombosed hemorrhoid appears as a prominent, blue, and firm perianal lump. Patients who present within 72 hours of onset of symptoms benefit from excision of the hemorrhoid rather than evacuation of the thrombosed clot (Figure 3). In contrast, patients who present after 72 hours should be treated expectantly with conservative supportive care, including sitz baths, normalization of bowel habits with fiber or stool softener, and pain management. The natural history in these cases is for the thrombosed clot to gradually be reabsorbed within several weeks. In many cases, a residual skin tag is noted by the patient and can interfere with anal hygiene.

### Anal Fissure

An anal fissure is a tear in the anoderm extending proximally into the anal canal and initially resulting from a traumatic bowel movement. Fissures typically occur in the setting of constipation or diarrhea. Most acute fissures will heal, but some patients have prolonged symptoms, causing them to seek medical attention. The pathophysiology of anal fissures is still not completely understood but is related to local ischemia caused by hypertonia of the internal sphincter. Most anal fissures are located at the posterior midline; some also occur at the anterior midline (Figure 4). Lateral fissures are rare and can be associated with anal malignancy, anorectal Crohn disease, HIV, syphilis, or tuberculosis. In these cases, a biopsy should be strongly considered to confirm the diagnosis.

Patients who present with anal fissure most often have a tearing pain that is associated with bowel movements and continues after defecation along with bright red bleeding with bowel movements. Physical examination demonstrates a tear in the anoderm with an

**Figure 4** Distribution of the location of anal fissures.

exposed internal sphincter on separation of the anus. Chronic cases also demonstrate a sentinel tag overlying the distal aspect of the fissure.

Conservative treatment for acute anal fissures includes normalization of bowel habits to minimize recurrent trauma to the anoderm and sitz baths for comfort. In cases in which the fissure is chronic or unresponsive to conservative treatment, topical therapy to relax the internal sphincter (i.e., a *chemical sphincterotomy*) is prescribed. Classically, nitroglycerin ointment (0.2%<sup>1,6</sup> to 0.4% [Rectiv]) has been used but is associated with headaches and lightheadedness. Diltiazem ointment (2%)<sup>1,6</sup> is a commonly used alternative without associated side effects. Either ointment can be applied topically two to three times per day for approximately 8 weeks. Application

<sup>1</sup>Not FDA approved for this indication.

<sup>6</sup>May be compounded by pharmacists.

before bowel movements works best to help with pain on defecation. Reported healing rates are similar and range from 40% to 100%. An alternative agent that can be used for chemical sphincterotomy is botulinum toxin A (Botox)<sup>1</sup>, which can be injected in the office or operating room with a single application into the internal sphincter. Although botulinum toxin A appears to be as effective as topical therapy, it is significantly more expensive.

Surgical lateral internal sphincterotomy is the most effective treatment to resolve anal pain associated with fissures and to expedite healing, but it is associated with a small risk of fecal incontinence. This procedure is performed in the outpatient setting and should be considered in cases in which topical medication has failed. This procedure can be performed with an open approach (incising mucosa and exposing muscle) or a closed approach (using landmarks and then dividing muscle by palpation) and can be full thickness (entire internal sphincter) or tailored (partial thickness and length). Most surgeons perform a tailored sphincterotomy from the level of the top of the fissure distally, with partial division of the internal sphincter muscle to decrease the risk of postoperative fecal incontinence.

### Anorectal Abscess and Fistula

Anorectal abscess is most commonly a self-limiting process thought to result from obstruction and infection of anal glands located in the crypts along the dentate line. Clinicians should be aware that perianal Crohn's disease, trauma, and malignancy can cause an anorectal abscess or fistula. Anorectal abscesses typically manifest with acute pain in the perianal area, acutely painful defecation, an indurated painful area, or fever. Most anorectal abscesses manifest with pain and swelling either superficially at the anal verge or deeper within the ischioanal fossa. These patients have obvious tenderness, induration, or fluctuance on external and/or digital examination. In contrast, patients with intersphincteric abscesses have severe pain but minimal findings on external examination and are only suspected on digital rectal examination.

The mainstay of therapy is surgical drainage. Superficial abscesses can be drained using local anesthesia, but more extensive infections typically require general anesthesia. When the abscess is fluctuant and appears easily accessible, an incision and drainage with a local anesthetic can be considered in a motivated patient. Important principles in draining an anorectal abscess include keeping the patient comfortable, using aspiration with a large-bore (14- or 16-gauge) needle to help in the event of difficult localization, using a cruciate incision to ensure adequate drainage, and keeping the incision near the anus to keep any potential fistula tract as short as possible. After the abscess is drained, the area is allowed to heal by secondary intention. Patients are given analgesics and encouraged to take sitz baths. When the abscess is large and extensive, sometimes drainage tubes, débridement, or additional dressing changes are required.

In most patients, drainage of the anorectal abscess is sufficient. However, in one-third of patients, these do not heal and form a fistula with the external opening beyond the anal verge and the internal opening within an infected crypt gland at the dentate line. A recent, small randomized trial suggested that 7 to 10 days of antibiotics after abscess drainage could decrease the risk of fistula formation. Patients developing a fistula can have what appears to be a nearly healed wound but continue to intermittently drain purulent material from the external opening, and some patients continue to have signs and symptoms of infection. Anorectal fistulas are defined by their anatomy and path relative to the sphincter muscles and are classified typically as superficial, intersphincteric, transsphincteric, suprasphincteric, and extrasphincteric, as classically described by Parks (Figure 5). In most cases, patients can proceed directly to the operating room for initial definition of the anatomy and placement of a seton (a length of suture or soft plastic vessel loop that is looped through the fistula), which allows drainage of infection within the tract, prevents recurrent infection, and allows the fistula to mature. Recurrent and complex fistulas may be better defined anatomically with the use of magnetic resonance imaging or endorectal ultrasonography.

Superficial, intersphincteric, or low transsphincteric fistulas can be treated with simple fistulotomy, which opens up the fistula

**Figure 5** Classification of anal fistulas. ES, Extrasphincteric; IS, intersphincteric; S, superficial; SS, suprasphincteric; TS, transsphincteric.

tract and allows the tissue to heal by secondary intention. This, however, can result in impaired fecal continence, particularly if the fistula involves a significant amount of sphincter muscle.

If the fistula is too deep for a fistulotomy because of concern about transecting too much sphincter muscle, a variety of methods can be used to repair the fistula. One classic technique is the use of a cutting seton, where a taut seton is progressively tightened over several weeks or months to form a scar in place of the fistula and muscle. A cutting seton may be painful, and the scar is associated with impaired continence in some cases. Fibrin glue and fistula plugs have been proposed as a method to repair a fistula, but the recurrence rate with long-term follow-up is high (>85%). Endorectal advancement flaps are the most well-established method to repair an anal fistula. With this technique, the internal orifice is closed, and healthy tissue is brought down over the internal fistula opening to allow the area to heal. This procedure can be technically difficult: failure most commonly results from ischemia of the flap, and repeat flap procedures are often not anatomically feasible because of scarring and fibrosis. Success rates have been reported between 50% and 80%.

The ligation of intersphincteric fistula tract (LIFT) has been investigated for transsphincteric and suprasphincteric fistulas and shows modest success with the benefit of avoiding any sphincter division. In this procedure, the fistula tract is ligated and partially excised through an intersphincteric approach. Although long-term results are still unknown, reports are favorable (on the order of 60% to 80%) for the short-term success of this technique.

## HEPATITIS A, B, D, AND E

Method of

Varun Takyar, MD; and Marc G. Ghany, MD

### CURRENT DIAGNOSIS

#### Hepatitis A

- Typical prodromal symptoms are nonspecific (i.e., fever, anorexia, nausea, vomiting, diarrhea, abdominal pain, and weight loss). In about one-half of patients, prodromal symptoms are followed by icterus (i.e., jaundice, pruritus, and dark urine) lasting 2 weeks.
- Serum aminotransferase levels increase to 10 to 20 times the upper limit of normal during the prodromal phase. Total serum bilirubin increases but rarely exceeds 10 mg/dL during the icteric phase. Biochemical recovery usually occurs within 3 months.
- Acute hepatitis A virus (HAV) infection is diagnosed by the presence of anti-HAV immunoglobulin M (IgM). Anti-HAV IgG appears in the convalescent phase and remains detectable for life. Anti-HAV IgG positivity with the absence of anti-HAV IgM antibodies reflects past exposure or vaccination. The antibody test for HAV usually includes total antibodies (IgM and IgG); thus diagnosis of acute hepatitis A requires specific anti-HAV IgM testing.

#### Hepatitis B

- Acute hepatitis B virus (HBV) infection may be asymptomatic or present with nonspecific symptoms of anorexia, nausea, and fever with development of icterus, pruritus, right upper quadrant pain, or, rarely, acute liver failure. Globally, it is a major cause of chronic hepatitis.
- Serum alanine aminotransferase (ALT) levels peak with the onset of symptoms.
- Suspected acute HBV infection is diagnosed by the detection of hepatitis B surface antigen (HBsAg), hepatitis B e-antigen (HBeAg), IgM antibody to hepatitis B core antigen (anti-HBc), and HBV DNA in serum in the appropriate clinical setting. Anti-HBc IgM is detected during acute HBV infection and may be detected during reactivation of chronic HBV infection.
- Chronic infection is defined as the persistence of serum HBsAg for greater than 6 months. If HBsAg is present, serum HBeAg, antibody to hepatitis B e-antigen (anti-HBe), HBV DNA, and serum ALT are used to determine the four phases of chronic infection (immune tolerant, HBeAg-positive and HBeAg-negative immune-active, and inactive carrier).

### CURRENT THERAPY

#### Hepatitis A

- Treatment is predominately supportive. Avoid hepatotoxic medications and drugs metabolized by the liver. Acute liver failure with encephalopathy and impaired synthetic function occurs rarely and is more common in patients older than 50 years of age and/or those who have coexisting chronic HBV or hepatitis C virus (HCV) infections.
- Prevention includes administration of the inactivated or attenuated vaccine for children at 1 year of age and older and for at-risk populations (e.g., intravenous drug users, travelers to regions with high or intermediate HAV rates, men who have sex with men, patients with chronic liver disease or clotting factor disorders).
- Preexposure passive immunization with pooled human anti-HAV immunoglobulin may be used for those at high or intermediate risk of hepatitis A virus exposure.

- Postexposure passive immunization with pooled human anti-HAV immunoglobulin may be used for close personal contacts of an individual with laboratory-confirmed HAV infection, staff and attendees of child care centers if one or more children and/or staff are diagnosed with HAV infection, and food handlers during a common-source exposure. Concurrent immunization with inactivated or attenuated vaccines for these at-risk contacts is also warranted.

#### Hepatitis B

- Acute HBV infection in an adult generally only requires supportive care because of high rates of spontaneous recovery. For people with evidence of acute liver failure, prompt institution of antiviral therapy with a potent nucleos(t)ide analogue and referral to a transplant center is recommended. Peginterferon alfa-2a (Pegasys)<sup>1</sup> is contraindicated in persons with acute liver failure.
- Treatment goals of chronic hepatitis B are sustained suppression of HBV DNA to prevent the development of cirrhosis, hepatocellular carcinoma, and liver-related mortality. Cure of chronic HBV infection is currently not possible. Treatment recommendations for chronic HBV differ depending on the phase of infection but are generally indicated for immune-active HBeAg-positive patients with confirmed HBV DNA greater than 2000 to 20,000 IU/mL and serum ALT two or more times the upper limit of normal; for immune-active HBeAg-negative patients with HBV DNA greater than or equal to 2000 IU/mL and serum ALT two or more times the upper limit of normal; and patients with liver biopsy-proven moderate to severe inflammation and/or moderate fibrosis. Treatment decisions outside these parameters should be individualized based on the risk for complications (e.g., older age [ $>40$  years], family history of cirrhosis or hepatocellular carcinoma, presence of cirrhosis) and the risk of therapy (e.g., chronic kidney disease, previous treatment history). Four agents are considered first line—peginterferon alfa-2a (Pegasys), entecavir (Baraclude), tenofovir (Viread), and tenofovir alafenamide (Vemlidy)—based on their safety, effectiveness, and low rates of antiviral resistance. Peginterferon is generally recommended for those who prefer a finite course of treatment and who have clinical and laboratory features predictive of a response to peginterferon (high ALT, low HBV DNA, young age, female gender, and HBV genotype A or B). Peginterferon is contraindicated in persons with decompensated cirrhosis, compensated cirrhosis with clinically significant portal hypertension, autoimmune illnesses, or active psychiatric illness and during pregnancy. Nucleos(t)ide analogues are more potent inhibitors of HBV DNA replication, generally better tolerated than peginterferon, and usually administered long term. The ideal endpoint of treatment is loss of HBsAg, though it is rarely observed with any therapy.
- Prevention includes completion of a three-dose HBV vaccination series for all children by 18 months of age, with the first dose administered within 24 hours of birth. Infants whose mothers are HBsAg positive or whose HBsAg status is unknown should receive the last dose by 6 months of age.
- Hepatitis B immune globulin (HyperHEP B) and HBV vaccination are recommended at birth for infants whose mothers are HBsAg positive. In mothers with viral loads greater than 200,000 IU/mL, antiviral therapy with tenofovir (Viread), telbivudine, or lamivudine (Epivir HBV) in the third trimester of pregnancy (gestation weeks 28 to 32) can be considered.

<sup>1</sup>Not FDA approved for this indication.

Five viruses, hepatitis A to E, account for the majority of cases of acute and chronic viral hepatitis. Chronic hepatitis is arbitrarily defined as the persistence of elevated serum aminotransferase levels for 6 or more months. Complications of chronic hepatitis (predominantly cirrhosis and hepatocellular carcinoma) account for the majority of morbidity and mortality caused by viral hepatitis.

**TABLE 1** Hepatitis A, B, D, and E Characteristics

	HEPATITIS A	HEPATITIS B	HEPATITIS D	HEPATITIS E
Classification	Picornavirus, ssRNA(+)	Hepadnavirus, dsDNA	Deltavirus, ssRNA(-)	Hepevirus, ssRNA(+)
Source	Stool	Blood	Blood	Stool

\*Not available in the United States.

<sup>†</sup>Higher in pregnancy at 5% to 20%  
HCC, Hepatocellular carcinoma.

Effective vaccines are available for the prevention of hepatitis A, B, and D infections. In addition, safe and effective therapy is available for treatment of chronic hepatitis B and C. Therefore, it is important to screen individuals who are at high risk for chronic viral hepatitis to provide them access to care, reduce complications, and offer counseling to prevent transmission of infection.

## Hepatitis A Virus

### Introduction

HAV is a positive-sense, single-stranded RNA virus of the *Hepatovirus* genus belonging to the Picornaviridae family. Its genome encodes four structural and seven nonstructural proteins. Four genotypes have been identified, but there is only one serotype. Therefore, exposure to one HAV genotype confers immunity to all genotypes.

### Natural History

HAV is a cause of acute hepatitis and acute liver failure but not chronic hepatitis (Table 1). In ~5% of cases, a prolonged cholestasis lasting more than 3 months may occur, and in ~10% of cases, a relapsing hepatitis has been observed up to 6 months after the acute illness with recrudescence of symptoms and flare of hepatitis. Cases of relapsing hepatitis continue to remain infectious with fecal shedding of the virus. These atypical presentations of acute hepatitis A should not be mistaken for evolution to chronic hepatitis, as resolution is the rule. Recovery of HAV is associated with development of lifelong immunity.

HAV replication occurs in hepatocytes, and the virus is shed into the intestine via the biliary system. Viral levels peak during the asymptomatic period, and virus shedding continues until around 2 weeks into the icteric phase. HAV is detectable in the blood, but levels are 1000-fold higher in the feces. Children may shed the virus longer than adults.

The incubation period usually lasts 14 to 28 days. This is followed by the onset of symptoms. The presence and severity of symptoms are variable and age related. Generally, more than 70% of adult patients have a symptomatic illness, compared with only 10% of children younger than the age of 10 years. Typical symptoms are nonspecific and include fever, anorexia, nausea, vomiting, diarrhea, abdominal pain, and weight loss. This prodromal phase is followed by an icteric phase in 40% to 70% of patients with jaundice, pruritus, and dark urine. Physical examination findings are usually unremarkable, but hepatomegaly may be observed. Extrahepatic manifestations are uncommon and may include an evanescent rash and arthralgias.

Laboratory studies during the prodromal phase reveal elevated serum aminotransferase levels greater than 10 to 20 times the upper limit of normal. During the icteric phase, total serum bilirubin increases but generally does not exceed 10 mg/dL. In most patients, jaundice lasts 2 weeks, and a complete clinical and biochemical recovery can be expected in 2 to 3 months.

### Epidemiology

Hepatitis A occurs throughout the world (Figure 1), either sporadically or in epidemics. The prevalence of HAV correlates with the level of sanitation and hygiene of a region. In developing countries, more than 90% of children are infected before 10 years of age. In developed countries, including the United States, infection rates are low. Lack of exposure at a young age leads to higher susceptibility in certain high-risk adults including travelers to endemic areas, injection drug users, and men who have sex with men.

In the United States, HAV infection rates have declined by 95% since the introduction of mandatory childhood vaccination in 1995. The overall incidence rate in 2019 was 5.7% per 100,000 persons, representing a 1,325% increase in cases between 2015 and 2019 due to person-to-person outbreaks in homeless persons and persons who use injection drugs. HAV is spread primarily by the fecal-oral route through the ingestion of contaminated food or water. Humans are the only known reservoir of the virus.

### Diagnosis

Serologic testing for antibody to HAV can confirm the diagnosis of acute infection, past exposure, and immunity to the virus. Acute HAV infection is diagnosed by the presence of anti-HAV IgM. Anti-HAV IgG appears in the convalescent phase of infection and remains detectable for life. Past exposure or vaccination confers immunity and is reflected by anti-HAV IgG positivity with the absence of anti-HAV IgM antibodies. The antibody test for HAV usually includes total antibodies (IgM and IgG). Thus, to diagnose acute hepatitis A, it is important to order anti-HAV IgM.

### Treatment

Given the self-limiting nature of acute hepatitis A, treatment is predominately supportive. Caution should be taken when using hepatotoxic medications or medications metabolized predominately in the liver. Rarely, acute liver failure with encephalopathy and impaired synthetic function can occur. The patients at highest risk for this complication are generally older than 50 years of age and may have coexisting chronic HBV or HCV infections.

**Figure 1** Global prevalence of hepatitis A and infection risk. Hepatitis A has a worldwide prevalence. Prevalence is related to regional income, sanitation, and hygiene. High-income areas (e.g., North America, Western Europe, Australia, New Zealand, Japan, the Republic of Korea, and Singapore) have low levels of hepatitis A virus (HAV) endemicity and subsequently a high proportion of susceptible adults. Low-income regions (sub-Saharan Africa and parts of South Asia) have high endemicity levels and very few susceptible adolescents and adults. Middle-income regions have a mix of intermediate and low endemicity levels.

Individuals presenting with acute liver failure are more appropriately managed at a liver transplant center.

### Prevention

Both inactivated and attenuated vaccines have been licensed against HAV. Inactivated vaccines include HAVRIX (GlaxoSmithKline), VAQTA (Merck), TWINRIX (a combined hepatitis A and B vaccine from GlaxoSmithKline), AVAXIM (Sanofi Pasteur),<sup>2</sup> EPAXAL (Crucell),<sup>2</sup> and HEALIVE (Sinovac).<sup>2</sup> The only live attenuated vaccine is BIOVAC-A (Pukang).<sup>2</sup> The World Health Organization (WHO) recommends routine childhood vaccination for HAV in areas with intermediate infection rates. In the United States, the Advisory Committee on Immunization Practices recommends that all children be vaccinated at 1 year of age. Other at-risk populations for whom vaccination is recommended include intravenous drug users, travelers to regions with high or intermediate HAV rates, men who have sex with men, persons in close contact with new adoptees from countries of high or intermediate hepatitis A endemicity, and patients with chronic liver disease or clotting factor disorders.

Passive immunization with immunoglobulin may also be used for preexposure protection among individuals who are at high or intermediate risk of HAV exposure. Pooled human anti-HAV immunoglobulins (GamaSTAN [IGIM]) decrease the HAV infection risk by 90% for up to 3 months. Passive immunization is also recommended for postexposure protection in cases of close personal contacts to an individual with laboratory-confirmed HAV infection, to staff and attendees of child care centers if one or more children and/or staff are diagnosed with HAV infection, and to food handlers during a common-source exposure. Concurrent immunization for HAV in these at-risk contacts is also warranted.

### Hepatitis E

#### Introduction

Hepatitis E virus (HEV) is a nonenveloped, single-stranded, positive-sense RNA virus of ~7300 bases in length and the sole member of the Hepeviridae family. Its genome contains three

overlapping open reading frames. ORF1 encodes four nonstructural proteins, ORF2 encodes the capsid protein, and ORF3 encodes a protein of unknown function. Human infection has been reported with the *Orthohepevirus A* (HEV-A) and *Orthohepevirus C* (HEV-C) species of HEV. HEV-A has eight distinct genotypes of which five (genotypes 1, 2, 3, 4, and 7) infect humans. HEV-C, genotype 1 (C-1), that predominantly infects rats, may cause acute and chronic infection in immunosuppressed individuals. Similar to HAV, only one serotype exists, and infection with one strain confers immunity to all others. HEV is likely a zoonosis with multiple nonhuman vectors.

#### Natural History

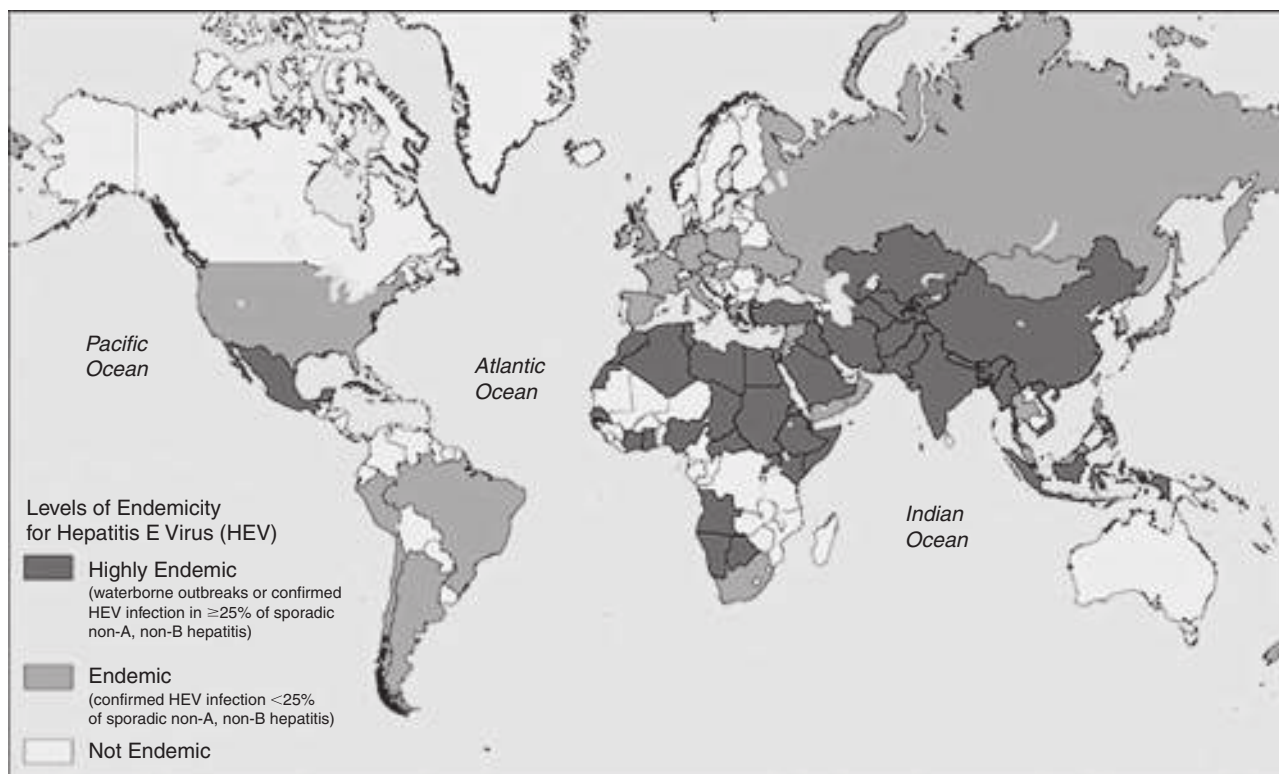

HEV is a cause of acute hepatitis and acute liver failure (see [Table 1](#)). It can cause chronic hepatitis in immunocompromised individuals. The majority of acute HEV infections are asymptomatic or minimally symptomatic. The incubation period is between 15 and 60 days, and if symptoms arise, they generally consist of anorexia, nausea, vomiting, diarrhea, and abdominal pain. Acute HEV infection rarely causes jaundice, and most symptoms resolve within 6 weeks from onset. A notable exception to the generally favorable outcome is an increased risk of acute liver failure among pregnant women during the second and third trimesters in endemic regions. This leads to a high maternal mortality rate of 15% to 25% and poorer maternofetal outcomes in third-trimester infections. Acute HEV infection may also be associated with a lymphocytic destructive cholangitis.

Chronic HEV infection is defined as the presence of HEV RNA in the serum or stool for more than 6 months. It is uncommon and has been observed in solid-organ transplant recipients, HIV-positive subjects, and other immunocompromised hosts. Chronic HEV infection has only been reported with HEV-A genotype 3 infections. It is unknown if other HEV genotypes can cause chronic HEV infection. Development of cirrhosis has been described as a consequence of chronic infection.

#### Epidemiology

HEV is found worldwide and can be divided into three distinct geographical patterns: highly endemic, endemic, and nonendemic (sporadic) ([Figure 2](#)). Large waterborne epidemics in highly endemic

<sup>2</sup>Not available in the United States.

**Figure 2** Global prevalence of hepatitis E virus. Hepatitis E is found worldwide. High endemic areas, defined by greater than or equal to 25% prevalence of sporadic non-A, non-B hepatitis, include parts of Central America and Mexico, Africa, the Middle East, and most of Asia. Endemic areas, defined as less than 25% prevalence of sporadic non-A, non-B hepatitis, include the United States, Europe, Russia, and parts of South America. Remaining regions are regarded as nonendemic.

regions are caused by infection with HEV genotypes 1 and 2 in Central America, Africa, and Asia. Sporadic cases of HEV in developed countries (Europe, North America, and Far East Asia) are caused by HEV-A genotypes 3 and 4. The reservoir for autochthonous HEV is unknown but thought to be domestic swine. Sporadic cases may occur in travelers to endemic areas. Interestingly, males are more affected than females in sporadic infections, but this gender bias is not observed during epidemics. HEV is spread by the fecal-oral route, usually through ingestion of contaminated water.

### Diagnosis

There are no commercially licensed tests for HEV detection in the United States. Testing is limited to research laboratories and can be obtained through the Centers for Disease Control and Prevention.

The diagnosis of acute HEV is made by detection of anti-HEV IgM in serum or HEV RNA in stool or serum. Anti-HEV IgG has limited utility in diagnosis of HEV infections and may be a serologic marker for past infection. In immunocompromised patients, antibody testing can be falsely negative, making HEV RNA the more reliable marker of acute and chronic infection. Chronic HEV is diagnosed when HEV RNA is present in sera or stool for more than 6 months in suspected cases.

### Treatment

Because most acute HEV infections are mild, treatment is generally supportive. Patients who develop acute liver failure should be managed at a liver transplant center. The initial approach to management of chronic HEV infection in posttransplant recipients is to reduce the level of immunosuppression. If this is unsuccessful, then off-label use of antiviral therapy with peginterferon alfa-2a (Pegasys)<sup>1</sup> or ribavirin (Rebetol)<sup>1</sup> may be considered. In immunocompromised individuals, therapy with peginterferon alfa-2a<sup>1</sup> or ribavirin<sup>1</sup> may be considered.

### Prevention

Prevention of hepatitis E relies principally on good sanitation and the availability of clean drinking water. Prevention of

transmission in travelers to endemic areas includes avoiding consumption of tap water, street foods, raw vegetables, and raw or undercooked meats such as pork and seafood. A commercially available vaccine for HEV, HECOLIN<sup>2</sup> (Xiamen Innovax Biotech), has been available in China since 2012.

## Hepatitis B Introduction

HBV is a partially double-stranded DNA virus of ~3200 bases belonging to the Hepadnaviridae family. HBV consists of an outer lipid shell that surrounds a nucleocapsid consisting of the viral DNA and the polymerase. HBV has four overlapping reading frames (core, surface, polymerase, and x), which encode for seven viral proteins. HBsAg is the marker of infection, and HBeAg is a marker of high viral replication and infectivity. The virus is classified into 10 major genotypes (A to J) that have a distinct geographic distribution. Four major serotypes have been described. Humans and old world primates (e.g., chimpanzees) are the only known hosts.

### Natural History

Hepatitis B virus is a cause of acute hepatitis and acute liver failure (see Table 1). Globally, it is a major cause of chronic hepatitis. Infection with HBV is notable for a long incubation period ranging from 1 to 6 months. The majority (two-thirds) of persons with acute HBV infection are asymptomatic, one-third have an icteric presentation, and less than 1% present with acute liver failure. Symptoms of acute HBV are nonspecific and include anorexia, nausea, pruritus, and right upper quadrant pain. Symptoms usually resolve in ~1 to 3 months. Serum ALT levels peak with the onset of symptoms. The outcome of acute hepatitis B is strongly influenced by age at exposure. Resolution of acute infection occurs in 95% of persons exposed as adults, but chronic infection ensues in more than 90% of persons exposed as infants.

The natural history of chronic HBV infection depends on a complex interplay between the virus and the host immune response. Chronic HBV infection is often viewed in four phases (immune

<sup>1</sup>Not FDA approved for this indication.

<sup>2</sup>Not FDA approved for this indication.

**Figure 3** Phases of chronic hepatitis B virus (HBV) infection. Chronic hepatitis B can be viewed in phases defined by HBeAg status and serum HBV DNA and ALT levels. The initial phase is the immune-tolerant phase, characterized by HBeAg positivity, high HBV DNA level (>10<sup>7</sup> IU/mL), and persistently normal ALT levels. This is seen only in persons who acquire the infection at birth or infancy and persists for two to three decades of life. The next phase is the immune-active phase, defined by continued HBeAg positivity, high HBV viral load (>10<sup>5</sup> IU/mL), and elevated ALT levels. The next phase is characterized by loss of HBeAg and development of anti-HBe and heralds a transition from a phase of high viral replication to one of low replication. The viral load is typically less than 10<sup>3</sup> IU/mL, and serum ALT is normal. This phase is termed the *inactive carrier phase*. A proportion of individuals develop raised HBV DNA and ALT levels after HBeAg seroconversion. These persons are said to have transitioned to the immune-escape or HBeAg-negative immune-active phase.

tolerant, HBeAg-positive and HBeAg-negative immune active, and inactive carrier) based on HBeAg status and serum HBV DNA and ALT levels (Figure 3). This classification is useful for providing advice on prognosis and need for treatment. Approximately 25% to 40% of persons with chronic infection will be at risk for development of cirrhosis. The 5-year cumulative incidence of cirrhosis in untreated chronic HBV infection is 8% to 20%. Once cirrhosis develops, the 5-year cumulative incidence of decompensated liver disease (ascites, variceal hemorrhage, hepatic encephalopathy) is approximately 20%, and the annual risk of hepatocellular carcinoma is 2% to 5%. Persons who have resolved chronic infection (cleared HBsAg) should be counseled of the risk for viral reactivation with use of chemotherapy or other immunosuppressive therapies.

### Epidemiology

An estimated 2 billion people worldwide have evidence of past HBV infection, and of these an estimated 257 million have chronic HBV infection. The prevalence of HBV infection is declining worldwide because of the availability of an effective vaccine and implementation of successful vaccination programs. The prevalence of HBsAg, the serologic marker of chronic infection, is highest (≥8%) in sub-Saharan Africa and Central Asia (Figure 4) and lowest (<2%) in Western Europe, Australia, Canada, and the United States (except Alaska) (see Figure 4). HBV is transmitted vertically, sexually, or through percutaneous routes and is more infectious than human immunodeficiency virus or hepatitis C virus. Individuals considered at high risk for acquiring HBV infection should be screened for chronic hepatitis B by testing for HBsAg (Table 2).

### Diagnosis

A number of serologic markers (viral antigens and antibodies to the viral antigens) and nucleic acid testing are available to diagnose acute and chronic HBV infection. Cases of suspected acute HBV infection are diagnosed by detection of HBsAg, HBeAg, IgM anti-HBc, and HBV DNA in serum in the appropriate clinical setting. Although anti-HBc IgM is detected during acute HBV infection, it is not specific for acute hepatitis B and may be seen during reactivation of chronic HBV infection.

Chronic infection is defined as persistence of HBsAg for greater than 6 months in serum. If HBsAg is present, it is advised to check HBeAg, anti-HBe, HBV DNA, and serum ALT to determine the phase of infection.

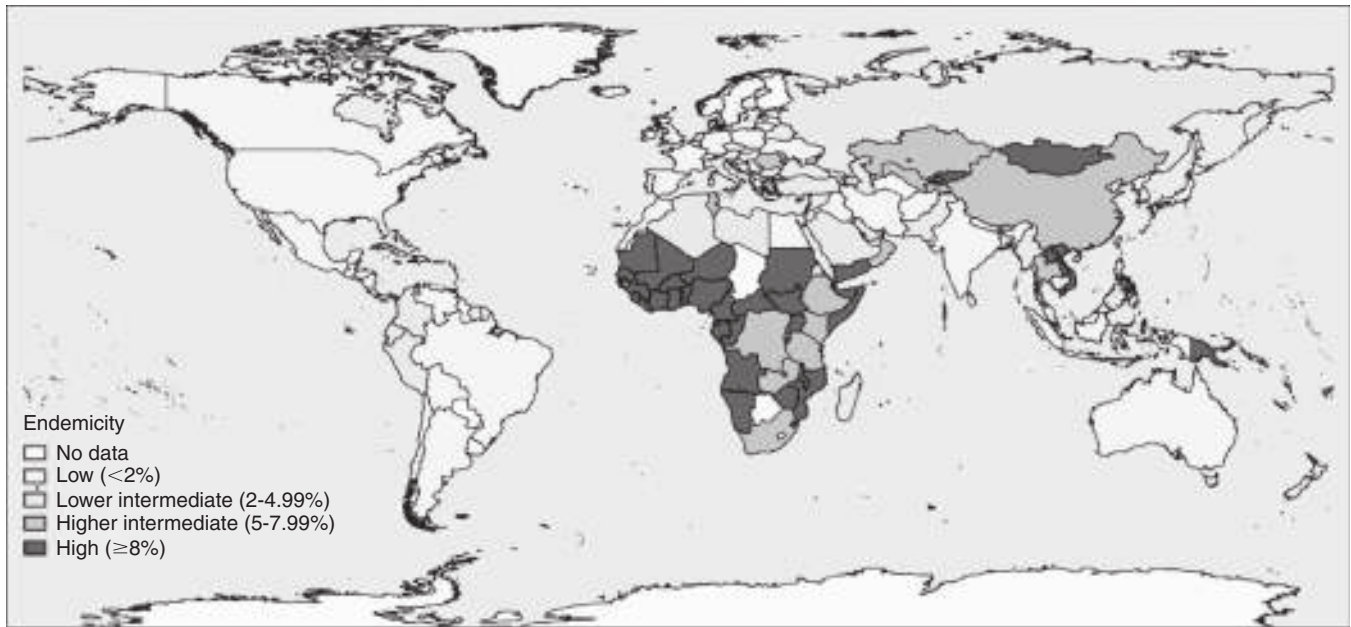

### Treatment

Acute HBV infection in an adult is associated with a high rate of spontaneous recovery, and antiviral treatment is rarely required. Supportive care is advised. For persons with evidence of acute liver failure, prompt institution of antiviral therapy with a potent nucleos(t)ide analogue and referral to a transplant center is recommended. Peginterferon alfa-2a (Pegasys)<sup>1</sup> is contraindicated in persons with acute liver failure.

The goals of treatment of chronic HBV are sustained suppression of HBV DNA to prevent the development of cirrhosis, hepatocellular carcinoma, and liver-related mortality. Cure of chronic HBV infection is currently not possible because of persistence of covalently closed circular DNA within the hepatocyte nucleus. Treatment recommendations differ among regional guidelines, but treatment is generally indicated for HBeAg-positive patients with confirmed HBV DNA greater than 2000 to 20,000 IU/mL and serum ALT two or more times the upper limit of normal, and for HBeAg-negative patients with HBV DNA greater than or equal to 2000 IU/mL and serum ALT two or more times the upper limit of normal and/or liver biopsy-proven moderate to severe inflammation and/or moderate fibrosis. The decision to treat persons outside these parameters should be individualized based on their risk for complications and risk of therapy. Eight agents are approved for the treatment of chronic HBV infection: two interferon preparations (interferon alfa-2b [Intron A has been discontinued by its manufacturer] and peginterferon alfa-2a [Pegasys]) and six nucleos(t)ide analogues (lamivudine [Epivir HBV], adefovir [Hepsera], entecavir [Baraclude], telbivudine, tenofovir disoproxil fumarate [Viread], and tenofovir alafenamide [Vemlidy]). Four agents are considered first line—peginterferon alfa-2a, entecavir, tenofovir, and tenofovir alafenamide—based on

<sup>1</sup>Not FDA approved for this indication.

**Figure 4** Global prevalence of chronic hepatitis B virus (HBV). Hepatitis B is found worldwide with varying geographic prevalence. High-prevalence areas defined as a prevalence of HBsAg greater than or equal to 8% include West Sub-Saharan Africa and Mongolia. Regions of high intermediate prevalence, defined as HBsAg prevalence of 5% to 7%, include China, Southeast Asia, and the remainder of Sub-Saharan Africa. Regions of low to intermediate prevalence, defined as HBsAg prevalence of 2% to 4%, include the Mediterranean region, India, the Middle East, Australia, and Japan. Regions with low prevalence, defined as HBsAg prevalence of less than or equal to 2%, include North America and Western Europe. Overall, the prevalence of HBV is declining worldwide.

**TABLE 2** Centers for Disease Control and Prevention Guidelines for Hepatitis B Virus Screening

Populations recommended or required for routine testing for chronic HBV infections

Persons born in regions of high and intermediate HBV endemicity (HBsAg prevalence >2%)

U.S.-born persons not vaccinated as infants whose parents were born in regions with high HBV endemicity (> 8%)

Injection drug users

Men who have sex with men

Persons with elevated alanine aminotransferase/aspartate aminotransferase of unknown etiology

Donors of blood, plasma, organs, tissues, or semen

Hemodialysis patients

All pregnant women

Persons needing immunosuppressive therapy

Infants born to HBsAg-positive mothers

Household, needle-sharing, or sex contacts of persons known to be HBsAg positive

HIV-positive persons

Persons who are the sources of blood or body fluids for exposures that might require postexposure prophylaxis (e.g., needlestick, sexual assault)

Modified from Centers for Disease Control and Prevention. Recommendations for Identification and Public Health Management of Persons with Chronic Hepatitis B Virus Infection.

ALT, low HBV DNA, young age, female gender, and HBV genotype A or B). Peginterferon alfa-2a is contraindicated in persons with decompensated cirrhosis, cirrhosis with clinically significant portal hypertension, autoimmune illnesses, or active psychiatric illness and during pregnancy. Nucleos(t)ide analogues are more potent inhibitors of HBV DNA replication and generally better tolerated than peginterferon alfa-2a. They are usually administered long term. The ideal endpoint of treatment is HBsAg loss, but this is rarely observed with any therapy (<10% with interferon and after 5 years of therapy with nucleos(t)ide analogues).

**Prevention**

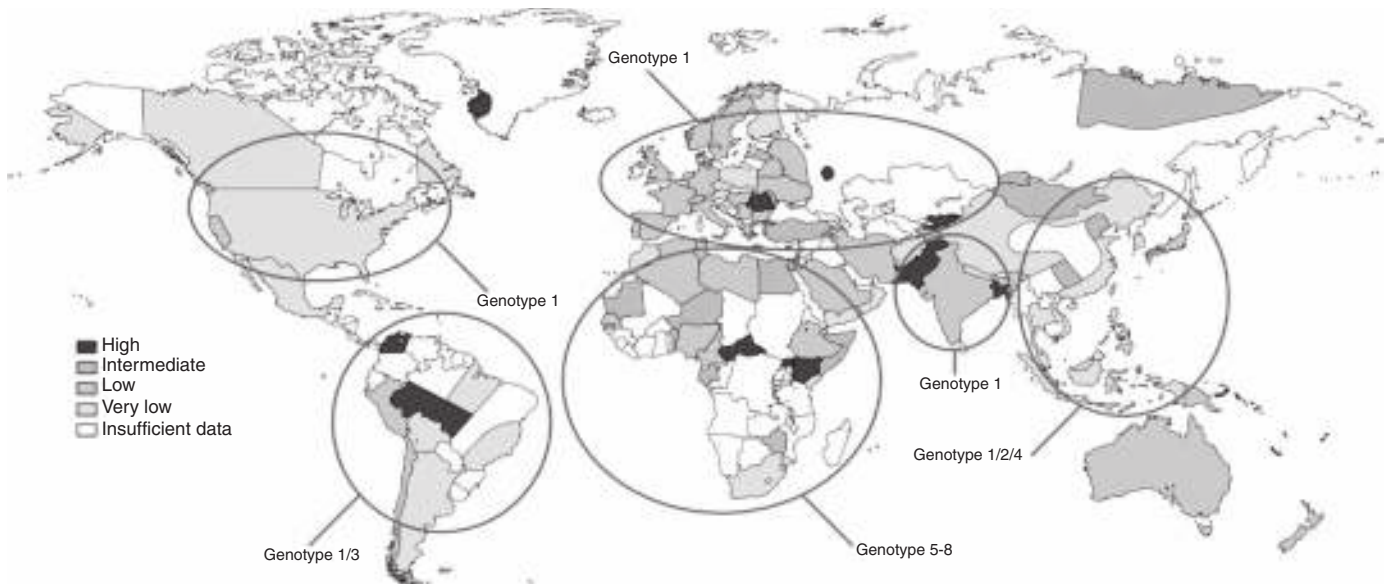

Vaccination is the primary method of prevention. An effective vaccine against HBV has been available since 1981. In the United States, the Advisory Committee on Immunization Practices (ACIP) has recommended that all infants complete the series of three vaccinations by 18 months of age with the first dose administered within 24 hours of birth. Infants whose mothers are HBsAg positive or whose HBsAg status is unknown should receive the last dose by 6 months of age. Hepatitis B immune globulin (Hyper-HEP B) and HBV vaccination is recommended at birth for infants whose mothers are HBsAg positive to prevent maternal-infant transmission of HBV. In mothers with viral loads greater than 200,000 IU/mL, antiviral therapy with tenofovir (Viread), telbivudine, or lamivudine (Epivir HBV) in the third trimester of pregnancy (gestation weeks 28 to 32) can be considered. Vaccination is recommended for all persons <19 years of age. In 2022, the ACIP recommended vaccination for adults 19 to 59 years of age and adults ≥60 years of age with risk factors for hepatitis B. Postexposure prophylaxis is recommended for anyone who is exposed to HBV and is considered susceptible to HBV infection and consists of hepatitis B vaccination and/or hepatitis B immune globulin depending on the HBsAg status of the exposure source.

**Hepatitis D**

**Introduction**

Hepatitis D virus (HDV) is a viroid that is dependent on HBV for its life cycle. The genome consists of a negative-sense, single-stranded circular RNA virus of ~1600 bases. The virus has an outer lipoprotein envelope HBsAg derived from HBV and is

their safety, efficacy, and low rates of antiviral resistance. Peginterferon alfa-2a is generally recommended in persons who would prefer a finite course of treatment and who have clinical and laboratory features predictive of a response to peginterferon (high

**Figure 5** Global prevalence of hepatitis D virus. Hepatitis D is found globally, but prevalence varies among geographic regions. The highest prevalence is observed in Central Africa, Central Asia, and the Amazon. Intermediate-prevalence regions include West Africa and Eastern Europe. Low-prevalence regions include North America, most of Western Europe, and Australia.

attached to a single structural protein, the HDV antigen (HDAG). There are eight known genotypes. Immunity to HBV prevents HDV infection.

#### Natural History

Hepatitis D virus is a cause of acute hepatitis, acute liver failure, and chronic hepatitis (see [Table 1](#)). Hepatitis D virus infection can occur either simultaneously with HBV (referred to as *coinfection*) or as an infection in a patient with chronic HBV infection (referred to as *superinfection*). The outcome of HBV/HDV coinfection depends on the course of acute hepatitis B infection and is generally self-limiting with a low risk of chronicity (~5%). In contrast, HDV superinfection of a chronic HBV carrier results in chronic HDV infection in more than 90% of cases. Acute liver failure is observed more commonly with coinfection than with superinfection. Chronic HDV infection has a variable course, from an asymptomatic carrier to cirrhosis and decompensated liver disease. In general, HDV infection is associated with more rapid progression to cirrhosis and decompensated liver disease and a higher rate of hepatocellular carcinoma compared with HBV monoinfection.

#### Epidemiology

In developed countries, the prevalence of HDV has decreased as a consequence of widespread vaccination against hepatitis B. Chronic HDV infection is predominately seen in intravenous drug users or hemophiliacs requiring frequent transfusions. HDV is prevalent in the Amazon basin, Africa, the Mediterranean basin, Central Asia, Mongolia, and Russia ([Figure 5](#)). HDV genotype 1 can be found worldwide, but all other genotypes are restricted to specific geographic areas.

HDV is spread by the same routes as HBV infection and is efficiently transmitted by parenteral and sexual exposure. In contrast with HBV, vertical transmission is not a common mode of transmission. Transmission cannot occur in the absence of HBsAg.

#### Diagnosis

Testing for hepatitis D should be considered in persons presenting with acute hepatitis B who have additional risk factors for HDV,

including a history of injection drug use; persons from endemic regions who present with a severe or protracted hepatitis; patients with chronic hepatitis B who develop an acute hepatitis of undetermined origin; and persons with HBsAg-positive chronic hepatitis B from endemic regions. Total anti-HDV (IgM and IgG) and anti-HDV IgM are the only commercially available assays in the United States. Initial testing for HDV should be with total anti-HDV. Chronic infection should be confirmed by a reverse transcriptase polymerase chain reaction assay for HDV RNA.

#### Treatment

The goals of treatment are long-term suppression of both HDV and HBV to prevent the development of cirrhosis, hepatocellular carcinoma, and liver-related death. There is no effective treatment for HDV. Peginterferon alfa-2a (Pegasys)<sup>1</sup> has been used for treatment of HDV. The most effective dose and duration of treatment have not been established. Peginterferon alfa-2a (Pegasys)<sup>1</sup> administered for 48 to 72 weeks results in sustained HDV RNA suppression after 6 months off therapy in 17% to 43% of patients. Liver transplantation with the use of hepatitis B immune globulin<sup>1</sup> is an option for patients with decompensated liver disease. Novel agents blocking viral entry and posttranslational prenylation are currently being investigated in clinical studies.

## HEPATITIS C

Method of

Arthur Y. Kim, MD

### CURRENT DIAGNOSIS

- Hepatitis C virus (HCV) is a common infection in the United States, with major morbidity and mortality.
- The incidence of HCV is rising, linked to the opioid epidemic.
- Given the asymptomatic presentation and long period before complications, screening is warranted: one-time routine opt-out testing for adults age 18–79 is recommended, as is periodic repeat testing for increased risk, especially in people who inject drugs (Table 1).
- Diagnosis is made with two-stage testing: initial screening for anti-HCV antibodies followed by HCV RNA testing to confirm the presence of virus.

### CURRENT THERAPY

- Novel therapeutic approaches that are safe and highly effective have revolutionized the care of HCV.
- The goal of therapy is cure of virus, which prevents liver-related complications and further transmission.
- Regimens of combination antivirals typically given for 8–12 weeks can cure over 95% of those living with HCV infection.

The diagnosis, management, and therapeutic approaches for patients living with HCV have been dramatically transformed in recent years. Most people (over 95%) living with HCV infection can be cured after 8 to 12 weeks of safe oral regimens involving combined antiviral agents. The availability of novel therapies enhances the effectiveness of screening patients for HCV infection who may otherwise be unaware of infection owing to its asymptomatic presentation.

### Virology, Pathogenesis, and Natural History

HCV is a single-strand RNA virus whose genome encodes several viral proteins, including nonstructural proteins (NS3/4A, termed protease; NS5A and NS5B, termed polymerase) that may each be specifically targeted by medications. There are seven known families of virus, commonly known as genotypes 1 through 7, many with subtypes (e.g., genotype 1a or 1b).

After acute infection in the majority of individuals, the virus establishes a chronic lifelong infection characterized by high levels of viremia easily detected in plasma; in a minority, the virus is spontaneously cleared. In the latter scenario, HCV is permanently eradicated, as the polymerase is an RNA-RNA polymerase and there is no DNA intermediate to establish latency in the host. Those who achieve clearance of virus, whether spontaneously or via treatment, are susceptible to reinfection if exposed again.

Both the acute and chronic phases of HCV infection are largely asymptomatic. A minority of those with acute infection may present with nonspecific symptoms such as abdominal pain and malaise, with less than 10% presenting with jaundice. Rarely, those with chronic infection may experience extrahepatic manifestations of HCV infection, such as cryoglobulinemic vasculitis, proteinuria or glomerulonephritis, or lymphoma. Otherwise, alanine transaminase (ALT) levels may be persistently or intermittently elevated but may also be within normal range in up to 20% of infected individuals; thus, ALT is considered an imperfect screening test for HCV.

After establishment of chronic HCV infection, fibrosis occurs at a variable rate and may progress to cirrhosis in about 15%

to 20% over a 20-year period. Fibrosis may be accelerated by other liver insults, such as alcohol use, nonalcoholic steatohepatitis, and coinfection with HIV or hepatitis B virus (HBV). Those with HCV-related cirrhosis may experience significant morbidity and mortality from various complications; screening for varices and hepatocellular carcinoma is recommended (see chapter on cirrhosis).

### Epidemiology

HCV is estimated to infect at least 70 million people worldwide. In the United States, it is the leading bloodborne pathogen and infects over 3 million Americans. The highest-risk groups are those born between 1945 and 1965 (so-called baby boomers), people who inject drugs, and HIV-positive men who have sex with men. In the United States, the incidence reached a peak in the 1970s and 1980s and then steeply declined; in the past decade there has been a resurgence of new incident cases linked to a widespread opioid epidemic.

Owing to the high number of infections that occurred decades ago, a large number of Americans within the baby-boomer cohort are now at risk for unidentified long-standing HCV infection, cirrhosis, and death; at present the mortality related to HCV exceeds that related to all other notifiable infectious diseases in the United States. HCV-related cirrhosis remains a leading indication for liver transplantation.

### Risk Factors

HCV is most efficiently transmitted via exposure to contaminated blood or its components. In the United States, injection drug use (IDU) is the most common mode of transmission. Nosocomial exposure to contaminated blood or blood products and poorly sterilized or reused contaminated medical equipment remains an important risk, especially if strict universal precautions are not instituted. Mother-to-child transmission is not efficient, as only about 5% of children born to HCV-infected women are infected, with higher rates if HIV/HCV coinfection is present. Sexual transmission is considered very rare in the context of heterosexual relationships but does occur at higher rates in men who have sex with men, particularly with HIV and/or practices that result in exposures to blood.

### Diagnosis

Two tests are used for the diagnosis of HCV infection: testing for anti-HCV antibodies and measuring HCV RNA. The suggested algorithm is initial serologic testing to assess exposure, followed by HCV RNA testing to determine current or cleared infection. Currently available anti-HCV testing is highly sensitive (>99%) but may be falsely negative in the earliest stages of infection (typically the first 4 to 12 weeks) or in the setting of immunosuppression (such as dialysis or HIV if CD4 cell counts are below 200/mm<sup>3</sup>). HCV RNA testing may be utilized to confirm current HCV RNA infection after an initial positive anti-HCV test or in settings when anti-HCV may be falsely negative. There are two types of HCV RNA tests: qualitative HCV RNA tests, which do not quantify the level of viral replication, and quantitative HCV RNA tests. Quantitative testing has improved in recent years and exhibits sensitivity similar to that of qualitative testing; therefore it is preferred in most situations.

Those with confirmed current HCV infection (positive HCV RNA) should also be tested for HIV and HBV (the latter typically by hepatitis B surface antigen [HBsAg]). Follow-up evaluation includes the HCV genotype, which defines therapeutic options. Discovery of advanced fibrosis or cirrhosis may affect the specifics of recommended antiviral regimens but also has prognostic implications. The likelihood of cirrhosis is dependent on various factors, including advancing patient age, duration of infection, and cofactors such as significant alcohol use or HIV. Noninvasive assessment with serologic testing (such as Fibrosure) or with novel imaging technologies (such as transient elastography) has largely replaced liver biopsies.

**TABLE 1** Recommendations for One-Time Screening

All adults aged 18–79 years without prior ascertainment of risk

## Risk factor–based screening

## Risk behaviors

- Injection drug use (current or ever, including those who injected only once)
- Intranasal drug use

## Risk exposures

- Persons on long-term hemodialysis (ever)
- Persons with percutaneous/parenteral exposures in an unregulated setting
- Health care, emergency medical, and public safety workers after needlesticks, sharps, or mucosal exposures to HCV-infected blood
- Children born to HCV-infected women
- Prior recipients of transfusions or organ transplants, including
  - Persons who were notified that they received blood from a donor who later tested positive for HCV infection
  - Persons who received a transfusion of blood or blood components or underwent an organ transplant before July 1992
  - Persons who received clotting factor concentrates produced before 1987
- Persons who were ever incarcerated

## Other considerations

- HIV infection
- Sexually active persons about to start preexposure prophylaxis for HIV
- Unexplained chronic liver disease and/or chronic hepatitis, including elevated alanine aminotransferase levels
- Solid-organ donors (deceased and living)
- Pregnant women

HCV, Hepatitis C virus.  
Modified from <http://hcvguidelines.org>.

**Prevention**

Prevention of HCV infection should be targeted to the highest-risk groups. For people who inject drugs, clean injecting equipment—including needles, syringes, and other components of drug preparation—is paramount. Risk reduction should also be achieved after viral clearance to prevent reinfection.

Prevention of fibrosis progression includes minimization or abstinence from regular alcohol use, avoidance of fatty liver, and avoidance of primary infection with or control of coexisting viruses (HIV or HBV). For individuals who are not immune, vaccination against hepatitis A virus and HBV is recommended. Patients with coexisting substance use disorder should be referred for appropriate care.

**Therapy**

Antiviral treatments for hepatitis C have been revolutionized with combination regimens of direct-acting antivirals (DAAs). These new drugs are used in combination with the goal to eradicate HCV. Cure is known as a sustained virologic response (SVR), defined as a negative HCV RNA test 12 or more weeks after cessation of therapy. This definition represents a durable cure in the absence of reinfection. Benefits of SVR include a significant reduction in future liver-related events, especially for those with advanced fibrosis or cirrhosis. Additional benefits include abrogation of further HCV transmission, amelioration of extrahepatic

manifestations (if present), and improvement in quality of life. Virtually all patients with current HCV infection are candidates for therapy.

Agents may be classified by the viral protein they target. The following are NS3/4A protease inhibitors: simeprevir, paritaprevir (which requires pharmacologic boosting with ritonavir), glecaprevir, and grazoprevir. NS5A inhibitors include daclatasvir, elbasvir, ledipasvir, ombitasvir, and pibrentasvir; the NS5A nonnucleoside inhibitor dasabuvir; and the NS5B nucleotide polymerase inhibitor sofosbuvir. Simeprevir (Olysio), daclatasvir (Daklinza), and sofosbuvir (Sovaldi) were developed as single agents, but the majority are parts of combination regimens, as described in Table 2. The Infectious Diseases Society of America (IDSA) and American Association for the Study of Liver Diseases (AASLD) maintain guidelines for providers at <http://www.hcvguidelines.org>, which provides updates with approval of novel agents and as new data become available.

One major consideration in choosing a regimen is the genotype of the virus, although certain regimens such as glecaprevir/pibrentasvir (Mavyret) and sofosbuvir/velpatasvir (Epclusa) are able to treat all genotypes (termed pangenotypic). Other potential influences include presence of cirrhosis, the potential for concomitant drug interactions (including those with HIV coinfection on antiretrovirals), prior treatment experience, and adherence to therapy. Certain regimens such as glecaprevir/pibrentasvir (Mavyret) have been tested for those with advanced renal impairment. Insurance formulary preferences may also dictate the choice. One regimen in particular, elbasvir/grazoprevir (Zepatier), requires testing of genotype 1a virus for resistance-associated substitutions (RASs) associated with decreased response; if these are present, the duration should be increased and ribavirin (Ribasphere) added. In general, almost all patient groups can be offered a regimen with a rate of SVR at or above 95%.

These combinations have favorable safety profiles, with phase III trials reporting very low discontinuation rates. The most common side effects of these regimens are headache and fatigue. At times, ribavirin may be added to the regimen, particularly in the cases of relapse after previous treatment and/or cirrhosis (especially if the patient is decompensated or was previously decompensated).

Drug-drug interactions are also potentially problematic. Sofosbuvir-containing regimens should not be coadministered with amiodarone (Cordarone) owing to reports of symptomatic bradycardia with poor outcomes. Medications may significantly decrease the absorption of HCV antivirals, especially rifampin (Rifadin), carbamazepine (Tegretol), oxcarbazepine (Trileptal), and St. John's wort.<sup>7</sup> For the combinations of ledipasvir/sofosbuvir (Harvoni) and sofosbuvir/velpatasvir (Epclusa), care must be taken if they are coadministered with medications that decrease gastric pH. The involvement of clinical pharmacists may be very useful, along with resources such as the website maintained at the University of Liverpool: <http://hep-druginteractions.org>.

**Monitoring**

Compared with previous regimens that were associated with more side effects and complications, current treatments are far more tolerable. Clinical visits or phone calls to monitor for side effects and to promote adherence are often performed monthly during treatment. A negative HCV RNA at approximately week 4 into therapy confirms adherence. Certain regimens may require more intensive monitoring in the presence of cirrhosis, as cases of decompensation have been reported. Those with active HBV replication who are untreated are at risk for reactivation of this virus once HCV is suppressed, with rare cases of liver failure reported; cotreatment of both viruses or very close monitoring is recommended for this subgroup. At this time there are no data for the use of these agents in pregnancy or during breastfeeding.

<sup>7</sup>Available as dietary supplement.

**TABLE 2** First-Line Combination Antiviral Regimens for Chronic Hepatitis C as of December 2019, Genotypes 1 to 4

GENOTYPE	COMBINATION	USE OF RIBAVIRIN (RBV)	DURATION (WEEKS)	NOTES
1	Elbasvir 50 mg/grazoprevir 100 mg FDC (Zepatier) qd	Add RBV and extend to 16 weeks if baseline NS5A RASs present (genotype 1a only)	12–16	Safe in advanced chronic kidney disease; not recommended in decompensated cirrhosis
	Glecaprevir 300 mg/pibrentasvir 120 mg FDC (Mavyret) qd	Not proven	8–16	8 weeks for treatment naive; 12–16 weeks for certain treatment-experienced patients
	Ledipasvir 90 mg/sofosbuvir 400 mg FDC (Harvoni) qd	Add RBV if both interferon-experienced and cirrhosis (12 weeks)	8–24	Antacids reduce absorption; 8 weeks consideration only for naive patients with F0-2 and HCV RNA less than 6M IU/mL
	Sofosbuvir 400 mg/velpatasvir 100 mg FDC (Epclusa) qd	Consider in select circumstances	12–24	Antacids reduce absorption
2	Glecaprevir 300 mg/pibrentasvir 120 mg FDC (Mavyret) qd	Not proven	8–12	8 weeks for treatment naive; 12 weeks for certain treatment-experienced patients
	Sofosbuvir/velpatasvir FDC (Epclusa) qd	Consider in select circumstances	12	Antacids reduce absorption
3	Glecaprevir 300 mg/pibrentasvir 120 mg FDC (Mavyret) qd	Not proven	8–16	8 weeks for treatment naive (unless cirrhosis + Y93H mutation); 12–16 weeks for certain treatment-experienced patients
	Sofosbuvir/velpatasvir FDC (Epclusa) qd	Consider in select circumstances	12–24	Antacids reduce absorption
4	Elbasvir/grazoprevir (Zepatier) qd	Consider adding RBV for cirrhosis, prior nonresponder	12–16	
	Ledipasvir/sofosbuvir FDC (Harvoni) qd	Consider for previous SOF failure	12	
	Glecaprevir 300 mg/pibrentasvir 120 mg FDC (Mavyret) qd	Not proven	8–16	8 weeks for treatment naive; 12–16 weeks for certain treatment-experienced patients
	Sofosbuvir/velpatasvir FDC (Epclusa) qd	Consider in select circumstances	12	Antacids reduce absorption

Daclatasvir may need dose adjustments with certain medications that interact with cytochrome P450.

FDC, Fixed-dose combination; NS5A, nonstructural protein 5A; RASs, resistance-associated substitutions; RBV, ribavirin; SOF, sofosbuvir.

## INFLAMMATORY BOWEL DISEASE

Method of

**Mona Rezapour, MD, MHS; Danny Avalos, MD; and Oriana M. Damas, MD\*,†**

### Introduction and Epidemiology

Inflammatory bowel disease (IBD) is a chronic relapsing inflammatory disorder of the gastrointestinal (GI) tract that includes

Crohn disease (CD) and ulcerative colitis (UC). A subset of patients with IBD have indeterminate colitis (IC), a classification that is determined when clinical features and diagnostic tests do not fit specifically into either CD or UC.

In the United States, about 3 million people have a diagnosis of IBD. Recent epidemiologic studies indicate that although the incidence of IBD in Westernized countries has stabilized, disease burden is expected to continue to rise as the annual prevalence steadily increases. The demographics of the IBD population in the US are also changing. Traditionally a disease that afflicted mainly European whites and the Ashkenazi Jewish population, IBD is now increasingly common among African Americans and Hispanic Americans.

The majority of IBD cases are sporadic. However, a little less than 20% of cases report having a relative with IBD, and this is particularly higher in patients with CD. There is also a higher IBD concordance in patients with CD compared to UC, wherein 2% to 14% of patients with CD report a family history of CD. Previous studies report that first-degree relatives of individuals with IBD have a lifetime risk of developing CD of 5% to 8% and of developing UC of 1.6% to 5.2%. With two affected parents, the risk of developing IBD in offspring increases to as high as 33%. These findings clearly support the influence of underlying genetic susceptibility in IBD development.

There are now more than 200 IBD susceptibility genetic loci associated with IBD risk, with substantial overlap seen between

\* The authors disclose no relevant conflicts of interest.

†Funding for Oriana M. Damas was supported by: NIH N3U54MD010722-03S1.

UC and CD. Genome-wide association studies and meta-analyses, thereafter, provide fundamental insights into IBD pathogenesis. Implicated loci are enriched in genes involved in host-microbial interactions and are shared with other complex, immune-mediated diseases. Despite the discovery of these genetic underpinnings, established IBD loci actually explain only a fraction of the variance in disease risk and even less so of disease phenotype. This suggests that other factors, including environmental exposures, likely make larger contributions to pathogenesis and phenotype.

**Clinical Features**

IBD onset occurs primarily at a young age, between the second and fourth decade of life, although some studies suggest a bimodal distribution with another peak observed in the sixth and seventh decade of life. IBD can be difficult to diagnose because there is no single biomarker that can diagnose IBD. IBD diagnosis is made by a combination of clinical, serologic, radiographic, endoscopic, surgical, and histologic features. Adding further to the complexity is the fact that sometimes symptoms are vague. For example, fatigue, fever, chills, weight loss, failure to thrive in children, and development of extra-intestinal manifestations (EIMs) can at times precede luminal GI symptoms. When IBD is suspected and diarrhea is present, it is imperative that the patient’s stool is examined for infectious causes because these can mimic IBD on radiographic imaging and endoscopically. Table 1 describes in detail differences in clinical presentation as well as differences in disease location between UC and CD.

**Natural History**

Most patients with CD and UC have a chronic, relapsing course. In CD, the natural history of intestinal inflammation can ultimately lead to the development of intestinal complications such as strictures, fistulas, and abscesses (Figure 1). This is particularly true if patients do not receive appropriate timely medical treatment. In many cases, these complications result in need for procedures (such as perianal abscess drainage or seton placements) and surgeries. Similarly, patients with untreated UC may also end up with complications including spontaneous colon perforation

or megacolon, in which case a total colectomy is curative. UC patients with longstanding disease are also at risk for colon cancer. Recent studies suggest that progression of disease of both CD and UC is preventable by timely administration of biologic therapy, which can modify the disease course.

**Diagnosis**

**History and Physical**

The diagnosis of IBD first starts with a careful clinical assessment, including a detailed history and a thorough physical exam that includes a perianal exam to look for the presence of perianal disease. A family history of IBD in the setting of GI symptoms should also raise clinical suspicion. Based on the clinical exam, the provider can then order a set of diagnostic tests to confirm the diagnosis

**Laboratory Testing**

It is important to order stool studies if diarrhea is present, to exclude enteric infections, as well as other causes of diarrhea (e.g., pancreatic insufficiency). A stool test to measure inflammation, such as stool fecal calprotectin or lactoferrin, is a noninvasive marker to detect the presence of enteric (mainly colonic) inflammation. These tests are useful for diagnosis and for monitoring of clinical disease activity.

Laboratory results, including presence of iron deficiency anemia, elevated C-reactive protein, and erythrocyte sedimentation rate (ESR), can clue into the diagnosis, although on their own, they are insufficient to definitely diagnose IBD. IBD-associated antibodies, including *antisaccharomyces cerevisiae* antibodies (ASCA IgG and IgA), perinuclear antinuclear cytoplasmic antibody (pANCA), anti-flagellin (CBir1), antiouter membrane porin C (anti-OmpC), and antipseudomonas fluorescens-associated sequence I2 (anti-I2), can be measured in the blood and can aid in the diagnosis of IBD.

However, it is important to keep in mind that these antibodies can also be present in patients without IBD who have a family history of IBD. In prior studies, serologic markers such as pANCA detect 40% to 80% of UC patients and the ASCA detect

**TABLE 1** Clinical Presentation and Differences in Location of Disease Between Ulcerative Colitis and Crohn Disease

CLINICAL FEATURES	ULCERATIVE COLITIS	CROHN DISEASE
Bloody diarrhea	++	±
Passage of mucus	++	±
Urgency to have a bowel movement	++	++
Tenesmus	++	±
Abdominal pain	++ (mainly left lower quadrant)	++ (can be diffuse or commonly right lower quadrant)
Weight loss	++	++
Fevers (important to exclude infection)	++	++
Fatigue and exhaustion	++	++
Presence of extra-intestinal manifestations	++	++ (especially in Crohn colitis)
Depression	++	++
<b>Disease Location</b>		
Small bowel involvement	– (never)	± (can be present)
Upper-gastrointestinal tract (proximal to ligament of Treitz)	– (never)	± (can be present)
Fistula presence (enteric, perianal, or entero-vaginal/vesicular or enterocutaneous)	– (never)	± (can be present)
Colonic disease	++ (always)	± (can be present)

**Figure 1** The natural history of Crohn disease if left untreated, (Adapted from Pariente, B, Cosnes J, Danese S, et al. Development of the Crohn's disease digestive damage score, the Lemann score. *Inflamm Bowel Dis* 17(6):1415-1422, 2011.)

**Figure 2** Endoscopic images of ulcerative colitis (UC) and Crohn disease (CD). (A) UC with luminal bleeding, loss of vascular pattern, and ulcerations. (B) CD with large deep ulcerations and edema in the terminal ileum.

about 68% of CD patients. CD patients can also carry pANCA, as seen in approximately 40% of patients who have Crohn colitis. Therefore, although helpful when positive as they can raise clinical suspicion for either CD or UC on their own, serologic markers are insufficient to diagnose IBD.

### Imaging

CT and MRI provide information about the presence of inflammation in the small bowel and can be very useful in the diagnosis of IBD when there is clinical suspicion but no evidence of inflammation on ileocolonoscopy. CT or MR enterography (MRE) provide high contrast resolution that can help define mural and extra-mural complications. MREs are particularly helpful in defining the presence of disease activity in CD and in distinguishing between inflammatory and more complicated CD (such as fistulizing and/or stenotic disease). Pelvic imaging also helps identify the presence of perianal CD such as perianal/perirectal fistulas. An MRI is preferred over CT in patients younger than 17 years of age to prevent long-term exposure to radiation.

### Endoscopy and Histology

Colonoscopy with ileal intubation is considered the gold standard for diagnosis of IBD. The endoscopic location and appearance can

also help distinguish between CD and UC. Endoscopic hallmarks of CD include patchy areas of inflammation with surrounding normal intervening mucosa, inflammation characterized by edema, nodularity, and ulcerations causing a cobblestone appearance (Figure 2). Endoscopic findings of UC include ulceration, friability, and loss of vascularity starting in the distal rectum and extending proximally in a continuous pattern (see Figure 2). An isolated cecal patch of inflammation can be observed in UC patients with otherwise more distal disease and this should not be confused as a skip pattern seen in CD. Furthermore, the finding of mild ileal inflammation known as “backwash ileitis” is sometimes seen in UC patients with ileocecal valve inflammation and in the primary sclerosing cholangitis (PSC) patient. Small bowel capsule endoscopy is also helpful in visualizing the small bowel mucosa in patients with a high index of suspicion for small intestinal CD.

Histologic changes seen in CD and UC are distinct from those seen in acute infection and include mucosal separation, distortion and branching of crypts, presence of chronic inflammatory cells in the lamina propria, increase in number of lymphocytes and plasma cells in the crypt bases, and paneth cell metaplasia. In addition, the classical finding of granulomas is only seen in a minority of CD patients and although helpful, is not pathognomonic as they can also be seen in UC.

**Figure 3** Picture of a patient with erythema nodosum, characterized by red/purple, painful lumps present most commonly in the lower extremities. Erythema nodosum is seen more in Crohn disease and its presence parallels active gut inflammation.

### Extraintestinal Manifestations

EIMs occur in 21% to 36% of IBD patients. Arthropathy is the most common EIM. Some EIMs are associated with disease activity and others are independent of disease activity. EIMs that parallel disease activity include aphthous ulcers and peripheral, dermatologic (erythema nodosum, [Figure 3](#)), and ophthalmologic (episcleritis and scleritis) arthropathies. EIMs that do not correlate with luminal inflammation include axial arthropathy (ankylosing spondylitis), hepatobiliary (PSC), and some dermatologic manifestations (such as pyoderma gangrenosum). Although not an EIM, by strict definition, IBD can also result in other extraluminal disease complications including thromboembolic disease and osteoporosis.

### Management of Disease

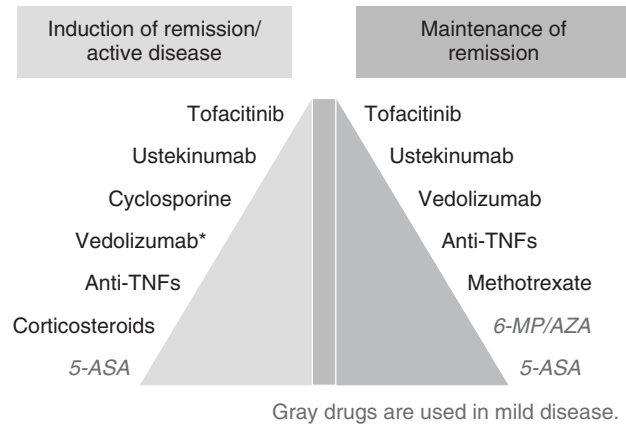

In IBD, we classify therapy as induction therapy, which controls the inflammation quickly, and as maintenance therapy, which sustains control of inflammation. [Figure 4](#) illustrates currently available inductive and maintenance therapies for IBD. The specific therapy is determined by several disease characteristics including disease location, extent of disease, and disease severity. The goal of therapy is control of inflammation, prevention of complications, and improvement in quality of life. These therapies include corticosteroids, 5-aminosalicylates (5-ASA), immunomodulators, and biologics. Therapeutic drug monitoring (TDM) of biologics is also an important component of therapy. TDM involves checking drug levels and the presence of antibodies to achieve a biologic-specific therapeutic target. TDM as a proactive or a reactive strategy is a topic of ongoing debate and beyond the scope of this chapter.

### Medical Therapy

#### Corticosteroids

Corticosteroids, in particular prednisone, are used in both UC and CD mainly to manage disease flares. In UC, it can also be used for induction of remission in those intolerant to 5-ASAs or those who have failed to respond to 5-ASA treatment. The dose commonly used is 40 mg/day until clinical improvement and then a taper of 5 to 10 mg weekly until 20 mg, at which time a slower taper of 2.5 mg weekly is followed. Methylprednisolone (Solu-Medrol) is an intravenous medication often used in severe disease

### Therapeutic pyramid for IBD

**Figure 4** Therapeutic algorithm. Patients with milder disease benefit from 5-aminosalicylates (5-ASA) therapies as inductive and maintenance therapies. Other therapies are for moderate-severe disease. \*Vedolizumab can be used as inductive therapy, although onset of action can take weeks. 6-MP/AZA, 6-mercaptopurine and azathioprine.

flares in hospitalized patients in doses from 40 to 60 mg/day. Controlled-release budesonide in the ileum (Entocort EC) and controlled-release budesonide in the colon (UCERIS) also serve as effective short-term corticosteroids with fewer side effects as compared to conventional oral corticosteroids due to their high liver first-pass metabolism and low systemic bioavailability. What limits the use of corticosteroids is their substantial side effect profile that includes psychiatric disturbances, hyperglycemia, impaired wound healing, metabolic bone disease, and ophthalmologic disease. Importantly, steroids, while a convenient oral medication often interpreted as less harmful than biologics, are actually associated with a higher risk of infection than anti-TNFs and do not reliably cause mucosal healing. Steroids are also not effective for maintenance of remission, as they do not alter the natural history of the disease in the same way that biologics can.

#### Aminosalicylates

Aminosalicylates are compounds that contain 5-ASAs that exert a topical antiinflammatory effect on the intestinal lining. In UC, both oral and rectal formulations can be used for induction and maintenance of remission in mild-moderate disease. Their effect in CD as induction and maintenance therapy is debatable because they do not have an effect on transmural inflammation and they work mostly in the colon. See [Table 2](#) for specific 5-ASA therapies and their location of action in the colon and/or small bowel. Patients should have yearly renal function and urine analysis testing given the rare but known side effect of acute interstitial nephritis associated with 5-ASA products.

#### Cytokine Inhibitors

##### TNF- $\alpha$ -antagonists (Anti-TNFs)

TNF- $\alpha$ -antagonists include infliximab (IFX [Remicade]), adalimumab (ADA [Humira]), certolizumab pegol (CZP [Cimzia]), and golimumab (GOL [Simponi]). They are indicated in moderately to severely active disease and most of them are effective in both UC and CD, although CZP and GOL have only demonstrated clinical efficacy in CD and UC, respectively. There is now evidence that earlier initiation of biologic therapy is more effective for induction of remission, prevention of disease complications, and reduction of steroid use. Early aggressive therapy is also associated with a higher likelihood of achieving mucosal healing, which is associated with the best clinical outcomes. Combination therapy with anti-TNF agents and immunomodulators was shown in the SONIC study to be more effective than monotherapy with anti-TNF or with immunomodulators alone in treatment-naïve patients. This finding we later learned is mainly

**TABLE 2** 5-Aminosalicylates Therapies Available in the US for the Treatment of Inflammatory Bowel Disease.

MEDICATION (BRAND NAME)	MESALAMINE CONTROLLED-RELEASE (PENTASA)	MESALAMINE EXTENDED-RELEASE (APRISO)	MESALAMINE DELAYED-RELEASE (LIALDA)	MESALAMINE DELAYED-RELEASE (ASACOL HD)	SULFASALAZINE (AZULFIDINE)	OLSALAZINE (DIPENTUM)	BALSALAZIDE (COLAZAL)
Dosages	<i>Induction:</i> 1 g PO 4 times daily	<i>Maintenance:</i> 1.5 g PO daily	<i>Induction:</i> 4.8 g PO daily <i>Maintenance:</i> 2.4 g PO daily	<i>Induction:</i> 1.6 g PO 3 times daily	<i>Induction:</i> 1 g PO 4 times daily <i>Maintenance:</i> 1 g PO twice daily	<i>Induction</i> <sup>1</sup> : 1.5–3 g daily <i>Maintenance:</i> 500 mg PO twice daily	<i>Induction:</i> 2.25 g PO 3 times daily <i>Maintenance</i> <sup>1</sup> : 3–6 g PO daily
Location of release	Stomach, Jejunum, Ileum, Colon	Ileum, Colon	Ileum, Colon	Ileum, Colon	Colon	Colon	Colon
Delivery system	Controlled release gradually throughout the GI tract and not pH-dependent	Delayed release and pH-dependent	Delayed release and pH-dependent	Delayed release and pH-dependent	5-ASA linked to Sulfapyridine	Two 5-ASAs joined with one azo bond	One 5-ASA linked to an inert unabsorbed carrier molecule
Drug Monitoring	UA + renal function testing annually	UA + renal function testing annually	UA + renal function testing annually	UA + renal function testing annually	UA + renal function testing annually	UA + renal function testing annually	UA + renal function testing annually

<sup>1</sup>Not FDA approved for this indication.  
5-ASAs, 5-Aminosalicylates; GI, gastrointestinal; UA, urinalysis.

due to the immunogenicity of anti-TNF agents, wherein introduction of immunomodulators as combination therapy reduces the frequency of antidrug antibody formation in the dual therapy group and promotes higher drug levels. Gastroenterologists starting anti-TNFs ultimately decide the need for dual therapy based on disease severity, but better algorithms for predicting who will do better on which regimen are needed.

TNF-blockers are contraindicated in patients with moderate-to-severe congestive heart failure (New York Heart Association functional class III/IV) and in patients with existing demyelinating diseases. Additionally, relative caution is advised for individuals with a prior lymphoma, known malignancies, a prior history of melanoma, and patients with a family history of demyelinating diseases. Patients should be cautioned about an increased risk of opportunistic infections, lymphoproliferative disorders, and melanoma development in patients who start anti-TNFs. However, mounting evidence suggests that the risk of lymphoproliferative disorders is actually mostly secondary to patients previously exposed to thiopurines. Recent studies show that the risk of non-Hodgkin lymphoma (NHL) is increased fourfold in IBD patients treated with thiopurines. Anti-TNF medications are also associated with an increased risk of NHL of about sixfold (6.1 per 10,000 patient-years); however, all these patients had been treated with immunomodulators previously. This is comparable to the expected rate of NHL in the general population of 1.9 per 10,000 patient-years.

#### Interleukin-12 and Interleukin-23 Inhibitors

Ustekinumab (Stelara) blocks both interleukin (IL)-12 and IL-23 by binding to the p40 subunit of IL-12 and IL-23, inhibiting their interaction with the IL-12 and IL-23 cell receptor binding complexes. Ustekinumab was found effective for induction of remission and as maintenance therapy for moderate to severe CD in the UNITI trials that incorporated close to 1300 CD patients. Ustekinumab is also now increasingly considered as a first-line therapy for moderate to severe CD due to its rapid onset of action, desirable safety profile, and improved efficacy when used as a first-line agent. Importantly, long-term tolerability and safety trials in both psoriasis and CD have so far reported a favorable safety profile for ustekinumab, including no serious opportunistic infections, injection-site reactions,

anaphylaxis, serum sickness-like reaction, or increased rate of malignancies. On post hoc analysis of patients in the UNITI pivotal trials, there was a 1.5-fold increase in inducing fistula response in patients with perianal fistulizing CD. Lastly, the phase 3 UNIFI trial showed that a single IV dose of ustekinumab can induce clinical remission at week 8 in patients with moderate to severe UC who have previously failed conventional or biologic therapy.

#### Immunomodulators

##### Calcineurin Inhibitors

Cyclosporine (Neoral, Sandimmune) is effective as salvage therapy in patients with severe steroid-refractory UC and was as effective as IFX in preventing colectomy in this cohort of inpatients. Cyclosporine is not effective in CD. Unfortunately, its safety profile and adverse effects limit its use. These side effects include diarrhea, nausea, vomiting, headache, tremors, hypertension, hepatotoxicity, nephrotoxicity, and neurotoxicity. Cyclosporine can be used in severe or fulminant, steroid-refractory UC, although long-term remission is only improved with the addition of either thiopurines or IFX. It can also be used in severe, steroid-refractory UC patients who have previously failed IFX therapy or have a low albumin level (particularly because low albumin is associated with high clearance of IFX), or as an inpatient bridge to vedolizumab.

##### Thiopurines

Thiopurines are used in both CD and UC, as either monotherapy or as adjunctive therapy to TNF-blockers. Thiopurines include azathioprine (Imuran)<sup>1</sup>, mercaptopurine (6-MP [Purinethol])<sup>1</sup>, and thioguanine (6-TG [Tabloid])<sup>1</sup>. Azathioprine is a pro-drug that is metabolized to 6-MP. The metabolic pathway of thiopurines involves three enzymes that convert 6-MP to its two by-products, 6-methylmercaptopurine (6-MMP), 6-thiouric acid, or 6-thioguanine nucleotide (6-TGN). 6-TGN is the therapeutic, targeted pathway. Thiopurine methyltransferase (TPMT) enzyme activity is tested prior to initiation of therapy to determine whether patients can obtain the drug at all and to determine the dosage. Once the drug is initiated, metabolite levels of 6-TGN

<sup>1</sup>Not FDA approved for this indication

and of 6-MMP are checked to assess for appropriate treatment efficacy. 6-TGN levels greater than 235 are associated with therapeutic efficacy. In addition, one study showed that 6-TGN levels greater or equal to 125 were sufficient to incur a higher level of anti-TNF in combination therapy. 6-TGN at levels above 400 can lead to myelosuppression and 6-MMP levels above 5700 can lead to hepatotoxicity. For these reasons, patients on thiopurines require more frequent blood monitoring than patients on biologics. Patients should have a hepatic function panel and a CBC checked every 4 months once steady drug dosages and drug levels have been achieved.

### Methotrexate

Methotrexate<sup>1</sup> is used in the treatment of CD. It is a folic acid analogue that inhibits dihydrofolate reductase and subsequent folate-dependent synthetic reactions, which suppress inflammation. In CD, intramuscular methotrexate (dose 15 to 25 mg/week) is effective in the maintenance of remission. Oral methotrexate (12.5 to 15 mg/week) is not superior to placebo for maintenance of remission. In addition, methotrexate can be used as adjunctive therapy with anti-TNFs to reduce anti-TNF immunogenicity. Methotrexate is not effective in the treatment of patients with UC. The adverse effects of methotrexate include myelosuppression, alopecia, nausea, vomiting, diarrhea, hepatotoxicity, nephropathy, and neuropathy. Patients should be counseled about alcohol abstinence and contraceptive use.

### Agents Targeting Leukocyte Trafficking

Leukocyte trafficking agents are now available for the treatment of severely active UC and CD. Natalizumab (Tysabri), a nonselective anti- $\alpha$ 4 integrin antibody, interferes with the systemic trafficking of leukocytes to both vascular cell adhesion molecule-1 and mucosal addressin cell adhesion molecule-1 (MAdCAM-1). It was first approved for use in CD in 2007 when it was shown to have efficacy for induction and maintenance of remission in active CD. However, the risk of progressive multifocal leukoencephalopathy (PML) caused by JC virus has greatly limited its use in practice. Vedolizumab (Entyvio), approved in 2014, is a selective  $\alpha$ 4 $\beta$ 7 integrin inhibitor that binds specifically to peripheral blood lymphocytes and inhibits its adhesion to a gut specific receptor, MAdCAM-1. Therefore it is a gut-specific leukocyte trafficking agent with no cases of PML reported with its use and with an overall very low systemic toxicity. Vedolizumab has a lower side effect profile, including a lower risk of systemic infections and no reported risk of lymphoproliferative disorders. It is a safer drug to use in conjunction with other immunosuppressants, for example, in patients with transplants who are already immunosuppressed. However, its slower onset of action limits its use in the acute, more urgent, setting.

### Small Molecules

#### Agents Targeting Janus Kinase Family

Tofacitinib (Xeljanz) is the first small molecule approved for the induction and maintenance of remission of moderately to severely active UC. Tofacitinib is an oral, small molecule Janus kinase (JAK) inhibitor that preferentially inhibits *JAK3* and *JAK1*. JAK-STAT pathways regulate signaling of several immune-related mediators including type I interferon and interferon- $\delta$ . Inadvertent *JAK1* inhibition by tofacitinib results in higher rate of serious infections including herpes zoster. In addition, in psoriasis and rheumatoid arthritis patients, tofacitinib is associated with an increase in lipid levels, although the significance of this increase in causing cardiovascular events is not seen. Because of the high risk of shingles in patients taking tofacitinib, it is recommended that all patients starting tofacitinib receive the inactivated form of the herpes zoster vaccine, Shingrix, prior to starting therapy.

### Pregnancy in Inflammatory Bowel Disease

Pregnancy is possible in patients with IBD. Women with IBD are more likely to have voluntary childlessness due to concerns

with heritability of their IBD, risks of congenital abnormalities, and medication side effects and teratogenicity. It is important for patients and providers to know that there is no reduction in fecundity or fertility in women with IBD. This is true in most women with IBD, unless they have previously undergone pelvic surgery, such as in the setting of an ileoanal pouch anastomosis (IPAA) surgery. In this case, reduced rates of fecundity are possible but can be overcome by in vitro fertilization. Women with IBD should undergo disease activity evaluation prior to conception because active disease is the most important determining factor for a healthy, uneventful pregnancy. Patients with active disease during pregnancy are at risk for complications including premature births, low birth weight, babies born too small for gestational age, and of having cesarean deliveries.

In pregnant IBD patients, oral and rectal 5-ASAs, thiopurines, and most biologics should be continued throughout pregnancy to maintain long-term control of inflammation, which is the most influential determinant of a healthy pregnancy. However, medications such as methotrexate, cyclosporine, and allopurinol (Zyloprim)<sup>1</sup> are contraindicated during pregnancy and should be discontinued. Methotrexate should be discontinued in women and men planning to conceive, ideally 3 months prior to conception. Although mesalamines are considered one of the safest drugs during pregnancy, due to a few animal studies, women taking dibutyl phthalate (DBP)-containing 5-ASA (Asacol-HD) should switch to a non-DBP-containing formulation due to potential teratogenicity.

Anti-TNFs can be safely used during pregnancy. It is generally recommended to hold the last dose of an anti-TNF, due to increased placental transfer in the third trimester. That said, many GI providers may choose to continue the therapy based on presence of active inflammation and/or a historically difficult to control IBD. Certolizumab is the only anti-TNF with no placental transfer during pregnancy and can, therefore, be continued without reservations throughout the third trimester.

Several large registries have found that anti-TNFs and thiopurines have an adequate safety profile for the newborn. Studies looking at postnatal outcomes find that babies born of mothers on anti-TNF monotherapy have no increased infection risk during the first year of life. However, a small increased risk of immediate postnatal infections was seen in babies born of mothers on dual therapy with anti-TNF and immunomodulators.

Other biologics, when used as monotherapy, show similar safety profiles. Recent trials show that there are no increased safety risks to babies born of mothers treated with vedolizumab during pregnancy. Similarly, data on ustekinumab during pregnancy, largely derived from the rheumatology literature, appear to demonstrate an adequate safety profile. However, the verdict is still out on tofacitinib. So far, observed outcomes of congenital malformations (seen in 1% of patients) and spontaneous abortions (seen in 10.8% of patients) reported in tofacitinib studies mirror the background risks seen in the general population. Nevertheless, due to limited data on tofacitinib during pregnancy, no definitive conclusions or recommendations can be made regarding its use in pregnancy.

### Preventive Care in Inflammatory Bowel Disease

IBD is a chronic medical condition associated with an increased risk of complications from influenza, pneumococcal pneumonia, and an increased prevalence of several cancers, including skin cancer. Despite several studies demonstrating this, IBD patients receive less preventive healthcare than other patients with chronic medical conditions. In the following we highlight important health maintenance screening measures for an IBD population. Several checklist resources are available for easy implementation into clinical practice (Figure 5).

### Vaccinations

Administration of live vaccines, when deemed appropriate, should be administered to IBD patients off immunosuppression

## CCFA Health Maintenance Checklist for Adult IBD Patients

Vaccine-Preventable Illnesses	Which Patients	How Often
Influenza (inactive)	All	Annually
Pneumococcal PCV13	If on/planning immunosuppression	Once <sup>1</sup>
Pneumococcal PPSV23	If on/planning immunosuppression	At baseline, repeat in 5 years
Tdap	All	Every 10 years
HPV	All aged 18-26	Once (3 doses within 6 mos.)
Meningococcal meningitis	All adult patients at risk of meningitis	Once
Hepatitis A	If non-immune	Once (2 doses within 6 mos.)
Hepatitis B	If non-immune	Once (3 doses within 6 mos.)
MMR (live vaccine)	If non-immune <sup>2</sup>	Once (1-2 doses)
Varicella (live vaccine)	If non-immune <sup>2</sup>	Once (1-2 doses within 6 mos.)
Zoster (live vaccine)	All aged > 50 years <sup>3</sup>	Once
<b>Cancer Prevention</b>		
Cervical PAP smear	All on systemic immunosuppression <sup>4</sup>	Annual
Skin screen	All on systemic immunosuppression <sup>4</sup>	Annual
Colonoscopy	All with extensive disease for >8 years	Every 1-3 years
<b>Other Screenings</b>		
DEXA Scan	High risk; women with low BMI, post-menopausal, chronic steroid exposure	At least 2 years apart
PPD or IGRA	Prior to anti-TNF or anti-IL-12/23	Once
Smoking status	All	Annual
Depression check	All	Annual

The evidence base for this checklist varies from "insufficient to assess benefits" to "moderate net benefits."

Developed by the CCFA Professional Education Committee Sub-Group: Alan Moss MD, Francis Farraye MD, MSc, Glenn Gordon MD, Raluca Vrabie MD • Approved by Committee Chairs: Samir Shah MD, Millie Long MD • V2\_January\_2017

1. Recommended timing of serial pneumococcal vaccination with both PPSV23 and PCV13 available in ACIP recommendation
2. Patients treated with systemic immunosuppressive therapy (steroids, thiopurines, anti-TNFs) should not receive live (attenuated) vaccines (e.g. measles, mumps, rubella, nasal influenza, varicella, and yellow fever)
3. Patients receiving anti-TNFs, anti-IL-12/23, or >20 mg prednisone should NOT be given the live zoster vaccine. Vaccine can be administered if on methotrexate < 0.4 mg/kg/week, 6-mercaptopurine < 1.5 mg/kg/day or azathioprine < 3 mg/kg/day
4. "Systemic immunosuppression" currently includes azathioprine, mercaptopurine, methotrexate, anti-TNFs, anti-IL-12/23

**Figure 5** Health maintenance checklist. At the time of this print, the inactivated form of the shingles vaccine was not available. This guideline mentions the zoster vaccine, which has now fallen out of favor in our immunosuppressed population. Adapted from the Crohn's and Colitis Foundation (website: <http://www.crohnscolitisfoundation.org/science-and-professionals/programs-materials/health-maintenance-checklist.pdf>).

or in patients on low dose immunosuppression. Ideally, these vaccines should be given 4 weeks or less prior to onset of immunosuppression and should be avoided within 2 weeks of initiation of immunosuppression, although vaccinations should never hold off need for urgent treatment of IBD. Low-level immunosuppression includes individuals who have received steroids at a low dose ( $\leq 20$  mg/day) and for a short period of time ( $< 2$  weeks), or individuals taking the following medications at low doses: methotrexate  $\leq 0.4$  mg/kg/week, azathioprine  $\leq 3.0$  mg/kg/day or 6-mercaptopurine  $\leq 1.5$  mg/kg/day. Live vaccines such as the measles, mumps, and rubella vaccine (MMR), the yellow fever vaccine, and the live herpes zoster vaccine (Zostavax) are contraindicated in individuals already on immunosuppressive therapy. Fortunately, there is now an inactivated, recombinant herpes zoster vaccine (Shingrix) that is available to patients over the age of 50 and to those anticipating immunosuppression.

IBD patients should receive all age-appropriate vaccinations. Additionally, all IBD patients, irrespective of immunosuppressant medications, should receive the inactivated influenza vaccine annually and the pneumococcal vaccine (PCV13 and PPSV23). The human papilloma virus (HPV) vaccine can also be administered to patients on chronic immunosuppression from age 27 years to 45 years due to recent FDA approval extending the age group.

### Cervical Cancer Screening

Women with IBD on immunosuppressive therapy are at an increased risk of cervical high-grade dysplasia and cancer.

Therefore both the American College of Gastroenterology (ACG) and the European Crohn's and Colitis Organization recommend that women with IBD on immunosuppressive therapy should have annual cervical cancer screening.

### Melanoma and Nonmelanoma Skin Cancer Screening

IBD increases the risk of melanoma independent of medications. Anti-TNF therapies have also been linked to an increased risk of melanoma. Nonmelanoma squamous cell skin cancer (NMSC) is associated with both current and past use of chronic immunosuppression, specifically thiopurines. In the CESAME study, the hazard ratios for NMSC in IBD who received thiopurines was 5.9 for ongoing treatment and 3.9 for past exposure. Taken altogether, it is, therefore, prudent that all IBD patients undergo evaluation by a dermatologist. Patients on anti-TNFs and on thiopurines should undergo yearly dermatologic examinations.

### Depression and Anxiety Screening

IBD patients have an increased prevalence of depression and anxiety disorders, irrespective of their disease severity. In a recent systematic review, about 19% of patients with IBD developed anxiety and 21.2% developed depression. Therefore several recent guidelines now recommend screening patients with IBD for depression and anxiety. Depression and anxiety can be assessed by the Hospital Anxiety and Depression Scale, the Beck Depression inventory (BDI), the Spielberger Anxiety inventory, and the Perceived Stress Questionnaire.

## Osteoporosis Screening

The pathogenesis of bone loss in IBD is multifactorial, due to steroid treatment, systemic effects of chronic inflammation, calcium and vitamin D deficiencies, and malnutrition. That said, not all IBD patients need to be screened for osteoporosis. IBD patients should be screened if they report a history of steroids for at least 3 months in a dose of greater than 7.5 mg/day or if they have any non-IBD established risk factors for osteoporosis, such as decreased body mass index, dietary deficiency of vitamin D and calcium, and previous fracture history.

## Smoking Cessation Counseling in Inflammatory Bowel Disease Patients

Cigarette smoking is the strongest environmental factor impacting onset and disease course of CD. Cigarettes are associated with an increased need for steroids, development of postsurgical neo-TI strictures, and development of arthropathy. By corollary, smoking is also associated with an increased risk of colon cancer. In UC, cigarette smoking can ameliorate disease inflammation and smoking cessation can result in UC onset and/or flare-up. However, the global adverse effects of cigarette smoking are above any potential therapeutic benefit to smoking in UC.

## Colon Cancer Screening and Surveillance

UC patients and CD patients with colitis are at an increased risk for colorectal cancer (CRC). The risk factors for developing CRC are similar in UC and CD and include duration, severity and extent of disease, PSC, and a family history of CRC. This risk is usually seen 8 to 10 years after the diagnosis of pancolitis. Patients with less involvement of the colon, specifically with less than a third of the colon involved, can start screening for colon cancer later, after 15 years of disease. Once screening starts, surveillance should take place every 1 to 2 years as recommended by several task force guidelines. Patients with PSC, however, need to undergo an annual surveillance colonoscopy, irrespective of duration of disease, due to their high risk of colon cancer.

## Conclusion

IBD is a chronic, complex disease associated with high morbidity if untreated. In this chapter, we discuss new therapies available that can significantly alter the natural history of disease and improve quality of life. Primary care doctors, at the forefront of care, should be well acquainted with the diagnostic workup of IBD as well as with pertinent preventive health measures that are specific to an immunosuppressed population. We expect that future studies will deliver more patient-specific care models that improve delivery of healthcare, response to treatment, and ultimately IBD outcomes.

## INTESTINAL PARASITES

Method of

Tarvinder Gilotra, MD

## CURRENT DIAGNOSIS

### Signs and Symptoms

- Watery diarrhea—Most protozoal infections: *Giardia*, *Blastocystis*, *Dientamoeba*, *Cryptosporidium*, *Cyclospora*, *Cystoisospora*, *Microsporidia*
- Dysentery—Most commonly *Entamoeba histolytica*; less commonly *Balantidium coli*, *Trichuris trichiura* (whipworm)
- Eosinophilia—Throughout chronic infection: *Strongyloides*, schistosomiasis, *Cystoisospora*; usually only in early infection: *Ascaris*, hookworm, whipworm
- Prolonged or severe diarrhea in HIV infection—Spore-forming protozoal infections: *Cryptosporidium*, *Cyclospora*, *Cystoisospora*, *Microsporidia*
- Visible worms passed in stool—*Ascaris*, *Taeniasis*, *Diphyllobothrium*

### Diagnosis of Parasitic Infections

- Stool antigen assay: *Entamoeba histolytica*, *Giardia*, *Cryptosporidium*
- Serology\*: *Strongyloides*, schistosomiasis
- Stool microscopy for ova and parasites: All intestinal parasites. Sensitivity is increased with repeat examinations if necessary. Concentration, preservation, and staining improve diagnosis of certain pathogens.
- Molecular tests: Traditional polymerase chain reaction (PCR), both nested and multiplexed, real-time PCR, and newer gene amplification technologies including loop-mediated isothermal amplification (LAMP) and Luminex-based assays are gaining popularity in detecting some parasitic infections, especially in low parasite load specimens.
- Proteomics: Mass spectrometry technique. Surface-enhanced laser desorption/ionization-time-of-flight (SELDI-TOF) mass spectrometry, which is based on matrix-assisted laser desorption/ionization time of-flight (MALDI-TOF) mass spectrometry, has been used to identify biomarkers associated with some parasitic diseases such as African trypanosomiasis, Chagas disease, cysticercosis, and fascioliasis.

Note: Key features of intestinal parasitic infection may overlap with other conditions, including nonparasitic infections, and extraintestinal parasites.

\*Optimal method of diagnosis in returned travelers and immigrants from endemic to nonendemic areas. Does not distinguish between active and resolved infections.

Intestinal parasites are a diverse group of pathogens with local and global significance. Immigration, international adoption, travel, and the frequency of HIV/AIDS and other immune-compromising conditions (e.g., malignancy, organ transplantation) have all contributed to a need for ongoing or increased awareness of parasitic infections in the United States. Persons who reside in chronic care facilities, children in daycare, and persons whose sexual practices increase the likelihood of fecal-oral contact are also at risk for acquiring intestinal parasitic infection.

Globally, intestinal parasites are responsible for an enormous burden of disease. Although these pathogens are rarely fatal, ongoing exposure to intestinal parasites among persons in endemic areas exacerbates malnutrition, carries multiple morbidities, and causes stunting of growth and development in children, all of which have far-reaching consequences.

Patients who present with diarrheal illness (especially prolonged or travel-associated), unexplained eosinophilia, or expulsion of worms should be evaluated for intestinal parasites. In such cases, a careful history should focus on the patient's country of

origin, detailed travel and recreational activities, dietary habits and new or unusual food exposures, occupation, sexual history, sick contacts, and risks for or known immunodeficiency. Some specialists advocate obtaining a complete blood count with differential to assess eosinophil count in all international adoptees and immigrants from areas where parasitic infections are common. If eosinophilia is present, antibody testing for schistosomiasis and strongyloidiasis—two chronic parasitic infections with potentially serious consequences—should be performed, and appropriate therapy should be administered if infection is discovered. For key features of common intestinal parasitic infections, see the Current Diagnosis box.

Diagnosis of intestinal parasites has improved recently with the advent of quick, simple, and accurate stool antigen tests for some major pathogens, such as *Entamoeba*, *Giardia*, and *Cryptosporidium* species. However, the fecal examination for ova and parasites is still the mainstay of diagnosis in many cases. Whenever possible, stool specimens should be sent to a laboratory with clinical expertise in parasitology, where wet preparation, concentration, or staining can identify most pathogens. Evaluation of fresh specimens and repeated examinations improve diagnostic sensitivity. Key diagnostic points are summarized in the Current Diagnosis box.

This review focuses on basic understanding, recognition, diagnosis, and treatment of common intestinal parasites in the United States and throughout the world. Within each section, parasites are listed in order of relative clinical significance.

## Protozoa: Amoebae, Flagellates, and Ciliates

### *Entamoeba histolytica*

*Entamoeba histolytica*, the cause of amoebic dysentery and amoebic liver abscess, is a worldwide pathogen of major clinical significance. Approximately 10% of the world's population and up to 60% of children in highly endemic areas show serologic evidence of infection, and *E. histolytica* is estimated to cause 100,000 deaths per year globally. In the United States, infection is almost exclusively found among returned travelers, immigrants from endemic areas (especially Mexico and Central and South America), men who have sex with men (MSM), and institutionalized persons. *Entamoeba dispar*, *Entamoeba bangladeshi*, and *Entamoeba moshkovskii* are morphologically indistinguishable from *E. histolytica*. Although these species are usually considered nonpathogenic species, there have been increasing reports of *E. moshkovskii* infections associated with gastrointestinal symptoms in humans in endemic areas. Other *Entamoeba*, including *Entamoeba hartmanni*, *Entamoeba coli*, *Entamoeba polecki*, and others, can be individually identified on microscopy. Again, these organisms are of uncertain pathogenicity and generally considered as commensal organisms, however *E. polecki*, *Dientamoeba fragilis*, and *Iodamoeba bütschlii* have occasionally been associated with diarrheal illness.

*E. histolytica* exists in two forms: the hardy cyst (infective form) characterized by four nuclei and the trophozoite (responsible for invasive disease), which has a single nucleus and survives poorly outside the human body. *E. histolytica* infection is acquired by ingestion of cysts in contaminated water or food or by sexual transmission through fecal-oral contact. Acquisition of the parasite can result in asymptomatic infection (most common), diarrheal illness, or extraintestinal infection, the latter most commonly manifesting as amoebic liver abscess. An appropriately robust layer of colonic mucin may be protective against symptomatic infection, whereas trophozoite attachment to the intestinal epithelium results in penetration of the organism into the submucosal layer, where extensive tissue destruction can take place in the form of apoptosis and lysis of cells, hence the name *histolytica*.

Symptoms of classic amoebic dysentery usually begin insidiously over 1 to 3 weeks after infection. Diarrhea is almost universal and typically consists of numerous small-volume stools that can contain mucus, frank blood, or both. Stools are almost always heme positive if not grossly bloody. Abdominal pain and tenesmus are common; fever is present in approximately 30% of cases.

Some patients have a chronic course characterized by weight loss, intermittent loose stools, and abdominal pain. Rare presentations of amoebic dysentery include amoebomas, which can mimic malignancy, and perianal ulcerations or fistulae. Severe disease can occur in the form of fulminant colitis or toxic megacolon; the latter almost universally requires colectomy. Young age, pregnancy, corticosteroid use, malignancy, malnutrition, and alcoholism predispose to severe infection. Although persons with HIV infection or AIDS can develop invasive disease, *E. histolytica* does not appear to be a common opportunistic infection, and infection is curable in this population.

Amoebic liver abscess is the most common extraintestinal complication of *E. histolytica* that traffics to the liver via the portal venous system. Cerebral and ocular amoebiasis have also been reported. Amoebic liver abscess affects children of both sexes equally, but it is up to 7 to 10 times more common in men, indicating that a hormonal milieu likely plays a role. Amoebic liver abscess almost always manifests within 3 to 5 months of initial infection, but it can surface years later. Illness is characterized by fever and right upper quadrant abdominal pain that worsens over several days to weeks. Weight loss, jaundice, and cough from diaphragmatic irritation can also occur. Symptoms of dysentery usually are not present, and diarrhea is reported in less than one-third of cases. Hepatomegaly and point tenderness over the liver is present in about 50% of cases. Rupture of the abscess can occur into the abdomen or pleuropulmonary space, manifesting as acute abdomen or empyema. Laboratory abnormalities include leukocytosis without eosinophilia, transaminitis, elevated alkaline phosphatase, and elevated sedimentation rate. Abscess is usually identified as a well-circumscribed hypoechoic mass on ultrasonography, a low-density mass with enhancing borders on computed tomography (CT), and hypointense on T1 and hyperintense on T2-weighted magnetic resonance imaging (MRI). Chest radiograph often demonstrates elevation of the right hemidiaphragm, and pleural effusion may be present. Radionuclide uptake liver scans can help distinguish amoebic abscesses as “cold” compared with pyogenic abscesses that are usually “hot.”

Diagnosis of intestinal *E. histolytica* infection has classically relied on stool microscopy, and this remains the only available method in most parts of the world. At least three stool specimens should be examined to improve sensitivity. Cysts visualized in stool cannot differentiate active disease from colonization, and *E. dispar*, *E. moshkovskii*, and *E. histolytica* species. Presence of trophozoites with ingested red blood cells (hematophagous trophozoites) on stool preparation and/or mobile amoebae seen on fresh biopsy material stained with iron hematoxylin and/or Wheatley's trichrome are diagnostic of invasive intestinal amoebic disease. Contrary to the common belief, presence of hematophagous trophozoites on stool microscopy is not pathognomonic of *E. histolytica*, as they can be seen with *E. dispar* infections as well.

Serology can distinguish between *E. histolytica* (generates antibodies) and *E. dispar* (does not generate antibodies) infection with good sensitivity in detecting antibodies within 5 to 7 days of infection. Positive serostatus, however, does not discriminate between acute and past infection, but negative serology is quite sensitive in endemic countries. Indirect hemagglutination serology remains the most sensitive test in non-endemic settings.

Diagnosis and species distinction of *Entamoeba* infection has improved greatly with the advent of antigen tests, now available as enzyme-linked immunosorbent assays (ELISAs), radioimmunoassays, and immunofluorescent probes. The Techlab ELISA *E. histolytica* stool antigen test is highly sensitive and specific if used on fresh stool specimens. It becomes positive with onset of symptomatic disease and resolves on treatment of infection.

Parasite DNA/RNA PCR, RT-PCR, multiplex PCR (can detect multiple pathogens), and LAMP fecal probes are highly sensitive and can differentiate *Entamoeba* species.

Aspirate of liver abscess may be necessary to distinguish from pyogenic liver abscess or when empiric therapy fails. Aspirated specimens consist mainly of necrotic hepatocytes (“anchovy paste”), and trophozoites are only seen in less than 20% of cases.

Nested multiplex PCR tests on hepatic aspirates might be useful, although sensitivities range from 75% to 100%. As simultaneous colitis and amebic liver abscess are rare, negative stool microscopy and PCR for *E. histolytica* does not preclude amebic liver abscess. In a patient at high risk for amebic liver abscess (e.g., young male immigrants), an adequate response to a trial of antimicrobial therapy can help confirm the diagnosis as well.

All patients who have confirmed *E. histolytica* infection and reside in nonendemic areas should be treated regardless of whether they are symptomatic because invasive disease can develop in the future. Asymptomatic cyst passers may be treated with an intraluminal agent alone, such as paromomycin (Humatin) or diiodohydroxyquin (iodoquinol [Yodoxin]).<sup>2</sup> In the United States, the most readily available effective treatment for patients with amebic colitis or liver abscess is metronidazole (Flagyl). It can be given intravenously for patients who are unable to tolerate oral medications. Recommended management is at least a 10-day course of the metronidazole (or tinidazole [Tindamax]) followed by an intraluminal agent (paromomycin for 7 days, or diiodohydroxyquin<sup>2</sup> for 20 days, or diloxanide furoate<sup>2</sup> for 10 days) for all cases of invasive *E. histolytica*. See Table 1 for medications and doses.

### Giardiasis

*Giardia duodenalis*, previously known as *Giardia lamblia* or *Giardia intestinalis*, is the most commonly identified diarrheal parasitic infection in the United States, with an estimated 100,000 to 2.5 million cases per year. It is globally distributed and found in fresh water throughout mountainous regions of the United States and Canada. The organism is a flagellated aerotolerant anaerobe that exists in cyst and trophozoite form. Cysts can survive for several weeks in cold water. Contaminated food and water are the most common sources of infection, but the organism can also be passed by person-to-person contact. In the United States, giardiasis is primarily diagnosed among international travelers, persons with recreational water exposure, institutionalized persons and children in day care, and persons with anal-oral sexual practices.

Illness can result from ingestion of as few as 10 to 25 cysts, which transform into trophozoites in the small intestine and attach to and damage the small bowel wall. Symptomatic disease begins insidiously over approximately 2 weeks in 25% to 50% of persons who ingest *Giardia* cysts. Others become asymptomatic cyst passers (5% to 15%) or have no signs of infection (35% to 50%). Hallmarks of infection are watery diarrhea, bloating, flatulence, abdominal pain, and weight loss; less commonly, patients have nausea, vomiting, or low-grade fever. Steatorrhea and malabsorption, particularly secondary to *Giardia*-induced lactase deficiency, is frequently observed. Chronic *Giardia* infection should be considered in the differential diagnosis for a long-standing diarrheal illness, especially if there is history of exposure to possibly contaminated water. Patients with common variable immune deficiency, X-linked agammaglobulinemia, and IgA deficiency syndromes are at risk for fulminant and sometimes incurable disease, suggesting a significant role for humoral immunity in control of infection. Patients with HIV infection or AIDS usually have a similar presentation as in non-HIV patients, can remain asymptomatic, and can be typically cured of infection with standard therapy. However, profound immunosuppression can be associated with more severe, atypical, disseminated and refractory disease requiring combination therapy with quinacrine<sup>2</sup> and metronidazole.<sup>1</sup>

Diagnosis of giardiasis is made by examination of fresh or preserved stool or by stool antigen assays. Stool microscopy can be specific but has low sensitivity because of intermittent shedding of *Giardia* cysts. Trophozoites may be directly visualized in fresh liquid stool; semiformal and preserved stool are likely to contain only cysts and should be stained with polyvinyl alcohol and/or formalin preparation. Antigen detection assays including immunochromographic assays, direct immunofluorescence assays, and ELISAs have higher sensitivity with rapid turnaround time. Many

assays are commercially available including the ImmunoCard STAT! Cryptosporidium/Giardia Rapid Assay (Meridian Bioscience, Cincinnati, Ohio) that tests for both pathogens simultaneously. Multiplex nucleic acid amplification tests (NAATs) are frequently used to detect various bacterial, viral, and parasitic pathogens as a workup for infectious diarrhea. Although it is rarely necessary, the diagnosis can sometimes be made on duodenal biopsy.

For details of treatment options, see Table 1. Tinidazole (Tindamax) and nitazoxanide (Alinia) are now the preferred agents for initial treatment of giardiasis. Metronidazole<sup>1</sup> is no longer the first-line therapy because of its adverse effects including metallic taste, nausea, gastrointestinal discomfort, and headache. Patients who fail first-line therapy might have a persistent source of infection (contaminated water source, close contact with an infected person), immune deficiency predisposing to difficult eradication, or persistence of cysts. Once possible sources of reinfection have been investigated and eliminated, relapsed infections should either be retreated with a longer course of therapy (21 to 28 days) or treated with a different agent. Quinacrine<sup>2</sup> is reserved for refractory cases but is contraindicated in pregnancy. Paromomycin<sup>1</sup> is an alternative in those with contraindications to other agents such as in pregnancy. Patients who fail more than one course of therapy should undergo immunologic workup.

Prevention of *Giardia* infection, as with other parasitic infections, involves primarily close attention to personal hygiene, hand washing, and avoidance of ingestion of fresh unfiltered water. Boiling water or use of a 0.2- to 1- $\mu$ m water filter offer optimal protection against *Giardia* and other parasitic pathogens, although such filters still might not protect against *Cryptosporidium*.

### Blastocystis

*Blastocystis*, formerly considered a yeast, has now been related to *E. histolytica* and is thought to be an anaerobic protozoan. The pleomorphic nature and karyotype diversity of this organism, its worldwide distribution, and varying diagnostic techniques have led to challenges in its identification and taxonomy. Although it has a worldwide distribution, its prevalence is higher in developing countries and is most commonly isolated in tropical regions. In temperate regions, *Blastocystis* (*B. hominis*) is detected at a high rate among MSM. It is a commensal of humans and several other animals. It appears to be transmitted via the fecal-oral route, possibly from waterborne sources. *Blastocystis* was long thought to cause only asymptomatic colonization, but there is some evidence to suggest a role in human disease, although this remains controversial. *Blastocystis* has marked morphologic variability and has been known to exist in at least four forms: vacuolated, amoeba-like, granular, and cystic, the latter of which is likely to be the infectious form. Ongoing molecular analysis has identified at least 17 subtypes of *B. hominis* (hence now referred to as *Blastocystis* spp., formerly identified as *Blastocystis hominis*) with varying degrees of pathogenicity in humans.

As suggested previously, the majority of infections appear to be entirely asymptomatic, and number of organisms does not appear to accurately predict severity of illness. Symptoms consist mainly of watery diarrhea, bloating, flatulence, abdominal cramps, urticaria, and fatigue. There are typically no pathologic findings on colonoscopy, and there are no reports of invasive disease. Infection is diagnosed by stool microscopy with use of a trichrome or hematoxylin-stained preserved specimen. Fecal leucocytes are generally not found. PCR techniques have also been developed with excellent sensitivity and are available worldwide. The organism is susceptible in vitro to numerous antimicrobials. Asymptomatic detection does not need treatment. Metronidazole<sup>1</sup> and tinidazole<sup>1</sup> are preferred agents for treating symptomatic disease. Trimethoprim-sulfamethoxazole (TMP-SMX, Bactrim)<sup>1</sup> and paromomycin<sup>1</sup> are alternative agents with good efficacy; details are listed in Table 1.

<sup>1</sup>Not FDA approved for this indication.

<sup>2</sup>Not available in the United States.

<sup>1</sup>Not FDA approved for this indication.

<sup>2</sup>Not available in the United States.

**TABLE 1** Pharmacologic Treatment of Major Protozoan Infections.

CLINICAL SITUATION	DRUG	ADULT DOSE	PEDIATRIC DOSE	COMMENTS
<b>Amebiasis</b>				
<b>(Entamoeba histolytica)</b>				
Asymptomatic	Paromomycin* <i>or</i>	25–35 mg/kg/d in 3 doses × 7 d	25–35 mg/kg/d in 3 doses × 7 d	Treatment should be followed by a course of iodoquinol or paromomycin in the dosage used to treat asymptomatic amebiasis.
	Iodoquinol <sup>†,2</sup> <i>or</i>	650 mg tid × 20 d	30–40 mg/kg/d (max 2 g) in 3 doses × 20 d	
	Diloxanide furoate <sup>‡,2</sup>	500 mg tid × 10 d	20 mg/kg/d in 3 doses × 10 d	
Mild to moderate intestinal disease	Metronidazole <i>or</i>	500–750 mg tid × 7–10 d	35–50 mg/kg/d in 3 doses × 7–10 d	
	Tinidazole <sup>1,5</sup>	2 g once daily × 3 d	≥3 y: 50 mg/kg once daily (max 2 g) × 3 d	
Severe intestinal or extraintestinal disease	Metronidazole <i>or</i>	750 mg tid × 7–10 d	35–50 mg/kg/d in 3 doses × 7–10 d	
	Tinidazole <sup>5</sup>	2 g once daily × 5 d	≥3 y: 50 mg/kg once daily (max 2 g) × 5 d	
<b>Balantidiasis</b>				
<b>(Balantidium coli)</b>				
Symptomatic and asymptomatic disease	Recommended: Tetracycline <sup>1,4</sup>	500 mg qid × 10 d	40 mg/kg/d (max 2 g) in 4 doses × 10 d	
	Alternatives: Metronidazole <sup>1</sup> <i>or</i>	500–750 mg PO tid × 5 d	35–50 mg/kg/d in 3 doses × 5 d	
	Iodoquinol <sup>2,†</sup>	650 mg tid × 20 d	30–40 mg/kg/d (max 2 g) in 3 doses × 20 d	
<b>Blastocystis hominis</b>				
Symptomatic disease only				Organism's pathogenicity is uncertain. <sup>4</sup>
<b>Cryptosporidiosis</b>				
<b>(Cryptosporidium)</b>				
Immunocompetent	Nitazoxanide	500 mg bid × 3 d	1–3 y: 100 mg bid × 3 d 4–11 y: 200 mg bid × 3 d ≥12 y: adult dose	FDA approved as a pediatric oral suspension for treating <i>Cryptosporidium</i> in immunocompetent children <12 y and for <i>Giardia</i> . It might also be effective for mild to moderate amebiasis. Nitazoxanide is available in 500-mg tabs and an oral suspension; it should be taken with food.
Immunocompromised	No optimal therapy available			All HIV-infected patients with cryptosporidiosis should receive HAART whenever possible. Nitazoxanide, <sup>1</sup> paromomycin, <sup>1</sup> or paromomycin + azithromycin <sup>1</sup> may have a role in decreasing diarrhea in chronic cases of HIV-infection.

**TABLE 1** Pharmacologic Treatment of Major Protozoan Infections.—cont'd

CLINICAL SITUATION	DRUG	ADULT DOSE	PEDIATRIC DOSE	COMMENTS
<b>Cyclosporiasis</b>				
<b>(Cyclospora cayetanensis)</b>				
	Recommended: TMP-SMX (Bactrim, Septra) <sup>1</sup>	160 mg TMP, 800 mg SMX (1 DS tab) bid × 7–10 d	5 mg/kg TMP, 25 mg/kg SMX bid × 7–10 d	In immunocompetent patients, usually a self-limiting illness. Immunosuppressed patients might need higher doses, longer duration (TMP-SMX qid × 10 d, followed by bid × 3 wk) and long-term maintenance.
	Alternative: Ciprofloxacin <sup>1</sup>	500 mg PO bid × 7 d	(No recommended pediatric dose) <sup>1</sup>	
<b>Dientamoebiasis</b>				
<b>(Dientamoeba fragilis)</b>				
Symptomatic disease only	Iodoquinol <sup>2,†</sup> or	650 mg tid × 20 d	30–40 mg/kg/d (max 2 g) in 3 doses × 20 d	
	Paromomycin <sup>1,*</sup> or	25–35 mg/kg/d in 3 doses × 7 d	25–35 mg/kg/d in 3 doses × 7 d	
	Metronidazole <sup>1</sup>	500–750 mg tid × 10 d	35–50 mg/kg/d in 3 doses × 10 d	
<b>Giardiasis</b>				
<b>(Giardia lamblia)</b>				
All symptomatic disease and asymptomatic carriage in nonendemic areas	Recommended: Metronidazole <sup>1</sup> or	250 mg tid × 5–7 d	15 mg/kg/d in 3 doses × 5 d	Treatment should be followed by a course of iodoquinol <sup>2</sup> or paromomycin in the dosage used to treat asymptomatic amebiasis.
	Nitazoxanide or	500 mg bid × 3 d	1–3 y: 100 mg bid × 3 d 4–11 y: 200 mg bid × 3 d	
	Tinidazole <sup>§</sup>	2 g once	50 mg/kg (max 2 g) once	
	Alternatives: Quinacrine <sup>2,**</sup> or	100 mg tid × 5 d	6 mg/kg/d (max 300 mg/d) tid × 5 d	
	Furazolidone <sup>2</sup> or Paromomycin <sup>1</sup>	100 mg qid × 7–10 d 25–35 mg/kg/d in 3 doses × 7 d	6 mg/kg/d in 4 doses × 10 d 25–35 mg/kg/d in 3 doses × 7 d	Nonabsorbed luminal agent; may be useful for treating giardiasis in pregnancy

**TABLE 1** Pharmacologic Treatment of Major Protozoan Infections.—cont'd

CLINICAL SITUATION	DRUG	ADULT DOSE	PEDIATRIC DOSE	COMMENTS
<b>Cystoisosporiasis</b>				
<i>(Cystoisospora belli)</i>				
	TMP-SMX <sup>1</sup>	160 mg TMP, 800 mg SMX bid × 7–10 d	5 mg/kg TMP, 25 mg/kg SMX bid × 7–10 d	In immunocompetent patients, usually a self-limiting illness. Immunosuppressed patients might need higher doses, longer duration (TMP-SMX <sup>1</sup> qid × 10 d, followed by bid × 3 wk) and long-term maintenance. For isosporiasis in sulfonamide-sensitive patients, pyrimethamine <sup>1</sup> 50–75 mg qd in divided doses ( <i>plus</i> leucovorin <sup>1</sup> 10–25 mg/d) is effective.
<b>Microsporidiosis</b>				
<i>Enterocytozoon bieneusi</i>				
Intestinal disease	Fumagillin <sup>2+</sup>	20 mg PO TID × 14 d		Oral fumagillin (Sanofi Recherche, Gentilly, France) is effective in treating <i>E. bieneusi</i> but is associated with thrombocytopenia and neutropenia. HAART can lead to microbiologic and clinical response in HIV-infected patients with microsporidial diarrhea. Octreotide (Sandostatin) <sup>1</sup> has provided symptomatic relief in some patients with large-volume diarrhea.
	Albendazole <sup>1</sup>	400 mg PO bid × 21 d	15 mg/kg/d in 2 doses (max 400 mg/dose)	
<i>Encephalitozoon intestinalis</i>				
Diarrheal or disseminated disease	Albendazole <sup>1</sup>	400 mg bid × 21 d	15 mg/kg/d in 2 doses (max 400 mg/dose)	

<sup>1</sup>Not FDA approved for this indication.

<sup>2</sup>Not available in the United States.

\*Should be taken with meals.

†Should be taken after meals.

<sup>‡</sup>The drug is not available commercially, but may be available through compounding pharmacies.

<sup>§</sup>A nitroimidazole similar to metronidazole, tinidazole is FDA approved and appears to be as effective and better tolerated than metronidazole. It should be taken with food to minimize GI adverse effects. For children and patients unable to take tablets, a pharmacist may crush the tablets and mix them with cherry syrup. The syrup suspension is good for 7 d at room temperature and must be shaken before use. Ornidazole, a similar drug, is also used outside the United States. Dosing recommendations are only available for children ≥3 years of age.

<sup>||</sup>Contraindicated in pregnant and breastfeeding women and children <8 years of age.

<sup>¶</sup>Clinical significance of these organisms is controversial; metronidazole 750 mg tid × 10 d, iodoquinol 650 mg tid × 20 d, or TMP-SMX<sup>11</sup> double-strength tab bid × 7 d are effective. Metronidazole resistance may be common. Nitazoxanide is effective in children.

\*\*Should be taken with liquids after a meal.

DS, Double strength; GI, gastrointestinal; HAART, highly active antiretroviral therapy; max, maximum; tab, tablet; TMP-SMX, trimethoprim-sulfamethoxazole.

Modified from World Health Organization. Drugs for parasitic infections, *Med Lett Drug Ther.* 2010;8(Suppl).

***Dientamoeba fragilis***

*Dientamoeba fragilis* was originally classified as an amoeba, but it is more closely related to the flagellates such as *Trichomonas vaginalis*. It is distributed globally, including in the Western nations; however, it is generally more prevalent in areas of the world with limited public sanitation. *D. fragilis* has only recently been recognized as a clinically significant pathogen, possibly because it is difficult to visualize without specific staining techniques. Illness has commonly been found in travelers and MSM,

but it can affect anyone. Some studies suggested a coinfection of *D. fragilis* with *E. vermicularis* as trophozoites were believed to survive in *E. vermicularis* eggs. However, this association has not been consistently demonstrated.

Similar to most other intestinal parasites, *D. fragilis* is now known to exist in both trophozoite and cystic form, although it was known to only have a trophozoite phase for a long time. Despite its genetic relationship to the flagellates such as *Trichomonas*, *D. fragilis* does not have a flagellum and is immotile.

Trophozoites range in size from 7 to 20  $\mu\text{m}$  and can be binucleate. Cysts and precystic forms have recently been identified from human fecal specimens, suggesting a fecal-oral mode of transmission.

Most patients are asymptomatic; however, numerous case reports and small series describe patients with no other organisms identified to cause their symptoms who improve significantly after treatment and documented clearance of *D. fragilis* from their stool. Illness is typically subacute to chronic and is characterized by abdominal pain, watery diarrhea, anorexia, fatigue, and malaise. Unlike most other enteric parasites, *D. fragilis* is associated with marked peripheral eosinophilia and can masquerade as allergic colitis. Diagnosis can be challenging because the trophozoites are fragile and usually missed on direct microscopy. If *D. fragilis* is suspected, stool should be preserved with polyvinyl alcohol and quickly stained with iron-hematoxylin and trichrome. PCR-based assays are very sensitive and being increasingly used for diagnosis.

Metronidazole<sup>1</sup> remains the drug of choice and has been efficacious in eradication of *D. fragilis* with a 10-day course. Other nitroimidazoles such as tinidazole<sup>1</sup> (better tolerated than metronidazole), secnidazole (Solosec),<sup>1</sup> and ornidazole<sup>2</sup> have been tested with good efficacy, but data are limited. Paromomycin<sup>1</sup> appears to be efficacious but is only backed up by limited data. Iodoquinol (Yodoxin)<sup>2</sup> has been successfully used very commonly in the past; however, its availability has now declined. See Table 1 for medications and doses.

### *Balantidium coli*

*Balantidium coli* is the largest protozoan that infects humans and is the only ciliate. Balantidiasis is a relatively rare cause of illness and is found primarily in rural agrarian communities in Southeast Asia, Central and South America, and Papua New Guinea. *B. coli* is highly associated with animal farming, in particular, pigs and primates; humans are incidental hosts. The parasite is transmitted by direct contact with animals or on ingestion of water or food contaminated by animal excrement. Persons with malnutrition or immune deficiency are particularly susceptible to infection.

*B. coli* invades the intestinal mucosa from the terminal ileum to the rectum. About one-half of infections are asymptomatic; the other half result in a subacute or chronic diarrheal illness with abdominal cramping, nausea, vomiting, weight loss, and occasional low-grade fever. Fewer than 5% of patients present with severe or even fulminant dysentery, and rare cases of colonic penetration with peritonitis, mesenteric lymphadenitis, or hepatic infection have been reported.

Diagnosis is made by visualization of trophozoites in fresh stool specimens or preserved and permanently stained samples. The trophozoite is relatively large (40 to 200 microns) and ciliated; cysts are difficult to distinguish. It displays a distinct spiraling motility that can be seen under low power. On stained sample, visualization of *B. coli*'s characteristic bean-shaped macronucleus and spiral micronucleus can help confirm the diagnosis. All patients should be treated regardless of symptoms. Tetracycline<sup>1</sup> (Sumycin and others) is the therapy of choice; alternative agents include metronidazole,<sup>1</sup> tinidazole<sup>1</sup> and paromomycin<sup>1</sup>; see Table 1 for medications and doses.

### Spore-Forming Protozoa and Microsporidia

#### *Cryptosporidium*

*Cryptosporidium* is an intracellular pathogen with worldwide distribution that has been increasingly reported in the United States and other countries including Nordic countries, Denmark, England, and Scotland in the past decade. Humans are most commonly infected by the recently reclassified *Cryptosporidium hominis* (formerly *C. parvum* genotype 1), but *Cryptosporidium parvum* (previously *C. parvum* genotype 2), primarily a bovine pathogen, also causes human disease.

*Cryptosporidium* is known to be an important parasitic cause of diarrhea globally; however, it is more frequently associated with overcrowded and poor sanitary environments. In the United States and other developed countries, the incidence is higher in children than in adults. *Cryptosporidium* infections have been reported as sporadic outbreaks of diarrhea and malnutrition syndrome in children from developing countries and as chronic and severe illness in immunocompromised hosts (especially with HIV infection). It is primarily a waterborne illness and has caused multiple outbreaks in the United States secondary to recreational water exposure (e.g., swimming pools, water parks). The best-known outbreak occurred from contamination of the drinking water supply in Wisconsin in 1993 that was thought to be secondary to runoff from the cattle pastures versus contaminated water from melting ice entering water treatment plants through Lake Michigan. It resulted in 403,000 documented cases of cryptosporidiosis and contributed to the deaths of dozens of persons with advanced HIV infection or malignancy.

*Cryptosporidium* is a coccidian spore-forming protozoa obligate intracellular parasite with a complex life cycle that matures and reproduces both asexually and sexually entirely within human hosts, thereby enabling infection to occur both from environmental sources and by direct person-to-person contact. Its oocysts, the source of infection on ingestion, are markedly hardy; they can withstand heavy chlorination, survive for months in cold water, and are small enough to occasionally evade even the smallest available water filtration systems. As few as 100 oocysts can cause infection, which results when the parasite penetrates small bowel epithelium and replicates just beneath its surface. Villous flattening and small bowel wall edema are seen on pathologic examination from infected persons.

*Cryptosporidium* infection can be asymptomatic, or it can manifest as mild diarrhea to severe enteritis with or without biliary involvement. Mild illness is usually self-limiting in 10 to 14 days without treatment in immunocompetent patients, although a substantial percentage of patients report a relapse of symptoms after initial improvement. It can have a protracted course with more severe symptoms in immunocompromised hosts. Fulminant and chronic infection has been frequently reported in those with HIV infection (especially those with CD4 <50), malignancy, and in malnourished children. The incubation period ranges from 3 to 28 days following the ingestion of oocysts and appears to be associated with the number of ingested oocysts. The hallmark of infection is explosive watery diarrhea, which can be so voluminous as to resemble cholera and can cause significant dehydration and electrolyte imbalance. Abdominal discomfort, nausea, vomiting, fever, malaise, and myalgia can also be present, and weight loss is common. Extraintestinal manifestations including biliary tract (cholecystitis, cholangitis, pancreatitis) and lung involvement have been reported, particularly in patients with HIV infection.

Diagnosis of *Cryptosporidium* has improved dramatically in recent years with the advent of antigen tests, which are highly sensitive and specific and can be used on a single sample of fresh stool. The ImmunoCard STAT! *Cryptosporidium*/Giardia Rapid Assay is useful because it can detect both pathogens. PCR is also available, has more sensitivity than direct microscopy, and can differentiate between various genotypes. When such tests are not available, stools submitted for examination should be fixed in formalin and stained for trophozoites or cysts; availability of multiple stool specimens improves the diagnostic sensitivity. Luminal fluid or biopsy specimens obtained during endoscopy can also reveal the organism.

Infection with *Cryptosporidium* is typically a self-limiting illness in otherwise healthy persons, but symptoms can be improved and the course shortened with the antiparasitic nitazoxanide. If nitazoxanide is not available or tolerated, paromomycin can be used, although it is not specifically indicated for this infection. *Cryptosporidium* remains an extremely challenging and potentially devastating infection in immunocompromised patients, especially those with HIV and a low CD4 count (counts <200

<sup>1</sup>Not FDA approved for this indication.

<sup>2</sup>Not available in the United States.

increase risk of severe illness, and counts <50 markedly increase risk). Although anticytosporeidial therapies in this population have shown very limited efficacy, restoration of immune function with highly active antiretroviral therapy (HAART) often effects cure. Limited data suggest that a trial of nitazoxanide may be reasonable in this circumstance as well. Appropriate supportive measures are also crucial in all patients with *Cryptosporidium*, including fluid and electrolyte replacement; avoiding lactose products is likely to be beneficial during the first 2 weeks after infection as the brush border regenerates. Appropriate treatment doses for nitazoxanide (Alinia) are listed in Table 1.

Prevention of *Cryptosporidium* infection requires a highly developed public water purification system including flocculation, sedimentation, and filtration. Use of 0.2- to 1- $\mu$ m personal water filters for campers and hikers greatly reduces but does not eliminate the risk of infection, whereas boiling water before drinking kills oocysts. Close attention to hygiene and avoidance of fecal-oral contact is the mainstay of prevention in the settings of institutional and community outbreaks. Patients should avoid swimming in public pools for 2 weeks after diarrhea resolution.

### Cyclospora

*Cyclospora cayetanensis* is a coccidian with a structure similar to that of *Cryptosporidium*. *C. cayetanensis* is distributed worldwide, most commonly in the tropics and subtropics including Latin America (Guatemala, Peru, Mexico), the Indian subcontinent, and Southeast Asia. Outbreaks in the United States have been associated with import of contaminated produce such as raspberries and snow peas from Guatemala in 1996 and 2004, respectively. Similar outbreaks were attributed to contaminated lettuce and basil from Peru and to cilantro and prepackaged salad from Mexico. It has also become increasingly recognized as a cause of infectious diarrhea in return travelers. Unlike *Cryptosporidium*, *C. cayetanensis* oocysts are shed in the stool as unsporulated oocysts (uninfected) and require a few days of humid environmental conditions to become sporulated infective oocysts, therefore close person-to-person contact as a means of acquiring the infection is unlikely.

All persons are susceptible to infection, but those with HIV are at risk for more severe and prolonged disease, as seen with cryptosporidiosis and isosporiasis. Symptomatic disease appears to be most common in adults who do not have previous exposure to *Cyclospora*, such as travelers or persons who have relocated to endemic areas. Illness begins about 1 week after ingestion of sporulated oocysts and is characterized by watery diarrhea, abdominal cramping, bloating, anorexia, and weight loss. Low-grade fever can occur; marked fatigue is common and can last for weeks or even months, and untreated infections can relapse after apparent resolution. Biliary involvement can occur in patients with HIV coinfection, as with cryptosporidiosis. Cyclosporiasis, similar to infection with other coccidians, causes damage to the small bowel epithelium, with resultant crypt flattening, edema, and inflammatory infiltrate. Lactose deficiency can remain for months after initial infection.

Diagnosis is made by stool examination. As with diagnosis of other parasitic infections, multiple stool specimens improve sensitivity. In the case of *Cyclospora*, concentration of the stool specimen also increases yield. If cyclosporiasis is suspected, specific testing should be requested because the organism exhibits unique properties. Similar to *Cryptosporidium*, organisms can be stained and visualized with Kinyoun acid-fast stain, but they are about two times the size of *Cryptosporidium* (8 to 10  $\mu$ m in diameter). The cell wall of their oocysts also maintains its autofluorescence under ultraviolet microscopy, and *Cryptosporidium* does not. The commonly used BioFire FilmArray multiplex antigen detection test (BioFire Diagnostics, Salt Lake City, UT) includes *C. cayetanensis*. Various conventional and real-time PCR techniques have been developed with good sensitivity. No serologic tests are available yet.

Cyclosporiasis is best treated with trimethoprim-sulfamethoxazole (Bactrim)<sup>1</sup>; nitazoxanide and ciprofloxacin may be effective for

patients who have a sulfa allergy. Patients with HIV infection can require longer courses of treatment or chronic suppressive therapy; appropriate antiretroviral therapy is also important in the treatment of severe or relapsing infections. See Table 1 for details.

### Cystoisospora

*Cystoisospora belli*, formerly *Isospora belli*, is a large coccidian distributed worldwide; however, infections are more frequent in tropical and subtropical areas. In the United States, infections are largely identified in travelers from endemic areas and foreign-born HIV-positive patients. This is the most common parasitic cause of diarrhea in HIV-infected patients in India. Similar to *Cyclospora*, it requires a period of maturation (sporulation) outside the human body and therefore cannot be spread directly from person to person.

It appears to cause largely asymptomatic or mild infection in tropical areas to which it is endemic; the exception is among patients coinfecting with HIV and particularly those with AIDS, in whom it is a very common cause of chronic diarrhea in the Caribbean and Central America. Currently in wealthy countries it is found primarily in travelers returning from endemic areas. Illness is typically mild and self-limiting, consisting primarily of watery diarrhea. However, some immunocompetent persons can develop a chronic spruelike syndrome with malabsorption, and those with HIV infection or AIDS often have severe and prolonged diarrhea. *Cystoisospora* can invade to the lamina propria and can cause eosinophilia, which is different from other protozoan infections.

Diagnosis is made by observation of cysts in stool. As with *Cyclospora* and *Cryptosporidia*, they are usually not detected on routine stool ova and parasite examinations, hence acid-fast staining or ultraviolet microscopy techniques should be requested for high suspicion. Stool may also contain Charcot-Leiden crystals. No antigen detection tests are yet available. PCR tests have been developed; however, they are not widely available.

Illness is usually self-limiting in immunocompetent hosts, hence antimicrobial therapy is only indicated when symptoms do not resolve spontaneously in 5 to 7 days. Symptomatic HIV-positive and other immunocompromised patients should always be treated. Trimethoprim-sulfamethoxazole (Bactrim)<sup>1</sup> is the treatment of choice. Ciprofloxacin (Cipro)<sup>1</sup> or pyrimethamine (Daraprim)<sup>1</sup> may be used in cases of sulfa allergy. See Table 1 for medications and doses.

### Microsporidia

Microsporidia are eukaryotic organisms that have been recently reclassified as fungi based on molecular genotyping. They are distributed globally, and more than 100 genera have been identified, seven of which contain species known to be pathogenic in humans: *Encephalitozoon*, *Enterocytozoon*, *Trachipleistophora*, *Pleistophora*, *Nosema*, *Vittaforma*, and *Microsporidium*. These pathogens cause a wide variety of systemic and focal illness throughout the world.

Many immunocompetent patients in wealthy nations exhibit positive serology for certain types of microsporidial infections without a history of disease or travel. Microsporidia are most commonly associated with systemic infection in immunosuppressed persons, particularly those with HIV and a CD4 count of less than 100 or patients with organ transplants. The mode of transmission is not entirely clear, but the pathogen likely is spread both from water sources and possibly from close household contact.

*Encephalitozoon intestinalis* and *Enterocytozoon bieneusi* are responsible for intestinal microsporidial infections. *E. bieneusi* has been associated with self-limiting diarrheal illness; *E. intestinalis* is commonly found in stool specimens throughout the developing world, but its pathogenicity is often not certain. Symptomatic infections, most often in patients coinfecting with HIV, typically include a gradual onset of watery diarrhea, which may be worse in the morning and after oral intake. Significant volume and electrolyte depletion can occur, as well as fatigue, anorexia, weight loss, and malabsorption. *E. intestinalis* can disseminate and cause

<sup>1</sup>Not FDA approved for this indication.

acute abdomen with peritonitis, cholangitis, nephritis, and keratoconjunctivitis, and *E. bieneusi* infection can result in cholangitis and nephritis as well as rhinitis, bronchitis, and wheezing. Other microsporidia are implicated in disseminated disease with a wide variety of extraintestinal manifestations including ocular, pulmonary, cerebral, renal, and muscular, both in previously healthy and immunosuppressed hosts.

Diagnosis of microsporidiosis is attained by visualization of spores in stool or in tissue specimens. As suggested by their name, microsporidial spores are much smaller than those produced by spore-forming protozoal infections; most are approximately 1  $\mu\text{m}$  in length and can easily be confused with bacteria or debris on slides. Special staining techniques have been described, but electron microscopy is required for species identification. PCR assays have been increasingly used for highly sensitive identification and speciation. Indirect immunofluorescence assays (IFA) are also available for *Encephalitozoon* spp. and *E. bieneusi*. Albendazole (Albenza)<sup>1</sup> is the treatment of choice for *E. intestinalis*. Treatment of *E. bieneusi* is more challenging. Although some response to albendazole has been reported, oral fumagillin<sup>2</sup> may have more efficacy. Unfortunately, it is not currently commercially available in the United States. Use of appropriate antiretroviral therapy is perhaps the most important treatment for patients with HIV infection or AIDS and chronic microsporidial infections. See Table 1 for medications and doses.

## Helminths

### Nematodes

Nematodes (roundworms) are cylindrical nonsegmented organisms that are found throughout the world both as free-living species and as human and animal pathogens. Nematodes are the most common type of human parasitic infestation, found in approximately one-fourth of the world's population; often, susceptible hosts carry multiple different pathogenic nematodes. There are at least 60 species that have been shown to infect humans and 10 times that many that cause disease in other animals, but a few pathogens account for the bulk of human infections, in particular *Ascaris*, hookworm, and whipworm. These three organisms all require a period of maturation outside the human body—typically in warm, moist soil—underscoring the fact that repeated contact with fecally contaminated soil or food and water is necessary to sustain the cycle of infestation. *Strongyloides* and *Enterobius* are unique in that they can both complete their life cycle on or within human hosts and therefore can cause chronic infection and be transmitted directly by close person-to-person contact where there is the possibility of fecal-oral contamination.

### *Ascaris*

*Ascaris lumbricoides*, the most common human helminthic infection, is estimated to affect 20% to 25% of the world's population. Up to 80% of community members are infected in heavily endemic areas, namely in Africa, Asia, and Central and South America. Cases of *Ascaris* infestation are also seen in rural areas in the southeastern United States. *A. lumbricoides* are white to pinkish worms that range from 10 to 40 cm in length. Transmission in humans occurs most commonly by ingestion of infectious human or pig eggs that are oval white bodies with an adherent mucopolysaccharide capsule that clings to multiple surfaces and aids in transmissibility of the parasite. Eggs are also remarkably durable, capable of surviving up to 6 years in moist soil, and able to weather brief droughts and periods of freezing. Another means of transmission is by ingesting uncooked pig or chicken liver containing *Ascaris suum* larvae.

Fecal contamination of water, food, and environmental surfaces such as doorknobs and countertops provides the means of transmission for *Ascaris*, and recurrent infection occurs as long as living conditions that predispose people to infection remain

unchanged. Lack of adequate public sanitation, use of human feces as fertilizer (night soil), and frequent contact with soil or shared contaminated surfaces among close household members are risk factors for infection. Persons who move to environments with improved sanitation typically lose their infection within 2 years as all of the adult worms die. Eggs excreted by an infected person must mature outside the human body for approximately 2 weeks. On ingestion by a susceptible host, mature eggs hatch in the small intestine and release larvae, which penetrate the intestinal wall and travel through the venous circulation to the lungs, where they are coughed up and swallowed. They then undergo maturation into adult worms in the intestine and produce eggs by 2 to 3 months after initial infection. The eggs are excreted in the feces and mature outside the body to continue the cycle.

Most persons with *Ascaris* infection are asymptomatic. Approximately 15% of infected people have morbidity, which is associated with young age, large burden of worms, coinfection with other intestinal parasites, and genetic predisposition. In children, infection contributes to malabsorption of protein, fat, and vitamins A and C, and treatment of heavily infected children can improve their nutritional status. *Ascaris* infection can also cause intestinal, pancreatic, or biliary obstruction as a result of worm mass or worm migration. Despite the low incidence of obstructive complications per infected person, the *Ascaris*-related acute abdomen is a significant problem on a global level given the enormous number of people infected. Some patients with intestinal *Ascaris* infection report vague abdominal complaints, such as abdominal discomfort, nausea, vomiting, or diarrhea, but these are relatively rare. Pulmonary migration of a large quantity of worms can produce Loeffler syndrome, or eosinophilic pneumonitis.

Diagnosis is easily attained with standard saline stool preparation, and large numbers of eggs are typically seen. Larvae or worms can also sometimes be seen in sputum or stool samples. In cases of intestinal obstruction, worms may be visualized on upper gastrointestinal series, CT, and even ultrasonography. Multiplex PCR assays are highly sensitive at identification and quantification but are currently not routinely used. Peripheral eosinophilia with *Ascaris* infection is found only during the larval migratory phase, but not at all times. Chronic eosinophilia in an at-risk person suggests another parasitic infection, often *Strongyloides*. Sputum eosinophilia and Charcot-Leyden crystals can be seen, although this is common with many parasitic eosinophilic pulmonary infections.

All persons documented to carry *Ascaris* who have migrated to nonendemic areas should be treated to prevent complications in the future; in endemic areas, adults need only be treated if they are symptomatic. Children have been shown to benefit from intermittent anthelmintic therapy in heavily affected areas of the world. For patients with intestinal obstruction, bowel rest and intravenous hydration are usually sufficient to relieve the obstruction, at which time anthelmintic therapy can be administered. In such cases, gastroenterology consultation should be obtained. In rare cases, surgical intervention is required. Treatment of pulmonary infection is controversial; however, most experts recommend steroid therapy for severe infections followed 2 to 3 weeks later (at the time full-grown worms will have migrated to the intestine) by administration of anthelmintic therapy. *Strongyloides* infection should be ruled out before corticosteroid administration as the latter can induce *Strongyloides* hyperinfection syndrome. The benzimidazoles (mebendazole [Emverm, Vermox], albendazole [Albenza],<sup>1</sup> levamisole<sup>2</sup>) exhibit excellent activity against *Ascaris*. Ivermectin (Stromectol)<sup>1</sup> and nitazoxanide (Alinia)<sup>1</sup> are suggested as reasonable alternatives. Doses and other options are listed in Table 2. Pregnant women should be treated with pyrantel pamoate (Pin-Away) as albendazole and mebendazole carry a pregnancy class B label. Pyrantel pamoate is a depolarizing neuromuscular blocking agent that causes paralysis in helminths, which prevents them from invading the intestinal wall, eventually resulting in their natural

\*Should be taken with a fatty meal.

†Safety of ivermectin in young children (<15 kg) and pregnant women is not yet established. Ivermectin should be taken on an empty stomach with water.

‡Limited availability; can be mixed with juice or water to improve palatability.

§Should be taken with liquids during a meal.

¶Limited or no availability in the United States.

†Available in the United States only from the manufacturer. Must be chewed or crushed thoroughly and swallowed with a small amount of water. Limited or no availability in the United States.

Modified from World Health Organization. Drugs for parasitic infections, *Med Lett Drug Ther.* 2010;8(Suppl).

expulsion from the intestinal lumen. Because no consistent teratogenic effects have been demonstrated with albendazole use in late pregnancy, the World Health Organization (WHO) has allowed the use of albendazole to treat mass infections in the second and third trimesters.

Sanitary conditions that allow for proper management of human feces are crucial in control and prevention of *Ascaris* infection; boiling water kills the eggs.

### Whipworm (*Trichuris*)

*Trichuris trichiura* has become recognized in recent years as a worldwide pathogen and is frequently found as a coinfection with *A. lumbricoides* as they share a similar scope and environmental conditions. Almost 90% of individuals from endemic regions are infected. Sanitary conditions that predispose to ingestion of food and water contaminated with human feces place people at risk for infection.

The adult organism is a small worm about 4 cm in length with a unique whiplike structure that allows its thin tail to become embedded in colonic crypts. Infection is acquired by ingesting *Trichuris* eggs that have undergone embryonation in the soil for 2 to 4 weeks after excretion from a previous host. Larvae emerge from eggs in the intestine and migrate into crypts, where they begin to mature. Egg production begins approximately 3 months later.

Most persons with whipworm carry few worms (approximately 20) and are asymptomatic. As with many other intestinal parasites, children are at greater risk for symptomatic infection, which can cause failure to thrive, anemia, clubbing, inflammatory colitis, and rectal prolapse. Adults with a high worm burden can also experience inflammatory colitis characterized by frequent—often

bloody—diarrhea and tenesmus. Infection has been shown to result in production of tumor necrosis factor (TNF)-α by lamina propria cells in the colon, which can contribute to poor appetite and wasting that can be seen with significant infection.

Diagnosis is made by standard stool microscopy without a need to concentrate stool because large numbers of eggs are excreted. Whipworm eggs have a characteristic barrel shape with mucous (hyaline) plugs at either end. Worms can also be seen on colonoscopy, or they can be visualized grossly in cases of rectal prolapse. PCR tests are now available with improved but variable sensitivity for species identification. Peripheral eosinophilia may be seen.

Treatment of symptomatic infections can be accomplished with mebendazole (Emverm, Vermox), albendazole (Albenza),<sup>1</sup> or ivermectin (Stromectal)<sup>1</sup>; see Table 2 for details.

### Hookworm

Like other helminthic infections, hookworm affects a substantial portion of the world's population, particularly in rural subtropical and tropical communities where human feces is used as a component of fertilizer. Infection results primarily from parasite penetration into the skin; therefore persons with an agrarian lifestyle and significant soil contact are at greatest risk.

Two species are responsible for the majority of human hookworm: *Necator americanus* and *Ancylostoma duodenale*. *N. americanus* is a smaller and less aggressive pathogen with a longer life span than *A. duodenale*. Both parasites are found in warm climates throughout the world; *A. duodenale* exists in smaller pockets in Mediterranean countries, Iran, India, Pakistan, and the Far East, whereas *N. americanus* is widely distributed throughout impoverished rural areas of

<sup>2</sup>Not available in the United States.

the tropics in the Americas, Asia, and Africa. *Ancylostoma ceylanicum*, a hookworm of dogs and cats, has been identified as one of the human zoonotic infections in Southeast Asia, tropical Australia, and the Melanesian Pacific Islands. *Ancylostoma braziliense*, a canine intestinal pathogen, causes cutaneous larval migrans in humans because the pathogen cannot penetrate the human dermis.

Hookworms are small helminths, between 0.5 and 1 cm in length. Infection results from larval penetration of the skin on contact with contaminated soil. An intensely pruritic, erythematous, papulovesicular rash called *ground itch* can develop at the site of entry. Parasites then enter the venous or lymphatic circulation and travel to the lungs, at which point an urticarial rash with cough can develop. The larvae are swallowed and migrate to the small intestine, where they attach to the bowel wall with teeth or biting plates and take a continuous blood meal by sucking with strong esophageal muscles. As the larvae lodge in the small intestine, peripheral eosinophilia peaks, and gastrointestinal discomfort with or without diarrhea can result. Large oral ingestion of *A. duodenale* can cause Wakana syndrome, characterized by cough, shortness of breath, nausea, vomiting, and eosinophilia. The most important clinical manifestation of hookworm infection is iron-deficiency anemia, which can be mild or severe and may be accompanied by malabsorption of protein in hosts with heavy burden of disease. Infants and pregnant women can become extremely ill or even die as a result of the anemia.

Hookworm may be difficult to diagnose because light infections often do not produce enough eggs to be readily seen on stool examination; stool should therefore be concentrated if infection is suspected. Eggs do not appear in stool until approximately 2 months after dermal penetration of *N. americanus* and up to 38 weeks from cutaneous entry of *A. duodenale*, hence patients with pulmonary complaints will not yet have a positive stool examination. Multiplex PCR assays that detect *A. lumbricoides*, *T. trichiura*, and hookworm have higher sensitivity than direct microscopy; however, these are not as widely available yet.

Hookworm infection can be eradicated with benzimidazole anthelmintics; see Table 2 for details. Prevention of hookworm infection, as with other parasites, lies in improved sanitary conditions; wearing shoes is especially important because the majority of infections are acquired through the skin. Mass anthelmintic treatment campaigns have shown some efficacy in reducing disease in children; however, reinfection and concern for development of resistance continue to present significant challenges. Candidate vaccines are currently under investigation.

### Toxocara

Human infection is most commonly from the dog ascarid, *Toxocara canis*, and rarely from the cat ascarid, *Toxocara cati*. Humans are infected by embryonated eggs shed by a definitive host (dogs, cats) in contaminated soil or food, and direct contact with a definitive host is usually not a classical mode of transmission. Eggs then hatch into larvae that penetrate the intestinal wall to enter the circulation and embed in various tissues, leading to both visceral larva migrans (VLM), which affects the lungs, liver, heart, muscle, and brain, and ocular larva migrans, which affects the eyes. VLM usually presents as hepatitis (nodular lesions) and pneumonitis (typically with bilateral peribronchial infiltration). Pericarditis, myocarditis, Loeffler endocarditis, heart failure, cardiac tamponade, eosinophilic meningo-encephalitis, cerebral vasculitis, and myelitis have been rarely reported. Ocular larva migrans (OLM) results from a granulomatous inflammatory response to embedded larva that typically presents as a whitish elevated granuloma but red eye from scleritis or uveitis. Visual impairment leading to blindness from retinal detachment are more serious complications.

ELISA immunoglobulin G (IgG) serology in the appropriate clinical setting is the most commonly used diagnostic modality but cannot differentiate active from past infections. Sensitivity of ELISA for OLM is lower than that for VLM. PCR testing is commercially not available yet. Definite diagnosis is established with biopsy that is rarely indicated.

The treatment of choice is albendazole (Albenza),<sup>1</sup> which is preferred over mebendazole (Emverm, Vermox),<sup>1</sup> especially in neurologic disease and OLM because the latter does not cross the blood-brain barrier. Antiinflammatory corticosteroids are used as adjunctive therapy for cardiac, neurologic, and severe vision-threatening illness.

### Strongyloides

*Strongyloides stercoralis* is a global pathogen that is estimated to affect as many as 100 million people, mostly in tropical regions of the world. In recent years, it has become more commonly recognized in the United States among immigrants as a cause of chronic eosinophilia as well as symptomatic infection.

*Strongyloides* infection results when filariform larvae dwelling in fecally contaminated soil penetrate the skin or mucous membranes of a susceptible host. Larvae move to the lungs and subsequently to the trachea, where they are coughed up and swallowed. Females, about 2 cm in length, lodge in the lamina propria of the duodenum and proximal jejunum, where they begin to oviposit. Rhabditiform larvae (noninfectious form) emerge from these eggs and either transform into infectious filariform larvae (infectious form) that can repenetrate the intestinal wall (autoinfection; unique to *S. stercoralis* among other helminths) or are passed into the feces, at which point they can begin a free-living cycle and reproduce sexually or can molt directly into an infectious form ready to enter a subsequent susceptible host.

Persons infected with *Strongyloides* are typically asymptomatic. Those who have symptoms might report abdominal discomfort, diarrhea alternating with constipation, or, rarely, blood-tinged stool. Severe intestinal infections can occur and are manifest by chronic watery or mucous diarrhea. In such cases, colonoscopy reveals excessive bowel wall thickening and copious secretions, or edema (catarrhal enteritis or edematous enteritis). Parasite migration through the dermis can manifest as pathognomonic serpiginous, erythematous, and pruritic patches along the buttocks, perineum, and thighs, known as *larvae currens* (“running” larvae).

*Strongyloides* appear to attain a balanced state in their host, with similar numbers of adult worms throughout the many years of infection. During periods of host immunocompromise, particularly in patients taking corticosteroids, *Strongyloides* can enter into a state of rapid autoinfection and rampant reproduction called *hyperinfection syndrome*, which results in devastating illness. Persons with HIV infection do not seem to be at particular risk for symptomatic disease or hyperinfection, but hyperinfection has been linked to human T-lymphotropic virus type 1 (HTLV-1) infection. *Strongyloides* has also caused hyperinfection in organ transplant patients whose donor had been infected asymptotically with the parasite. Although it has long been thought that steroid-induced immune compromise was the major trigger for hyperinfection, growing evidence suggests that steroids themselves may be the culprit by directly inducing the accelerated life cycle in the parasite.

The hyperinfection syndrome is characterized by systemic illness with fever, cough, hypoxia, patchy or diffuse pulmonary infiltrates with alveolar microhemorrhages, and dermatitis; it can include myocarditis, hepatitis, splenic abscess, meningitis and cerebral abscess, and endocrine organ involvement. Larvae migrating out of the intestines can drag bacteria with them, resulting in gram-negative or polymicrobial sepsis. The prognosis of *Strongyloides* hyperinfection syndrome is grave, even with highly effective anthelmintic treatment given the diffuse nature of this disease. However, earlier recognition and intensive supportive care result in cure.

Diagnosis of uncomplicated *Strongyloides* infection in endemic areas can be challenging because few larvae are passed in stool, and numerous examinations may be necessary to detect them. ELISA IgG serologies to filariform larvae are highly sensitive, but

<sup>1</sup>Not FDA approved for this indication.

positive results cannot distinguish between active and past infections. Moreover, serologies can be falsely negative in immunocompromised hosts. It is, however, the test of choice for persons who have migrated to nonendemic areas, and all persons in this setting should be treated. Ivermectin (Stromectol) is the treatment of choice; albendazole (Albenza)<sup>1</sup> has some activity against *S. stercoralis* and can be tried as an alternative; see Table 2 for medications and doses. During the first days of treatment, patients can experience intense dermal pruritus as parasites die. Eosinophilia and positive ELISA results can persist for months, even after effective therapy.

### Enterobius

Human pinworm infection, caused by the threadlike nematode *Enterobius vermicularis*, is found throughout the world and continues to be diagnosed commonly in the United States, especially in children 5 to 10 years of age. It is the most common helminthic infection in the United States and Europe. Its persistence is likely related to the fact that pinworm does not require a period of maturation outside the human body, and autoinfection or transmission by very close contact sustains the parasite within communities. *E. vermicularis* is at maximum 1 cm long with a tapered tail, and it dwells in the cecum, appendix, and adjacent colon. At night, female worms travel to the anus and lay small (25 to 50  $\mu\text{m}$ ), double-walled oval eggs in the perianal skin. Within 6 hours, the eggs embryonate within their capsule and are infectious. In scratching the perianal area and subsequently bringing his or her hand to the mouth, the host ingests the embryos, which then hatch in the bowel about 2 months later and continue the cycle of infection. Embryonated eggs can also attach to bedclothes, thereby placing other household members with close contact at risk for infection. In family groups, infection is associated with close living quarters, poor hand washing, and infrequent washing of clothes and sheets. It can also be prevalent among institutionalized persons.

Infection is often asymptomatic, but it can cause perianal itching, which helps facilitate persistent infection by encouraging frequent touching of the perianal area. Rarely, worms migrate into ectopic foci and produce painful genitourinary tract disease with granulomatous inflammation; pinworm infection rarely results in pain that mimics acute appendicitis.

Pinworm infestation is best diagnosed by the classic Scotch tape test, which involves placing and immediately removing a piece of sticky tape firmly across the perianal area early in the morning when the eggs have been deposited. The tape can then be brought into a physician's office or laboratory, where it is placed sticky-side down for microscopic examination to detect the eggs. Sensitivity can be increased by examining at least three specimens. Eggs are small (25  $\times$  50 microns) with a characteristic "bean-shaped" appearance. It is also sometimes possible to see the white small female worms directly on the perianal region, although they are so small (8 to 13 mm in length) that they may easily be mistaken for residual bits of toilet paper. Although *E. vermicularis* is susceptible to standard albendazole<sup>1</sup> or mebendazole (see Table 2), pyrantel pamoate (Pin-Away, OTC) is most frequently used in the United States as it is cheap and effective. All household contacts should be empirically treated with the same regimen to avoid reintroducing infection from family members who may be asymptotically carrying the parasite. Careful laundering of all bedclothes is recommended as well.

### Anisakiasis

*Anisakiasis* is a descriptive term for human infection with parasites of two distinct genera: *Anisakis* and *Pseudoterranova*. Humans are incidental hosts for these roundworms that inhabit multiple species of fish and other marine animals (tuna, mackerel, hake, cod, sardines, and cephalopods) as intermediate hosts, and marine mammals such as whales, seals, sea lions, and walrus as final hosts. Humans acquire the parasite in its larval stage by

eating undercooked or raw fish (e.g., sushi, ceviche), therefore the condition predominates in cultures in which uncooked fish is consumed. Cases are most commonly reported from Japan but are seen throughout the world in other coastal nations and among restaurateurs.

On consumption of fish with anisakid larvae embedded in its musculature, humans can experience immediate symptoms in the form of itching or burning in the throat, which can provoke coughing that expels the parasite. If the parasite is swallowed, the larva attempts to embed in the gastric musculature at the pylorus. This can produce acute, short-lived epigastric abdominal pain and possibly immediate vomiting, at which point the parasite might again be ejected. If the larva does manage to penetrate gastric tissue, it dies because it is incapable of further tissue invasion in humans. An intense inflammatory response to the dead pathogen can then result, with gastric pain, nausea, and occasionally diarrhea with blood or mucus if a gastric ulcerative lesion has resulted. Eosinophilic enterocolitis, ileitis, appendicitis, and focal peritonitis and abscess formation from penetration of larva into the peritoneum are also rarely reported. Bronchoconstriction, angioedema, and anaphylaxis have been described mimicking seafood allergy. *Pseudoterranova* appears to cause milder symptoms and less tissue invasion, and the worm might simply be vomited several days after initial ingestion and presented to a physician, often by an alarmed patient. Because the vast majority of infections are caused by a single organism, vomiting of the parasite results in a definitive cure, and patients can be reassured. Diagnosis in patients with ongoing symptoms related to an embedded parasite is ultimately endoscopic. Effective cure results on endoscopic or surgical removal of the worm. Albendazole<sup>1</sup> as an effective therapy is reported; however, data are limited.

### Trematodes

#### *Schistosoma*

Schistosomes are freshwater pathogens that are found in areas of endemicity in Africa, South America, Southeast Asia, and parts of the Middle East. These small trematodes cause varied, often chronic infections that can carry significant morbidity, although some species cannot invade beyond the dermis in humans and result strictly in cercarial dermatitis or swimmer's itch. There are five species of schistosomes known to cause disease in humans: *Schistosoma haematobium*, found through much of Africa and parts of the Middle East; *Schistosoma mansoni*, also native to Africa and the Middle East as well as Latin America; *Schistosoma japonicum*, present in China, Southeast Asia, and the Philippines; *Schistosoma mekongi*, found only in the Mekong River basin in Laos and Cambodia; and *Schistosoma intercalatum*, endemic only in West Africa.

All persons who come in contact with schistosomes are at risk for infection, even with brief exposure to fecally contaminated freshwater in which the intermediate hosts of the pathogen (snails) reside. Frequency and degree of infection tend to be highest in children in endemic areas and then level off in the early teenage years, likely secondary to level of environmental exposure and possibly to host immunity. *S. haematobium* causes disease in the genitourinary system; the others cause intestinal, hepatic, and sometimes pulmonary diseases.

Infection is acquired rapidly on contact with freshwater (including brief swims or by repeated splashing, as can occur during river rafting), when free-living fork-tailed schistosomal larvae (cercariae) penetrate human skin and lose their tail. These schistosomulae can cause intense itching and a papulovesicular, pruritic rash at the site of penetration, swimmer's itch. Invasive schistosomulae then enter the venous bloodstream and reach the liver through portal venules, where they mature into adults. Adult worms then migrate against the portal venous flow to the mesenteric venules of the gut (*S. mansoni*, *S. japonicum*, *S. intercalatum*, *S. mekongi*) and vesical venous plexus (*S. haematobium*), where male and female forms mate for life. Females begin to

<sup>1</sup>Not FDA approved for this indication.

<sup>1</sup>Not FDA approved for this indication.

oviposit, and the resultant inflammatory response to the eggs can cause either acute illness or chronic fibrosis and granulomatous inflammation of the tissues in which they reside.

Acute illness, called *Katayama fever*, is more common among hosts who have not been previously exposed to the organism and can be quite severe and even fatal. Katayama fever begins 3 to 8 weeks after infection, with acute onset of fever, chills, myalgias, cough, urticaria, angioedema, abdominal pain, hepatomegaly, and lymphadenopathy. Eggs might not yet be present in stool at the time of diagnosis. Chronic schistosomiasis is a slowly progressive illness presenting chiefly with intermittent abdominal pain, diarrhea, and anorexia. Colonic ulceration with gastrointestinal bleeding and iron-deficiency anemia from huge parasitic burden has been described. Hepatosplenic schistosomiasis can be caused by granulomatous inflammation surrounding the eggs, eventually leading to periportal fibrosis (Symmers pipe-stem fibrosis), portal hypertension, and splenomegaly. Portal hypertension can then lead to portosystemic collateral vessel development along with deposition of eggs in the pulmonary vasculature. Granulomatous inflammation in the pulmonary tissues eventually causes endarteritis, fibrosis, pulmonary hypertension, and cor pulmonale. *S. haematobium* infection can manifest as gross or microscopic hematuria, irritative urinary symptoms, and chronic bacterial urinary tract infections; ultimately ureteral fibrosis, hydronephrosis, and granulomatous genital lesions also can ensue. Neuroschistosomiasis can cause both myelopathy and intracerebral lesions and can have varied presentation including seizures, focal deficits, encephalopathy, and rapidly progressive transverse myelitis.

Diagnosis of schistosomiasis is by observation of eggs in stool (intestinal disease), urine (urinary tract disease), or biopsy specimens, or by serum antibody testing. Concentration of stool may be necessary to detect the pathogen. The eggs of the three most common species of schistosomes can be readily identified microscopically: *S. haematobium* has an inferior spine, *S. mansoni* has an inferolateral spine, and *S. japonicum* lacks a spine. Quantification of eggs is important as the parasitic burden is proportional to the risk of complications and is usually reported as light (up to 100 eggs/gram), moderate (100 to 400 eggs/gram), and severe (>400 eggs/gram) in stool specimens. Eosinophilia is a hallmark of chronic infection and is a common cause of asymptomatic eosinophilia among immigrants from endemic regions of the world. Serology is useful, particularly in return travelers with low parasitic burden; however, it can be negative in early infection as it takes 6 to 12 weeks after exposure to become positive. It is highly specific but cannot distinguish acute, chronic, or cleared infection. Antigen testing targeting specific schistosomal glycoproteins, circulating cathodic antigen (CCA, genus specific) and circulating anodic antigen (CAA, more specific to *S. mansoni*) is more sensitive than microscopy and can lead to rapid diagnosis, particularly in specimens with low parasitic burden. Highly sensitive PCR assays have been developed to be used on blood, stool, and urine specimens; however, these are not as widely available. Histopathology is better than microscopy, particularly in ectopic manifestations, but is usually not required.

All patients with schistosomiasis should be treated, and those with chronic manifestations might experience significant regression of even late-stage organ-specific disease. Treatment of choice is praziquantel (Biltricide); see Table 2 for details.

Prevention of schistosomiasis involves improving access to treated water and exploration of avenues to eliminate the intermediate snail hosts. Host immunity does appear to occur, and efforts are underway to better understand and induce such immunity in the form of a vaccine.

## Cestodes

### *Taenia*

Human tapeworm infection has long been implicated in North American oral folklore as a cause of insatiable appetite and excessive weight loss. In reality, despite their impressive size of up to 12 meters, tapeworm infection tends to be minimally symptomatic.

*Taenia solium*, pork tapeworm, and *Taenia saginata*, beef tapeworm, are the two most common flatworm infections of humans (humans are the only definitive hosts) worldwide and occur in any setting in which raw or undercooked meat is served and cattle and pigs have access to feed contaminated with human feces. *T. saginata* is still found in areas of North America and Europe as well as in Central and South America and Africa; *T. solium* is common throughout Mexico, Central and South America, Africa, China, and the Indian subcontinent. Although humans are the definitive hosts for both parasites, *T. solium* is best known for its pathogenicity in the form of cysticercosis. Cysticercosis is not an intestinal parasitic infection.

Domesticated animals acquire infection on ingestion of eggs or gravid proglottids excreted by humans; the eggs mature in their musculature and develop a scolex. When humans consume infected meat, the scolex attaches to the small intestine, and the adult tapeworm develops over approximately 2 months. Adult tapeworms are made up of hundreds to thousands of gravid proglottids and can live for up to 25 years with intermittent shedding in the stool.

Symptoms tend to be mild or absent but can include nausea, abdominal pain, loose stools, anal pruritus, and occasionally weakness or increased appetite, especially in children. Serious illness rarely results when tapeworm proglottids become lodged in the appendix or the biliary or pancreatic duct or are coughed up and aspirated. Some patients come to medical attention when the worm is noted emerging from the anus or on extrusion of proglottids in the stool.

Diagnosis of taeniasis can be made on visualizing the round eggs with hooks and double wall with characteristic striations, however the species cannot be determined unless their proglottids are examined (*T. saginata* has 12 or more uterine branches, whereas *T. solium* has <10). Because the eggs and proglottids are shed intermittently, the sensitivity of microscopy is poor. Serum antibody and antigen tests as well as stool PCR have been developed for diagnosis but are not widely used in clinical practice. Eosinophilia and elevated immunoglobulin E (IgE) levels may be present. Single-dose praziquantel (Biltricide)<sup>1</sup> (see Table 2) is curative in almost all cases, but infectious eggs can still be released in the feces for some time after worm eradication; ingestion of these could result in subsequent development of cysticercosis, so patients should be counseled to avoid fecal-oral contact.

Proper cooking of meat is the mainstay of prevention; disposal of human waste away from animals would also be effective in interrupting the life cycle.

### *Diphyllobothrium*

*Diphyllobothrium latum* (fish tapeworm) is the longest parasite known to infect humans (10 to 12 m). It is found in freshwater lakes in areas of the Americas, Northern Europe, Africa, China, and Japan and has a complex life cycle involving two intermediate hosts: crustaceans and small fish. Humans and other fish-eating mammals are the definitive hosts and acquire the infection on ingestion of raw fish or roe.

Eggs and proglottids are intermittently shed in human stool that embryonate in the water. Coracidae hatch from the eggs and are ingested by small crustaceans, the first intermediate hosts. Coracidae mature into proceroid larvae in the crustaceans that are then ingested by the small freshwater fish (the second intermediate host). Proceroid larvae develop into plerocercoid larvae (sparganum) that are then passed onto the large predator fish (later intermediate host) that is then consumed by humans (definitive host). Sparganum develops into the adult worm inside the human intestine.

The mature adult tapeworm attaches within the small intestine, and hosts are usually asymptomatic. Infected persons might complain of increased appetite, nausea, or abdominal discomfort. Many patients present after passage of portions of the tapeworm in stool, as with taeniasis. In others, diagnosis is incidental on

<sup>1</sup>Not FDA approved for this indication.

stool examination performed for other purposes or during screening colonoscopy. As with other worms, the parasite occasionally migrates into biliary ducts or causes intestinal obstruction. Attachment of the parasite higher in the intestine competes the host for vitamin B<sub>12</sub> absorption and can result in vitamin B<sub>12</sub> deficiency (pernicious anemia).

Diagnosis is made either by visualizing eggs with an operculum (lidlike opening) in an unconcentrated stool or by encountering the adult worm. Proglottids can be differentiated from those in taeniasis by the presence of a rosette-shaped uterus. Eosinophilia is present in a minority of cases. Treatment with praziquantel<sup>1</sup> is curative; see Table 2. Vitamin B<sub>12</sub> supplementation is necessary in cases of severe or symptomatic deficiency, but it will not recur once the tapeworm is eliminated. Prevention involves not ingesting undercooked fish.

<sup>1</sup>Not FDA approved for this indication.

## IRRITABLE BOWEL SYNDROME

Method of

Arnold Wald, MD

### CURRENT DIAGNOSIS

- Fulfilling diagnostic criteria for irritable bowel syndrome (IBS) using Manning or Rome criteria is mandatory but not sufficient, as some organic diseases may also meet these criteria.
- Against the diagnosis of IBS is new onset in old age, a steady progressive course, frequent awakening by abdominal pain or urge to defecate, and weight loss not attributed to depression.
- The diagnostic approach to patients with IBS symptoms with no “alarm signs” includes a complete blood count; stool testing for occult blood or calprotectin; C-reactive protein and colonoscopy if patient is >50 years of age, has positive stool, or aforementioned blood test results; or if there is a poor response to treatment.
- After a diagnosis of IBS is established with confidence, repeated testing is counterproductive unless there is a distinct change in clinical symptoms or new alarm signs develop.

### CURRENT THERAPY

- A robust patient–healthcare provider relationship is perhaps the most important determinant of outcome and reduction of healthcare utilization in patients with IBS.
- There is significant support for the use of a low-FODMAP (fermentable oligosaccharides, disaccharides, monosaccharides, and polyols) diet in patients with IBS. Gluten restriction is part of this diet and will cover those patients who believe that they are gluten intolerant in the absence of celiac disease.
- Pharmacologic agents can be divided into those for IBS-C or IBS-D or in any patient with IBS to ameliorate abdominal pain. The evidence to support these agents varies in quality and strength, and none is effective in the majority of patients who have been tested.
- Cognitive behavioral therapy (CBT) can be very effective in IBS with unrelenting symptoms but may also be effective for any patient with IBS who exhibits poor stress management.

## Introduction and Definitions

Irritable bowel syndrome (IBS) is a chronic functional disorder of the gastrointestinal (GI) tract characterized by chronic abdominal pain and altered bowel habits in the absence of an organic disease. In the absence of a biologic disease marker, the diagnosis has traditionally been based on a cluster of symptoms. The earliest was the so-called *Manning criteria*, which was based most stringently on the presence of three or more characteristic symptoms (Table 1).

Subsequently, there have been various iterations of IBS criteria created by the Rome study groups that are currently used for research purposes (see Table 1). When evaluating the relevant literature for IBS, it is important to note that various studies have used different criteria that may result in variable data concerning prevalence and economic costs considerations.

From a clinical standpoint, subtypes of IBS have been defined as follows:

- IBS with predominant constipation (IBS-C): Patient reports that abnormal bowel movements are usually constipation (types 1 and 2 in the Bristol Stool Form Scale [BSFS]).
- IBS with predominant diarrhea (IBS-D): Patient reports that abnormal bowel movements are usually diarrhea (types 6 and 7 in the BSFS).
- IBS with mixed bowel habits (IBS-M): Patient reports that abnormal bowel movements are usually both constipation and diarrhea (more than one-fourth of all the abnormal bowel movements are constipation, and more than one-fourth are diarrhea) using the BSFS.
- IBS Unclassified (IBS-U): Patients who meet diagnostic criteria for IBS but cannot be accurately categorized into one of the other three subtypes.

## Epidemiology

### Prevalence

Numerous surveys have reported the prevalence of IBS in the community. The majority of these studies have used accepted diagnostic criteria, and some have used more than one definition within the same population. In one meta-analysis, 23 studies used the Manning criteria, 24 used Rome I criteria, 36 used Rome II criteria, and 5 used Rome III criteria. The prevalence ranged from 5% to 10% (United States, China) to 15% to 20% (Canada, Brazil, Russia). There were little or no data from Africa, Central America, and large parts of South America.

The majority of studies did not report the predominant stool pattern in IBS. Of the nine that included IBS-U subtypes as well, there was an even distribution, ranging from 22% to 24% mean prevalence for each of the four subgroups. In

**TABLE 1** Criteria for IBS

MANNING CRITERIA	ROME IV CRITERIA*
Looser stools with onset of pain	Recurrent abdominal pain on average at least 1 day per week in the past 3 months associated with two or more of the following:
More frequent bowel movements at onset of pain	• Related to defecation
Visible distension	• Associated with a change in stool frequency
Feeling of distension	• Associated with change in form of stool (appearance)
Mucus per rectum	
Feeling of incomplete emptying (often)	
Strict criteria >3 of above	
Less strict criteria >2 of above	

\*Criterion fulfilled for the past 3 months with onset of symptoms at least 6 months before diagnosis.

general, the pooled prevalence was higher in women than in men (14%; range 11% to 16% vs. 9%; range 7.3% to 10.5%) with significant heterogeneity between studies. There appeared to be no relationship between socioeconomic status in the four studies that reported it and no strong influence of age as well.

It is important to note that the meta-analysis was restricted to studies based on the general population and excluded those based on convenience samples. This makes the data more generalizable to community individuals with IBS.

### Causality: A Biopsychosocial Model of Functional Gastrointestinal Disorders Such as IBS

The ability to study causality in a disorder with no biologic disease markers is fraught with difficulties. This is certainly the case with IBS as a representative of functional GI disorders. Many hypotheses have been advanced and found wanting. The current (and in my opinion most relevant) conceptual model is the biopsychosocial construct, as shown in Figure 1.

Figure 1 indicates that predeterminants such as early life experiences together with psychosocial factors may interact with altered gut physiology via the brain-gut axis. This concept infers that these factors are bidirectional and mutually interactive and therefore influence both the clinical presentation and clinical outcomes of the disorder. Among the physiologic processes that may lead to GI symptoms are abnormal gut motility, visceral hypersensitivity, immune dysregulation, inflammation and barrier dysfunction, the intestinal microbiome, diet, and the brain-gut axis. No one factor alone accounts for the symptoms of IBS, and all must be considered in the management of affected patients. This becomes apparent when considering treatment approaches (see later).

### Impact on Population Health

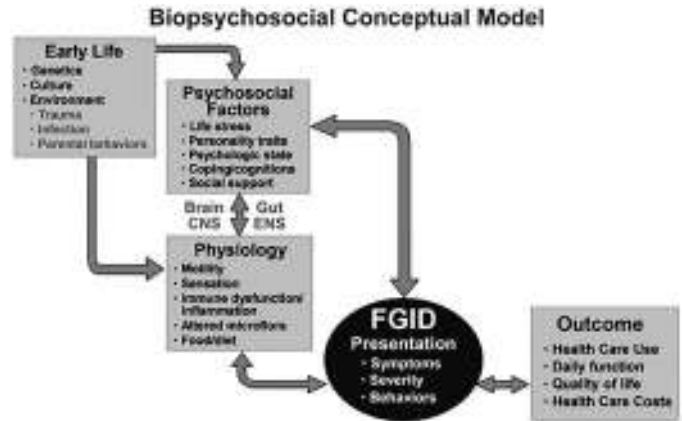

Although there is no mortality associated with IBS, symptoms are long lasting, and there are no curative therapies available. As a chronic illness, the economic impact of this disorder is considerable.

In a 2015 survey conducted by the American Gastroenterological Association (AGA), IBS patients reported that their symptoms interfered with work productivity on an average of 9 days per month and missed work on an average of 2 days per month. Indirect costs (e.g., loss of work and reduced productivity) have been estimated to be up to \$20 billion annually in the United States, with an estimated annual cost per patient of \$9933 (in 2021 U.S. dollars)

In a recent study of indirect costs, impairment experienced at work (presenteeism) accounted for approximately 75% of the total annual indirect costs for respondents with IBS, far in excess of absenteeism from work. Compared with controls, IBS respondents missed significantly more work (5.1% vs. 2.9%), experienced higher levels of presenteeism (17.9% vs. 11.3%), and had greater overall work productivity loss (20.7% vs. 13.2%) and higher daily activity impairment.

### Direct Healthcare Costs

Almost 30 years ago, it was estimated that up to 25% of all visits to gastroenterologists in the United States were for IBS,

**Figure 1** Predeterminants such as early life experiences, together with psychosocial factors, may interact with altered gut physiology via the brain-gut axis. This concept infers that these factors are bidirectional and mutually interactive and therefore influence both the clinical presentation of the disorder and the clinical outcomes. Among the physiological processes that may lead to GI symptoms are abnormal gut motility, visceral hypersensitivity, immune dysregulation, inflammation and barrier dysfunction, the intestinal microbiome, diet, and the brain-gut axis. No one factor alone accounts for the symptoms of IBS, and all must be considered in the management of affected patients. This becomes apparent when considering treatment approaches. CNS, Central nervous system; ENS, enteric nervous system; FGID, functional gastrointestinal disorder. Reprinted with permission from Drossman DA. Functional gastrointestinal disorders: history, pathophysiology, clinical features and Rome IV. *Gastroenterology* 2016; 150:1262–1279.

with additional others for other functional GI disorders. This accounted for 3.5 million visits to healthcare practitioners in 1991 and undoubtedly is much higher today. Earlier studies showed that IBS patients made twice as many health visits per year as did age-matched controls and that 78% of the excess visits were for non-GI complaints. A subsequent analysis of this phenomenon suggests that comorbidity in IBS may be a consequence of the psychological trait for somatization, defined as the tendency to amplify the intensity and overinterpret the significance of any somatic sensation. This excess comorbidity is the primary determinant of excess healthcare costs associated with IBS, although it does not apply to all patients with IBS.

Recent attempts to identify factors leading to high utilizers with IBS have been made. The investigators used a conceptual framework for accessing healthcare services that holds that a decision to use healthcare is related to (1) predisposition to use services; (2) ability to use services; and (3) need for services. The important conclusion was that decisions to use healthcare are not simply influenced by symptom-specific factors but by a variety of lifestyle and (most importantly) economic factors such as health insurance coverage.

### Evaluation of Patients with Suspected Irritable Bowel Syndrome

The diagnosis of IBS should be made based on the clinical history, physical examination, minimal laboratory testing, and colonoscopy or other appropriate tests when clinically indicated. Fulfilling diagnostic criteria is, of course, mandatory but insufficient, as some organic diseases may also meet these criteria. The prevalence of organic disease is lowest in IBS-C and highest in IBS-D, followed by IBS-M; the most common consideration would be Crohn's disease. Against the diagnosis of IBS include new onset in old age, a steady progressive course, frequent awakening by pain or need to defecate, and weight loss not attributed to depression. Additional features that would increase concern about organic disease would include a positive family history of colorectal cancer or inflammatory bowel disease as well as rectal bleeding or anemia associated with iron or vitamin B<sub>12</sub> deficiency.

**TABLE 2** Diagnostic Approach to Patients with IBS Symptoms (No “Alarm Signs”)

Complete blood count
Stool for occult blood
Routine colon cancer screening at ages >45 years
C-reactive protein (inflammatory marker)*
Fecal calprotectin/lactoferrin (indicators of inflammation)*
Stool for <i>Giardia</i> *
Celiac serologies*
Diagnostic colonoscopy <45 years of age (if poor response to Rx)

\*For IBS with predominant diarrhea (IBS-D).

In the absence of “alarm signs,” a consensus diagnostic approach to patients with IBS symptoms is listed on [Table 2](#) (Rome IV).

### Tests of Unproven Value

A high prevalence of small intestinal bacterial overgrowth (SIBO) has been claimed by some centers leading to the frequent utilization of either lactulose or glucose breath tests. This hypothesis is based on poor methodology and erroneous conclusions. The original studies have not been reproduced by other centers using either similar and/or better techniques. This has led to the frequent use of expensive antibiotics that can be effective in some patients with bloating and IBS but not because these patients have SIBO.

Food allergy testing is not routinely recommended. Stool for ova/parasites is not recommended unless the patient has traveled to an undeveloped area. Lastly, after a diagnosis of IBS has been established with confidence, repeated testing is counterproductive unless there is a distinct change in clinical symptoms or new alarm signs develop. This is especially so if endoscopy procedures have already been performed.

### Treatment

A validated standardized algorithm for the treatment of IBS does not exist. Treatment therefore depends on the type and severity of symptoms and the nature of associated psychosocial issues in an individual patient. A strong guiding principle is that a robust patient–healthcare provider relationship is an important determinant of outcome and reduction of healthcare utilization. Treatments may generally be divided into dietary and lifestyle modifications, pharmacologic agents, and behavioral therapies, all of which have been validated by randomized controlled studies.

### Dietary Modifications

Although fiber supplements are widely recommended for IBS, a meta-analysis of seven high-quality studies failed to find significant benefit, although some benefits might occur with soluble fiber (psyllium) versus insoluble fiber (bran) in IBS-C. Unfortunately, fiber supplements may exacerbate symptoms such as abdominal bloating and discomfort.

Other dietary interventions such as gluten-free and low FODMAP (fermentable oligosaccharides, disaccharides, monosaccharides, and polyols) diets have become increasingly popular. Several studies support the benefit of gluten-free diets in a subset of IBS patients in the absence of celiac disease. It remains uncertain whether the clinical benefits are a consequence of gluten withdrawal, elimination of other wheat proteins and highly fermentable short-chain fatty acids, or a placebo effect. Adding a gluten-free diet to patients who are already on a low FODMAP diet offers no additional benefits. Monash University has a number of resources including an app that are helpful to patients (<https://www.monashfodmap.com/>).

There is accumulating evidence from prospective controlled studies that dietary FODMAP restriction is associated with significant symptom improvement in many patients with IBS ([Table 3](#)). It appears that restriction of both fructose and fructans is most beneficial. Significant symptom improvement was noted in IBS patients compared with a standard Australian diet and also a National Institute for Health and Care Excellence (NICE; England) diet.

Response to a low FODMAP diet is usually assessed after about 2 weeks. Responders are then asked to engage in a structured reintroduction of restricted foods to allow the individual to tailor his or her diet. It is optimal to involve a properly trained dietitian or nutritionist in the care of these patients.

### Pharmacologic Agents

Pharmacologic approaches to IBS may be divided into medications for IBS-C, patients with IBS-D, and for any patient with IBS in order to ameliorate abdominal pain ([Table 4](#)).

Most drugs work through different pathophysiologic mechanisms. For example, for patients with IBS-C, linaclotide (Linzess), plecanatide (Trulance), and lubiprostone (Amitiza) increase intestinal chloride and water secretion to combat constipation, whereas PEG (polyethylene glycol 3350 [Miralax])<sup>1</sup> does so through a hyperosmolar effect. Tenapanor (Ibsrela) is a new agent that inhibits sodium absorption to increase water secretion. For IBS-D, rifaximin (Xifaxan) is an antibiotic, loperamide (Imodium)<sup>1</sup> is a peripheral  $\mu$ -opioid agonist, alosetron (Lotronex) works through the serotonin 3 receptor, and eluxadoline (Viberzi) has effects on all three opioid receptors in the gut ( $\mu$ ,  $\kappa$ , and  $\delta$ ). Tricyclic antidepressants (TCAs) presumably work via central neurochemical changes, and antispasmodics (dicyclomine [Bentyl], encapsulated oil of peppermint<sup>7</sup>) work largely through peripheral anticholinergic pathways. The large and diverse number of drugs are indicative of the lack of fundamental understanding of IBS. Moreover, few drugs are effective in the majority of IBS patients, and there is no more than a 10% to 15% improvement over placebo in most published studies.

The AGA guidelines published in 2014 incorporated the Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology and best practices as outlined by the Institute of Medicine. Recommendations are either strong or conditional (weak). The evidence that provides the basis for recommendation is rated high, moderate, or low quality. A similar grading system was used in the recently published American College of Gastroenterology (ACG) guidelines in 2021.

Of the pharmacologic agents for IBS-C, linaclotide (Linzess) received a strong recommendation with high-quality evidence, lubiprostone (Amitiza) received a conditional recommendation on moderate-quality evidence, and PEG<sup>1</sup> was given a conditional recommendation based on weak evidence. The first two agents showed modest benefit over placebo, whereas there are no data to support the use of PEG. For all three agents, adverse effects were relatively few, and diarrhea is perhaps the major side effect. Both linaclotide and lubiprostone are costly (as are eluxadoline [Viberzi] and plecanatide [Trulance]) and may involve high out-of-pocket expenses for patients.

For IBS-D, both rifaximin (Xifaxan) and alosetron (Lotronex) received conditional recommendations based on moderate-quality evidence. The latter is approved by the U.S. Food and Drug Administration (FDA) only for women who have failed all other treatments. There is a very small risk (approximately 1 case/1000 patient years) for ischemic colitis with alosetron. Although loperamide (Imodium)<sup>1</sup> has very low-quality evidence to support its use, it can be very effective if used in a proactive fashion.

The case for TCAs and antispasmodics is based on low-quality evidence, but both agents can be very effective for abdominal pain and, in the case of TCAs, for reducing diarrhea in IBS patients.

<sup>1</sup>Not FDA approved for this indication.

<sup>7</sup>Available as dietary supplement.

**TABLE 3** Low-FODMAP Diet

AVOID OR REDUCE THESE FOODS			
FRUCTOSE	LACTOSE	OLIGOS	POLYOLS
Fruits: Apple, mango, pear, watermelon, juice, dried fruit	Milk: Milk from cows/goats/sheep; custard; ice cream; yogurt; eggnog	Vegetables: Beets, broccoli, brussels sprouts, cabbage, fennel, garlic, onion, chicory root	Fruits: Apricot, avocado, blackberry, cherry, nectarine, peach, plum, prune, fig
Other: Asparagus, honey, high-fructose corn syrup, molasses	Cheese: Soft, unripened cheese	Other: Barley, beans, chickpeas, couscous, inulin, lentils, pistachios, rye, soy milk, wheat (pasta, bread), veggie burgers	Vegetables: Cauliflower, corn, mushroom, sweet potato Sweeteners: Ending in "ol" (e.g., xylitol, sorbitol), isomalt

FODMAP, Fermentable oligosaccharides, disaccharides, monosaccharides, and polyols.

**TABLE 4** Pharmacologic Agents for IBS

INDICATION	DRUG	DOSE
IBS-C	Linaclotide (Linzess)	72–290 mcg/d <sup>3</sup>
	Plecanatide (Trulance)	3 mg/d24 mcg bid <sup>3</sup>
	Lubiprostone (Amitiza)	8 mg bid
	PEG-3350 (Miralax) <sup>1</sup>	8.5–17 g/d
	Tenapanor (Ibsrela)	50 mg bid
IBS-D	Rifaximin (Xifaxan)	550 mg tid × 2 weeks
	Alosetron (Lotronex)	1 mg qd to bid
	Eluxadoline (Viberzi)	75–100 mg/d
	Loperamide (Imodium) <sup>1</sup>	2–16 mg/d
IBS-All	Dicyclomine (Bentyl)	20–40 mg qid
	Desipramine (Norpramin) <sup>1</sup>	10–100 mg/d (desipramine)

<sup>1</sup>Not FDA approved for this indication.

<sup>3</sup>Exceeds dosage recommended by the manufacturer. Per Amitiza's manufacturer package insert, the recommended dose for IBS-C is 8 mcg bid.

### Behavioral Therapy

For patients with unrelenting IBS symptoms, cognitive-behavioral therapy (CBT) and gut-directed hypnosis have been found to be beneficial. Such therapies should be performed by experienced and well-trained behavioral specialists who are an integral part of the medical team that treats patients with functional GI disorders. The most robust data for efficacy are for CBT. One potential drawback is that these treatments are provider-intensive approaches, but recent studies suggest that CBT can be as effective when given in a shortened course as the traditional method.

## MALABSORPTION

Method of

Lawrence R. Schiller, MD

### CURRENT DIAGNOSIS

- Recognize the presence of generalized malabsorption by the combination of typical symptoms: diarrhea, greasy stools, flatulence, weight loss, fatigue, edema.
- Recognize the presence of malabsorption of specific nutrients by associated symptoms and those symptoms particular to deficiency states of the malabsorbed substance: flatus, diarrhea, anemia, dermatitis, glossitis, neuropathy, paresthesias, tetany, ecchymosis.
- Documentation of generalized malabsorption is best done by stool analysis demonstrating steatorrhea and acid stools (reflecting carbohydrate malabsorption). Diagnosis depends on visualization of the small bowel by endoscopy or radiography and small bowel biopsy. Additional tests may be needed.
- Documentation of specific malabsorption is best done by demonstrating low blood levels of the malabsorbed substance or by tests designed to measure absorption of that substance. Diagnosis depends on studies designed to identify the likely diagnosis for a given situation.

### CURRENT THERAPY

- Once a diagnosis is reached, therapy can be directed toward that specific problem:
  - Gluten-free diet for celiac disease
  - Antibiotics for bacterial overgrowth
  - Pancreatic enzymes for exocrine pancreatic insufficiency
  - Lactose-free diet for lactase deficiency

Every day the average human being consumes 2000–3000 kcal of food, much of it in the form of polymers or other complex molecules that must be digested and absorbed by the gut. The processes of digestion and absorption are complex and are readily disturbed by pathologic processes. More than 200 conditions have been described that can adversely affect nutrient absorption.

Strictly speaking, *maldigestion* refers to impaired hydrolysis of nutrients, usually due to lack of luminal factors, such as bile acids and pancreatic enzymes, and *malabsorption* refers to impaired mucosal transport. For clinical purposes, “malabsorption” is used to describe both processes.

Malabsorption can be generalized (panmalabsorption) or limited to a specific category of nutrients. Generalized malabsorption is usually due to maldigestion or to extensive mucosal dysfunction. Specific malabsorption occurs when a single transport mechanism is disabled.

The causes of malabsorption can be divided into three categories: impaired luminal hydrolysis, impaired mucosal function (mucosal hydrolysis, uptake, packaging, and excretion), and impaired removal of nutrients from the mucosa (Box 1).

## Diagnosis

### Symptoms and Signs

Most patients with panmalabsorption have changes in their stools (Box 2). Steatorrhea (excess fat in stools) is characterized by pale color, bulkiness, greasiness, and a tendency to float (probably because of incorporated gas). Occasionally patients with malabsorption present with watery stools due to the osmotic effects of unabsorbed carbohydrates and short-chain fatty acids.

## BOX 2 Symptoms and Signs of Malabsorption or Maldigestion

- Changes in stool characteristics
  - Floating stools
  - Pale, bulky, greasy stools
  - Watery diarrhea
- Increased colonic gas production
  - Abdominal distention
  - Borborygmi, increased flatus
- Vitamin and mineral deficiencies
  - Anemia
  - Cheilosis
  - Glossitis
  - Dermatitis
  - Neuropathy
  - Night blindness
  - Osteomalacia
  - Paresthesia
  - Tetany
- Ecchymosis
- Fatigue, weakness
- Edema
- Weight loss, muscle wasting

## BOX 1 Causes of Malabsorption or Maldigestion

- Impaired luminal hydrolysis or solubilization
  - Bile acid deficiency
  - Impaired mucosal hydrolysis, uptake, or packaging
  - Pancreatic exocrine insufficiency
  - Postgastrectomy syndrome
  - Rapid intestinal transit
  - Small bowel bacterial overgrowth
  - Zollinger-Ellison syndrome
- Brush border or metabolic disorders
  - Abetalipoproteinemia
  - Glucose-galactose malabsorption
  - Lactase deficiency
  - Sucrase-isomaltase deficiency
- Mucosal diseases
  - Amyloidosis
  - Crohn’s disease
  - Celiac sprue
  - Collagenous sprue
  - Eosinophilic gastroenteritis
  - Immunoproliferative small intestinal disease (IPSID)
  - Lymphoma
  - Nongranulomatous ulcerative jejunoileitis
  - Drug-induced enteropathy (e.g., olmesartan enteropathy)
  - Radiation enteritis
  - Systemic mastocytosis
- Infectious diseases
  - AIDS enteropathy
  - *Mycobacterium avium-intracellulare*
  - Parasitic diseases
  - Small bowel bacterial overgrowth
  - Tropical sprue
  - Whipple’s disease
- After intestinal resection
- Chronic mesenteric ischemia
- Impaired removal of nutrients
  - Lymphangiectasia

Abdominal distention and excess flatus also commonly occur due to fermentation of unabsorbed carbohydrate by colonic bacteria. This can occur not only with panmalabsorption but also with malabsorption of specific carbohydrates (e.g., lactase deficiency).

Weight loss is typical with severe panmalabsorption, but it might not be very prominent with lesser degrees of malabsorption due to compensatory hyperphagia. Weight loss is most prominent early in the course of the illness, but body weight usually stabilizes as calorie absorption and body weight come into balance again. This is in contrast to illnesses like cancer or tuberculosis that produce continuing weight loss. If a patient with malabsorption has continuing weight loss, inflammatory bowel disease or lymphoma should be considered.

Abdominal pain is usually not present with malabsorption, although some cramping may be associated with diarrhea. Severe pain should bring chronic pancreatitis, Zollinger-Ellison syndrome, lymphoma, Crohn’s disease, or mesenteric ischemia to mind.

Constitutional symptoms of fatigue and weakness commonly occur, even early in the course. In contrast, appetite is impaired only late in the course of most malabsorption states. Edema is uncommon until late in the course unless protein-losing enteropathy is present.

Vitamin and mineral deficiencies can lead to several symptoms or signs. Glossitis and cheilosis are common in patients with water-soluble vitamin deficiencies. Florid beriberi, pellagra, and scurvy are not commonly seen unless malabsorption has been particularly severe or long-lasting. Fat-soluble vitamin deficiencies also are unlikely to develop except when malabsorption has been long-standing because of substantial body stores.

Miscellaneous findings occasionally seen in patients with malabsorption can provide clues to the diagnosis. Aphthous ulcers in the mouth may be seen with celiac disease, Behçet’s syndrome, or Crohn’s disease. Hyperpigmentation is seen in Whipple’s disease, and dermatitis herpetiformis (pruritic, blistering skin lesions) is seen in celiac disease. Scleroderma can manifest with tight skin, digital ulceration, nail changes, and Raynaud’s phenomenon. Chronic sinusitis, bronchitis, and recurrent pneumonia suggest cystic fibrosis or IgA deficiency. Several systemic diseases can be associated with malabsorption syndrome (Box 3).

**BOX 3** Systemic Diseases Associated with Malabsorption or Maldigestion**Endocrine Diseases**

- Addison's disease
- Diabetes mellitus
- Hypoparathyroidism
- Hyperthyroidism, hypothyroidism

**Collagen-Vascular and Miscellaneous Diseases**

- AIDS
- Amyloidosis
- Scleroderma
- Vasculitis (systemic lupus erythematosus, polyarteritis nodosa)

**Tests****Routine Laboratory Tests**

Routine laboratory tests (Box 4) commonly are abnormal in patients with established malabsorption syndrome. Anemia is common but not universal. Iron deficiency anemia may be the only finding in some patients with celiac disease. Microcytic anemia may be present in Whipple's disease (due to occult blood loss) and in lymphomas manifesting with malabsorption. Macrocytic anemia due to folate or vitamin B<sub>12</sub> deficiency can occur in short bowel syndrome, small bowel bacterial overgrowth, or ileal disease. Lymphopenia may be present in patients with AIDS or lymphangiectasia.

Electrolyte abnormalities may be due to a combination of poor intake and excess loss in stool. Renal function usually is well maintained in malabsorption syndrome, but blood urea nitrogen may be low due to poor protein absorption, and serum creatinine concentration may be low due to depletion of muscle mass. Serum calcium levels may be low due to malabsorption, vitamin D deficiency, or intraluminal complexing of calcium by fatty acids. Hypomagnesemia can produce hypocalcemia or hypokalemia that is resistant to intravenous repletion. Serum phosphorus, cholesterol, and triglyceride levels may be reduced due to poor intake or malabsorption. Liver tests may be abnormal due to fatty liver. Serum protein and albumin levels are well preserved in patients with malabsorption unless protein-losing enteropathy or an acute illness is present.

Prothrombin time is normal unless vitamin K malabsorption (typically associated with steatorrhea), anticoagulant therapy, antibiotic therapy, or colectomy is present.

Assays are available for several potentially malabsorbed substances, including iron, vitamin B<sub>12</sub>, folate, 25-hydroxyvitamin D, and β-carotene. Malabsorption tends to lower blood levels, but substantial body stores of many of these can mitigate the reduction in concentration that otherwise might occur. Thus, the sensitivity and specificity of these assays for malabsorption are poor.

**Tests for Malabsorption**

**Fat Malabsorption.** The simplest test for fat malabsorption is a qualitative microscopic examination of stool using a fat-soluble stain, such as Sudan III. The finding of more than five stained droplets per high-power field is abnormal and correlates well with quantitative measurement of fecal fat excretion. The test is subject to false-positive results with some drugs and food additives, such as mineral oil, orlistat, and olestra.

A more precise estimate of fat absorption is obtained by a quantitative analysis of a timed stool collection (48 or 72 hours). During the collection, a diary of dietary intake should be maintained so that fat excretion can be assessed as a percentage of intake. Normal fat excretion is <7% of intake when stool weight is normal, but it can be twice as high due to voluminous diarrhea without indicating defective mucosal transport of fat. Thus, fat excretion must be judged against stool weight. Stool fat concentration (grams of fat per 100 grams

**BOX 4** Laboratory Tests for Evaluation of Malabsorption or Maldigestion**Complete Blood Count**

- Hemoglobin/hematocrit
- Platelet count
- WBC differential count

**Biochemistry Tests**

- Blood urea nitrogen
- Prothrombin time
- Serum albumin
- Serum calcium
- Serum creatinine
- Serum Potassium

**Blood Levels of Potentially Malabsorbed Substances**

- Serum iron, vitamin B<sub>12</sub>, folate, 25-OH vitamin D, carotene

**Fat absorption**

- Qualitative fecal fat (Sudan stain)
- Quantitative fecal fat (Timed collection)

**Protein Absorption and Protein-Losing Enteropathy**

- α<sub>1</sub>-Antitrypsin clearance
- Fecal nitrogen excretion

**Carbohydrate Absorption**

- Osmotic gap in stool water
- Quantitative excretion (anthrone)
- Stool pH <5.5
- Stool reducing substances
- D-Xylose absorption test
- Oral glucose, sucrose, and lactose tolerance tests
- Breath hydrogen tests

**Vitamin B<sub>12</sub> Absorption**

- Serum B<sub>12</sub> level

**Bile Acid Malabsorption**

- Fecal bile acid excretion
- Serum 7α-hydroxy-4-cholesten-3-one (C4)
- <sup>75</sup>SeHCAT retention

**Small Bowel Bacterial Overgrowth**

- <sup>14</sup>C-xylose breath test
- Glucose breath hydrogen test
- Quantitative culture of jejunal aspirate

**Exocrine Pancreatic Insufficiency**

- Secretin/CCK test
- Stool elastase or chymotrypsin concentration

**Serologic Testing for Celiac Disease**

- Anti-tissue transglutaminase antibody (IgA)
- Anti-endomysial antibody (IgA)

*Abbreviations:* CCK = cholecystokinin; SLE = systemic lupus erythematosus; <sup>75</sup>SeHCAT = selenium-75-labeled taurochenocholic acid; WBC = white blood cell.

of stool) also is of value. Pancreatic exocrine insufficiency is associated with high fecal fat concentration (>10 g/100 g stool) because, unlike hydrolyzed fat, unhydrolyzed fat does not stimulate colonic water and electrolyte secretion that would dilute fecal fat concentration.

**Protein Malabsorption.** Fecal nitrogen excretion can be employed as a marker of protein malabsorption, but is not often used in clinical medicine because it adds little to the evaluation. If protein-losing enteropathy is suspected, an α<sub>1</sub>-antitrypsin clearance study can be done. In this study, fecal excretion of α<sub>1</sub>-antitrypsin, a serum protein that is relatively resistant to hydrolysis by luminal enzymes, is divided by serum concentration of α<sub>1</sub>-antitrypsin, and the volume of serum leaked into the lumen

can be calculated. Values of more than 180 mL/day are associated with hypoalbuminemia.

**Carbohydrate Malabsorption.** Carbohydrate malabsorption is difficult to measure directly because fermentation of malabsorbed carbohydrate by colonic bacteria reduces the amount of intact carbohydrate that can be recovered in stool. Indirect estimates of carbohydrate malabsorption can be made by examining fecal pH (<5.5 with carbohydrate malabsorption) or fecal osmotic gap (> 100 mOsm/kg with osmotic diarrhea) based on chemical analysis of stool water. Oral carbohydrate tolerance tests may be used to evaluate absorption of sugars, such as lactose or fructose. Following an oral load of a given sugar, blood glucose levels are monitored; failure of blood glucose to increase suggests malabsorption.

Another test for carbohydrate malabsorption is the D-xylose absorption test. In this test, a 25-gram dose of D-xylose is given orally; blood xylose levels are measured 1 and 3 hours later, and urinary excretion of xylose is measured for 5 hours. Failure of blood xylose to rise above 20mg/dL at 1 hour or above 22.5 mg/dL at 3 hours or failure of urinary excretion to exceed 5g in 5 hours suggests malabsorption. In addition, because xylose does not require pancreatic enzymes or bile acids for absorption, an abnormal D-xylose test suggests a mucosal problem as the cause for malabsorption. The results of this test can be misleading if the patient is dehydrated or has ascites, if renal function is compromised, or if bacterial overgrowth is present in the upper small bowel.

Breath hydrogen testing is another method to assess carbohydrate absorption. If substrates such as lactose or sucrose are not absorbed in the small intestine, they pass into the colon, where bacterial fermentation produces hydrogen gas. The hydrogen is absorbed into the bloodstream and then is exhaled. The concentration of hydrogen in exhaled breath can be measured easily; a rise of more than 10 to 20 ppm after ingestion of a specific substrate is consistent with malabsorption. False-positive results can be seen in patients with small bowel bacterial overgrowth, and false-negative results can be seen in patients who lack hydrogen-producing flora or who have been on antibiotics recently.

**Vitamin B<sub>12</sub> Malabsorption.** Although the Schilling test has been used to measure Vitamin B<sub>12</sub> absorption, commercial testing kits are no longer available in the United States. Instead, serum B<sub>12</sub> levels are measured: low levels are consistent with enough B<sub>12</sub> malabsorption, but normal levels do not exclude it because enough B<sub>12</sub> is stored in the liver to maintain serum levels for several years.

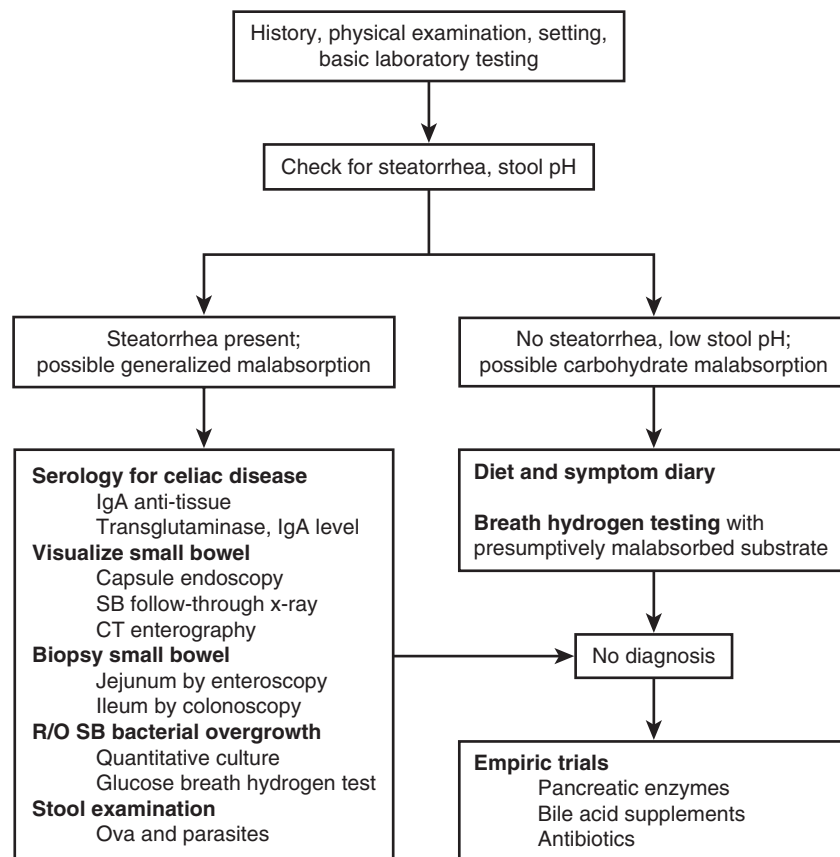

**Bile Acid Malabsorption.** Direct measurement of fecal bile acid excretion in a timed stool specimen can be used to evaluate bile acid malabsorption in the United States. Retention of a radioactive taurocholic acid analogue (SeHCAT, selenium-75-labeled tauroho-mocholic acid) is used in Europe to assess bile acid malabsorption. Serum 7 $\alpha$ -hydroxy-4-cholesten-3-one (C4) reflects bile acid synthesis; higher levels reflect increased synthesis in patients with bile acid malabsorption.

**Small Bowel Bacterial Overgrowth.** The gold standard method used to test for small bowel bacterial overgrowth in the upper intestine is quantitative culture of jejunal fluid. The sample can be obtained during endoscopy and sent to the laboratory with instructions to quantitate the aerobic and anaerobic flora. Finding more than 10<sup>5</sup> bacteria per mL confirms bacterial overgrowth. Breath tests using glucose, <sup>14</sup>C-xylose, and lactulose also have been described for this purpose.

**Pancreatic Exocrine Insufficiency.** Tests for pancreatic exocrine insufficiency are not commonly used. The gold standard test is a secretin test. This study requires duodenal intubation, injection of secretin, and measurement of bicarbonate output. Measurement of fecal chymotrypsin or elastase activity is only moderately useful in predicting the presence of exocrine pancreatic insufficiency. For most situations, a therapeutic trial using a high dose of pancreatic enzymes with monitoring of the effect on steatorrhea is the best that can be done.

### Evaluation of Suspected Malabsorption

When malabsorption is suspected because of the history, physical findings, and setting, the physician must decide if the malabsorption involves just carbohydrates or represents a generalized process (Figure 1). If the malabsorption seems to be limited to

**Figure 1** Flow chart for evaluation of malabsorption or maldigestion. *Abbreviations:* CT = computed tomography; R/O = rule out; SB = small bowel.

carbohydrates because stool pH is less than 6 and no steatorrhea is present, a diet and symptom diary, breath tests using the presumptively malabsorbed substrate, and stool pH to identify acid stools seen with carbohydrate malabsorption are reasonable diagnostic maneuvers.

Suspected generalized malabsorption requires a more intense evaluation. If steatorrhea is confirmed, serology for celiac disease (IgA anti-tissue transglutaminase, and IgA level to exclude IgA deficiency) should be obtained and the small bowel should be visualized with either capsule endoscopy or radiography (small bowel follow-through examination or computed tomography) and biopsied from above by enteroscopy and from below by colonoscopy. During enteroscopy, an aspirate of small bowel contents can be obtained for quantitative culture to look for small bowel bacterial overgrowth. An alternative method to detect small bowel bacterial overgrowth is breath testing (see earlier). Stool samples also should be examined with microscopy or immunoassay for the presence of parasites that may be associated with malabsorption.

This sequence of evaluation often leads to a specific diagnosis. When it does not, empiric trials of high-dose pancreatic enzyme replacement, low-dose bile acid supplementation, or antibiotics can lead to a presumptive diagnosis of pancreatic exocrine insufficiency, bile acid deficiency, or small intestinal bacterial overgrowth. Hard endpoints (e.g., reduction in quantitative fat excretion) should be used to assess the effectiveness of these empiric trials.

## Specific Disorders Associated With Malabsorption

### Malabsorption of Specific Nutrients

#### *Disaccharidase Deficiency*

Ingested disaccharides such as lactose and sucrose and starch-digestion products such as maltotriose and  $\alpha$ -limit dextrins must be hydrolyzed by brush border enzymes into monosaccharides for absorption by the mucosa. If these brush border enzymes are not active or if the brush border is damaged, malabsorption of the specific carbohydrate substrate results. This can result in gaseousness or osmotic diarrhea when those substrates are ingested. This rarely occurs on a congenital basis, but it commonly occurs as an acquired disorder.

Lactase deficiency is the most common acquired disaccharidase deficiency. Infant mammals all rely on lactose as the carbohydrate source in milk, but lactase activity is shut off after weaning in most species. Most human populations lose lactase activity during adolescence as a normal part of maturation. Members of the northern European gene pool typically maintain lactase activity into adult life, but lactase activity declines gradually in many. At some point the amount of lactose ingested might exceed the ability of the remaining enzyme to hydrolyze it, resulting in lactose malabsorption and symptoms. This also can occur with acute conditions such as gastroenteritis that can disturb the mucosa and temporarily reduce lactase activity. Patients might not recognize lactose ingestion as a cause of their problem because they have not had difficulty tolerating lactose in the past. Restriction of lactose in the diet (or use of products that have predigested lactose) mitigates symptoms. Use of exogenous lactase as a tablet may only be partially effective because of incomplete hydrolysis of ingested lactose.

#### *Transport Defects at the Brush Border*

Glucose-galactose malabsorption is a rare congenital disorder resulting from an inactive hexose transporter in the brush border. Hydrolysis of lactose is intact, but transport across the apical membrane of the enterocyte fails to occur. Fructose absorption, which is mediated by a different carrier, is unaffected.

In all human beings, the ability to absorb fructose is limited by the availability of carriers in the brush border and may be overwhelmed when excess fructose is ingested. This can occur relatively easily nowadays, because high-fructose corn syrup is used frequently as a sweetener in commercial products such as soda pop. Limiting the amount of fructose ingested will reduce symptoms.

Abetalipoproteinemia is a rare condition that prevents absorption of long-chain fatty acids due to failure to form chylomicrons.

Use of medium-chain triglycerides that do not require transport in chylomicrons can bypass this defect.

Pernicious anemia develops when failure to secrete intrinsic factor in the stomach prevents vitamin B<sub>12</sub> absorption by the ileal mucosa. Parenteral replacement with cyanocobalamin by injection (Cyanject) or nasal spray (Nascobal) is necessary.

## Generalized Malabsorption

### *Celiac Disease*

Celiac disease (also known as celiac sprue) is a disorder in which the mucosa of the small bowel is damaged due to activation of the mucosal immune system by ingestion of gluten, a protein component found in wheat, barley, and rye. People who have HLA-DQ2 or DQ8 are susceptible to this condition because these specific antigen-presenting proteins produce particularly strong reactions by interacting with a unique peptide digestion product of gluten. Tissue transglutaminase, an enzyme produced in the mucosa, is an important cofactor in pathogenesis by amplifying the immunogenicity of gluten peptide fragments and is the target of autoantibodies that are characteristic of this disease. The condition produces generalized malabsorption by destroying the villi of the small intestine, reducing the surface area available for absorption.

In addition to malabsorption syndrome with diarrhea and weight loss, celiac disease can produce a host of nonspecific symptoms, including abdominal pain, fatigue, muscle and joint pains, and headaches and seemingly unrelated problems such as iron deficiency anemia, abnormal liver tests, and osteoporosis. These protean manifestations mean that celiac disease must be considered in the differential diagnosis of many conditions. The clinical course is quite variable, with symptoms coming and going. Symptoms can develop during childhood and produce growth retardation or first become manifest in adulthood.

Testing for celiac disease has been simplified by the development of an assay for anti-tissue transglutaminase antibodies. This test largely supplants measurement of antiglutin antibodies, although these remain of some use in evaluating adherence to a gluten-free diet. IgA antibodies are the most useful for diagnosis, but IgA deficiency is common enough that an IgA level should be measured concomitantly.

Although serologic tests have high sensitivity and specificity, the implications of adhering to a gluten-free diet are so extreme that the diagnosis of celiac disease should be confirmed whenever possible by small bowel mucosal biopsy, now obtained routinely by endoscopy. An empiric trial of a gluten-free diet may be difficult to interpret because many persons with gastrointestinal symptoms improve with dietary carbohydrate restriction. Wheat starch is particularly hard to digest; ordinarily 20% of wheat starch is not digested and absorbed by the small bowel, and enters the colon.

Treatment of celiac disease at present involves strict lifetime exclusion of gluten from the diet. This is a difficult regimen that excludes most processed foods. Assistance of a dietitian is most helpful. The prognosis with effective treatment is very good. Symptoms should respond to the diet within weeks; failure to do so should prompt an examination of compliance with the diet or reconsideration of the diagnosis. Failure to respond may be seen when lymphoma or adenocarcinoma complicate the course of celiac disease or in cases of “refractory sprue” or “collagenous sprue,” which can have a different autoimmune basis from classic celiac disease and which might respond to immunosuppressive drugs such as corticosteroids or azathioprine (Imuran).<sup>1</sup> Persistent diarrhea may be observed in patients with celiac disease who have concomitant microscopic colitis, another condition that is linked to HLA-DQ2 and HLA-DQ8.

Olmesartan (Benicar) and perhaps other angiotensin II receptor blockers can produce enteropathies resembling celiac disease clinically, but which are not related to gluten ingestion. Diarrhea and malabsorption resolve with discontinuing the medication.

<sup>1</sup>Not FDA approved for this indication.

### Inflammatory Diseases

Diseases that produce extensive mucosal damage by inflammation cause generalized malabsorption by reduction of mucosal surface area, by promotion of small bowel bacterial overgrowth, by ileal dysfunction, or by development of enteroenteral or enterocolic fistulas. Examples include jejunoileitis due to Crohn's disease, nongranulomatous ulcerative jejunoileitis, radiation enteritis, and chronic mesenteric ischemia. With Crohn's disease, previous resection can add to the problem (see later). Therapy aimed at the underlying process can improve absorption; in some cases (e.g., radiation enteritis), no effective therapy is available for the underlying problem, and symptomatic management is all that is possible. This includes use of antidiarrheal drugs to prolong contact time between luminal contents and the small bowel mucosa, ingestion of a reduced-fat diet to reduce steatorrhea, and use of vitamin and mineral supplements to prevent deficiency states.

### Infiltrative Disorders

Several conditions involve infiltration of the intestinal mucosa with cells or extracellular matrix that impede absorption or modify mucosal function by secretion of cytokines and other regulatory substances. These include eosinophilic gastroenteritis, systemic mastocytosis, immunoproliferative small intestinal disease (IPSID), lymphoma, and amyloidosis. These conditions are diagnosed by mucosal biopsy, but special stains might have to be employed to identify the infiltrating cells or matrix accurately.

Treatment of the underlying processes can improve absorption, but it is not uniformly effective. For eosinophilic gastroenteritis, a hypoallergenic (elimination) diet and corticosteroids may be useful. Mild systemic mastocytosis is treated with the mast cell-stabilizer sodium chromoglycate, H<sub>1</sub>- and H<sub>2</sub>-receptor antagonists, and low-dose aspirin.<sup>1</sup> More advanced disease might respond to interferon or cytotoxic chemotherapy. IPSID initially is treated with antibiotics, because small bowel bacterial overgrowth may be a causative factor. Once malignant change has occurred, it is treated like lymphoma with cytotoxic chemotherapy. Amyloidosis affecting the gut is not amenable to therapy and is usually fatal.

### Infectious Diseases

**Small Bowel Bacterial Overgrowth.** Small bowel bacterial overgrowth in the jejunum can produce generalized malabsorption. It can occur whenever the mechanisms that reduce overgrowth are compromised. These situations include achlorhydria or hypochlorhydria, motility disorders of the small intestine (e.g., diabetes mellitus or scleroderma), and anatomic alterations (e.g., diverticulosis, gastrocolic fistula, or blind loops postoperatively). Fat malabsorption is attributed to bacterial deconjugation of bile acid. Bacterial toxins or free fatty acids can produce patchy mucosal damage, leading to less efficient carbohydrate and protein absorption. Bacteria also can compete with the mucosa for uptake of certain nutrients such as vitamin B<sub>12</sub>.

Diagnosis of small bowel bacterial overgrowth can be difficult (see earlier). Treatment consists of antibiotic therapy unless a surgically correctable anatomic defect is discovered. Tetracycline is no longer uniformly effective; amoxicillin-clavulanic acid (Augmentin), cephalosporins, ciprofloxacin (Cipro), metronidazole (Flagyl), and rifaximin (Xifaxan)<sup>1</sup> may be employed. Therapy should be given for 1 to 2 weeks initially and then discontinued. It should be restarted when symptoms recur. If this occurs quickly, longer treatment periods should be considered. Continuous antibiotic therapy is needed rarely.

**Tropical Sprue.** Tropical sprue is a progressive, chronic malabsorptive condition occurring in both the indigenous population and in visitors residing in certain tropical countries for extended periods. The prevalence of tropical sprue seems to be decreasing for uncertain reasons. The disease starts as an acute diarrheal disease that becomes a persistent diarrhea associated with substantial weight loss and typically megaloblastic anemia. Villi become

shortened and thickened (partial villous atrophy), but the flat mucosa of celiac disease is not usually present. Enterocytes have disrupted brush borders and can have megaloblastic changes; the submucosa has a chronic inflammatory infiltrate. Intestinal biopsy is required for diagnosis.

Currently, tropical sprue is believed to represent a form of bacterial overgrowth with organisms that secrete enterotoxins. Most patients have evidence of excessive gram-negative bacterial colonization of the jejunum. The declining prevalence of tropical sprue may be due to improved nutrition, better sanitation, or prompt treatment of acute diarrhea with antibiotics. Treatment consists of pharmacologic doses of folic acid (folate) (5 mg daily<sup>3</sup>), injection of cyanocobalamin (if deficient), and antibiotic therapy for 1 to 6 months. Tetracycline 250 mg four times a day or sulfonamide is the treatment of choice. Newer antibiotics have not been tested extensively in this condition. Improvement should be noted after a few weeks. The prognosis with treatment is excellent; without treatment, tropical sprue can be fatal. Recurrence can occur.

**Whipple's Disease.** Whipple's disease is a rare chronic bacterial infection with multisystem involvement. The small bowel typically is heavily infiltrated with foamy macrophages containing periodic acid-Schiff (PAS)-positive material, distorting the villi. Small bowel biopsy with special stains or electron microscopy or a specific polymerase chain reaction (PCR) is diagnostic. Foamy macrophages and bacteria can be found outside the intestine in lymph nodes, spleen, liver, central nervous system, heart, and synovium. Accordingly, symptoms are protean. The bacterium has been identified as *Tropheryma whipplei*, a relative of *Acinetobacter*. It does not appear to be very contagious, and no direct person-to-person transmission has been demonstrated. Presumably, differences in host resistance allow proliferation within macrophages without clearance of the bacteria.

Whipple's disease occurs mainly in older white men, but women and all ethnic groups are susceptible. Patients can present with malabsorption syndrome or with symptoms related to the extraintestinal disease (arthritis, fever, dementia, headache, or muscle weakness). Gross or occult gastrointestinal bleeding can occur. Protein-losing enteropathy may be present.

Treatment with any of several antibiotics (penicillin, erythromycin, ampicillin, tetracycline, chloramphenicol, or trimethoprim-sulfamethoxazole [TMP-SMX]) produces excellent symptomatic responses within days to weeks, but it should be continued for months to years. Even with protracted courses, relapses are common.

**Other Infections.** *Mycobacterium avium-intracellulare* is another chronic bacterial infection that can cause malabsorption, particularly in patients with AIDS. Mucosal biopsy with special stains to distinguish it from Whipple's disease is essential. Antibiotic therapy can reduce the intensity of infection; clearance depends on immunologic reconstitution with antiretroviral therapy. Clarithromycin (Biaxin) and ethambutol (Myambutol) are recommended as initial therapy.

Parasitic diseases can produce malabsorption by competing for nutrients and causing mechanical occlusion of the absorptive surface and epithelial damage. Protozoa that may be associated with malabsorption include *Giardia lamblia*, *Cystoisospora belli*, *Cryptosporidium*, and *Enterocytozoon bieneusi*. Tapeworms associated with malabsorption include *Taenia saginata* (beef tapeworm), *Hymenolepis nana* (dwarf tapeworm), and *Diphyllobothrium latum* (fish tapeworm).

*Giardia lamblia* is a cosmopolitan parasite acquired from contaminated water or from another person by fecal-oral transmission. Cysts are relatively hardy, and ingestion of as few as 10 cysts is sufficient to establish infection. Patients with dysgammaglobulinemia (especially IgA deficiency) are likely to become infected. Diagnosis depends on finding the organism (cysts or trophozoites) in stool by microscopy (sensitivity ~50% for a single specimen), or detection of giardia antigens by immunologic testing of stool

<sup>1</sup>Not FDA approved for this indication.

<sup>3</sup>Exceeds dosage recommended by the manufacturer.

(sensitivity >90%), multiplex PCR testing (sensitivity >95%), or discovery of the organism on small bowel biopsy.

Therapy consists of a single dose of tinidazole (Tindamax) (2 g), metronidazole (Flagyl)<sup>1</sup> (250 mg three times a day for a week), nitazoxanide (Alinia) (500 mg twice a day for three days), or quinacrine<sup>2</sup> (100 mg three times a day for a week).

*Cystoisospora* and *Cryptosporidium* spp. are coccidia, protozoa that disrupt the epithelium by intracellular invasion (*Cystoisospora*) or by attaching to the brush border, destroying microvilli (*Cryptosporidium*). Stool examination or small bowel biopsy can identify the organism. *Cryptosporidium* can be discovered by antigen immunoassay or multiplex PCR testing on stool with excellent sensitivity. *Cystoisospora* can be treated with trimethoprim/sulfamethoxazole (TMP-SMX)<sup>1</sup> or furazolidone.<sup>2</sup> *Cryptosporidium* can be treated by nitazoxanide.

Microsporidia are intracellular organisms now believed to be most closely related to fungi and are implicated in diarrhea and malabsorption in patients with AIDS and other immunodeficiency states. Small bowel biopsy can show partial villous atrophy, and electron microscopy displays characteristic changes. Stool examination occasionally is helpful. No treatment is of proven value.

Tapeworms compete with their hosts for nutrients in the lumen. *Diphyllobothrium latum* can produce vitamin B<sub>12</sub> deficiency. The others can result in more extensive nutritional deficiencies. Diagnosis is based on stool examination, and treatment depends on the particular organism identified.

### Luminal Problems Causing Malabsorption

**Pancreatic Exocrine Insufficiency.** Pancreatic exocrine insufficiency is the most common luminal problem that results in maldigestion. Patients develop symptoms of malabsorption when pancreatic enzyme secretion is reduced by >90%. There are several clinical features that distinguish pancreatic exocrine insufficiency from mucosal disorders, such as celiac disease. When fat is not digested, it is transported through the gastrointestinal tract as intact triglyceride, which can appear as oil in the stool. In contrast, if fat is digested but not absorbed, it is in the form of fatty acids that can produce secretory diarrhea in the colon, resulting in more voluminous, even watery stools. This has two important ramifications: fecal fat concentration is lower with mucosal disease (typically <9% by weight), and hypocalcemia due to formation of soaps (calcium plus 2 fatty acids) is seen with mucosal disease but not with pancreatic exocrine insufficiency. In addition, patients with mucosal disease tend to have more problems with water-soluble vitamin deficiencies than those with pancreatic exocrine insufficiency. In some patients with pancreatic exocrine insufficiency, carbohydrate malabsorption can produce substantial bloating, flatulence, and watery diarrhea.

Tests to document pancreatic exocrine insufficiency are not widely available or are nonspecific (see earlier), and so diagnosis usually hinges on a consistent history, demonstration of anatomic problems in the pancreas (calcification or abnormal ducts), and documentation of a response of steatorrhea to empiric treatment with a large dose of exogenous enzymes.

**Bile Acid Deficiency.** Bile acid deficiency is a less common cause of maldigestion, and malabsorption in this setting is limited to fat and fat-soluble vitamins. The usual setting is a patient with an extensive ileal resection (see later), but this also occurs in certain cholestatic conditions in which bile acid secretion by the liver is markedly compromised, such as advanced primary biliary cholangitis or complete extrahepatic biliary obstruction. As with pancreatic exocrine insufficiency, stools tend to have high fat concentrations (>9% by weight) when bile acid secretion is limited by hepatic or biliary disorders.

**Zollinger-Ellison Syndrome.** Zollinger-Ellison syndrome produces several abnormalities that can affect absorption. High rates of gastric acid secretion produce persistently low pH in the duodenum, which

precipitates bile acid and inactivates pancreatic enzymes. In addition, excess acid can damage the absorptive cells directly.

### Postoperative Malabsorption

Substantial malabsorption can result from bariatric or other gastric surgeries. Weight loss can result from inadequate intake due to early satiety or symptoms of dumping syndrome. Malabsorption can result from impaired mechanical disruption of food, mismatching of chyme delivery and enzyme secretion, rapid transit, or small bowel bacterial overgrowth due to loss of the gastric acid barrier. In addition, gastric surgery sometimes brings out latent celiac disease.

Short intestinal resections are well tolerated, but more extensive resections produce diarrhea and malabsorption of variable severity. When these symptoms are associated with weight loss or dehydrating diarrhea, short bowel syndrome is said to exist. In general, nutrient absorptive needs can be met if at least 100 cm of jejunum are preserved, but fluid absorption will be insufficient and diarrhea may be profuse. The process of intestinal adaptation permits improved absorption with time; it depends on exposure of the absorptive surface to nutrients. Absorption of specific substances, such as bile acids or vitamin B<sub>12</sub>, is reduced permanently by resection of the terminal ileum.

Malabsorption in short bowel syndrome is not due solely to loss of absorptive surface area. Gastric acid hypersecretion, bile acid deficiency, rapid transit (due to loss of the ileal brake), and bacterial overgrowth may be present. These conditions are amenable to treatment and therapy with antisecretory drugs, exogenous bile acids, opiate antidiarrheals, or antibiotics can produce substantial improvement. Injection of teduglutide (Gattex), a glucagon-like peptide-2 intestinal growth factor, or growth hormone in combination with glutamine and a special diet have been approved as treatments for short bowel syndrome; they can reduce the volume of parenteral fluid or nutrients required. Results with small bowel transplantation are improving with the use of better immunosuppressive regimens, and it remains the only cure for select patients with postresection malabsorption.

Attention to nutrition is vital in any patient with malabsorption. If adequate nutrition cannot be maintained by oral intake, nutritional therapy is needed. Because of impaired bowel function, success with enteral nutrition may be impossible; parenteral nutrition may be needed. It is important to distinguish between the need for supplemental fluid and electrolytes and the need for nutrients; total parenteral nutrition is not a good choice for patients who only require fluids and electrolytes.

## NONALCOHOLIC FATTY LIVER DISEASE

Method of

Vladimer Bakhutashvili, MD; and Adnan Said, MD, MS

### CURRENT DIAGNOSIS

- Suspected in patients with steatosis noted on imaging or elevated liver enzymes (alanine aminotransferase, aspartate aminotransferase,  $\gamma$ -glutamyl transferase)
- Diagnosis of exclusion
  - Exclude alcohol excess by history (>21 drinks/week for men and 14 units/week for women)
  - Hepatitis C virus antibody, hepatitis B surface antigen
  - Review medications that can cause steatosis (methotrexate [Trexall], tamoxifen [Nolvadex], diltiazem [Cardizem], amiodarone [Pacerone], steroids)
  - Check serum ferritin, iron saturation (hemochromatosis)
  - Check serum ceruloplasmin and unbound copper (Wilson disease)
  - Check autoantibodies (ANA, antismooth muscle antibody) (autoimmune hepatitis)
- Liver biopsy gold standard.
  - Not essential for diagnosis
  - Useful for diagnosis of nonalcoholic steatohepatitis (NASH) and fibrosis
  - Useful in excluding other conditions (if above tests raise suspicion)
- Noninvasive serum tests (more useful for diagnosis or exclusion of advanced fibrosis and potentially in decision of whom to biopsy)
  - Nonalcoholic fatty liver disease fibrosis score
  - FIB-4 index
- Noninvasive imaging tests for diagnosis of steatosis
  - Transient elastography with controlled attenuation parameter score
  - Right upper quadrant ultrasound
  - Magnetic resonance imaging of liver with proton density fat fraction
- Noninvasive imaging tests for diagnosis of fibrosis
  - Transient elastography with FibroScan
  - Magnetic resonance elastography

### CURRENT THERAPY

#### Lifestyle Modifications Mainstay of Therapeutic Plan

- Goal is to lose 7% to 10% of body weight gradually
- Lose no more than 1 to 2 lbs/week

#### Dietary Modification

- Reduce calories by 30% (500 to 1000 kcal/day)
- Reduce sugars, carbohydrates, fructose-enriched foods, and sugar sweetened beverages
- Reduce consumption of processed foods and saturated fat
- Coffee consumption (>2 cups/day, avoid adding sugar, syrups) has been shown to be beneficial

#### Exercise

- 150 to 200 minutes per week divided over 3 to 5 days
- Moderate to vigorous intensity (swimming, biking, jogging, playing tennis, weights)
- Pioglitazone (Actos)<sup>1</sup> can be used for diabetic or nondiabetic NASH but causes weight gain and does not treat fibrosis.
- Vitamin E (800 IU/day)<sup>7</sup> can be used for nondiabetic NASH
- Bariatric surgery can be considered if indicated for morbid obesity, complications of metabolic syndrome

<sup>1</sup>Not FDA approved for this indication.

<sup>7</sup>Available as a dietary supplement.

## Nonalcoholic fatty liver disease

Nonalcoholic fatty liver disease (NAFLD) is defined as the presence of hepatic steatosis (hepatic fat accumulation), on imaging or liver biopsy, in the absence of secondary causes for the fat accumulation (such as excessive alcohol consumption, hepatitis C, certain medications). NAFLD is closely associated with metabolic comorbidities, including obesity, diabetes, dyslipidemia, and hypertension, and is the most common cause of chronic liver disease worldwide.

NAFLD comprises a spectrum of disease spanning from isolated steatosis (sometimes called *nonalcoholic fatty liver* or NAFL) to more advanced liver disease such as nonalcoholic steatohepatitis (NASH) (Figure 1). NASH signifies steatosis with inflammation and hepatocyte injury and has a higher likelihood of progress to cirrhosis, liver failure, and occasionally liver cancer. Besides liver disease, NAFLD is also closely associated with cardiovascular disease (CVD) and malignancy.

### Epidemiology of NAFLD

The global prevalence of NAFLD is estimated at 25% according to a recent systematic review, with the highest prevalence reported in South America (31%) and the Middle East (32%) followed by Asia (27%), the United States (24%), Europe (23%), and Africa (14%). The largest datasets for these prevalence studies come from North America, Asia, and Europe, with lower numbers from the Middle East, Africa, and South America.

In the United States, the prevalence of NAFLD is highest in Hispanic Americans (22% to 45%), followed by non-Hispanic whites (15% to 33%) and blacks (13% to 24%). A significant contribution to this ethnic difference can be explained by genetic differences, particularly a single nucleotide polymorphism (SNP) in a gene (PNPLA3) that is involved in triglyceride (lipid) hydrolysis in the liver, and the ethnic prevalence that mirrors the ethnic differences in the frequency of NAFLD.

NAFLD prevalence increases with age, with a range from 22% to 30% from age 30 to a peak in the sixth decade. Very few studies report on NAFLD prevalence after age 70. Pediatric NAFLD is on the rise paralleling childhood obesity trends, but population data are scant, with estimated population prevalence of 7% to 8% in the United States. An autopsy study of 742 children (ages 2 to 19) who died of unnatural causes used liver histology as the gold standard and demonstrated a NAFLD prevalence of 9.6% adjusted for age, sex, race, and ethnicity. Pediatric obesity clinic studies have shown NAFLD prevalence of 34.2% in a meta-analysis. Differences in sex prevalence also exist, with some studies reporting the prevalence of NAFLD in men as almost double that of women.

Although the prevalence of alcohol and infectious hepatitis has remained stable, the prevalence of NAFLD has been rising in the global and US adult and pediatric population, growing in parallel with the epidemic of obesity and metabolic syndrome. From 2000 to 2015, the worldwide prevalence of NAFLD progressively increased from 20% to 27%. A recent study using data from the U.S. National Health and Nutrition Examination Survey found that NAFLD prevalence doubled between the survey periods of 1988–1994 and 2005–2008 from 5.5% to 11%.

In higher-risk populations such as patients with diabetes, the prevalence of NAFLD is higher, varying from 33% to 70%. In patients with morbid obesity attending bariatric surgery clinics, the prevalence of NAFLD has been reported at 95%.

### Risk Factors for NAFLD

NAFLD is a complex disease that has genetic predispositions and is affected by various environmental factors. The degree of contribution of each of the risk factors requires further study and may vary depending on the region of the world.

NAFLD is regarded as the hepatic manifestation of the metabolic syndrome (presence of at least three of the following: abdominal obesity, hypertriglyceridemia, low high-density lipoprotein levels, hypertension, and high fasting glucose levels). Obesity (defined as waist circumference >102 cm in men or >88 cm in women or

**Figure 1** Histology of NAFLD. (A) Hepatic steatosis. Arrow points to macro-vesicular steatosis in Hepatocytes. (B) NASH. Arrow points to ballooned hepatocytes. Arrowhead points to lobular inflammation. (C) NASH with cirrhosis. Arrow points to fibrosis bands (collagen) trichrome stain.

simplified to body mass index (BMI)  $\geq 30$ ) and diabetes are two of the primary associated risk factors for NAFLD. Underpinning the rising prevalence of these associated conditions and NAFLD are societal and individual trends in unhealthy eating habits (proliferation of high-caloric processed foods and diets with a high content of sugar, corn syrup, and fat) and decreased physical activity levels. The industrialization of food production, as well as deficiencies in neighborhood planning with poor walkability and public transport system availability, are partly to blame for this epidemic. Being overweight in childhood and adolescence, especially weight gain during school years, is a significant risk factor for development of NAFLD by late childhood and adulthood.

Several genetic risk factors have been reported, with non-synonymous SNPs in two genes in particular, PNPLA3 (patatin-like phospholipase domain-containing protein 3) and TM6SF2 (transmembrane 6 superfamily member 2), being the most consistently validated. The prevalence of the PNPLA3 SNP is highest in the Hispanic population and leads to the higher prevalence of NAFLD in this population. I148M PNPLA3 genetic mutation has consistently been shown to be the most common genetic determinant of NAFLD and correlates with hepatic steatosis, as well as severity of liver disease and risk of cirrhosis and liver cancer in NAFLD.

Heavy alcohol intake and obesity have been shown to act synergistically in increasing the risk of liver disease. The effect of more moderate alcohol consumption on NAFLD is unclear currently and will require more study of cumulative lifetime alcohol consumption. There are population data suggesting that low levels of alcohol use (1 or fewer drinks per day), wine in particular, may be associated with lower risk for development of NAFLD compared with those who drink more or do not drink at all. NASH, which has a higher chance of progression to fibrosis and cirrhosis, is independently associated with diabetes, age, BMI, as well as genetic polymorphisms in PNPLA3.

### Pathophysiology of NAFLD

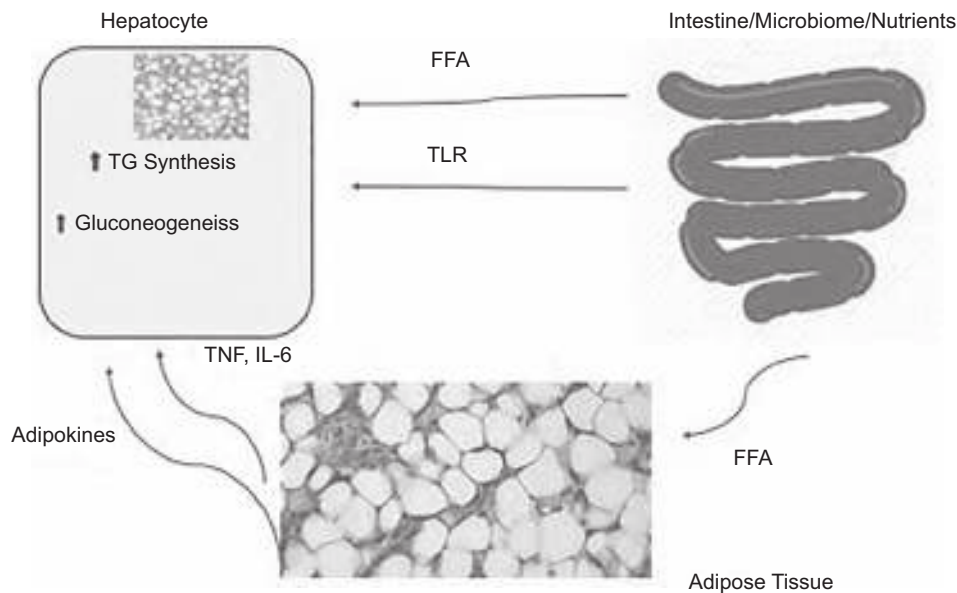

The hallmark finding of NAFLD is accumulation of triglyceride in the cytoplasm of hepatocytes. This is caused by an imbalance between lipid buildup (fatty acid uptake and de novo lipogenesis) and removal (mitochondrial fatty acid oxidation and export as a part of very low-density lipoprotein particles). Further factors contributing to transition from a healthy liver to NAFLD include adipose tissue dysfunction, hepatic insulin resistance, dysbiosis of the gut microbiome, toxic metabolites, and genetic factors (Figure 2).

Along with storage of triglycerides, adipose tissue is involved in the secretion of hormones, cytokines, and chemokines, called *adipokines*. Overnutrition and sedentary lifestyle cause obesity and adipose tissue dysfunction, which likely plays a pivotal role in the development of insulin resistance and NAFLD. Obesity results in excess free fatty acids entering the liver through the portal circulation, which can increase lipid synthesis and gluconeogenesis. Increased levels of circulating free fatty acids also lead to peripheral insulin resistance, along with inflammation and induction of cytokine production, thereby contributing to NAFLD. In NASH, liver cell injury occurs (ballooning hepatocytes, inflammation) along with steatosis and varying degree of fibrosis.

### Clinical Manifestations of NAFLD

NAFLD patients are typically symptom free until the condition progresses to cirrhosis. Early in the course of disease, it is often found incidentally on abdominal imaging including ultrasound, computed tomography (CT) or magnetic resonance imaging (MRI) (hepatic steatosis). Hepatomegaly may be the presenting symptom in some patients. Vague right upper abdominal discomfort, malaise, or fatigue can occur in patients with NASH but is very nonspecific.

The other common presentation of NAFLD is with elevation of liver enzymes, with mild to moderate elevations in aspartate aminotransferase (AST) and alanine aminotransferase (ALT).

**Figure 2** Pathophysiology of NAFLD. An interaction between intestine, adipose tissue and hepatocytes. *Abbreviations:* FFA = free fatty acids; TNF = tumor necrosis factor; IL = interleukin; TLR = toll-like receptor.

However, even advanced NAFLD can present with normal liver enzyme levels in up to 30% of individuals.

Patients with NAFLD frequently have comorbidities including hyperlipidemia, obesity, metabolic syndrome, hypertension, and type 2 diabetes mellitus. Associated conditions also include hypothyroidism, obstructive sleep apnea, and, less commonly, hypopituitarism, hypogonadism, polycystic ovarian syndrome, pancreaticoduodenal resection, and psoriasis among others.

In a community study of more than 7 years of follow-up from Minnesota, patients with NAFLD were shown to have excessive risk of mortality compared to population-based age- and sex-matched control subjects (SMR 1.34, 1.003-1.76). Given the commonality of risk factors for NAFLD and CVD, cardiac disease is the leading cause of death in these patients. A meta-analysis of observational studies also confirmed that the increased risk of CVD is NAFLD (odds ratio [OR] 1.64, 1.26–2.13) and in NASH as well (OR 2.58, 1.78–3.75). Obesity, diabetes, and metabolic syndrome are also risk factors for carcinogenesis, and a multitude of cancers are increased in patients with NAFLD, including liver cancer, breast cancer, kidney cancer, and colon cancer, among others. Liver disease mortality from cirrhosis and liver cancer is the third most common risk of death in these patients.

NAFLD is an increasingly common reason for decompensated cirrhosis and liver cancer. Over their lifetime 5% to 10% of patients with NAFLD progress to cirrhosis. Isolated hepatic steatosis without evidence of hepatocellular injury carries a minimal risk of progression to cirrhosis (<2%). NASH has a higher likelihood of progress to cirrhosis (5% to 12%), liver failure, and occasionally liver cancer. Patients who are older and have type 2 diabetes are at higher risk for progressing to NASH and fibrosis, and in these patients liver disease mortality predominates the clinical picture. Complications of cirrhosis, including variceal hemorrhage, ascites, hepatic encephalopathy and liver failure, can occur.

NAFLD is the second-most common cause of liver transplantation in the United States after chronic hepatitis C and is on track to becoming the most common indication by 2020. In the US general population NAFLD is already the most common reason for developing liver cancer, and the risk of developing liver cancer in patients with NAFLD related cirrhosis is 1% to 2% per year. Hepatocellular cancer (HCC) in NASH, as in most other chronic liver diseases, occurs predominantly in the setting of cirrhosis. Age, obesity, diabetes, and PNPLA3 I148M SNP are risk factors for HCC in these patients. NAFLD associated HCC is the third-most common cause of HCC in the United States, and the

incidence of NAFLD-associated HCC is increasing the fastest by a 9% annual incidence rate compared with other causes of HCC.

### Diagnosis of NAFLD (Figure 3)

The diagnosis of NAFLD is made by confirming the presence of hepatic steatosis on either imaging or liver biopsy, in the absence of alternative explanations for the steatosis. Diagnosing NAFLD based on elevated liver enzymes alone (without imaging or biopsy) is not recommended. Not \*\*\* are elevation of liver enzymes non-specific, but they are also frequently normal in patients with NAFLD including in those with advanced liver disease.

Alternate causes of steatosis that must be excluded before diagnosing NAFLD include the following:

- Alcohol excess (typically defined as greater than 21 standard drinks of alcohol per week in men and greater than 14 drinks per week in women)
- Hepatitis C infection
- Medications that cause steatosis (amiodarone [Pacerone], tamoxifen [Nolvadex], methotrexate [Trexall], diltiazem [Cardizem], prednisone)
- Hemochromatosis
- Wilson disease

These conditions are easily screened for by history and serologic studies (hepatitis C virus antibody, ferritin and iron saturation, serum ceruloplasmin and copper, and serum autoantibodies).

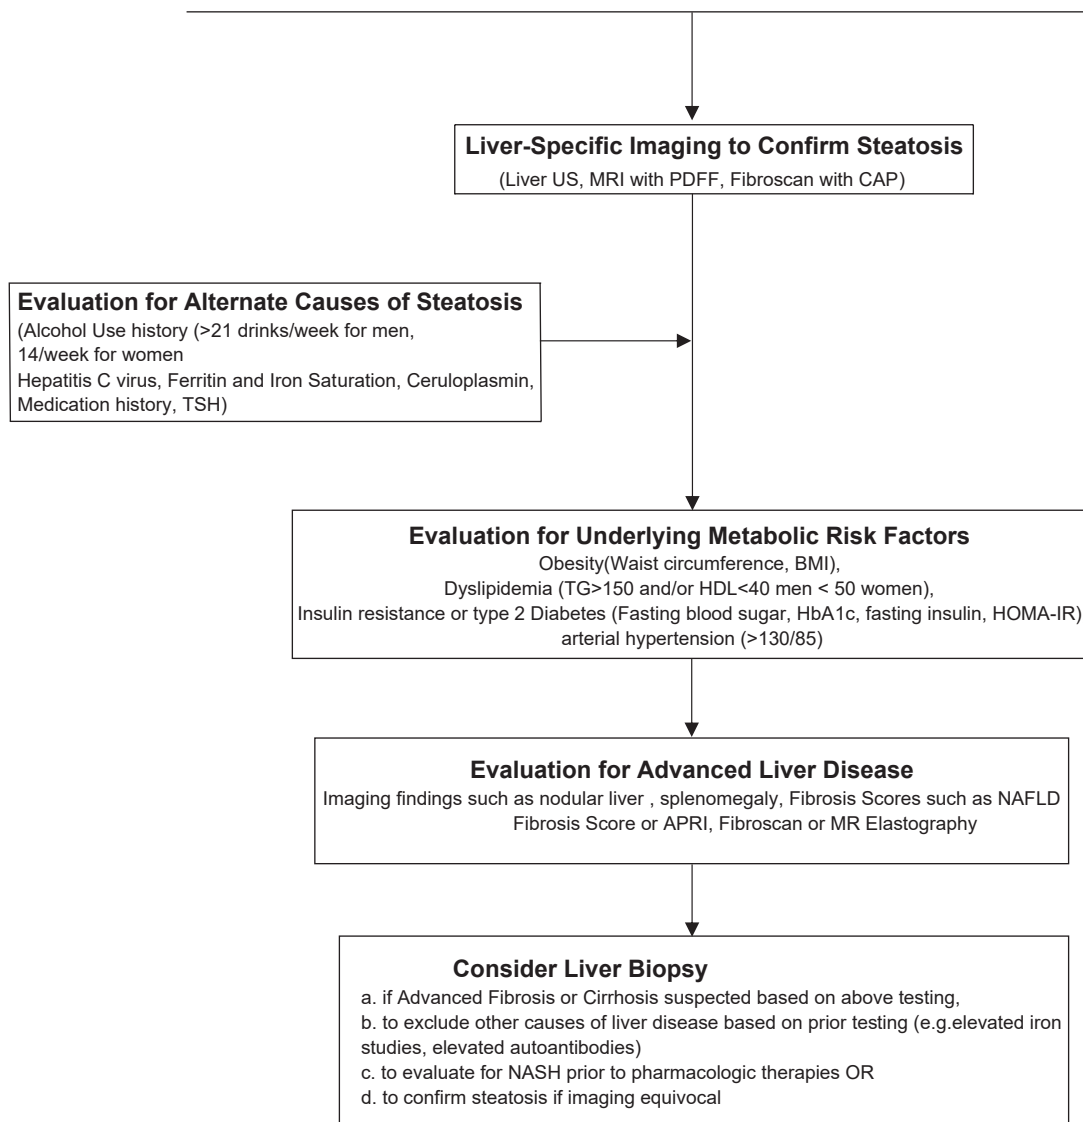

During serologic workup in patients with suspected NAFLD, it is common to find elevated ferritin, and this is due to NAFLD itself in the majority of cases. In patients with significantly elevated ferritin and transferrin saturation, serum testing for mutations in the hemochromatosis gene (HFE) should be performed, and if there are heterozygous or homozygous mutations in this gene, then a liver biopsy should be performed for iron quantification. It is also common to find autoantibodies in NAFLD that are often elevated in autoimmune hepatitis (ANA > 1:160, Antismooth muscle antibody > 1:40). These are often epiphenomena, but if the level of liver enzymes is significantly elevated (> 5 fold above normal), then a liver biopsy can be done to exclude autoimmune hepatitis.

NAFLD is usually diagnosed in one of two common scenarios: Patients with unsuspected hepatic steatosis detected on imaging done for other indications (Ultrasound or CT) or

Patients with unexplained abnormal liver chemistries (liver enzymes). These patients should be assessed for associated metabolic risk factors (obesity, diabetes mellitus, or dyslipidemia).

Routine Screening for NAFLD in high-risk groups attending primary care, diabetes, or obesity clinics is not advised at this

## Evaluation of elevated liver enzymes or Incidental Steatosis on imaging (US, CT, MRI)

**Figure 3** Diagnostic evaluation for suspected NAFLD. *Abbreviations:* US = ultrasound; PDFF = proton density fat fraction; CAP = controlled attenuation parameter; TG = triglyceride; HDL = high-density lipoprotein; HOMA-IR = homeostatic model assessment- insulin resistance; APRI = AST to platelet ratio index.

time, but there should be a high index of suspicion for NAFLD and NASH in patients with type 2 diabetes. This is primarily due to gaps in our knowledge regarding the natural history of NAFLD and treatment outcomes in NAFLD discovered by screening.

It is essential to emphasize that a diagnosis of NAFLD includes the determination of whether progressive liver disease, NASH, and fibrosis, are present to tailor treatment and monitoring. The state of comorbidities including dyslipidemia, obesity, insulin resistance, diabetes, hypothyroidism, polycystic ovary syndrome, and sleep apnea is important to evaluate at the initial evaluation to recommend specific treatment for these associated disorders.

### Role of Liver Biopsy in NAFLD

Currently, the gold standard for establishing a diagnosis of NAFLD and staging fibrosis is liver biopsy. In NAFLD liver histology typically shows steatosis graded as mild (<33% of hepatocytes involved), moderate 33% to 66% or severe (>66% steatosis). Other findings seen in NASH include lobular inflammation and hepatocyte ballooning indicative of hepatocyte injury, as well as varying degrees of fibrosis from none (stage 0) to cirrhosis (stage 4).

Although liver biopsy is not essential for diagnosing hepatic steatosis, liver biopsy should be considered in patients with NAFLD who are

At increased risk of having steatohepatitis (NASH) or advanced fibrosis because no serum or radiologic marker thus far can reliably differentiate NASH from isolated steatosis. Thus patients who are older (>50), have long-standing metabolic syndrome, or have noninvasive scores that indicate advanced fibrosis (NAFLD or FIB-4 scores, or elevated liver stiffness measured by imaging techniques such as vibration-controlled transient elastography or MRE) may fall into this category.

Liver biopsy should also be considered when presence or severity of coexisting chronic liver diseases cannot be excluded without a liver biopsy. This may include patients with serum antibodies in whom coexistent autoimmune hepatitis cannot be excluded or patients with significantly elevated ferritin and iron saturation.

Despite the useful information obtained in some patients with NAFLD, liver biopsy has several limitations, including sampling error and intraobserver and interobserver variability in interpretation. It is costly and invasive and also carries risks including a mortality risk of up to 0.1% after the procedure, pain,

intra-peritoneal bleeding, bile leaks, and infection. As a result, it is not practical for screening millions of at-risk individuals or for frequent repeated assessments. Noninvasive approaches to diagnosis of NAFLD are thus widely used and include imaging of the liver, liver stiffness testing, and biological marker testing.

## Noninvasive Testing in NAFLD

### Hepatic Steatosis

Abnormal hepatic steatosis is defined by a liver fat content of  $\geq 5\%$ . The most accurate noninvasive method to quantify liver fat content is magnetic resonance spectroscopy. However, this modality requires special expertise, is time consuming to perform, and is not readily available clinically. A good alternative is MRI that uses proton density fat fraction (MRI-PDFF), which provides an accurate estimate of liver fat content, as well as spatial imaging of the liver. Conventional ultrasonography remains the most commonly used imaging modality to diagnose hepatic steatosis. It is wide availability and lower in cost than MRI, but it has limited accuracy, especially in obese individuals. It is not sensitive in detecting mild steatosis ( $<33\%$ ) and is also less specific than MRI with fibrosis and iron, also resulting in similar findings.

Transient elastography-based techniques are increasingly used to diagnose steatosis and estimate the degree of hepatic fibrosis. Fat and fibrosis affects shear wave propagation through tissue, and this property can be used to measure liver attenuation (steatosis) and velocity (fibrosis) using a FibroScan machine. This machine uses an ultrasonic probe placed over the skin in the right upper quadrant to produce shear waves of 50MHz that pass through the liver. Measurements of shear wave attenuation called *controlled attenuation parameter* assess for presence and grade of hepatic steatosis. Controlled attenuation parameter has been shown to be less accurate than MRI-PDFF in diagnosing steatosis, but it is cheaper and is a point-of-care quantitative modality.

Currently there are many widely available serum-based diagnostic panels for NAFLD that use a mix of serum tests and other demographic, anthropometric measures that are combined in single measurements for diagnosis of NAFLD. Examples include fatty liver index (triglycerides, BMI,  $\gamma$ -glutamyl transferase, waist circumference) and NAFLD Liver Fat Score (metabolic syndrome, type 2 diabetes mellitus, fasting insulin, alanine aminotransferase, aspartate aminotransferase). These panels have been found to have sensitivities and specificities in the 70% range and show reasonable accuracy for predicting steatosis. These tests are not as accurate as imaging or biopsy tests and therefore are less often used clinically and more often used as research tools in epidemiologic research.

### Assessing Fibrosis

Fibrosis is highly correlated with outcomes in liver disease and a marker of worse outcomes. Fibrosis histologically is categorized (staged) as follows on liver biopsy:

- F0: no fibrosis
- F1: portal fibrosis without septa
- F2: portal fibrosis with few septa, extending outside of portal areas
- F3: bridging fibrosis or numerous septa without cirrhosis
- F4: cirrhosis

F3 and F4 are categorized as advanced fibrosis and F0-F1 are considered none-minimal fibrosis.

Clinical decision aids such as *NAFLD fibrosis score* (<https://www.mdcalc.com/nafl-d-non-alcoholic-fatty-liver-disease-fibrosis-score>) (biomarkers evaluated: age, glucose level, BMI, platelet count, albumin, and AST/ALT ratio) or *fibrosis-4 index* (<https://www.mdcalc.com/fibrosis-4-fib-4-index-liver-fibrosis>) (FIB-4 biomarkers measured include age, AST, platelet count, ALT) use a combination of serum and clinical variables to predict the presence of advanced fibrosis or cirrhosis. These tests are most useful in distinguishing patients who may have advanced fibrosis from those without fibrosis and thus may aid in clinical decision making including whether to perform a liver biopsy or make a referral to a liver specialist (in patients with test indicating advanced fibrosis).

Imaging-based techniques such as vibration-controlled transient elastography (FibroScan) or MRI-based elastography can be used to identify those at low or high risk for advanced fibrosis (bridging fibrosis or cirrhosis) with more accuracy than serum-based markers. The drawbacks to these methods include cost and availability (MRE) and limited utility in obesity, ascites, and acute inflammation (FibroScan). However FibroScan is increasingly available and widely used at point of care in liver clinics for fibrosis assessment.

### Therapy of NAFLD (Table 1)

Treatment of NAFLD entails treatment of the liver disease, as well as of the associated metabolic syndrome (obesity, diabetes, hyperlipidemia and hypertension).

### Lifestyle Modifications in NAFLD

Lifestyle modifications are integral in the treatment of NAFLD at any stage and are the principal intervention for patients with isolated steatosis and NASH without fibrosis. Patients are advised to lose  $\geq 7\%$  of body weight if overweight or obese (3–5% weight loss will improve steatosis, 7–10% is needed to improve histopathologic features of NASH and fibrosis).

This weight loss is best achieved gradually (losing no more than 1 to 2 lbs per week) and sustained through a combination of diet and exercise.

Basic principles of diet include reducing calories (by at least 30% or by 750–1000 kcal/day for an average US adult) and reducing consumption of simple carbohydrates and saturated fat. Reduction of sugar-sweetened beverages and of fructose-enriched food and drinks is recommended. In general, using fresh fruits and vegetable and lean meats and minimizing processed foods is recommended. Although many different diets have been studied and shown to be beneficial (Mediterranean diet), studies have also shown that any diet that follows the basic principle noted above and results in weight loss achieves the benefits of reversing NASH.

Significant alcohol use can exacerbate steatohepatitis, and limiting consumption of alcohol ( $\leq 1$  drink/day for women and  $\leq 2$  drinks/day for men) is recommended.

A preponderance of epidemiologic data also shows that consumption of coffee (2 or more cups) per day is associated with reduced prevalence of NAFLD. If coffee is consumed, it should be caffeinated; addition of sweetened syrups, sugar, and large servings of milk/other calories may negate any beneficial effects.

Recommendations for physical activity include at least 150 to 200 minutes of moderate- to vigorous-intensity physical activity per week (examples are moderate jogging, weight training, sports such as tennis, swimming, or biking). For patients who do not exercise, a gradual buildup to this level is recommended. Limited data suggest that the combination of diet and exercise may be more beneficial than either in isolation.

### Pharmacotherapeutics in NAFLD

Currently there are no pharmacologic agents that have an FDA indication specifically for NAFLD or NASH. There are, however, pharmacologic treatments aimed at different components of metabolic syndrome that can be used off label for NAFLD-related liver disease based on controlled trials studies and published guidelines. These agents, when used for NAFLD, should generally be limited to those with biopsy-proven NASH and fibrosis.

Pioglitazone (Actos)<sup>1</sup> is an insulin-sensitizing agent used in diabetes (PPAR Gamma agonist) and can be used to treat patients with and without type 2 diabetes with biopsy-proven NASH. It has been shown to improve histologic changes in NASH, including steatosis, ballooning, and inflammation but not fibrosis. For nondiabetic adults with biopsy-proven NASH, vitamin E<sup>7</sup> administered at a daily dose of 800 IU/day can be used as well and can cause similar histologic improvements as pioglitazone.

<sup>1</sup>Not FDA approved for this indication.

<sup>7</sup>Available as a dietary supplement.

**TABLE 1** Therapy of NAFLD

Assessment of steatosis versus more advanced liver disease (NASH, fibrosis)  
Consider pharmacotherapy or investigational agents for more advanced liver disease in addition to lifestyle modifications

Lifestyle modifications aimed at weight loss

#### Goals

Lose 7% to 10% of body weight

Gradual weight loss, no more than 2 lbs per week till at goal

#### Diet changes

Reduce calories by 30% (750–1000 kcal/day), reduce simple sugars, decrease saturated fat, reduce sugar sweetened beverages and foods including fructose enriched foods

#### Exercise

150–200 minutes per week spaced over 5 days; moderate to vigorous intensity (e.g., jogging, playing tennis, swimming laps, biking)

Treatment of associated metabolic factors as per best practices

#### Diabetes

No particular agent proven beneficial as primary treatment for NAFLD although pioglitazone (Actos)<sup>1</sup> may benefit histologic NASH. Causes weight gain

Metformin (Glucophage)<sup>1</sup> no proven benefit for NASH

Insulin can cause weight gain and insulin resistance associated with NASH

#### Dyslipidemia

Treat per standard guidelines

Statins are safe to use if indicated (except in decompensated cirrhosis)

Pharmacotherapy for NASH

#### Pioglitazone<sup>1</sup>

Histologic benefits in diabetic and non-diabetic NASH except for fibrosis

Can cause weight gain

#### Vitamin E<sup>7</sup>

Histologic benefits in non-diabetic NASH except for fibrosis

Concerns for long term use: small risk in all-cause mortality, increase risk of prostate cancer

Investigational trials (generally for biopsy proven NASH)

<sup>1</sup>Not FDA approved for this indication.

<sup>7</sup>Available as dietary supplement.

There are numerous pharmacologic agents in phase 1 and phase 2 trials and a few in phase 3 trials for NAFLD. Some of these agents work on glucose or lipid metabolism in the liver, whereas others are antifibrotic or antioxidant. Obeticholic acid (Ocaliva)<sup>1</sup> and elafibranor<sup>5</sup> are two compounds that show promise and are undergoing phase 3 registration trials. More safety and efficacy data are needed before they can be recommended.

Foregut bariatric surgery can be considered in otherwise eligible obese individuals with NAFLD or NASH, although it is not an established option to treat NASH specifically. Case series have shown improvement in histologic markers of NASH in patients after bariatric surgery.

### Prevention of NAFLD

Prevention of NAFLD is imperative and is a societal challenge that should focus on reducing obesity and the metabolic syndrome. Early education and focus on healthy nutrition and childhood physical activity are key initiatives, as are neighborhood planning for improving access to healthy foods and healthy spaces.

### Monitoring of NAFLD

Patients with NASH, especially those with significant fibrosis, are at the greatest risk for increased progression to cirrhosis and mortality. Patients with NASH and F0 or F1 fibrosis are monitored annually for liver disease progression via blood work (liver enzymes and function tests, platelet counts) and physical examinations. Evaluation of fibrosis progression in these patients through repeat liver biopsy or noninvasive testing such as FibroScan or MR elastography can be done approximately 5 years after diagnosis; however, with high interindividual variation in fibrosis progression, the timeline of testing is tailored to each individual.

For patients with more advanced fibrosis (F2 or higher) at NASH diagnosis, severity of the fibrosis governs the management. Once F3 or F4 fibrosis occurs, the risk of liver-related illness and death increases significantly, making closer follow-up appropriate.

Patients with NASH cirrhosis should be screened for gastroesophageal varices (upper endoscopy) and considered for hepatocellular carcinoma screening (guidelines from the American Association for the Study of Liver Diseases recommend ultrasound of the liver and serum alpha-fetoprotein measurements every 6 months).

<sup>5</sup>Investigational drug in the United States.

It must be noted that trials of these agents in NASH were generally limited to 24 months or less, and longer-term benefits are not known. Consideration to side effects must also be given; pioglitazone can cause weight gain, has been associated with osteoporosis, and has been known to exacerbate heart failure in susceptible individuals. Vitamin E has some concerns regarding increased all-cause mortality, potentially small increased risk of hemorrhagic stroke, and, in a large trial, increased risk of prostate cancer.

Patients with NAFLD are at high risk for cardiovascular morbidity and mortality, and aggressive modification of CVD risk factors should be considered in all patients with NAFLD. Statins can be used to treat dyslipidemia in patients with NAFLD, NASH, and NASH cirrhosis, but they should be avoided in patients with decompensated cirrhosis.

Currently, the following drugs are not recommended as specific treatment for NAFLD because they have shown no specific benefit for NASH: metformin (Glucophage) and GLP-1 agonists are agents that can be used for diabetes, including in patients with NAFLD; however, they have no beneficial effects specifically on NASH, although trials with GLP-1 agonists are ongoing; ursodeoxycholic acid (ursodiol [Actigall])<sup>1</sup> and omega-3 fatty acids<sup>7</sup> (can consider for hypertriglyceridemia concurrent with NAFLD) do not specifically improve NAFLD.

## PANCREATIC CANCER

Method of

Joshua S. Jolissaint, MD; and Alice C. Wei, MD, MSc

### CURRENT DIAGNOSIS

- Pancreatic cancer remains highly lethal. The majority of patients present with advanced-stage disease, and 5-year survival remains below 10%.
- Patients with pancreatic cancer commonly present with jaundice, malaise, fatigue, weight loss, and abdominal pain.
- Routine screening for pancreatic cancer for patients at average risk is not recommended. For high-risk patients, screening may be considered on a case-by-case basis.
- Diagnostic workup should include a contrast-enhanced, pancreas-protocol computed tomography (CT) scan; serum carbohydrate antigen 19-9 (CA 19-9); and staging CT scans of the chest and pelvis.
- Histologic diagnosis is confirmed with endoscopic ultrasound (EUS)-guided fine-needle aspiration (FNA) or biopsy.

### CURRENT THERAPY

- Surgical resection is the only available potentially curative treatment; however, only 20% of patients will have resectable disease at presentation.
- Patients with localized cancer and vascular involvement (borderline resectable [BR] or locally advanced [LA]) may be candidates for neoadjuvant therapy with chemotherapy and/or radiation. If neoadjuvant therapy is effective at stabilizing or downsizing the tumor, these patients may then be eligible for resection.
- Systemic chemotherapy is the mainstay of therapy for unresectable patients.
- Palliation of symptoms may require endoscopic or surgical management for both extrahepatic biliary obstruction and gastric outlet obstruction.

### Epidemiology

In 2020 there were an estimated 57,600 new cases of pancreatic cancer in the United States. Although pancreatic cancer comprises only 3.2% of all new cancer diagnoses, it is the fourth leading cause of cancer-related death, contributing to 7.8% of cancer-associated mortality and carrying a 5-year overall survival of only <10%. Survival varies based on stage at presentation, with a 5-year survival for patients with early-stage disease of 39.4%, compared with 2.9% for those with metastatic disease. The incidence of pancreatic cancer has been relatively stable over the last decade, at approximately 12.5 cases per 10,000 person-years. Incidence increases with age, peaking between 65 and 74 years, with a median age at diagnosis of 70 years; it is higher in men than in women (14.9 vs. 11.6 per 10,000 person-years). African Americans are 12.8% to 22.8% more likely than white Americans to be diagnosed with pancreatic cancer and may have incidence rates 75% higher than patients of other races/ethnicities.

### Types of Pancreatic Cancer

Cancer of the exocrine pancreas comprises 93% of pancreatic cancer cases, with pancreatic ductal adenocarcinoma (PDAC) as the most common histologic subtype. Less common subtypes include acinar cell carcinoma, adenosquamous carcinoma, and

colloid carcinoma. Tumors of the endocrine pancreas, pancreatic neuroendocrine tumors (PNETs), and islet cell tumors comprise the remaining 7% of pancreatic malignancies.

### Risk Factors for Pancreatic Ductal Adenocarcinoma

Multiple genetic and modifiable risk factors for PDAC have been elucidated. Smoking is the strongest risk factor and is associated with approximately one-fourth to one-third of diagnoses. Some studies have demonstrated that smoking may double an individual's risk of developing PDAC. Heavy alcohol use (three or more drinks per day) increases the risk of PDAC in a dose-dependent manner. Obesity and both types 1 and 2 diabetes mellitus are also associated with an increased risk; however, the relationship between these metabolic factors is unclear. Studies have demonstrated an increased risk of PDAC with obesity in early adulthood in addition to a greater risk associated with hyperglycemia, insulin resistance, and low levels of physical activity. Chronic pancreatitis may confer more than a seven-fold increased relative risk of PDAC, and the mechanism can be either modifiable (e.g., alcohol-related pancreatitis) or hereditary.

Approximately 10% of PDAC cases have a hereditary/genetic component (Table 1). The *BRCA1* and *BRCA2* genes encode proteins involved in DNA repair, and germline mutations in these genes are highly penetrant, significantly increasing the risk of breast and ovarian cancer in female carriers. Although the risk of PDAC among patients with *BRCA1* mutations is less well established, *BRCA2* mutations confer an approximately threefold increased relative risk. *BRCA2* mutations are seen with high frequency among both familial and sporadic PDAC cases. Other hereditary syndromes, such as Lynch syndrome or hereditary nonpolyposis colorectal cancer (HNPCC) (*MLH1*, *MSH2*, *MSH6*, or *PMS2* genes), familial adenomatous polyposis (FAP) (*APC* gene), Peutz-Jeghers syndrome (*STK11* gene), and familial atypical multiple mole melanoma (FAMMM) (*CDK2NA* gene) also confer an increased risk of PDAC. Mutations in the *ATM* gene and non-O blood groupings have also been associated with an increased risk of pancreatic cancer. In addition, having a single first-degree relative with PDAC increases a patient's risk of developing PDAC by more than four-fold; however, approximately 80% of patients with a family history of PDAC have no known predisposing genetic mutation or cause.

Lastly, 68% to 80% of hereditary pancreatitis is attributed to germline mutations in the *PRSS1* gene, which are inherited in an autosomal dominant fashion and highly penetrant (approximately 80%). Both the *SPINK1* and *CFTR* genes are also associated with familial pancreatitis. Patients who develop symptoms of pancreatitis in this setting have an increased risk of PDAC that increases with age. By the age of 75 years, patients may have a greater than 50% cumulative incidence of pancreatic cancer.

### Screening

Currently there is no role for routine screening for pancreatic cancer for patients at average risk. The US Preventive Services Task Force (USPSTF) has issued a grade D rating (meaning that there is moderate or high certainty that these diagnostic methods have no benefit or that the harm outweighs the risk, thus discouraging the use of this service) for either abdominal ultrasonography, abdominal palpation, or serologic markers. For high-risk patients, those with multiple first-degree relatives with PDAC, or individuals with certain germline mutations (see "Risk Factors," earlier), screening may be considered on a case-by-case basis. Some authors have suggested the use of EUS or magnetic resonance cholangiopancreatography (MRCP), although the efficacy of these modalities as screening tools is still unknown. CA 19-9 is a serum biomarker used to track disease progression or recurrence in PDAC; however, CA 19-9 testing should not be used as a screening tool in otherwise healthy patients.

**TABLE 1** Selected Genetic Syndromes With Associated Cancer Risk

SYNDROME	GENE	ESTIMATED CUMULATIVE RISK OF PANCREATIC CANCER*	ESTIMATED RISK COMPARED WITH THE GENERAL POPULATION*
Peutz-Jeghers syndrome	<i>STK11</i>	11%–36% by age 65–70 years	132-fold
Familial pancreatitis	<i>PRSS1, SPINK1, CFTR</i>	40%–53% by age 70–75 years	26- to 87-fold
Melanoma–pancreatic cancer syndrome	<i>CDKN2A</i>	14% by age 70 17% by age 75 years	20- to 47-fold
Lynch syndrome	<i>MLH1, MSH2</i>	4% by age 70 years	9- to 11-fold
Hereditary breast-ovarian cancer syndrome	<i>BRCA1, BRCA2</i>	1.4%–1.5% (women) and 2.1%–4.1% (men) by age 70	2.4- to 6-fold
Familial pancreatic cancer	Unknown in most families	More than three first-degree relatives with pancreatic cancer: 7%–16% by age 70 Two first-degree relatives with pancreatic cancer: 3% by age 70	Three or more first-degree relatives with pancreatic cancer: 32-fold Two first-degree relatives with pancreatic cancer: 6.4-fold One first-degree relative with pancreatic cancer: 4.6-fold

### Presentation and Diagnosis

The presentation of patients with PDAC is variable. The most common presenting symptoms are jaundice and conjugated hyperbilirubinemia due to biliary tract obstruction, both of which are seen more commonly in tumors of the pancreatic head. Non-specific complaints can include malaise, fatigue, weight loss, steatorrhea, dyspepsia, and abdominal pain radiating to the back. A new diagnosis of diabetes mellitus in patients 50 years of age or older may also indicate the presence of underlying pancreatic cancer; new-onset diabetes mellitus compared with long-standing diabetes mellitus may convey a greater than twofold increase in risk, particularly in African American and Hispanic patients.

If a diagnosis of PDAC is suspected, the initial diagnostic workup should include a contrast-enhanced dual-phase pancreas protocol CT scan and measurement of serum CA 19-9. Early multidisciplinary consultation is encouraged to optimize symptom management and establish the best treatment. Endoscopic intervention may be both diagnostic and therapeutic; if the patient presents with biliary tract obstruction, endoscopic retrograde cholangiopancreatography (ERCP) may be used to relieve jaundice and to obtain a tissue diagnosis (with ERCP and/or EUS-guided FNA and/or biopsy). Staging should be completed with cross-sectional imaging of the chest and pelvis to evaluate for distant metastases. Magnetic resonance imaging (MRI) and positron emission tomography (PET)/CT may be useful adjuncts in characterizing the tumor or ruling out metastatic disease.

### Treatment

Surgical resection is the only potentially curative treatment option. However, only approximately 20% of patients with PDAC will have clearly resectable disease (i.e., without mesenteric or portovascular involvement). For this subset of patients, surgical resection is the preferred initial treatment. Tumors of the pancreatic head may be removed by pancreaticoduodenectomy (i.e., the Whipple procedure), whereas tumors of the pancreatic tail may require a distal pancreatectomy with or without splenectomy. More central or larger tumors may require a central pancreatectomy or total pancreatectomy. Patients with vascular involvement and no evidence of metastases are classified as either borderline resectable (BR) or locally advanced (LA).

The current National Comprehensive Cancer Network (NCCN) Pancreatic Adenocarcinoma guidelines recommend neoadjuvant chemotherapy with consideration of resection, depending on the patient's tolerance of chemotherapy, their fitness, and the stage of the disease. Currently accepted systemic neoadjuvant chemotherapy regimens include FOLFIRINOX-based regimens (14-day cycles of 85 mg/m<sup>2</sup> oxaliplatin [Eloxatin]<sup>1</sup>, 400 mg/m<sup>2</sup> leucovorin<sup>1</sup>, 180 mg/m<sup>2</sup> irinotecan [Camptosar]<sup>1</sup>, and 400 mg/m<sup>2</sup> 5-fluorouracil [Adrucil] bolus followed by 2400 mg/m<sup>2</sup> infusion over 46 hours), mFOLFIRINOX (without 5-fluorouracil bolus) or gemcitabine (Gemzar) (1000 mg/m<sup>2</sup>) and N-albumin-bound (nab) paclitaxel (Abraxane) (125 mg/m<sup>2</sup>) (biweekly for 4 weeks). Some patients may benefit from chemoradiation prior to consideration of resection. The optimal duration of neoadjuvant therapy has not been established; however, most clinicians restage after 2 to 3 months of chemotherapy and reevaluate the potential for resection.

For patients who undergo upfront resection, adjuvant chemotherapy has been demonstrated to improve survival following surgery. The most active regimens include mFOLFIRINOX (85 mg/m<sup>2</sup> oxaliplatin<sup>1</sup>, 400 mg/m<sup>2</sup> leucovorin<sup>1</sup>, 150 mg/m<sup>2</sup> irinotecan<sup>1</sup>, and 2400 mg/m<sup>2</sup> 5-fluorouracil infusion over 46 hours every 14 days for 12 cycles), gemcitabine plus capecitabine (Xeloda)<sup>1</sup> (1660 mg/m<sup>2</sup>/day on days 1 to 21 every 4 weeks), gemcitabine plus nab-paclitaxel (Abraxane), gemcitabine monotherapy, or 5-fluorouracil plus folinic acid (leucovorin) may also be offered for patients who do not tolerate other regimens due to side effects. Systemic chemotherapy dosing and recommendations for patients who do receive neoadjuvant chemotherapy are varied and dependent on clinical considerations.

Most patients will present with unresectable or metastatic disease. For these patients, FOLFIRINOX or gemcitabine plus nab-paclitaxel are the preferred regimens for those with a good performance status (European Cooperative Oncology Group [ECOG] status 0-1). For patients with ECOG performance status of 2, gemcitabine alone is recommended, whereas for patients with a performance status equal to or greater than 3, emphasis should be placed on palliation, with cancer-directed therapy administered on a case-by-case basis. Routine testing

<sup>1</sup>Not FDA-approved for this indication.

of tumor tissue for deficient mismatch repair (dMMR) or high levels of microsatellite instability (MSI-H) using immunohistochemistry (IHC), polymerase chain reaction (PCR), or next-generation sequencing (NGS) is now recommended. The programmed cell death protein 1 (PD-1) inhibitor pembrolizumab (Keytruda) has been approved as second-line therapy in patients who test positive for dMMR or MSI-H.

### Managing Symptoms and Complications

Once a diagnosis of pancreatic cancer has been established, all patients should be evaluated for symptomatology, physical function, and fitness. The active treatment of symptoms and introduction of palliative care services should be considered early. Modern palliative care is not synonymous with hospice, and palliation has been shown to both improve quality of life and decrease the use of aggressive care measures at the end of life.

**Pain** can be a predominant symptom in patients with pancreatic cancer and may be described as a midepigastic pain radiating to the back. This can be often managed by traditional multimodal analgesia, including opioid/narcotic analgesia; however, consideration can be given to celiac plexus neurolysis or palliative radiation for refractory pain due to local tumor invasion. As described earlier, many patients will also present with **jaundice** due to extrahepatic biliary tract obstruction. Decompression can be achieved with endoscopic, surgical, or percutaneous interventions. Endoscopic stent placement is considered the first line of treatment. Although endoscopically placed stents may be associated with higher rates of readmission for in-stent occlusion or recurrent biliary obstruction, these modalities are generally associated with lower rates of adverse events than percutaneous stent placement. Current guidelines recommend placing a self-expanding metal stent (SEMS) when feasible and only after a histologic diagnosis has been made;

however, the decision as to whether to place a plastic, covered metal, or uncovered metal stent is nuanced and should be assessed by a multidisciplinary team, including a surgeon and gastroenterologist when available. For patients receiving neoadjuvant chemotherapy, fully covered SEMS are preferred as they are easily removed/exchanged. If endoscopic or percutaneous interventions are unavailable or if unresectable disease is discovered at the time of surgery, surgical biliary bypass in the form of choledochojejunostomy may be performed. This may be accompanied by a gastrojejunostomy for the treatment or prevention of **gastric outlet obstruction** (also known as a “double bypass”) (Figure 1). As many as 20% of patients with PDAC of the pancreatic head will develop symptomatic gastric outlet obstruction. If not discovered intraoperatively or in patients with short prognoses or limited functional status, endoscopically placed duodenal stents can provide adequate relief of obstructive symptoms.

Pancreatic cancer is generally regarded as one of the highest risk states that predispose patients to **venous thromboembolism (VTE)**, conferring a four- to sevenfold higher risk than that faced by the general population. All patients should be counseled about signs and symptoms that may indicate the presence of VTE—either deep venous thrombosis or pulmonary embolism. Current guidelines recommend the use of low molecular weight heparin (LWMH) (enoxaparin [Lovenox]) in lieu of warfarin for patients who develop a cancer-related VTE. Routine prophylactic anticoagulation has not been widely adopted due to a lack of survival benefit despite a reduction in VTE events.

Finally, patients with pancreatic cancer may develop **pancreatic exocrine insufficiency** due to pancreatic resection, tumoral destruction of the parenchyma, or blockage of the pancreatic duct. Symptoms include steatorrhea, weight loss, abdominal pain, and malnutrition due to malabsorption of fat-soluble nutrients. Pancreatic enzyme replacement may be started empirically at a dose of 25,000 to 75,000 units of pancrelipase (Creon or Zenpep) per meal with 10,000 to 25,000 units per snack (off-label dosing).

### Summary

Pancreatic cancer remains a highly lethal disease. Most patients are not candidates for resection; therefore emphasis should be placed on the palliation of symptoms. However, improvements in chemotherapy over the last decade have increased both survival and rates of resectability.

## TUMORS OF THE COLON AND RECTUM

Method of

Richard Huettemann, MD; Colleen A. Donahue, MD; Thomas Curran, MD, MPH; Virgilio V. George, MD; and Pinckney J. Maxwell IV, MD

### CURRENT DIAGNOSIS

- Screening of asymptomatic average-risk patients should begin at 45 years of age.
- Colonoscopy should be performed if any screening test results are positive.
- Colonoscopy should be performed on any patient with signs or symptoms of colorectal cancer
- Screening of high-risk patients, those with inflammatory bowel disease (IBD), familial adenomatous polyposis (FAP), hereditary nonpolyposis colorectal cancer (HNPCC), or a significant positive family history, should begin at an earlier age and occur more frequently.

### CURRENT THERAPY

- Patients with FAP and HNPCC should undergo early prophylactic colon resection.
- Colon tumors should be treated with segmental laparoscopic or open resection.
- Chemotherapy is offered for colon cancers with locally advanced, nodal (stage III), or metastatic (stage IV) disease.
- Rectal tumors that are small (<3 cm), <25% of the rectal circumference, superficial (Tis or T1), lack nodal involvement, and have favorable pathologic characteristics should be removed by transanal techniques.
- Rectal tumors that are larger, locally invasive, or have nodal involvement should be removed by formal open resection, with sphincter preservation if possible.
- Combination chemotherapy and radiation therapy is offered for advanced (stage II), nodal (stage III), or metastatic (stage IV) rectal cancer.
- Postoperative surveillance includes frequent office evaluations, carcinoembryonic antigen (CEA) levels, endoscopy, and imaging.

### Background, Epidemiology, and Etiology

Colorectal cancer is the third most common cancer in men and women, after prostate and lung/bronchus in men and breast and lung/bronchus in women. The American Cancer Society (ACS) expects an estimated new diagnoses of colon cancer and an estimated 44,850 new diagnoses of rectal cancer in 2022. The incidence of colorectal cancer has been decreasing since the mid-1980s, with a more dramatic decrease in the past decade. This decrease is likely related to an increase in screening with removal of precancerous polyps. The ACS expects an estimated 52,580 deaths from colorectal cancer in 2022, which accounts for 8.6% of all cancer deaths. There has been a similar decrease in mortality since the mid-1980s, again with a sharper decline in the past decade likely related to improved screening as well. Colorectal cancer is a highly treatable and frequently curable malignancy when detected early, highlighting the need for better screening.

The development of colorectal cancer is related to a number of factors, including age, diet, activity, environmental exposures, family history, and genetics. Ninety percent of colorectal cancers are diagnosed after 50 years of age, and fewer than 5% of cases are diagnosed before 40 years of age. The peak incidence of

diagnosis is in the seventh decade of life. Dietary factors play a role in carcinogenesis as well. Western diets, consisting of high-fat and low-fiber, and the intake of red or processed meats and alcohol have been associated with increased rates of colorectal cancer. It is likely that this low-fiber Western diet slows transit time, leading to increased exposure to carcinogens. Activity level also can play a role in carcinogenesis, as studies have shown an increase in cancer among those with sedentary jobs and a decreased incidence among those with regular exercise. Exposure to cigarette smoke increases the risk of colorectal adenomas and cancers. The ACS Cancer Prevention Study II revealed that 12% of colorectal cancer deaths in the general U.S. population can be attributed to smoking. Family history and genetics also play a significant role in carcinogenesis, as approximately 10% of patients diagnosed have a first-degree relative with colorectal cancer.

### Adenomatous Polyps

The progression from normal mucosa to an adenomatous polyp to an invasive colorectal cancer proceeds through a well-defined process, over many years. Aberrant crypt foci develop into microadenomas and then into adenomatous polyps. Dysplastic cells develop within the polyp, continue to multiply, become a tumor, and then break through the subepithelial barrier and invade through the layers of the bowel wall, eventually spreading to pericolonic tissues or to lymph nodes and distant sites. A number of genes have been implicated in carcinogenesis, including proto-oncogenes (*K-ras*, *src*, *c-myc*), tumor-suppressor genes (*APC*, *DCC*, *p53*, *MCC*, *DPC4*), and DNA mismatch repair genes (*HMSH2*, *MLH1*, *PMS1*, *PMS2*, *GTBP*). Sporadic colorectal cancers generally develop as a result of several cumulative genetic insults involving these genes (Figure 1).

### Familial Colorectal Cancer Syndromes

Familial adenomatous polyposis (FAP) is an inherited, non-sex-linked, Mendelian-dominant disease that accounts for approximately 1% of all colorectal cancers. The high penetrance of FAP means that there is a 50% chance of development within affected families. However, 25% of FAP patients have no family history, likely representing a new, spontaneous mutation. The disorder is caused by mutations in either the tumor-suppressor *APC* gene, which is located on chromosome 5 (5q21–q22), or in the *MUTYH* gene, which is located on chromosome 1 (1p34.3–p32.1). FAP is characterized by the progressive development of hundreds to thousands of adenomatous polyps located throughout the entire colon. The clinical diagnosis is based on the histologic confirmation of at least 100 adenomas. All patients will eventually develop colorectal cancer. Adenomas generally appear by the mid-20s, and cancers generally appear by the late-30s. An attenuated form of FAP is recognized in which fewer adenomas (12–100) are identified, with cancer developing between 50 and 70 years of age. FAP also exhibits extracolonic manifestations including gastric/duodenal/small bowel polyps, osteomas and desmoid tumors (Gardner syndrome), eye lesions (congenital hypertrophy of retinal pigment epithelium [CHRPE]), papillary thyroid cancer (up to 12% of FAP patients), epidermoid cysts, and brain neoplasms (Turcot syndrome).

Hereditary nonpolyposis colon cancer (HNPCC), also called *Lynch syndrome*, is an inherited, non-sex-linked, Mendelian-dominant disease with virtually complete penetrance. HNPCC is caused by a defect in any of a number of DNA mismatch repair genes (*MLH1*, *MSH2*, *MSH6*, *PMS1*, *PMS2*), which leads to microsatellite instability (*MSI-H*). A number of criteria have been generated for the diagnosis of HNPCC, including the Amsterdam I and II criteria and the Bethesda guidelines (Box 1). According to the EPICOLON study, the revised Bethesda guidelines are the most discriminating set of clinical parameters for diagnosing HNPCC.

HNPCC is subdivided into Lynch syndrome types I and II. Lynch type I refers to site-specific nonpolyposis colon cancer, and Lynch type II (formerly called *familial cancer syndrome*) refers to cancers that develop in the colon and related organs such as the endometrium, ovaries, stomach, pancreas, and proximal urinary tract, among others.

Figure 1 Adenoma to carcinoma sequence.

## BOX 1 Diagnosis of Hereditary Nonpolyposis Colon Cancer

### Amsterdam I Criteria, 1990

- Three or more family members with histologically verified colorectal cancer, one of whom is a first-degree relative (parent, child, sibling) of the other two
- Two successive affected generations
- One or more colon cancers diagnosed before 50 years of age
- Familial adenomatous polyposis has been excluded

### Amsterdam II Criteria, 1999

- Three or more family members with histologically verified HNPCC-related cancers (endometrium, ovary, stomach, small intestine, hepatobiliary, upper urinary tract, brain, and skin), one of whom is a first-degree relative (parent, child, sibling) of the other two
- Two successive affected generations
- One or more colon cancers diagnosed before 50 years of age
- Familial adenomatous polyposis has been excluded

### Revised Bethesda Guidelines, 2002

- Colorectal cancer diagnosed in a patient who younger than 50 years of age
- Presence of a synchronous, metachronous colorectal, or other HNPCC-related malignancy, regardless of age
- Colorectal cancer with the *MSI-H* histology diagnosed in a patient younger than 60 years of age
  - Presence of carcinoma-infiltrating lymphocytes, Crohn's-like lymphocytic reaction, mucinous/signet-ring differentiation, or medullary growth pattern
  - No general consensus based on this age
- Colorectal cancer diagnosed in one or more first-degree relatives with an HNPCC-related neoplasm
  - With one or more neoplasm being diagnosed before 50 years of age
- Colorectal cancer diagnosed in two or more first- or second-degree relatives With HNPCC-related malignancies, regardless of age

HNPCC, Hereditary nonpolyposis colorectal cancer.

Lynch syndrome differs from sporadic colorectal cancer in a number of important ways. It has an autosomal dominant inheritance, a predominance of proximal lesions (75% are found in the right colon), an excess of multiple primary colorectal cancers (18%), an early age of onset averaging 44 years, a significantly improved survival rate of right-sided lesions when compared with family members with distal colorectal cancer (53% vs. 35% 5-year survival), and an increased risk of development of metachronous lesions (24%). Patients and family members of those diagnosed with HNPCC and FAP should undergo genetic testing to aid in future diagnosis and treatment options.

### Inflammatory Bowel Disease

Both Crohn's disease and ulcerative colitis (UC) confer an increased risk of colorectal cancer, with UC approximately double the risk of Crohn's disease. The duration and severity of Crohn's disease and the duration and extent (left-sided colitis vs. pancolitis) of UC contribute to cancer risk in inflammatory bowel disease (IBD). Cancer

in Crohn's disease generally occurs in a stricture or bypass segment. Importantly, neoplasia in UC does not follow the adenoma-carcinoma sequence of sporadic colorectal cancer. This change has important screening and treatment implications.

### Screening the Average-Risk Patient

Patients with no personal history of colorectal polyps or cancers, no personal history of IBD, no symptoms suspicious for colorectal cancer, no family history of colorectal polyps or cancers, and no evidence of a familial or genetic syndrome can be screened as average risk. Two main categories of screening tests include those that detect adenomatous polyps and cancer (flexible sigmoidoscopy, colonoscopy, double-contrast barium enema, and computed tomography [CT] colonography) and those that primarily detect cancer (fecal occult blood testing [FOBT], fecal immunohistochemical testing [FIT], and stool DNA testing). The goal of screening is to reduce mortality by reducing the incidence of advanced disease. It seems intuitive that tests detecting polyps, the premalignant phase of colorectal cancer, would be preferred to tests detecting only cancers. However, testing for polyps and cancer is generally procedure related, while testing for only cancers can be conducted on stool studies alone. Screening with simple stool samples has the potential to more easily increase overall screening, but is not preventive without the ability for endoscopic polyp removal.

Regardless of the method employed, testing in the average-risk, asymptomatic patient should begin at 45 years of age based on the most recent updated guidelines because of the increasing disease burden in people younger than 50 years of age. A total colonoscopy is only required every 10 years, but it requires an oral bowel preparation and carries a small risk of perforation of approximately 1 in 1000. A flexible sigmoidoscopy is required every 5 years when combined with FOBT annually. The testing is more frequent, but it requires only enemas for preparation and carries a lower risk of perforation. Air-contrast barium enemas can be used for screening every 5 years, but they also require an oral bowel preparation and are only diagnostic. CT colonography is an evolving method for screening every 5 years and has the opportunity for more accessible screening; however, there are limitations on the identification of polyps less than 1 cm. It also requires an oral bowel preparation and is only diagnostic; thus it is used in conjunction with flexible sigmoidoscopy and FIT. FOBT and FIT require annual testing. The U.S Food and Drug Administration (FDA) has also approved a FIT-fecal DNA test that is performed at 3-year intervals; however, it is less specific and less cost-effective than FIT, making it unlikely to replace FIT. The most complete screening test, allowing removal of precancerous lesions if identified, remains total colonoscopy, and importantly, the patient should undergo full endoscopic evaluation if any other screening test is positive.

### Screening the High-Risk Patient

High-risk patients include those with a personal history of colorectal polyps or cancers, a family history of colorectal cancer in a first-degree relative, those with Crohn's disease or UC, and those with a personal or family history of FAP or HNPCC. Screening in these patients has been adjusted for changes in incidence and age of onset of neoplasia (Box 2).

### Symptoms and Diagnosis

Symptoms of colorectal cancer include bleeding (85%), a change in bowel habits, abdominal pain, malaise, and obstruction. Frequently, anemia may be the only sign a patient exhibits. Patients

**BOX 2** Screening the High Risk Patient for Colorectal Cancer

Risk Category	Age to Begin	Recommendation	Comment
Personal history of <3 adenomas with low- grade dysplasia	5–10 years after the initial polypectomy	Colonoscopy	Examination interval should be based on other clinical factors such as prior examination findings, family history, or preferences of the endoscopist or patient.
Personal history of 3–10 adenomas, or 1 adenoma >1 cm, or any adenoma with villous features or high-grade dysplasia	3 years after the initial polypectomy	Colonoscopy	Adenomas require complete excision. If the follow-up is normal, the next examination should be in 5 years. More than 10 adenomas should raise suspicion of a familial syndrome.
Personal history of colorectal cancer	1 year after resection	Colonoscopy	Patients should undergo high- quality preoperative clearing. Follow-up after normal examinations should be extended to 3 years and then to 5 years
Family history of adenomas or cancer in a first-degree relative <60 years of age or in two first-degree relatives at any age	40 years of age or 10 years before the youngest case	Colonoscopy	Every 5 years
Family history of adenomas or cancer in a first-degree relative >60 years of age or in two second-degree relatives with cancer	40 years of age	Colonoscopy	Screening should be initiated at an earlier age. Intervals based on findings or by the average-risk patient
FAP or suspected FAP	10–12 years of age	Annual FS, counseling for genetic testing if showing polyps	Colectomy should be considered for positive genetic testing/after puberty
HNPCC or risk of HNPCC	20–25 years of age or 10 years before the youngest case	Colonoscopy, counseling for genetic testing	Every 1–2 years. Genetic testing should be offered to first-degree relatives of persons with a known DNA mismatch repair gene, or with one of the first three Bethesda criteria
IBD, Crohn's, or chronic UC	8 years after the onset of pancolitis, or 12–15 years after the onset of left- sided colitis	Colonoscopies with random 4 quad biopsies every 10 cm for dysplasia	Screening should be offered every 1–2 years, and patients are best referred to a center with experience in the surveillance and management of IBD.

FAP, Familial adenomatous polyposis; FS, flexible sigmoidoscopy; HNPCC, hereditary nonpolyposis colorectal cancer; IBD, inflammatory bowel disease.

with symptoms suspicious for colorectal cancer should undergo colonoscopy. An anorectal source of bleeding should not preclude a complete colonic evaluation.

### Preoperative Management

Before operative intervention, a complete evaluation should occur, including a careful history and physical examination, routine laboratory testing, and a carcinoembryonic antigen (CEA) level. A complete evaluation of the colon is essential and utilizes colonoscopy with biopsy or barium enema or CT colonography if colonoscopy is incomplete. Bowel preparation is indicated as a routine preoperative measure for colonic surgery per the latest guidelines from the American Society of Colon and Rectal Surgeons (ASCRS).

Preoperative staging should be undertaken for colorectal cancers. CT scanning of the abdomen and pelvis are indicated to aid in the evaluation of the extent of localized or metastatic disease and the presence of enlarged lymph nodes. Staging of rectal cancers includes determining the distance from the anal verge (frequently utilizing a rigid proctoscope), the depth of invasion, and the presence of enlarged lymph nodes (utilizing endorectal ultrasonography or endoanal coil magnetic resonance imaging). Metastatic disease mandates neoadjuvant chemotherapy in the absence of acute symptoms of obstruction or exsanguination. Rectal cancers with evidence of local invasion into perirectal fat or adjacent

structures or evidence of enlarged metastatic lymph nodes may benefit from neoadjuvant chemotherapy and radiation. Preoperative staging allows for the application of neoadjuvant therapy in selected candidates, which can downstage and downsize tumors and can decrease rates of local recurrence in rectal cancer. Neoadjuvant therapy can also allow for sphincter-preserving procedures for previously bulky or very low rectal tumors.

### Surgery for Colonic Tumors

The primary therapy for tumors of the colon is operative. The basic principles of surgery for colon cancer include the following:

- Exploration: adequate visual, tactile, and potentially intraoperative hepatic ultrasound staging at the time of primary resection to evaluate for peritoneal, mesenteric, or hepatic disease
- Removal of the entire cancer with enough bowel proximal and distal to encompass the possibility of submucosal lymphatic tumor spread
- Removal of regional mesenteric pedicle, including draining lymphatics, based on the predictable lymphatic spread of the disease and the potential for regional mesenteric involvement without concurrent distant involvement
- En bloc resection of involved structures (T4 tumors)
- Segmental colonic resections (right, transverse, left, or sigmoid colectomy) based on the tumor location and blood supply with lymphatic drainage, specifically the ileocolic, middle colic, and

left colic arteries. These resections define both a convenient anatomic boundary for standard colonic resection and also provide for adequate regional lymph node clearance because the major draining lymphatics follow these blood vessels in the mesentery. Locally invasive tumors (T4) require en bloc resection of involved structures. Metastatic colonic tumors (M1) may require neoadjuvant chemotherapy before resection or palliation.

Numerous studies have proven that minimally invasive surgery is appropriate and perhaps preferred for colon cancer in experienced hands. There is evidence showing decreased length of stay for minimally invasive surgery without a decrease in oncologic outcomes; reduction in homeostatic insults likely leads to more favorable overall outcomes. The application of minimally invasive techniques for rectal cancer resection is still controversial but is gaining popularity.

### Surgery for Rectal Tumors

Two different approaches for rectal tumors include local excision and formal rectal resection. Local excision is the treatment of choice for a select, small group (3%–5%) of all patients diagnosed with rectal cancer. Tumors amenable to transanal excision are small (<3 cm), <25% of the rectal circumference, confined to the mucosa or submucosa (Tis or T1), lack nodal involvement by preoperative imaging, and have favorable pathologic characteristics (well or moderately differentiated with no lymphovascular invasion). Tumors in the lower or middle third of the rectum are accessible by simple transanal excision, but tumors of the upper rectum require the use of transanal endoscopic microsurgery (TEMS) techniques for resection. Local excision requires a 1-cm normal margin, but the defect generally does not require closure.

Tumors staged at T2 or greater require a formal resection, the type of which depends on the location of the tumor. Upper and middle rectal tumors can generally be managed with a low or very low anterior resection. Lower rectal tumors frequently require a proctectomy with coloanal anastomosis or an abdominoperineal resection (APR). The goal of resection is to obtain a 5-cm distal margin, however lower tumors can be managed with a 2-cm distal margin. Very low tumors or those involving the sphincter mechanism require an APR. Rectal tumors with a greater depth of rectal wall invasion (T3), evidence of fixation or local invasion (T4), or evidence of lymph nodal (N1–N2) or metastatic (M1) disease mandate neoadjuvant chemoradiation therapy. Proctectomy requires a specimen-appropriate total mesorectal excision (TME). This involves complete excision of all mesorectal tissue located behind the rectum and no carcinoma at the lateral or circumferential margins. The goal of the TME is to remove all malignant tissue to reduce or eliminate the possibility of locally recurrent disease. Locally advanced rectal tumors may preclude an effective or safe resection. Some indications for likely inoperability include extensive pelvic disease, invasion of ileofemoral vessels, extensive lymphatic involvement or significant lower extremity lymphedema, bony involvement, or life expectancy less than 3 to 6 months.

Minimally invasive surgical techniques are similarly being performed for rectal malignancies. Studies are underway to verify the efficacy and safety of these methods in rectal resection compared with traditional open resection. It has gained widespread popularity and is very commonly used.

### Complicated Disease

Colorectal tumors may present with complications including obstruction, perforation, or significant bleeding. These presentations are generally related to more advanced disease and may preclude a complete staging workup or potential neoadjuvant therapy. Unless patients are unstable or critically ill or the tumor is unresectable, an oncologic resection should be performed. An ostomy is generally performed, whether as an end ostomy or as a proximal loop diversion for a primary anastomosis. Colonic stenting is an attractive option for obstructing lesions as either palliation or as a bridge to resection after medical stabilization and staging for potential neoadjuvant therapy.

### Surgery for High-Risk Conditions

High-risk conditions for the development of colorectal malignancies include FAP, HNPCC, and chronic UC. Surgical management may be prophylactic or possibly therapeutic after a malignancy has been diagnosed. The mainstay of operative management in FAP and chronic UC is a total proctocolectomy. Reconstructive options include an ileal pouch-anal anastomosis, a continent ileostomy (Kock pouch), or an end ileostomy. A total abdominal colectomy with ileorectal anastomosis may be performed for temporary preservation of rectal function in selected cases of chronic UC with rectal sparing and FAP with few rectal polyps, but this requires aggressive surveillance of the remaining rectal mucosa's risk of malignancy. Patients with HNPCC should also undergo subtotal colectomy with ileorectal anastomosis, and a total hysterectomy with bilateral salpingoophorectomy should be offered because of the preponderance of associated gynecologic malignancy.

### Pathologic Staging and Adjuvant Therapy

Excellent pathologic sampling and review of the operative specimen provides important prognostic and therapeutic information. Current standards recommend at least 12 lymph nodes be removed for adequate staging of colon cancer. The decision for adjuvant chemotherapy and/or radiation therapy is based on pathologic staging. This information also provides prognostic information in terms of survival to the patient and their family. A number of staging systems have been developed, however the TNM system is most commonly used in the United States (Box 3).

Chemotherapy is offered for colorectal cancers with locally advanced, nodal (stage III), or metastatic (stage IV) disease. The combination of chemotherapy and radiation therapy for advanced rectal cancer (stages II to IV) has decreased local recurrence and increased survival. Numerous protocols are available for treatment, with the standard of care being FOLFOX: 5-fluorouracil (5-FU), leucovorin, and oxaliplatin (Eloxatin). Older adult patients or those with multiple comorbidities who may not be able to tolerate full-dose chemotherapy may be candidates for capecitabine (Xeloda) or 5-FU and leucovorin. Numerous study protocols are available at specialized centers evaluating other medications. Newer technologies continue to evolve, such as anti-angiogenesis agents and immunomodulatory agents.

#### BOX 3 Pathologic Staging Systems for Colorectal Cancer

Pathologic Features	Stage	TNM	Dukes	Astler-Coller	5-Year Survival
<b>Depth of Invasion</b>					
Lamina propria, muscularis mucosa	0	T0/Tis	A		>90%
Submucosa	I	T1	A	B1	
Muscularis propria	I	T2	A	B1	
Subserosa, pericolic fat	II	T3	B,	B1	70-85%
Adjacent organs, perforation	II	T4	B	B2	55-65%
<b>Lymph Nodal Involvement</b>					
None		N0			
1-3 nodes	III	N1	C	C1, C2	45-55%
>3 nodes	III	N2	C	C1, C2	20-30%
<b>Distant Metastatic Disease</b>					
Absent		M0			
Present	IV	M1	D		<5%

## Metastatic Disease

Surgical therapy is also available for metastatic disease in certain situations. Metastatic liver lesions amenable to resection can be addressed either at the time of colon resection or after the patient has healed from the colectomy. The lesions could be resected or treated using radiofrequency ablation (RFA), a newer technology allowing in-situ destruction of liver lesions. Similarly, selected pulmonary metastases can be resected, possibly using minimally invasive thoracoscopic techniques. The majority of deaths from colorectal cancer are from metastatic disease; over 20% of patients have widespread disease at diagnosis. A multidisciplinary approach to patients with metastatic disease should be undertaken to discern if it is resectable and what intervention should be pursued.

## Surveillance

Surveillance for colon and rectal cancer is a lifelong process. Patients are seen and examined in the office every 3 months for 2 years, then every 6 months for 3 years, and then yearly. CEA levels are routinely obtained as a marker for tumor recurrence. Endoscopy should be performed at 1 year postoperatively, given a high-quality preoperative study to clear the entire colon. Normal examinations allow subsequent colonoscopies to occur at 3 years and then every 5 years. Similarly, routine imaging utilizing chest radiography and CT of the abdomen and pelvis are obtained. Patients with increased or rising CEA levels or with evidence of recurrent disease can be evaluated using positron emission tomography (PET).

## TUMORS OF THE STOMACH

Method of

David (Sasha) Mahvi, MD; and Mark Fairweather, MD, PhD

### CURRENT DIAGNOSIS

- Screening programs exist in countries with a very high incidence of gastric adenocarcinoma and can be considered elsewhere for individuals at high risk.
- Esophagogastroduodenoscopy with biopsy is the gold standard for diagnosis of stomach tumors.
- Staging workup for adenocarcinoma includes computed tomography (CT) of the chest, abdomen, and pelvis to evaluate for metastatic disease and endoscopic ultrasonography (EUS) to assess T-stage.

### CURRENT THERAPY

#### Adenocarcinoma

- Treatment decisions should be made by multidisciplinary teams.
- Patients with T1a tumors and no further spread can be candidates for endoscopic or surgical resection.
- Patients with T1b tumors without nodal involvement should undergo upfront surgical resection.
- Patients with T2 or higher disease or any nodal involvement should receive perioperative chemotherapy, with the FLOT regimen (5-fluorouracil, leucovorin,<sup>1</sup> oxaliplatin,<sup>1</sup> and docetaxel [Taxotere]) being first-line treatment.
- Surgery consists of either a distal gastrectomy or total gastrectomy depending on tumor location and should include at least 15 lymph nodes for accurate staging.

#### Gastrointestinal Stromal Tumors

- All tumors greater than 2 cm should be considered for resection.
- No lymphadenectomy is required, and grossly negative margins are sufficient.
- Imatinib (Gleevec), a tyrosine kinase inhibitor, should be offered after surgery to patients with a high-risk of tumor recurrence (either a primary tumor >5 cm or a mitotic rate >5 per 50 high-power field).

#### Neuroendocrine Tumors

- Type 1 and type 2 tumors can undergo endoscopic resection if they are less than 2 cm in size and are not poorly differentiated or do not invade beyond the submucosa.
- Surgical resection should be performed for all type 3 tumors as well as for type 1 and 2 tumors that have positive margins, recur, or have the worrisome features listed earlier.
- Patients can develop carcinoid syndrome with liver metastases, which can be treated with somatostatin analogues, surgical cytoreduction, or liver-directed therapies.

#### Gastric Lymphoma

- Mucosa-associated lymphoid tissue (MALT) lymphomas often respond to *Helicobacter pylori* eradication.
- Other lymphomas are treated with chemotherapy, with surgery being reserved for patients with complications such as bleeding or perforation.

<sup>1</sup>Not FDA approved for this indication.

## Gastric Adenocarcinoma

Gastric adenocarcinoma is the fourth leading cause of cancer-related death worldwide, accounting for an estimated 768,000 deaths in 2020. Gastric cancer is the fifth most common cancer

worldwide, with just over 1 million new cases annually. Although the overall incidence has been downtrending as a result of screening in high-risk populations and the recognition of *H. pylori* as a significant risk factor, the overall crude number of cases has gradually increased because of the aging population. In the United States, gastric cancer is less prevalent, with the 14th highest incidence and 16th highest mortality rate estimated in 2022.

### Classification

Historically, gastric adenocarcinomas have been divided into two main subtypes by the Lauren classification system: intestinal and diffuse. Intestinal-type gastric cancers are similar to adenocarcinomas elsewhere in the gastrointestinal tract, appearing in glandular or tubular formations. Intestinal cancers are more likely to occur in male and older adult patients and have a more favorable prognosis. The diffuse subtype lacks cohesive molecules, specifically E-cadherin, and will invade without gland formation.

### Risk Factors

There are a number of risk factors for gastric cancer. Although most cancers are sporadic, 1% to 3% are caused by a genetic mutation (most commonly *E-cadherin/CDH-1* mutations). Numerous dietary factors have been linked to subsequent gastric cancer development, including salty or spicy diets, processed meat, smoked fish, refined grains, and lack of adequate fruits and vegetables. Additional lifestyle factors include alcohol and cigarette use. Men are also more likely to develop the disease than women.

A history of *H. pylori* infection or chronic atrophic gastritis also increases a patient's risk of developing subsequent stomach cancer. The International Agency for Research on Cancer estimates that *H. pylori* solely attributes to 36% of gastric cancers in developed countries and 47% in developing countries. Both intestinal and diffuse subtypes of gastric adenocarcinoma are associated with *H. pylori*. *H. pylori* strains with the *cagA* gene have a poorer prognosis. The chronic inflammation and subsequent development of atrophic gastritis can lead to intestinal metaplasia.

There has been an increasing incidence of proximal gastric cancers. Obesity and GERD are risk factors for more proximal lesions.

### Screening

National screening programs have been established in Japan and South Korea, both of which have a relatively high incidence of gastric cancer. In Korea, screening is recommended every 2 years starting at 40 years of age. In Japan, screening is performed every 2 to 3 years starting at 50 years of age. Both countries have shown diagnosis at earlier cancer stages improved with utilization of their screening programs. The relative utility and cost-effectiveness of national gastric cancer screening with either upper endoscopy or upper GI series has not been established in countries with a lower relative incidence of gastric cancer. Individualized screening can be considered for those with high-risk genetic syndromes, such as *CDH-1* mutation, Lynch syndrome, Peutz-Jeghers syndrome, and familial adenomatous polyposis. Screening can also be considered in patients with a strong family history of gastric cancer or previously established atrophic gastritis or intestinal metaplasia.

### Clinical Manifestations

Patients with gastric adenocarcinoma often have vague symptoms that may not be present until more advanced disease is present. Epigastric abdominal pain (52%) and weight loss (62%) are the most common symptoms, but early satiety, decreased appetite, and nausea can also be present. New-onset heartburn or reflux can be a presenting symptom and warrants further workup, especially in older adults. Melena and anemia can be seen in tumors that are bleeding. A rare subset of patients may have systemic manifestations of gastric cancer. These paraneoplastic syndromes include the Leser-Trelat sign, which is characterized by sudden

onset of multiple seborrheic keratoses, and acanthosis nigricans, which appears as dark pigmentation in skin folds. However, these manifestations are not specific to gastric cancer and are benign processes in the majority of patients.

### Diagnosis

Esophagogastroduodenoscopy (EGD) with biopsy is the gold standard for gastric cancer diagnosis. This allows for tissue diagnosis as well as anatomic location of the primary tumor. Of note, per the American Joint Committee on Cancer (AJCC) and the Union for International Cancer Control (UICC) TNM classification, 8th edition, esophagogastric junction tumors with an epicenter less than 2 cm into the proximal stomach are classified as esophageal cancers; those more than 2 cm into the stomach are staged as gastric cancers. Gastric adenocarcinomas usually appear as friable ulcerated masses endoscopically. However, it should be noted that the gastric mucosa can appear normal in linitis plastica (an aggressive form of diffuse-type adenocarcinoma), with the only endoscopic finding being poor stomach distensibility. Deep biopsies beyond the superficial mucosa must be obtained to evaluate for these lesions. Any suspicious lesion should have multiple biopsies taken to improve the diagnostic yield. For example, a single biopsy has a 70% sensitivity for diagnosis compared with 98% with seven biopsies. For this reason, six to eight biopsies are recommended for each suspicious lesion.

For lesions less than 2 cm in size, endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD) can be considered in experienced hands, which can be both diagnostic and therapeutic depending on the pathology of the specimen. The pathology report of the biopsy should include presence of invasion, histologic subtype (intestinal or diffuse), and tumor grade. Unfortunately, in the United States the vast majority of tumors present at later stages of disease.

### Staging

Once adenocarcinoma is diagnosed on endoscopic biopsy, patients should undergo CT of the chest, abdomen, and pelvis to evaluate for regional and metastatic disease. For suspicious lesions in the common sites of metastatic disease, such as the liver and lung, a biopsy should be performed for tissue confirmation. Ascitic fluid may be sampled by paracentesis and sent for cytologic and chemical analysis. Involvement of abdominal lymph nodes outside the standard lymphadenectomy resection (i.e., pancreaticoduodenal, peripancreatic, middle colic, para-aortic) are classified as distant metastasis.

In patients without evidence of metastatic disease on CT, EUS is recommended to assess the T stage. EUS can also identify enlarged nearby lymph nodes, which can be biopsied using fine-needle aspiration. If there is high clinical suspicion of metastasis but initial CT is unrevealing, integrated positron emission tomography (PET)/CT may be considered. Diagnostic staging laparoscopy may also be useful in detecting occult disease in patients with tumor invasion beyond the submucosa or in whom neoadjuvant therapy is being considered. Staging laparoscopy is superior to cross-sectional imaging for identifying peritoneal spread and allows for peritoneal fluid sampling for cytologic analysis. A complete blood count and comprehensive metabolic profile should be obtained to evaluate for anemia and electrolyte derangements.

The most recent AJCC/UICC TNM staging classifications were published in 2017. An important update in the new classification system is separate staging for patients with and without neoadjuvant therapy. Early gastric adenocarcinoma is defined as cancers that do not invade past the submucosa (T1); T1a tumors involve the mucosa, and T1b tumors involve the submucosa. T2 tumors involve the muscularis propria, T3 tumors penetrate to the subserosa, and T4 tumors invade beyond the serosa (T4a) or invade adjacent structures (T4b). Regional nodal classification is N1 for 1 to 2 lymph node metastases, N2 for 3 to 6 nodes, N3a for 7 to 15 nodes, and N3b for 16 or more involved nodes. The M1 stage indicates the presence of metastatic disease.

**TABLE 1** 8th Edition AJCC Staging of Gastric Adenocarcinoma

AJCC Stage	T-Stage	N-Stage	M-Stage
IA	T1	N0	M0
IB	T1	N1	M0
IB	T2	N0	M0

### Treatment

It is recommended that treatment decisions for all patients diagnosed with gastric cancer be discussed by a multidisciplinary team including medical oncology, radiation oncology, surgical oncology, gastroenterology, radiology, and pathology. Complete surgical resection of the cancer and adjacent lymph nodes offers the best opportunity for long-term survival when possible. Indicators of surgical unresectability include presence of metastatic disease, involvement of a major vascular structure such as the aorta, or encasement of the celiac axis, hepatic artery, or proximal splenic artery. It should be noted that involvement of the distal splenic artery can still represent resectable disease.

Patients with either Tis or T1a disease (tumor that does not invade past the submucosa) may be candidates for either endoscopic or surgical resection. Patients with T1b cancers (a tumor that invades the submucosa) should undergo upfront surgical resection. Patients with T2 or higher disease or any nodal involvement are recommended to undergo perioperative chemotherapy. Radiation therapy can be considered, especially in cases of locally advanced disease. Patients who are not candidates for curative surgical resection or with metastatic disease should be considered for palliative treatment in addition to systemic chemotherapy.

### Surgery

Endoscopic resection with either EMR or ESD can be considered adequate therapy for gastric tumors less than 2 cm in size that (1) are well-differentiated or moderately differentiated, (2) do not penetrate past the submucosa, and (3) do not have evidence of lymphovascular invasion.

Surgical resection typically consists of either a distal/subtotal or total gastrectomy depending on where the tumor is located. Tumors in the proximal third of the stomach typically require total gastrectomy, while a subtotal distal gastrectomy can be performed in the distal two-thirds. There is no survival difference between total and distal gastrectomy for distal tumors, and the

quality of life in patients has been shown to be superior with partial gastrectomy when possible oncologically. Patients undergoing surgery should be considered for a diagnostic laparoscopy to detect the possible presence of occult metastatic disease before committing to curative surgery. A 5-cm proximal margin should be obtained with at least a 2-cm distal margin on the duodenum. T4 tumors require en bloc resection of nearby involved organs or structures. Retrieval of at least 15 lymph nodes is necessary for accurate nodal staging.

Minimally invasive gastrectomy, when technically feasible, has been shown to be non-inferior oncologically to open surgery. Additionally, minimally invasive gastrectomy has been shown to have fewer wound complications, decreased postoperative pain, and shorter length of stay.

The appropriate extent of lymphadenectomy for gastric cancer is debated. Although D1 lymphadenectomy involves removal of the perigastric lymph nodes alone, D2 lymphadenectomy involves additional removal of lymph nodes around the left gastric, common hepatic, celiac, and splenic arteries. It is unclear if D2 lymphadenectomy provides an overall survival benefit, with most randomized trials not demonstrating a significant difference between D1 and D2 lymphadenectomy. However, in experienced hands, the additional D2 lymph nodes can provide improved staging information with a minimal increase in morbidity and is now what is typically performed in high-volume cancer centers. D3 lymphadenectomy (para-aortic lymph nodes), however, is associated with increased morbidity and is not presently recommended.

In cases that require reconstruction after a distal gastrectomy, options include Roux-en-Y gastrojejunostomy, Billroth I gastroduodenostomy, and Billroth II gastrojejunostomy. Reconstruction after total gastrectomy is performed with a Roux-en-Y esophagojejunostomy. Placement of a jejunal feeding tube should be considered at the time of operation, especially if a patient is likely to receive adjuvant chemoradiation and/or their nutritional status is poor, though their use is not standardized.

### Chemotherapy

The utility of chemotherapy in gastric adenocarcinoma has been established in multiple randomized trials. The first major trial (MAGIC) randomized 503 patients with resectable adenocarcinoma of the stomach, gastroesophageal junction, or lower esophagus to surgery alone versus surgery with perioperative ECF (epirubicin [Ellence],<sup>1</sup> cisplatin,<sup>1</sup> 5-fluorouracil). Chemotherapy consisted of three preoperative and three postoperative cycles. Perioperative ECF resulted in improved 5-year overall survival (36% compared with 23% for patients who received surgery alone). More recently, a randomized phase 2/3 trial of 716 patients with resectable stage II or III gastric or gastroesophageal junction adenocarcinomas was conducted to compare perioperative ECF and perioperative FLOT (fluorouracil, leucovorin,<sup>1</sup> oxaliplatin,<sup>1</sup> and docetaxel [Taxotere]). Survival was significantly improved with FLOT, with a median overall survival of 50 months compared with 35 months with ECF.

In patients who are medically fit and thereby recommended to receive perioperative chemotherapy, the FLOT regimen is recommended. Patients who are unable to tolerate this more aggressive chemotherapy regimen may undergo treatment with a fluoropyrimidine and oxaliplatin<sup>1</sup> or fluorouracil and cisplatin.<sup>1</sup> The ECF regimen is no longer first-line therapy.

For patients who do not receive neoadjuvant therapy, treatment recommendations are guided by the pathologic tumor classification, operative margins, and extent of lymphadenectomy. Those whose final surgical pathology reveals T3, T4, or any N-positive disease should be offered adjuvant chemotherapy. Those with T2N0 disease may be offered either adjuvant chemotherapy or surveillance. All patients with positive operative margins should receive adjuvant chemoradiation. Adjuvant chemotherapy is fluoropyrimidine-based. In patients who received less than a D2

<sup>1</sup>Not FDA approved for this indication.

lymphadenectomy, fluorouracil or capecitabine (Xeloda)<sup>1</sup> is recommended before and after fluoropyrimidine-based regimens. For patients who did have a D2 lymphadenectomy, oxaliplatin<sup>1</sup> and fluorouracil or capecitabine<sup>1</sup> is recommended.

### Immunotherapy

There are currently ongoing preclinical and early clinical phase trials of various immunotherapy agents in the treatment of gastric adenocarcinoma. However, their use remains investigational at this time.

### Radiotherapy

The benefits and indications for radiotherapy are less well-established for noncardia gastric adenocarcinoma. There are currently no randomized trials comparing adjuvant chemoradiotherapy to either surgery alone or surgery and chemotherapy. Preoperative chemoradiotherapy is beneficial in patients with esophageal, gastroesophageal junction, and gastric cardia tumors as shown in the CROSS trial, but its role specifically in gastric cancer is less clear. Radiotherapy can be considered as an adjunct in multidisciplinary discussions for patients with locally advanced disease.

### Palliation

The most common indications for palliative procedures in gastric cancer are gastric outlet obstruction, bleeding, and perforation. Choosing among the various palliative options involves consideration of the risks and benefits specific to each patient's case as well as the patient's goals of care. For patients with an obstructing tumor, especially in the pre-pyloric or antral regions, surgical or endoscopic interventions may be beneficial. For a patient whose life expectancy is greater than 6 months and who is medically fit, surgical gastrojejunostomy may be preferred if technically feasible in either an open or laparoscopic fashion. If the patient is not a surgical candidate, endoscopic stent placement or endoscopic gastrojejunostomy may be considered. Finally, a venting gastrostomy tube is another alternative. However, the patient will no longer be able to eat if this is the only therapy offered, and a feeding jejunostomy tube must be considered for enteral nutrition.

Patients who present with uncontrollable bleeding may initially undergo endoscopic treatment, but this is associated with a high likelihood of recurrent bleeding. Angiographic embolization or radiation therapy are potential alternatives. If these more conservative measures are unsuccessful, palliative resection should be considered. Should a patient pursue operative intervention, lymph node dissection is not required. If patients present with gastric perforation and surgery is within the patient's goals of care, urgent palliative resection may be attempted.

### Monitoring

Patients successfully treated with endoscopic resection should undergo a thorough history and physical examination every 3 to 6 months after treatment for the first 1 to 2 years, and then every 6 to 12 months for 3 to 5 years, followed by annual follow-up thereafter. EGD should be performed every 6 months for 1 year and then annually for up to 5 years. CT scans should be performed as clinically indicated by symptoms.

Patients with stage I disease treated by surgery should undergo a history and physical examination every 3 to 6 months after treatment for 1 to 2 years, and then every 6 to 12 months for 3 to 5 years, followed by annual follow-up thereafter. They should have EGD and/or CT scans as clinically indicated by symptoms. These patients must additionally be monitored for nutritional deficiencies, especially involving B<sub>12</sub> and iron.

Patients with stage II or III disease who received surgery should undergo a history and physical examination every 3 to 6 months after treatment for 1 to 2 years, and then every 6 to 12 months for 3 to 5 years, followed by annual follow-up thereafter. EGD may

be performed as clinically indicated. CT of the chest/abdomen/pelvis should be performed every 6 to 12 months for the first 2 years and then annually up to 5 years. PET/CT should be considered as clinically indicated when suspicion for disease recurrence and/or metastasis is high. These patients must also be monitored for nutritional deficiencies.

### Complications

In the early postoperative period, patients can develop peritonitis from an anastomotic leak or duodenal stump perforation. Bowel obstructions can also develop. It should be noted that acute afferent limb obstruction in patients who had a Billroth II reconstruction should be treated differently than other small bowel obstructions in that they typically require immediate operative intervention with either surgical revision of the gastrojejunostomy, conversion to a Roux-en-Y anastomosis, or a Braun's enteroenterostomy.

Clinically significant dumping syndrome is seen in approximately 20% of patients after distal gastrectomy. Early dumping, which occurs within 1 hour of eating, is associated with abdominal pain, cramping, nausea, diaphoresis, palpitations, and flushing. Late dumping occurs hours after eating and is caused by hypoglycemia after the postprandial insulin peak. Most patients can be managed conservatively with small, frequent meals and avoidance of exacerbating foods. Octreotide (Sandostatin)<sup>1</sup> can be a useful adjunct in patients with persistent symptoms. Rarely, surgical revision to a Roux-en-Y gastrojejunostomy is required.

### Gastrointestinal Stromal Tumors

Gastrointestinal stromal tumors (GISTs) are mesenchymal sub-epithelial neoplasms. The incidence of GISTs is 7 to 15 cases per 1 million, and the most common tumor location is the stomach. GISTs account for 1% to 3% of stomach neoplasms. GISTs are thought to arise from the interstitial cells of Cajal and are identified histologically by their overexpression of CD117 (KIT). The most common presenting symptom is gastrointestinal bleeding, occurring in approximately 50% of gastric GISTs. Preoperative endoscopic biopsy is not necessary if there is a high suspicion for GIST based on endoscopic submucosal lesion appearance and it is resectable; biopsy should be performed if there is diagnostic uncertainty, if there is concern for metastatic disease, or if neoadjuvant imatinib is being considered. The prognosis for GISTs has greatly improved after the discovery of imatinib, a receptor tyrosine kinase inhibitor that specifically targets c-KIT.

Surgery is the only curative option for patients with gastric GIST. All GISTs >2 cm should be considered for resection. Grossly negative margins are sufficient, and no lymphadenectomy is required given the very low rates of lymph node metastases in these tumors. Care should be taken to preserve the tumor capsule as intraoperative rupture increases the risk of recurrence. Neoadjuvant imatinib can be considered in patients with locally advanced or borderline resectable disease or in whom preoperative tumor shrinkage would potentially reduce surgical morbidity.

Imatinib (Gleevec) is an oral medication taken at a dose of 400 mg daily. Adjuvant imatinib should be offered to patients with a high risk of recurrence, specifically either primary tumor >5 cm in size and/or mitotic rate >5 per 50 high-power field. The phase III ACOSOG Z9001 established the significant improvement in recurrence-free survival with 1 year of adjuvant therapy compared with placebo (98 vs. 83% at 1 year,  $P < 0.0001$ ). Further, the Scandinavian Sarcoma Group XVIII phase III trial showed that 3 years of adjuvant imatinib was superior to 1 year in both recurrence-free survival (65.6 vs. 47.9% at 5 years) and overall survival (92.0 vs. 81.7% at 5 years). However, recurrences are not uncommon after discontinuation of imatinib, and further studies are ongoing to establish if a longer regimen may be more beneficial. For tumors resistant to imatinib, second-line therapy is sunitinib (Sutent), another tyrosine kinase inhibitor. Traditional

<sup>1</sup>Not FDA approved for this indication.

<sup>1</sup>Not FDA approved for this indication.

chemotherapy and hyperthermic intraperitoneal chemotherapy (HIPEC) are not standardly used now after the advent of tyrosine kinase inhibitor therapy.

### Neuroendocrine Tumors

Gastric neuroendocrine tumors (gNETs) arise from enterochromaffin-like cells and were previously referred to as *carcinoid tumors*. The incidence of gNETs has increased 15-fold from 1973 to 2012 as a result of increased awareness of the disease, an increased number of upper endoscopies, and possibly increased use of PPIs. There are three distinct subtypes of gNET. Type 1 gNETs are the most common (70% to 80%) and are associated with pernicious anemia and atrophic gastritis. Type 2 gNETs account for 5% to 10% and are associated with Zollinger-Ellison syndrome and multiple endocrine neoplasia type 1. Type 3 gNETs have normal gastrin and stomach acid levels, are solitary lesions, and are more aggressive and tend to metastasize. Neuroendocrine carcinomas are sometimes referred to as type 4 lesions and are poorly differentiated tumors that behave similarly to gastric adenocarcinoma.

Upper endoscopy and biopsy are indicated for diagnosis. The mitotic rate and Ki-67 proliferation index should be measured from the specimen to allow for tumor grading. Patients with type 3 gNETs or with worrisome features (size >2 cm, high grade) should undergo multiphasic abdominal CT or MRI for staging.

Type 1 gNETs less than 1 cm can undergo endoscopic resection or surveillance. If they are greater than 1 cm in size, not high-grade, and EUS shows no invasion beyond the submucosa, endoscopic resection can be performed. If they are poorly differentiated, have invasion beyond the submucosa, or have positive margins after endoscopic resection, surgical resection should be performed. If there is persistent or recurrent disease after surgery, an antrectomy can be considered. For type 2 tumors, gastrinoma resection or high-dose PPI therapy should be initiated. If tumor size is less than 2 cm without worrisome features on biopsy, endoscopic resection can be performed; otherwise surgical resection is recommended. Type 3 tumors, given their more aggressive behavior, should undergo anatomic surgical resection with lymphadenectomy.

If there is metastatic disease to the liver, carcinoid syndrome can occur. Surgical cytoreduction or liver-directed therapies can be offered. The most common systemic therapy utilizes somatostatin analogues (octreotide [Sandostatin] or lanreotide [Somatuline Depot]). If there is disease progression on somatostatin therapy, cytotoxic chemotherapy (i.e., etoposide [Toposar]<sup>1</sup> with carboplatin [Paraplatin]<sup>1</sup> or cisplatin<sup>1</sup>), everolimus (Afinitor),

or interferon-alpha-2b (Intron A)<sup>1</sup> can be given as second-line agents. Peptide receptor radionuclide therapy (PRRT) delivers radiation therapy via binding of the somatostatin receptor by 177-Lu-Dotatate and may be considered in locally advanced or metastatic gNETs.

### Gastric Lymphomas

The stomach is the most common extranodal site of lymphoma. Gastric lymphomas account for approximately 3% of gastric malignancies and 10% of lymphomas. The most common presenting symptom is epigastric pain, followed by anorexia, weight loss, nausea, and bleeding. Fever and night sweats are seen in 12% of patients. Diagnosis is established by endoscopic biopsy. The two most common subtypes in the stomach are diffuse large B-cell lymphoma and marginal-zone B-cell lymphoma of mucosa-associated lymphoid tissue (MALT). MALT lymphomas of the stomach often respond to *H. pylori* eradication. Patients with persistent or recurrent disease can undergo radiotherapy or chemotherapy. Surgery is only indicated in patients with complications from their disease such as significant bleeding or perforation.

## ACROMEGALY

Method of  
Moises Mercado, MD

### CURRENT DIAGNOSIS

#### Clinical

- Headaches, visual field defects
- Coarse features, increased size of hands (rings) and feet (shoes)
- Thick, oily skin, skin tags, acanthosis nigricans
- Arthralgias, osteoarthritis
- Paresthesias, carpal tunnel syndrome
- Hypertension, arrhythmia, heart failure
- Glucose intolerance, diabetes, hypertriglyceridemia
- Snoring, sleep apnea
- Risk of colon polyps or colon cancer
- Risk of thyroid cancer

#### Biochemical

- Glucose-suppressed growth hormone >0.4 ng/mL by ultrasensitive assays or >1 ng/mL by old radioimmunoassays
- Elevated age-adjusted insulin-like growth factor 1

#### Imaging

- Magnetic resonance imaging

### CURRENT THERAPY

- If a pituitary surgeon is available: Transsphenoidal surgery for microadenomas, intrasellar macroadenomas, and debulking or decompressing surgery in invasive macroadenomas
- Depot Somatostatin analogues (lanreotide autogel [Somatuline Depot] or octreotide LAR [Sandostatin LAR Depot]) as secondary treatment for patients failing surgery or waiting for radiotherapy effect to occur and as a primary treatment for patients with inaccessible lesions, contraindications for surgery, or preference
- Dopamine agonists: Cabergoline (DOSTINEX)<sup>1</sup> is effective alone or in combination with somatostatin analogues in 15% to 30% of patients
- Growth hormone receptor antagonists: Pegvisomant (Somavert) for patients resistant or intolerant to somatostatin analogues and who have tumors >5mm from the optic chiasm
- Radiotherapy for patients resistant or intolerant to pharmacologic therapy, with clinically and biochemically active disease and a tumor remnant on MRI

<sup>1</sup>Not FDA approved for this indication.

Acromegaly is a disorder resulting from an excessive secretion of growth hormone (GH), with a prevalence of 40 to 60 cases per million and an annual incidence of 3 to 4 per million.

### Physiology, Biochemistry, and Regulation of the GH/IGF-1 Axis

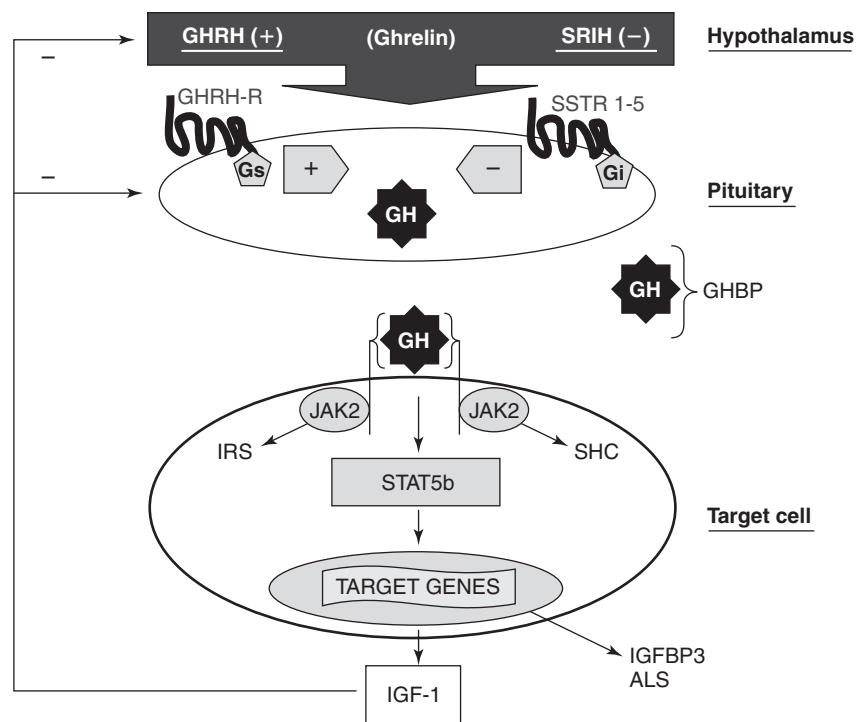

GH secretion is regulated at the hypothalamus (Figure 1). The pulsatile secretion of GH-releasing hormone (GHRH) stimulates somatotroph proliferation and GH gene transcription, whereas somatostatin, which is secreted tonically, inhibits GH synthesis. These two hypothalamic signals result in the pulsatile secretion of pituitary GH, with most pulses occurring during the night. GH is also stimulated by ghrelin, a hypothalamic and gastrointestinal orexigenic hormone that binds specific receptors in the somatotroph known as GH-secretagogue receptors. GH exerts its actions through a specific membrane receptor located predominantly in the liver and cartilage, but ubiquitously present in all tissues. One molecule of GH interacts with two molecules of GH receptor, resulting in functional dimerization and conformational changes that lead to the phosphorylation of several kinases and eventually the interaction with target genes such as the insulin-like growth factor (IGF)-1 gene.

IGF-1 is closely related to proinsulin and circulates in plasma bound to six binding proteins (IGFBPs) that are synthesized and released by the liver. IGFBP3 is the most important of these binding proteins and is also GH dependent; it forms a heterotrimeric complex composed of BP3, IGF-1, and the acid-labile subunit (ALS). IGF-1 is responsible for most of the trophic and growth-promoting effects of GH. Blood levels of IGF-1 are increased during puberty, coinciding with the acceleration of somatic growth, and decline with aging. Malnutrition, poorly controlled type 1 diabetes, hypothyroidism, and liver failure all result in diminished IGF-1 concentrations. IGF-1 is the main player in GH negative feedback regulation and it acts at both the pituitary and the hypothalamic levels. Glucose regulates GH release by increasing (hyperglycemia) or decreasing (hypoglycemia) somatostatin synthesis in the hypothalamus. Exercise and amino acids such as arginine also stimulate GH secretion.

### Etiopathogenesis of Growth Hormone–Secreting Tumors
